Algebra course. In the results of that study, we provided preliminary descriptions of student perceptions of the impact of relearning on their understanding of a particular topic, such as *confirming my understanding, jogging my memory,* and *reconstructing my memory with guidance*. These perceived impacts of relearning were used to guide the current investigation while still allowing for such descriptions to be expanded or refined (see Amman, 2022 for details). The second level pertains to "course-level" relearning. Course-level relearning experiences focus on holistic perceptions of what learning is like overall in a course, and is the perspective more commonly taken by studies that ask about student perceptions of their course experience, without focusing on any particular piece of content (e.g., students got a "refresher" of the subject of algebra in Cox & Dougherty, 2019). However, as demonstrated by the current study, course-level relearning perceptions are not necessarily simple aggregates of topic-level experiences formed at the end of a course, but may also already be formed by students early on in the semester and may help explain subsequent patterns in topic-level experiences. In the current study, we present findings that describe the relationship between one student's topic-level and course-level perceptions of relearning as she continued to encounter content involving the sub-topic of factorization throughout a developmental math course.

Methods

We conducted six longitudinal case studies each spanning two semesters between Spring 2021-Spring 2022 enrolled in either Elementary or Intermediate Algebra at a four-year university. Elementary and Intermediate Algebra are non-credit-bearing courses whose syllabi reflect those of a typical high school algebra course. Sierra, the pseudonym given to the participant whose data is the focus of this report, began the study as a freshman Intermediate Algebra student in Fall 2021 followed by Precalculus in Spring 2022. All participants were recruited at the beginning of the semester via email for a series of paid interviews focused on their experiences with relearning in their current math course and in the following semester. Interested students were given a recruitment survey in which they were shown topics that would be taught in their current course and asked to describe how well they remembered and how confident they were in their understanding of them. Participants were chosen to reflect an even distribution of starting course, memory, confidence in understanding of each topic, and semesters of experience with college algebra courses. Sierra, like the other participants, indicated that she knew she had learned *about* each course topic before, even if she could not always remember exactly what she had learned, and she had previously completed Algebra II, and Precalculus in high school. This indicated that much of her upcoming learning experience was likely to be characterized as relearning. Data collection consisted of six one-hour interviews per student, surveys and, when possible, responses to questions on course exams. For the sake of space, we describe only interviews 1-4, those focused on topic and course-level relearning, for this report.

Interviews 1-4 occurred in the first semester of study enrollment. In order to understand how previous learning experiences influenced students' relearning experiences, each interview contained sections for students to both predict and reflect on aspects of upcoming and recent relearning experiences, respectively. Specifically, students were asked to predict how their memory and current understanding of a topic would influence how they approached the task of relearning that topic in class (behaviorally and affectively) and what the anticipated impact of that relearning experience would be on their understanding. In terms of reflections, students utilized their own exam responses and their predictions from previous interviews to reflect on their relearning experience. At the end of every interview, we asked students to reflect on their course-level relearning experience by describing, overall, how they thought the experience of relearning had been different from learning new content in mathematics for the first time. Responses to this item were carried over to subsequent interviews for further reflection in order to understand students' evolving perception of relearning throughout the semester.

Formal analysis proceeded in multiple rounds. The first round focused on building descriptions of individual cases utilizing the main variables outlined in the theoretical framework. They are: perceptions of similarity to and confidence in understanding from the T1 learning experience, predictions and reflections of the impact of relearning on understanding, behaviors associated with relearning, and affective dispositions associated with relearning. The second stage involved cross-case comparisons resulting in preliminary themes that either connected variables within a type of relearning or helped explain linkages between variables across different types of relearning. This process involved engaging in explanation-building utilizing all data sources for an individual participant, then moving to the next participant in order to locate commonalities across experiences and produce evidence of rival explanations if that participant experienced a similar outcome despite different combinations of the study variables (Yin, 2009). The result of this stage of analysis was a set of preliminary themes that were refined over a period of several further rounds of analysis for consistency.

Results

How Relearning at the Topic-level Influences Behavior and Affect

Sierra came into her first interview with a vivid memory of a frustrating history with learning (and relearning) how to factor polynomial expressions. She recalled missing the first day of math class in 8th grade when factorization techniques were introduced. To quickly catch up, Sierra went online to "whatever was available" to teach herself what she had missed. While she performed well in Algebra I, her technique for learning about factorization did not allow the content to "stick"; she forgot everything when she reencountered the topic in her high school Algebra II class. Once again, Sierra felt she needed to catch up to the rest of the class and turned to outside sources to re-teach herself the factorization techniques that she was expected to already have learned. She then promptly forgot these techniques and relearned them again in her high school Precalculus course. Sierra was looking forward to using her time in Intermediate Algebra to end this cycle. In her first interview, she stated, "I want this to be the last time. I don't want to teach myself anymore." Sierra consistently received good grades in high school and was a member of an honors program at the University—she was confident that her main concern was not whether she could reteach herself factorization and perform well on assignments, but on her inability to recall any of what she had taught (and retaught) herself concerning this subtopic in the past. Specifically, she identified her behavior of inconsistently turning to various sources outside of the class each year as resulting in her struggle to remember what she had learned the following year. She predicted that by closely adhering to her professor's approach to factoring, she would be able to reorganize her knowledge in a way that would make it easier to remember in the future (Amman, 2022, termed this particular relearning outcome *Reorganization*).

Unfortunately, Sierra's anticipation of this change in behavior and subsequent change in understanding was not realized. Sierra found that she *remained stuck in her previous understanding* (Amman, 2022). In her second interview, Sierra reviewed her responses to items on the first exam involving factoring, almost all of which she received full credit for. Despite her high performance, Sierra lamented that she found herself stuck in her old relearning approach in which, "I just had to learn it [myself] again, like every time when it comes to factoring." Just as before, she found herself turning to outside sources to reteach herself, and once again did not feel she had addressed the root cause of her memory issues. Indeed, when encountering future problems involving factorization in class, she remarked in later interviews, “[my memory] wasn’t really helpful...I kind of knew I was on the right track because I remembered seeing it, but it didn't help me in terms of solving the actual problem.” As a result, Sierra found that her understanding of factoring after relearning was, “the same. I just get there faster [every time I learn it].” Sierra explained that she was able to pick up on factoring techniques more quickly than in previous algebra courses, but this was not accompanied by a feeling of improved understanding that could have come from the implementation of a more conceptual organizing principle of content that she had hoped for. When asked what had made her feel like she needed to use her old relearning approach again, she stated, “I think it’s more to like a mental thing. Like once I see the word factoring, I'm like, ‘oh I know I'm not going to do well on this unless I teach myself again.’” Here, we see that Sierra’s previous experiences with factoring triggered a prediction (“I’m not going to do well”) concerning the outcome of her topic-level relearning experience before her instructor had even begun the first lesson on factoring. This prediction was then used to motivate behaviors (“unless I teach myself again”) that impacted how she decided to approach studying this topic. Sierra’s previous experience learning this material also had an impact on her affective response to relearning it. She mentioned feeling discouraged from the moment the class had begun the factoring sub-unit and struggled with these negative feelings associated to her previous experiences throughout the rest of the classes in which factoring was mentioned. For instance, while reviewing for her first exam, she questioned, “why am I still doing this in college? That's what I was asking myself a lot while I was studying…I feel like every time I revisit this topic it's a little bit discouraging. Because it's not sticking and I don't know why.” In this way, Sierra’s ability to recognize previously learned material and make predictions surrounding the outcome of relearning had significant consequences for her (and other participants) in terms of her behaviors and affective states during course instruction.

How Topic-Level Relearning may Shape Perceptions of Course-Level Relearning

Sierra’s experience relearning factorization also came to impact her course-level relearning perceptions. In contrast to the idea expressed by other participants that previous experience must make relearning easier than learning something new, Sierra came to view her previous algebra learning experiences (in middle and high school) as a potential hindrance in the course. Discussions around this perception began in her third interview, after polynomials (and the factoring sub-topic) had been covered and she had experienced the shift from predicting that she would be able to reorganize her knowledge of factorization to subsequently reflecting she had remained stuck in her previous understanding of the topic. At that point in the semester, Sierra described her overall outlook on relearning in the course as, “I feel like as opposed to other subjects, I feel like math is all about confidence…If I don't have that confidence and I'm confident that I don't remember it, past [Sierra] didn't know how to do it, or couldn't figure out how to do it, then it’s gonna be a doozy trying to figure out how to solve it.” She explained in her fourth interview that her confidence throughout the semester came to be tied to her understanding of factoring, given that subsequent course topics such as combining rational expressions and solving quadratic equations involved factoring as a subtopic. In interview 4 she described changes in her confidence throughout the semester by saying “I was like ‘um what are doing?’ [every time] factoring came back in,” indicating that her confidence would dip down repeatedly every time factoring was reintroduced in a new topic. In essence, Sierra’s experience relearning about factorization seemed to have influenced her perspective of what to expect for the course as a whole: she saw an inability to use what she had previously learned as a warning sign that her relearning experience was about to be difficult and did not allow for the possibility of an improved experience relative to her first time learning these topics. In summary, Sierra's topic-level experience came to inform her overall outlook on relearning in the course, transforming her from a student who in Interview 1 was "looking forward to" intellectually grappling with questions like "Why am I getting this answer? Why do I have to do this step?" to a student who came to view the presence of such questions as hits to her confidence and indicators that her relearning experience would be more difficult than it should.

Sierra enrolled in Precalculus the following semester, another course which she had previously taken in high school. Although she was unable to achieve the impact of relearning on her understanding of factorization that she had predicted, she mentioned hoping that the combination of the short break between Fall and Spring semesters and the increased speed with which she arrived at her understanding of factoring would improve her results next semester. Unfortunately, this was not the case. In her fifth interview she noted that she had done poorly on her first exam, and that, "the ones that I struggled on, it was factoring, of course. The whole entire test was factoring." In this way, Sierra's topic-level experience could be understood as part of a self-reinforcing cycle that comes to inform her experiences with relearning not only within her algebra course, but also in future courses involving said algebraic topics.

Conclusions

By presenting Sierra's case, we intend to contribute to theoretical accounts of the experience of relearning as instantiated in developmental algebra courses. Studies in reforms of developmental math courses have begun to suggest that the most successful reforms are multifaceted in terms of the modifications they make to course experiences (e.g. Hodara, Jaggars & Karp, 2012; Yamada & Bryk, 2016). That is, successful reforms address placement into courses, instruction while students are enrolled in such courses, and alignment with students' overall goals for college after the course is over. Similarly, the results of this study suggest that fully understanding student experiences with relearning in developmental mathematics requires a multifaceted approach. Whereas topic-level perceptions help us to understand the decisions Sierra was making and the impact of the course on her understanding of factoring on a local level, her course-level perceptions allow us to understand the motivations behind patterns in her experiences that were more than the sum of her topic-level perceptions in terms of their impacts beyond one semester. We would argue that in our efforts to better evaluate developmental mathematics courses and understand exactly how they impacting students, we need to be aware of the limitations of taking the perspective of students at any one "level", and ensure that the claims we want to make about student experiences are aligned with this. For instance, co-requisite algebra courses are designed to improve alignment with students' overall goals for college and modify the algebraic content presented in class accordingly (e.g. Logue, Douglas & Watanabe-Rose, 2019). However, there are very few studies that seek to investigate the hypothesis that student *understanding* of algebra in these courses will be improved as a result of an ability to see more directly the purpose of relearning particular algebra concepts related to students' majors. This suggests we would do well to focus on student perceptions of relearning at both the topic- and course-level in these courses: how students view the relearning of specific topics as understanding of these topics is needed in the context of the college-level course, and how they view relearning of algebra as a whole in the special context of a co-requisite course. We suggest that future work seeking to qualify the impact of such courses on student understanding takes into account the particular components of relearning focused on here in order to be able to best explain student approaches to and reflections on course material.

This paper presents six categories of undergraduate student explanations and justifications regarding the question of whether a converse proof proves a conditional theorem. Two categories of explanation led students to judge that converse proofs cannot so prove, which is the normative interpretation. These judgments depended upon students spontaneously seeking uniform rules of proving across various theorems or assigning a direction to the theorems and proof. The other four categories of explanation led students to affirm that converse proofs prove. We emphasize the rationality of these non-normative explanations to suggest the need for further work to understand how we can help students understand the normative rules of logic.

Keywords: logic, proof, converse independence

Introduction

Proof-based mathematics education research has long attended to how students think about the relationship between mathematical proof and the truth of mathematical claims. Within mathematical practice, deductive proof is the dominant standard for declaring a theorem true. Similarly, we would like students learning proof-based mathematics to adopt normative standards for what kinds of proofs justify a given mathematical claim. In this paper, we specifically consider theorems that are universally quantified conditionals, meaning they can be expressed in the form "For all… , if P, then Q." Since many theorems in undergraduate mathematics are of this form, introduction to proof texts introduce standard proof techniques related to such statements: direct proof, converse proof, contrapositive proof, and proof by contradiction. Of these four types of proof, all prove the given theorem except for the second. A converse proof assumes Q is true and concludes why P must be true as a consequence. We call the principle that the converse proof never proves the given theorem *Converse Independence* (hereafter, "CI"). In common mathematical parlance, the theorem states that P implies Q and the converse proof proves that Q implies P, which are taken to be related, but independent claims.

Previous studies (e.g., Hoyles & Kuchemann, 2002; Yu, et al., 2004) have noted that students often strongly associate a conditional and its converse statement. It has also been suggested that making a distinction between a statement and its converse may be even more difficult when the statement and its converse are both true (Imamoglu & Togrol, 2015), though no explanation was provided for how students should understand CI in this case. CI is meaningfully different for theorems where the statement and converse are both true. Durand-Guerrier (2003) and Dawkins (2019) both discussed how students interpret mathematical statements to refer to the objects that make them true. This referential way of reasoning emphasizes a challenge: how might students distinguish converses that are not distinguished by their truth-values? Our study investigates the question: how do students' reason about the relationship between a converse proof and a conditional theorem, especially in cases where the theorem is true biconditionally?

We answer this research question by characterizing novice undergraduate students' explanations and justifications regarding the relationship between a converse proof and a conditional theorem. These findings help elaborate Hoyles & Kuchemann's (2002) findings of how students might interpret the relationship between converse statements. In other words, our study offers qualitative insights into the previously documented ways students closely associate converse claims. We shall emphasize the coherence and rationality of students' non-normative explanations, which suggest a need for greater attention to this topic in introductory logic.

Literature Review

There are three primary task types that have been used to study how students relate a conditional statement and its converse: inference tasks, statement tasks, and proof tasks. First, some studies consider the inferences that students make or endorse based on a conditional claim. The statement "If P, then Q" is taken to justify inferring Q given knowledge that P is true (often called *modus ponens*). However, according to mathematical logic the conditional statement above does not justify inferring P given knowledge of Q (*affirmation of the consequent*), though students often make this inference or endorse it as appropriate (Evans & Over, 2004; Inglis & Simpson, 2008; Alcock, et al., 2014). Attridge and Inglis (2013) compared inference task performance between UK secondary students studying mathematics and their peers studying English literature (and not mathematics). The year of mathematics study reduced the frequency of *affirmation of the consequent* responses more than the year of English study did, suggesting that general mathematics instruction influences this aspect of CI.

A second type of research task relevant to CI invites students to make judgments about conditional statements and their converse statements. For instance, some scholars (e.g., Hoyles and Kuchemann, 2002; Yu, et al., 2004) have shown that many middle school students believe that conditional statements and their converses say the same thing. Both studies explained this finding in light of the way that students interpreted the truth/falsehood of the statements. Many students affirmed and denied statements using affirming examples (which were provided in the task statement) or counterexamples (which the task did not provide). Accordingly, many students judged the false conditional claim to be true based on affirming examples, so the truth-value did not distinguish the statements.

Introduction to Proof textbooks generally justify CI either using 1) the truth-table or 2) example statements. The former argument (converses have different truth tables) assumes that students are using the truth-table definition to interpret conditional claims, though this has been long shown a poor model of how people interpret such statements (e.g., Evans & Over, 2004; Schroyens, 2010; Inglis, 2006). The second textbook argument is worth considering in more detail. Hammack's (2013) Introduction to Proof textbook provides an instance of this type of argument. It presents one example of a true conditional claim with false converse ("a is a multiple of 6 $\Longrightarrow$ a is divisible by 2") and explains, "Therefore the meanings of $P \Longrightarrow Q$ and $Q \Longrightarrow P$ are in general quite different… a conditional statement and its converse express entirely different things" (p. 44). This justification relies on an implicit meta-theorem about the nature of logic, which we shall call the *Fundamental Warrant of Logic (FWL)*. It states an argument of a given form is only valid if all examples of this argument with true premises have true conclusions. Thus, a single example of some form of argument that yields false results invalidates all other arguments of that same form. In this case, the argument in question would be "If (P⟹Q), then (Q⟹P)." The FWL asserts that the relationship between a statement and its converse must be the same for all conditional statements. The extent to which students agree with this justification or find it compelling is an open question that our study will begin to address.

A third type of task used in research invites students to consider the relationship between a conditional theorem and a converse proof. This is a novel type of task used in the sequence of experiments in which our data originated (see Dawkins & Cook, 2017; Dawkins & Roh, 2022), which we shall describe in the methods section.

Theoretical Framing

Our study draws upon the tradition of Piagetian constructivism both in theoretical orientation (e.g., von Glasersfeld, 1995) and methods (Steffe & Thompson, 2000). Piaget was fond of using logic to model children's reasoning (e.g., Inhelder & Piaget, 1958, 1964). However, the nature of his claims have been widely (mis)understood as claiming that adolescent reasoning comes to conform to formal logic in some strong sense (thought is the mirror of logic). This would violate Piaget's principle of the constructive independence of knowledge. We understand that Piaget used logic as a convenient organizing tool to describe patterns of reasoning (logic was the mirror of thought) that for the student were embedded in more complex systems of meaning (Piaget & Garcia, 2011). Only upon conscious reflection on the form of statements and reasoning can someone abstract conscious understandings of logic (see Beth & Piaget, 1966). A helpful distinction here is between what students construct *in activity* and what they have *reflexively abstracted* to some higher level of re-presentation (von Glasersfeld, 1995). In this study, we do not assume that students have stable re-presentations of logical structure or the abstract relationships between a statement and its converse. Instead, we seek to describe their often tenuous and provisional ways of reasoning about CI that may shift based upon the context of the statements and the task (what Thompson, et al., 2013, called *in the moment meanings*). As such, we present categories of explanations and justifications that students give in particular moments, which are neither mutually exclusive nor necessarily stable throughout their participation in our study. In other words, we seek to understand the subjective rationality of how students begin to reason about such logical relationships.

Methods

The data from this study comes from a larger series of constructivist teaching experiments (Steffe & Thompson, 2000) with undergraduate students from three large public universities in the United States. A total of six teaching experiments were conducted with pairs of students over the course of five years, resulting in a total of 12 participants. None of the students had previously taken a proof course. A key goal of the experiment was to support them in constructing more normative understandings.

The goal of this paper is to characterize students' explanations and justifications regarding whether a converse proof proves a conditional theorem. These explanations and justifications arose in response to What does it prove? tasks. These tasks involve presenting students with a theorem and an associated proof, and students are asked to decide, "Does the proof prove the theorem? Why or why not?" as well as "If the proof does not prove the theorem, what statement does it prove or disprove?" This invites students to attend to the structural relationship between the theorem and the proof and to begin comparing such relationships across theorem/proof pairs. In this paper, we focused on analyzing data from three What does it prove? tasks involving converse proofs (or disproofs). Table 1 presents the three theorems and the structure of the associated proof.

Theorem 1	**Theorem 2**	**Theorem 2'**
For every integer x, if x is a multiple of 6, then x is a multiple of 3.	For any integer x, if x is a multiple of 2 and a multiple of 7, then x is a multiple of 14.	For any integer x, if x is a multiple of 4 and a multiple of 6, then x is a multiple of 24.
Proof 1.2 Let x be an integer that is a multiple of 3. Then x could be 15, which is not a multiple of 6. Thus, it is not necessarily the case that x is a multiple of 6.	**Proof 2.2** Let x be an integer that is a multiple of 14. … Thus, x is a multiple of 2 and a multiple of 7.	**Proof 2.2'** Let x be an integer that is a multiple of 24. … Thus, x is a multiple of 4 and a multiple of 6.

Table 1. The three converse What does it prove? tasks studied in this report.

Though we engaged in the experiments overall to promote set-based reasoning (Dawkins, 2017), these tasks were implemented without instructor guidance toward the normative way of reasoning regarding CI. Since our goal was to categorize students' initial responses regarding CI, the analysis in this paper approached the data as task-based interviews (focusing only on the initial implementation of the three tasks above). Consistent with teaching experiment methodology, the researchers continuously generated and tested hypotheses about students' ways of reasoning. We thus had developed models of how each student reasoned about CI, and were struck by the coherence of students' explanations and justifications, especially those that were non-normative (i.e., argued that the converse proof did prove the theorem). Using comparative coding methods (Glaser, et al., 1968), we identified six categories for students' explanations and justifications for whether a converse proof proved the original theorem (henceforth we shall say "does prove" or "does not prove" always referring to the theorem that is converse to the proof). As noted above, these ways of reasoning were not always stable, nor were they mutually exclusive. However, some of the non-normative categories of explanation persisted with certain participants, suggesting they may be important for future work.

Results

In this section we describe the six categories of explanations and justifications regarding CI. The first two categories led students to the normative interpretation that converse proofs do not prove while the latter four led them to affirm that the converse does prove. Overall, four of the 12 students initially decided Proof 2.2 did not prove Theorem 2.

Category 1: Proof Rules Should be Universal

Students who were observed using this category of reasoning believed that proof rules should be universal, that is, a proof rule cannot be accepted unless it works in all cases (similar to Hammack's, 2013, explanation that implicitly invokes the FWL). Students using this category acknowledged that a statement and its converse can have different truth values (Theorem 1) and used this to conclude that there are cases where one can prove the converse of an implication while the implication itself is false (like Theorem 2'). Therefore, they claimed that a converse proof cannot be accepted as proof of an implication because it would only lead to the correct conclusion when the implication and its converse are both true (Theorem 2). One student, Theo (all names are pseudonyms), provided a justification for why Proof 2.2 did not prove Theorem 2 that fit into this category. He explained (imagining the truth-sets of the hypothesis and conclusion as circular regions):

> In this case, the circle of the "if" exists inside the "then," but it encompasses the whole "then." They're the same set. So, in 2.2, when we switch them around, the "if" and the "then" are still the same sets, but, if we had an example where the "if" is a subspace of the space, and then you switch it around, it's not necessarily true. In this case, it is, but, in general, if you switch them, it might not work.

Theo recognized that the truth sets were the same in this case, and thus each was contained in the other. He used this to explain why the implication and its converse are both true for Theorem 2. It is important that Theo treated all conditional theorems and proofs as instances of the same relationship, and judged that the relationship should remain invariant across the different theorems. Therefore, he claims that the proof of a converse cannot be accepted as proof of an implication because it would not always lead to the correct conclusion.

Category 2: Proofs Should Match the Theorem Direction

Students who used this category of reasoning understood that conditional statements and proofs both had an inherent direction. Accordingly, they judged that a proof should match the theorem's direction. This is distinct from the first category because it was not based on comparing proof relationships across different theorems. One student, Moria, gave an explanation that serves as an example of this category:

> I don't feel like the converse is inherently proving the theorem and if you do that across it's like the converse is proving the theorem… I think it has to do with the trickle down what you're starting with necessarily, if I start with 14, it's going to be a multiple of 14, that's just, it's not going to prove anything… Using those two [Proof 2.2 proving Theorem 2] is saying, "if you have a multiple of 14, it will be a multiple of 14" is what that kind of 2.2 to the theorem 2 is saying.

Moria claimed that combining Proof 2.2 and Theorem 2 would be tautological because the hypothesis of the proof is the same as the conclusion of the theorem. Since she viewed theorems and implications as paths from one claim to another, she argued that the proof began at the ending point of the theorem, which is "not going to prove anything." This led her to claim that Proof 2.2 did not prove Theorem 2 (affirming CI).

Category 3: Equivalent Properties Allows for Substitution

Students who were observed using this category of justification claimed that the properties in the theorem's hypothesis and the properties in the theorem's conclusion were equivalent. They then used this to argue that the direction of the proof did not matter because the properties being related were the same. One student, April, justified that proof 2.2 proved theorem 2 by writing the equation "2*7*k=14*k" and claiming that this shows that the properties "multiple of 2 and multiple of 7" and "multiple of 14" are equivalent. Another student, Jean-Luc, also provided this type of explanation. His partner had argued for CI, but he responded:

> I guess we're having trouble because multiple 14 breaks down into seven and two and then seven and two break down right into 14. So, I feel like it's saying the same thing, but I totally understand what you're saying. It's reversed.

While Jean-Luc acknowledged that the direction of the proof was the reverse of the direction of the theorem, his belief that "multiple of 14" and "multiple of 2 and multiple of 7" are "saying the same thing" led him to see no conflict between the proof and the theorem. Since he viewed "multiple of 14" and "multiple of 2 and multiple of 7" as being the same property, he treated them as though they were synonymous. This sense of identity led him to deny CI since the order did not distinguish the proof from the theorem.

Category 4: Set Equality has No Direction

Students who provided this category of explanation acknowledged that the set of objects that satisfied the hypothesis was equivalent to the set of objects that satisfied the conclusion. They then used this to argue that since the hypothesis and conclusion were referring to the same set of objects, they were interchangeable. This category is very similar to the previous; they differ with regard to whether the student is attending to sets of objects or properties. Mathematically speaking, the sets of objects are truly equal while the properties differ in definition. For example, the set of integers that are multiples of both 2 and 7 is the same as the set of integers that are multiples of 14. Students giving such justification thus did not find grounds to distinguish a converse proof from the conditional theorem. One student, Phil, reasoned in this manner:

> I was saying I feel like it's true because all multiples of 2 and 7 are all multiples of 14. So, if it's a multiple of 2 and a multiple of 7, then it's going to be a multiple of 14 because multiples of 2 and 7 are 14, 28, and 42, and then to whatever degree you want to go to.

Phil claimed that Proof 2.2 still proves Theorem 2 because both the hypothesis and the conclusion are referring to the same set of objects. Therefore, switching them around in a statement does not change the meaning of the statement.

Category 5: The Theorem, the Proof, and my Knowledge All Agree

Students who used this category of reasoning focused on what they knew to be true when deciding whether a converse proof proved. If there were no contradictions between the theorem, the proof, and what they knew to be true, then they affirmed that the proof proved. In biconditional situations, this led them to affirm the converse proof. One student, Carl, used this category of reasoning to justify why Proof 2.2 proved Theorem 2:

> I said that it proves that if x is a multiple of 14, then x is a multiple of 2 and 7. Which is kind of like the opposite, but not really, of Theorem 2. But because the statement is true it doesn't really matter.

Carl argued that because Theorem 2 and its converse are both true, the order of the proof "doesn't really matter." In other words, Carl did not distinguish the truth of the claim from the efficacy of the proof in justifying the claim, since both the theorem and the proof described accurate facts about the same objects and properties. This reflects the common phenomenon that people judge arguments very differently depending upon whether they believe the conclusion of the argument (Inglis & Simpson, 2007; Evans & Feeny, 2004).

Category 6: Error-free Proofs Prove

Students who used this category of justification did not attend to the direction of the proof at all. Instead, students only focused on dissecting the line-by-line content of the proof for errors. Two participants, Joaquin and Violet, had a long discussion about whether the inferences made within the proof were valid. They sought to determine whether they believed each line in the proof followed from the previous line. Since they concluded that this was the case, they also concluded that proof 2.2 did in fact prove theorem 2. Interestingly, they frequently stated that the theorem was "true" and the proof was "true," seemingly assigning the same epistemic roles to the two kinds of text. Whereas the previous type of explanation notes the reversed order and dismisses its importance, this kind of explanation does not entail attention to an explicit link between the proof and the theorem beyond discussing the same topics.

Discussion

We present six categories of student explanation and justification regarding the relationship between a converse proof and a conditional theorem. There is some overlap with Hoyles and Kuchemann's (2002) description of four types of reasoning about CI: converses are the same in general, converses are distinct in general, converses are the same with reference to data, and converses are distinct with reference to data. Our first category matches the view that converses are distinct in general. It depended upon students perceiving all conditional theorems and proofs as instances of the same relationship (in accordance with the FWL). Our second category is similar, though it depended upon students according some significance to the direction of a theorem and proof. Our latter four categories all correspond to the view that converses are the same with reference to data. We did not observe the view that converses are the same in general (possibly since we presented Theorem 1) or that converses are distinct with reference to data for Theorem 2 (since this theorem is true biconditionally).

Students rejecting CI (for Theorem 2) variously attended to properties, sets of objects, or to their judgments about what is true. In each case, they did not see a reason to distinguish converse proofs from the given theorem, even when their partners provided explanations from Categories 1 and 2. Indeed, we are struck by the coherence of these non-normative explanations. Once students perceive some kind of identity (of property or set), it is hard to understand why they would perceive it as having some direction. Furthermore, explanations in Categories 5 and 6 raise more fundamental issues of how students learn to distinguish what a proof accomplishes from what they believe to be the case. It is worth noting that many students providing explanations in Categories 3-5 recognized the reversed order and also recognized that the shared structure among the proofs that follow converse order. Nevertheless, they affirmed that converse proofs can prove the theorem and that this relationship differed by context. We interpret this as a rejection of the FWL as applied to this type of proof, which poses a major challenge for the teaching of logic and proof that we hope will be addressed in future research in this area.

What Do the Calculus I Students Say About the Impact of IBL on Their Math Anxiety

Harmon P. Aryal
Stockton University

Math anxiety negatively affects student learning and academic performance. Students with high math-anxiety exhibit physical, mental, and emotional symptoms. These symptoms often have a short-term and long-term impact on students' mathematics learning and their performance both inside and outside of school. This study investigated the effects of inquiry-based learning (IBL) on Calculus I students' math anxiety, compared to lecture-based instruction. The short version of the Mathematics Anxiety Rating Scale (MARS-S) was used as a pre- and post-test to identify the students whose anxiety from pre- to post-test—greatly increased, greatly decreased, and did not change much. The selected participants were interviewed one-on-one to understand their perceptions and experiences of learning Calculus I. The results showed that some activities, such as the opportunity to work in groups, optional and ungraded homework, and the instructor's welcoming, caring, and amicable nature decreased IBL students' anxiety. On the other hand, the instructor's readiness to explain the material in class when students asked him to do so and his care for student success decreased lecture-based students' anxiety. However, the tests and exams and anticipating the instructor's call for a response increased anxiety among both groups of students.

Keywords: math anxiety inquiry-based learning, collaboration

Math anxiety affects student learning and academic performance. Highly math-anxious students exhibit physical, mental, and emotional symptoms. Physical symptoms include nausea, sweaty palms, and increased cardiovascular activity (Ashcraft, 2002; Chang & Beilock, 2016). Mental symptoms include an inability to concentrate and mind blanking (Plaisance, 2009; Ruffins, 2007). Emotional symptoms include extreme nervousness and apprehension (Mattarella-Micke et al., 2011). These symptoms often have a short-term and long-term impact on students' mathematics learning and their performance both inside and outside of school. In a short term, students may begin to dislike mathematics and take fewer mathematics courses, and in the long term, they tend to avoid mathematics and mathematics-related courses (Godbey, 1997; Hembree, 1990).

Due to the substantial impact of math anxiety on mathematics learning and mathematics performance, it is essential to diagnose the causes of math anxiety and to determine some potential interventions to reduce such anxiety. Therefore, this study investigated the effects of inquiry-based learning (IBL) pedagogy on Calculus I students' math anxiety, with lecture-based instruction as a comparative group.

Literature Review

Math anxiety has been a part of the human experience for centuries. The verse, "Multiplication is vexation ... and practice drives me mad" goes back at least to the 16th century (Dowker et al., 2016). In 1957, Dreger and Aiken introduced the concept "number anxiety," and math anxiety received increasing attention thereafter. Richardson and Suinn (1972) conducted the first formal study of math anxiety, who characterize math anxiety as "feelings of tension and anxiety that interface with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations" (p. 551). Since then, studies on math anxiety have been substantially investigated.

Traditional lecturing, which is a predominant mode of instruction in college mathematics courses across the United States (Stains et. al., 2018) and is ineffective in helping students learn mathematics (Boaler, 2008), could be one of the possible reasons for evoking math anxiety among students. The lecture-based does not offer substantial opportunities for students to share each other's ideas and experiences with their teachers and peers. On the other hand, IBL, which is an active learning pedagogy, provides extensive opportunities for students where they can work in pairs or groups to make conjectures, gather information for problem-solving, and present their work to groups and to the whole class (Kogan & Laursen, 2014). Through a comparative study, Laursen et al. (2014) reported that students in IBL math-track courses achieved greater learning gains than their non-IBL peers in cognitive, affective, and collaborative areas. Similarly, Laursen et al. (2011) found that the IBL students were involved more in interacting with each other, with the instructor, and they were more involved in setting the course pace and direction. It is also reported that IBL enhances students' conceptual understanding (Jensen, 2006), communication skills, confidence, and self-efficacy (Laursen et al., 2011). Considering the benefits of IBL as a ground, this study sought to examine the relative changes in the scores of Calculus I students' math anxiety, using a short version of the Mathematics Anxiety Rating Scale (MARS-S).

Method

Research Context and Participants

The students, who were enrolled in Calculus I course and were taught using either IBL or lectures during Spring 2021at a university located in the Midwestern United States were the sample for this study. Students, who were engaged via IBL pedagogy were IBL group and those who were lectured were lecture-based group. In this study, about 65% (n = 15) of the students off the 23 from the two IBL sections and about 41% (n = 20) students off the 49 from one of the lecture-based sections responded to both the pre- and post-MARS survey. Table 1 shows the distribution of IBL and lecture-based participants by their gender and academic standing.

Table 1. Distribution of IBL and lecture-based students by their major and academic standing.

Characteristics	IBL Group		Lecture-Based Group	
	Frequency	Percentage	Frequency	Percentage
Gender				
Male/Man	5	33.3%	8	40.0%
Female/Woman	10	66.7%	11	55.0%
Non-Binary	0	0.0%	1	5.0%
Academic Standing				
Freshman	11	73.3%	15	75.0%
Sophomore	2	13.3%	1	5.0%
Junior	2	13.3%	4	20.0%
Senior	0	0.0%	0	0.0%

Regarding the instructors, the IBL instructor had 15 years of experience in teaching Calculus I at the university and high school level via active learning, including an IBL. The lecture-based instructor had 2 and a half years of experience in teaching Calculus I at the university level and 14 years of experience in teaching undergraduate-level mathematics courses via a lecture-based approach. Both the instructors taught remotely using audio-visual conferencing platform; the IBL instructor taught using Microsoft Teams, whereas the lecture-based instructor taught using Zoom. Throughout the semester, both IBL and lecture-based classes had class meetings every Monday, Wednesday, and Friday.

The IBL instructor engaged students collaboratively in sequentially organized pre-tasks and tasks in and out of the class. Students were supposed to practice the pre-tasks before the class for a better understanding of the material during the next day's class meeting. The instructor usually began the class by welcoming each student and briefly describing the tasks and activities for that day. Then, the students were sent to Teams breakout rooms, where they shared each other's ideas, asked questions, made conjectures, and solved problems while they were working with their small group members. The instructor visited each group at least once, or as needed and prompted students if they had any questions or concerns. In the end, the students were returned to the main room, where the instructor facilitated whole class discussion. On the other hand, the lecture-based instructor began the class by asking students whether they had any questions or concerns from the previous class. If they had, then, the instructor solved the examples or explained the concepts as needed. After that, the instructor usually began the lecture by solving preselected examples using the Notability app from his iPad. Occasionally, the instructor paused during the lecture and asked some questions to the whole class. Students were never sent to breakout rooms and never provided opportunities for group discussions.

Data Collection and Analysis

Qualtrics online survey was used to collect the pre- and post-MARS data from both IBL and lecture-based groups after receiving an institutional review board (IRB) approval. The MARS-S survey is the 30-item anxiety measuring instrument that was developed by Suinn and Winston (2003). The pre-MARS survey, in conjunction with a demographic questionnaire, was administered during the second week and the post-MARS was administered during the eleventh week of the class. Based on the change in anxiety scores from pre- to post-test, 9 students from the IBL group (3-greatly increased, 3-greatly decreased, and 3 did not change much) and 3 students from the lecture-based group (1 student from each of the categories) were invited for a semistructured interviews. Additionally, eight classes of each of the two sections of IBL group and eight class of one lecture-based group were observed remotely. The data thus collected were transcribed using NVivo, a qualitative data analysis software, and generated several codes. Thematic analysis was conducted to identify various emergent themes. The results were then organized based on the themes generated.

Results

In this section, I present the major findings from the analysis of the data obtained from observations and interviews. While doing this, I compare the findings from both the IBL and lecture-based groups.

The in-class group work and lecturing reduced IBL students' anxiety; out-of-class group chats reduced lecture-based students' anxiety. IBL students were partly lectured and partly engaged in collaborative work in each class; lecture-based students were fully lectured, but some students managed to chat via GroupMe. Because of the collaborative learning opportunities, IBL students became closer to each other and were not scared of asking questions, responding to their groupmates' questions, proposing their own solution strategies, and listening to their peer's various perspectives. Such types of activities made them feel relaxed and also reduced their anxiety. On the other hand, lecture-based students initiated out-of-class collaboration via GroupMe. They maintained it throughout the semester, where they felt comfortable asking questions and responding to each other. Cooperation and mutual support received by these students reduced their anxieties and frustrations with learning Calculus I.

Table 2 and 3 below show sample of the emergent themes, related codes, and student quotations, respectively, for the IBL and lecture-based groups.

Table 2. Emergent Themes, Related Codes, and Sample Student Quotations for IBL Group

Theme	Related codes	Sample quotation
Both lecturing and collaborative learning	• The instructor delivered minilectures • Students were engaged in small group works	He typically starts off with a small lecture … and then, we'll typically go into a group setting into our breakout rooms.
Students received optional and ungraded homework	• Assigned optional homework • Homework was not graded • Students were less stressed	I know they're just used for practice and prep for the exams and for class. So, I don't feel as stressed about them.
Instructor questioning	• Frequently asked short-answer-type questions • Asked to respond in chat	He would give each individual student a certain problem to do … and randomly call on people for it.
Engaging in behaviors that decreased anxiety	• Working in group • Asking questions of the instructor outside of class • Talking to groupmates	I think doing the task in a group reduced it for sure, and ... watching the videos in class, like that does not stress me out or anything.
Engaging in behaviors that increased anxiety	• Thinking of being called on by the instructor • Responding to the instructor questions in front of the colleagues	I would definitely say I don't enjoy going to class because I'm scared, he's going to call on me and ask me a question I don't know the answer to.

Instructors' readiness to meet and help students at any time decreased IBL students' anxiety; the long wait for the instructor's email replies increased lecture-based students' anxiety. The IBL instructor's readiness to meet with students at any time and discuss their questions, concerns, or problems in and out of the class decreased IBL students' anxiety. Students could ask questions to the instructor at any time—during the class, at the end of the class, right after the class, or by scheduling a virtual meeting—and discuss their problems. They could approach the instructor at "eleven o'clock" at night or "7:00 am that morning;" he was always ready to meet and talk with them. Students could also send their questions or concerns via email, to which he replied promptly. This kind of flexibility of the instructor made students calm down and reduced their anxiety. Alternatively, although the lecture-based instructor encouraged students to reach out to him with their questions, students had to wait for long hours for his responses. Students were disappointed and frustrated for not receiving a response to their emails for several days. Liz, for example, mentioned, "We have an assignment that's due on Friday, and I need help. And I can't afford to wait three days for you [the instructor] to email me back because this piece of information is necessary for me to do 60 percent of the assignment."

Table 3. Emergent Themes, Related Codes, and Sample Student Quotations for Lecture-Based Group

Theme	Related codes	Sample quotation
Students received too many online homework problems	• Too many online homework problems • The number of online homework problems gradually decreased	He gave us homework assignments that had eighty-seven problems. ... But that was really the only thing that made me feel anxious about the assignments.
Initiating and maintaining out-of-class collaboration	• Worked together through a GroupMe chat application • Liked helping each other	We all try to help each other out so I would say it's very collaborative.
Instructor questioning	• Frequently asked short-answer-type questions • Asked to respond in chat	He would give each individual student a certain problem to do … and randomly call on people for it.
The instructional environment that decreased students' anxiety	• Instructor's willingness to review the materials • Recitation classes • Recorded lecture videos	His [instructor] willingness to kind of like go over things makes me feel like very comfortable.
The instructional environment that increased students' anxiety	• Tests and exams • online homework • Online learning • Proctored-track exams	I still get nervous every time when quizzes [are] announced or an exam is announced because like I said, this material has been hard.

Optional tasks and ungraded assignments decreased IBL students' anxiety, and the overwhelming number of online homework problems, especially at the beginning of the semester, increased lecture-based students' anxiety. In addition to the midterms, the IBL instructor engaged students in both optional and mandatory works, which were rarely graded. His pretasks were optional and ungraded but recommended for students to complete before class. However, the tasks, mock exams, and group competitions were mandatory and were required to complete during class but were rarely graded. Students did not feel stressed working with the optional and ungraded tasks and activities because they did not impact their grades; rather, these activities reduced IBL students' anxiety by developing confidence and problem-solving ability. Lecture-based students, on the other hand, experienced stress, frustrations, and anxieties when they confronted as many as 87 online problems as homework assignments during the first week. Students were anxious, thinking that they might continue receiving problems in the same manner. However, their anxiety reduced as the online homework problems decreased as the semester progressed.

Both IBL and lecture-based students felt anxious about being called on during the lectures and whole-class discussions. Students in both groups experienced extreme anxiety in the class, more specifically during the whole-class discussions, thinking that the instructor might randomly call on them for a response at any time. Recall that IBL student Camila stated, "the rest of the time, I am comfortable until he directly calls on me." These students were worried about their colleagues' judgments when they could not respond to the instructor's questions correctly and instantly. Likewise, lecture-based students were worried about being called on during the lecture for similar reasons. Unlike the IBL students, lecture-based students were usually busy "trying to write everything down" that the instructor wrote, and they experienced nervousness when they did not respond quickly to the instructor's abrupt questions. One of the lecture-based students, Liz, stated "Occasionally he would … call on someone, and if they wouldn't know, he'd be like, you should know this. I would be, like, woo, I should know this by now, which would freak me out a little bit."

Tests and quizzes, online learning, and proctored-track exams increased both IBL and lecture-based students' anxiety. Both IBL and lecture-based students were anxious about taking exams, remote learning, and proctored-track exams. Although midterms and final exams were cumulative for IBL students, they were more anxious about taking the final exam than the midterms. In contrast, the lecture-based students were anxious about taking the tests and the final exams because they weighed the largest proportion of the overall grades. Also, lecture-based students were anxious to see a few questions on the exams because they would lose huge points if they did even a single problem incorrectly.

Online learning was another aspect that induced anxiety among both groups of students. IBL and lecture-based students occasionally missed a part of or the entire class due to the poor Wi-Fi connection, which added an extra pressure on students. Moreover, proctored-track exams caused anxiety among both groups of students. They were anxious about being watched by someone remotely and hearing a loud noise when someone asked clarifying questions to the instructor,

Instructors' questions increased both IBL and lecture-based students' anxiety. Instructor questions—either during lectures or whole-class discussions—increased IBL and lecture-based students' anxiety. Three out of nine IBL students said that they feared the instructor's questions, specifically when they were unsure of the answers and were still processing the information. Maria said she is terrified of instructor questions thinking of giving an incorrect answer in front of her colleagues, who were not from her small collaborative group. Although lecture-based students experienced similar types of anxieties in responding to instructor questions, they were also anxious by the instructor's verbal pressures, such as "There's been a couple of times when he [the instructor] said, you should know this, and I did not know it, and that made me very anxious," Recall what Liz from the lecture-based class said before.

Discussion

Findings from the analysis of the interviews and observations show that the factors, such as the instructor's amicable and cordial nature, readiness to help students at all times, in-class group work, and optional and ungraded homework assignments decreased IBL students' anxiety. However, some other factors, such as thinking of being called on for a response and asking questions in front of their peers, increased these students' anxiety. On the other hand, the classroom activities, such as the overwhelming number of online homework problems that were due every week, thinking of being called on for a response in class, responding to the instructor's questions in front of their colleagues, instructor's questions, and fast-paced teaching increased lecture-based students' anxiety. Still, other factors, such as the instructor's readiness to explain the materials in class reduced the anxiety of lecture-based students.

Based on the findings from the present study, I recommend that although some factors of the instructional environment, student behaviors, and instructor behaviors have been found to be increasing anxiety among both groups of students, there are many other factors that have lessened their stress, frustration, and anxiety. It is suggested to the instructors of Calculus I and other similar mathematics courses to implement IBL in their classes or at least transition toward the student-centered approaches to instruction because of the benefits of such instructional practices on students' ability to critical thinking, reasoning, and problem-solving. It is also suggested to avoid the instructional activities that have been found to increase students' anxiety.

Using Professional Learning in Practice: The Case of Novice College Instructors

Billy Jackson — University of Wisconsin
JenqJong Tsay — University of Texas Rio Grande Valley
Shandy Hauk — San Francisco State University

We report on findings from a mixed methods study on preservice elementary teacher learning outcomes as a result of being enrolled in courses where their instructors were participating in professional development designed for those new to teaching content courses for future teachers. The study contributes to the current sparse literature within the RUME community on student performance as a result of professional learning opportunities for mathematics faculty. Results indicate improved undergraduate learning outcomes among preservice teachers when instructors engaged in a professional short-course that both fostered growth of instructors' own Mathematical Knowledge for Teaching (MKT) for teaching undergraduates and provided instructors with opportunities to learn about and support prospective teachers' development of MKT (for teaching children).

Keywords: professional development, mathematical knowledge for teaching, teaching for robust understanding

There have been many calls in the last decade to devote time and effort to the professional development (PD) of faculty in mathematics departments who teach the courses for future K-8 teachers (Flahive & Kasman, 2013; Masingila et al., 2012; Masingila & Olanoff, 2022). Indeed, Greenberg and Walsh (2008) noted that mathematics faculty regularly seek professional support in the work of teaching prospective teachers. To the best of the authors' knowledge, there have been two documented efforts in the literature to meet the needs of this call. Castro Superfine and colleagues (2013, 2014) have discussed the design model for their NSF funded *Mathematical Knowledge for Teaching Teachers* (MKTT) project, while we (Jackson et al., 2020) elaborated on the design features of our NSF funded *Professional Resources and Inquiry into Mathematics Education* (PRIMED) *for K-8 Teacher Education* project. In the former, the use of a research-based curriculum by experienced teacher educators was associated with large learning gains by undergraduates (Castro Superfine et al., 2013). However, the work did not include explicit attention to investigating prospective teacher learning outcomes as a result of faculty participation in professional development or include instructors who were new to teaching future teachers. This report aims to provide at least a partial snapshot of the relationships among *novice* instructor PD and undergraduate learning. The study is part of a larger (PRIMED) project. Here we share results of examining measures of particular target outcomes – related to mathematical knowledge for teaching – among participating faculty and their undergraduate students.

Theoretical Foundations

Mathematical Knowledge for Teaching and Its Assessment

The types of knowledge required of mathematics teachers have emerged from several decades of research and development that have grown from seeds sown by Shulman (1986). In 2008, Ball and colleagues described *mathematical knowledge for teaching* (MKT). As initially conceptualized, MKT consists of *subject matter knowledge* and *pedagogical content knowledge.* Subject matter knowledge included *common content knowledge*, *specialized content knowledge*, and *horizon content knowledge*. In particular, common content knowledge is used in everyday activities by teachers and others such as mathematicians, engineers, or homemakers. By comparison, specialized content knowledge is the knowledge that is specific to the task of teaching. Within pedagogical content knowledge, there are *knowledge of curriculum*, *knowledge of content and students*, and *knowledge of content and teaching*. Knowledge of curriculum includes awareness of the content and connections across standards and texts . Knowledge of content and students blends knowledge for doing mathematics with knowledge for unpacking it in ways relevant to how students think about, know, or learn (Hill, et al., 2008). Knowledge of content and teaching is a knowledge of teaching moves for making unpacked meanings accessible to students.

The Learning Mathematics for Teaching (LMT) instrument developed by Hill, Schilling, and Ball (2004) is a validated and reliable tool for assessing MKT development. The instrument assesses common and specialized content knowledge in different domains of K-8 mathematics including number and operations; in addition, some items assess knowledge of content and students. Though the instrument was initially validated for the purposes of measuring MKT among in-service teachers, in recent years it has been used to measure MKT development in courses for future teachers (Flake, 2014; Namakshi et al., 2022). A sample released item from the LMT instrument assessing specialized content knowledge is shown in Figure 1.

3. Imagine that you are working with your class on multiplying large numbers. Among your students' papers, you notice that some have displayed their work in the following ways:

Student A	Student B	Student C
35 x 25 125 +75 875	35 x25 175 +700 875	35 x 25 25 150 100 +600 875

Which of these students would you judge to be using a method that could be used to multiply any two whole numbers?

Figure 1 Sample Item from LMT Instrument (Hill et al. 2004)

Teaching for Robust Understanding

Teaching for Robust Understanding (TRU, Figure 2) is a research-based framework designed to attend to particular aspects of instruction (Schoenfeld, 2016). The framework was developed for research and has proven useful in practice. The TRU framework is used to explore the attributes of equitable and robust learning environments that support each student in becoming a knowledgeable, flexible, and resourceful disciplinary thinker. The TRU framework is a powerful tool because it provides a working definition of *effective mathematics instruction* that includes attention to equity along with language for describing characteristics of classroom activity. Given the centrality of educational equity in the PRIMED project, the TRU framework served a dual purpose: as a resource to guide participants in examining their own and peers' responsiveness to prospective teachers in curricular and instructional choices, and as a resource for the developers in the design, development, implementation, and evaluation of the PRIMED short-course itself.

The Mathematics	Cognitve Demand	Equitable Access to Content	Agency, Ownership, and Identity	Formative Assessment
The extent to which the mathematics discussed is focused and coherent, and to which connections between procedures, concepts and contexts (where appropriate) are addressed and explained. Students should have opportunities to learn important mathematical content and practices, and to develop productive mathematical habits of mind.	*The extent to which students grapple with and make sense of central mathematical ideas and their use. Students learn best when they are challenged in ways that provide room and support for growth, with tasks that are not low level but not impossible. The level of cognitive demand should be conducive to what has been called productive struggle.*	*The extent to which classroom activity structures invite and support the active engagement of all of the students in the classroom with the core content being addressed by the class. Classrooms in which a small number of students get most of the "air time" are not equitable, no matter how rich the content: all students need to be involved in meaningful ways.*	*The extent to which students are provided opportunities to "walk the walk and talk the talk" – to contribute to conversations, to build on others' ideas and have others build on theirs – in ways that contribute to their development of agency (the willingness to engage), their ownership over the content, and the development of positive identities as thinkers and learners.*	*The extent to which classroom activities elicit student thinking and subsequent instruction responds to those ideas, building on productive beginnings and addressing emerging misunderstandings. Powerful instruction "meets students where they are" and gives them opportunities to deepen their understandings.*

Figure 2: Teaching for Robust Understanding (TRU) Framework, Schoenfeld (2016)

Effective Design and Implementation of PD for Instructors of Future Teachers

Castro Superfine and Li (2014) discussed features of high quality professional development that they considered effective for teacher educators:

(1) Participants should be engaged in learning that is grounded in the content of teaching and learning. In particular, it must pay special attention to the MKT that is used in the work of teaching undergraduates who are preservice K-8 teachers *in addition to* bringing awareness to the instructional challenges of teaching MKT (for K-8 teaching).

(2) The PD must create the possibility of cognitive disequilibrium. That is, instructors are challenged to think about what they believe future elementary teachers need to know about MKT and why. They must also reflect on how future teachers learn about MKT.

(3) Participants must be provided with opportunities for collaboration in order to form a professional community of practice. Thus, effective PD allows for the mutual sharing of ideas and lessons learned from the work of teaching future teachers.

(4) Learning opportunities and tasks within the PD must be embedded in or directly related to the particular specialized work of teaching future teachers. PD tasks are situated in the actual work that instructors do every day in their own local institutional contexts.

Whereas the four points above address the design and development aspects of effective PD, Guskey (2000) highlighted the critical stages involved in evaluation of PD (Figure 3). In Level 1, evaluation focuses on participants' experience of the PD. Participants are questioned in surveys, interviews, and/or focus groups about how useful they feel the experience was and of what use the PD was to them professionally. In Level 2, the focus is on measuring the knowledge and skills that instructors gained as participants in the PD – specific learning goals are outlined before the PD together with a plan for assessing those goals and assessments typically include things such as pencil-and-paper instruments, reflections, journals, discussion boards, portfolios. At Level 3, evaluation turns attention to the local contexts within which participants operate professionally; common questions at this level attend to how change was (or was not) supported at the departmental/college/university levels. In Level 4, evaluation examines if and how the knowledge and skills from the PD are actually applied in the instructors' professional practice – evidence occurs through such things as direct observations, documented instances in reflective journals or portfolios, and interviews with participants and/or their supervisors. At Level 5, evaluation considers if and how participation in the PD impacted student learning outcomes – indicators of student achievement may include cognitive aspects such as performance in things like course grades, assessment scores, or scores from standardized tests. However, affective and psychomotor outcomes are also commonly measured in lieu of/in addition to cognitive skills by examining such things as student attitudes and beliefs, dispositions, and classroom behaviors.

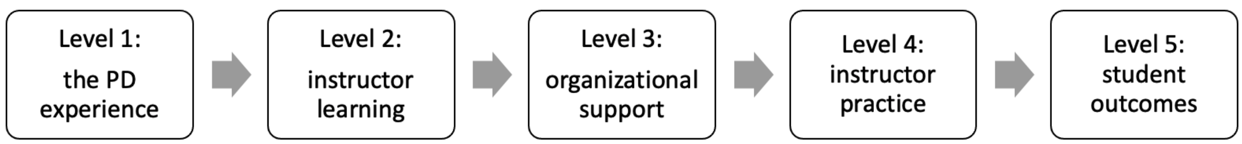

Figure 3: Five Critical Levels of PD Evaluation (Guskey, 2000)

The emphasis in the current study was to dig into the connections among **Levels 2, 4 and 5**. In particular, the aim in this report is to illustrate how the PRIMED design – which had the four principles documented by Castro Superfine and Li (2014) and incorporated use of the TRU framework – had downstream effects on Levels 2, 4 and 5. In this vein, the research question this study addressed was: *What is the nature of relationships among participation in PRIMED activities, college instructors' mathematical knowledge for teaching, and that of their students?*

Methods

For the PRIMED project, each participating college instructor agreed to complete various research tasks and agreed to include assignments in their courses through which their students completed assessments of the mathematical knowledge needed for teaching grades K-8 (the LMT). Instructors (n=15) and undergraduates (n=476) providing data for the study were from 12 different institutions of higher education (2 public community colleges, 7 master's granting [6 public, 1 private], 3 doctorate-granting [2 public, 1 private]).

The PRIMED design and learning goals are briefly described here (see Jackson et al., 2020 for a detailed description). The PRIMED professional learning experience was through the Canvas online course management system and was a hybrid: two of the five modules (Module 2 and Module 5) included both asynchronous and live online activity-based work by instructor teams from different colleges and universities; the other three modules were sets of self-paced asynchronous web-based activities completed by instructors individually with asynchronous discussion board interaction and the option of online meetings of the instructor teams. The short-course included assessments of instructor learning in each module. Participant teams rarely met in real time during the asynchronous modules and tended to check-in with each other by email or through the online discussions in Canvas.

Performance on the LMT was used as one of the outcome measures for Guskey's Level 2 (of instructors) and for Level 5 (of undergraduates). Participants who fully engaged in the short course completed three lesson experiments in which they enacted PD principles as part of their instruction using task-based active learning techniques. In addition to surveys, the project team collected artifacts from the course such as online discussion board posts about lesson experiment efforts by instructors, in-module assessments, and intake/exit interviews with each individual participant.

Results

For Guskey's Level 4 effects we examined details related to the second of the three lesson experiments. For Levels 2 and 5 we looked at gains on the LMT among the undergraduate future teachers (students) and level of PRIMED participation of instructors.

Evidence of Undergraduate Learning from Lesson Experiment Reporting

In the second lesson experiment, which occurred about halfway through the short-course, instructor participants were asked to search the practice literature in teams (of 2 or 3) for a task that had already been developed and implemented in a course for future K-8 teachers. After locating the task, each team agreed on two of the TRU dimensions to pay particular attention to while implementing the task in their own classes. The participants were asked to observe each other and debrief about the observation as each partner implemented the task. Each team was given the prompts below to document their experiences about the entire process:

Before the Lesson Prompts:

1. Which TRU framework dimensions have you selected? What do you hope to learn about yourself as an instructor by paying attention to those dimensions?
2. What is the task you have chosen? Say a little about why you chose it.
3. In terms of the selected TRU dimensions, what do you anticipate will be your greatest challenge with the lesson? How do you plan to address that challenge?

After the Lesson Prompts:

4. How was thinking about the two TRU dimensions challenging? How was it useful/beneficial?
5. How might paying attention to the TRU framework inform future task selection? Implementation?
6. [Bonus question!] Did any of the students get stuck at some point? What did you do or say to help them advance? Would you do the same thing in the future? Why or why not?

Notice that the prompts were written to have the participants actively reflect on their practice, implementing the recommendations set by Castro Superfine and Li(2014). The lesson experiment itself was structured within the work that they did as instructors, another aspect that followed the recommendations.

For the sake of space, we report here on the responses of one participant Sheila (a pseudonym) to demonstrate aspects of her own professional learning as well as that of her future teacher students. Sheila chose a task titled "Maren's Garden" in which the undergraduates in her class had to determine how many gardens could be planted with 4 bags of soil if each garden required ¾ of a bag of soil. Sheila also asked students how much soil would be left. In the Maren's Garden activity, students were asked to solve the problem in two different ways, one of which had to include pictures/diagrams. Sheila indicated that she was aware that future teachers might find it challenging to make sense of what the fractional part of the answer represented in terms of the context of the problem (i.e., that the 1/3 in the answer 5 1/3 referred to a unit of a garden rather than a bag of soil). Sheila indicated in the first prompt that she had chosen to focus on Cognitive Demand and Agency because she wanted the future teachers to make connections with their previous procedural knowledge of fraction division. For prompt 5, Sheila answered:

> Paying attention to the TRU framework will help me to choose tasks that give students opportunities to make connections between concepts or skills that they already know. For example, in the task I selected (which required students to compute 4÷3/4 in more than one way), we were able to compare/contrast solution methods and even provide a reason why multiplying by the reciprocal made physical sense in the problem!

In answering the prompt 6, Sheila noted that:

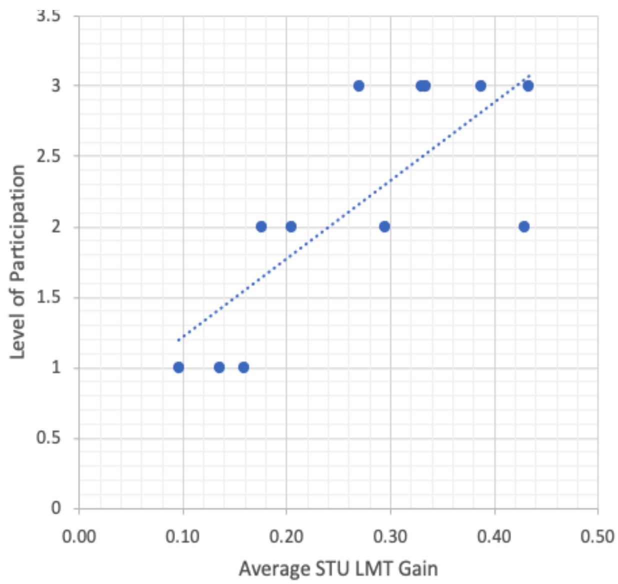
> Yes, students got stuck, and it was a great opportunity for learning! They got stuck when comparing their answers from two methods (one of which had to be visual). In the visual method, it was found that 4 bags of soil divided among gardens that each required 3/4 of a bag of soil meant that 5 full gardens could be made with 1/4 bag of soil remaining. Using the calculation, however, 4÷3/4=4×4/3=16/3=5 1/3. Students were puzzled why the calculation showed a left over part of 1/3 compared to the picture, which showed ¼.
>
> I asked them to think about what the fractional part represented in each case and then gave them some time to think about this. In the end, some of the groups realized that the calculation was counting gardens and so the 1/3 represented part of a garden, not a bag of soil. I would do this activity again and implement it in the same way.

For Sheila, an important part of her job as a teacher educator was to make sure that her students could develop their specialized content knowledge, to make connections between representations (i.e., the symbolic and diagramatic in this case). Sheila found it important to let her undergraduate students explore for themselves in order to become agentic, owners of their own learning. That this was happening was evidenced in her report of the future teachers exploring the distinction between the units involved in the problem.

Association Between Undergraduate Learning and Instructor Participation in PRIMED

The overall mean gain for undergraduates on the LMT was 0.29 standard deviations (sd), indicating they increased knowledge of target ideas. Other research on prospective teacher learning has indicated that one semester of instruction in a carefully designed course by an experienced teacher educator can lead to gains of up to 1sd (Castro Superfine et al., 2013). However, typical instruction when college instructors have professional development to strengthen their teaching has seen gains among their prospective teacher students of around 0.25 sd (Laursen et al., 2015). Here, the instructors were novices with teaching future teachers and had a comparable downstream effect (i.e., the average of 0.29sd across all instructors).

The research team also examined the relationship between an instructor's level of participation and their undergraduate students' average gain on the LMT instrument. Level 1 was assigned to the lowest amount of participation (less than one-third of the short-course activities engaged in/completed). For these instructors the average gain was about 0.13sd. Level 2 indicates moderate participation (up to two-thirds of activities completed; for example, parts of some modules not accessed or missing parts of one or two lesson experiment planning, implementation, or reflection activities). Learning gains among students in the classes of Level 2 participants averaged about 0.28sd. Level 3 indicates high participation in most activities and at least two completed lesson experiments. For the students of Level 3 instructors the average LMT gain was about 0.35sd. Instructors reported on their perceived participation in the exit interview: based upon evidence presented within the course, the research team agreed with all of the participants except for one who ranked herself at Level 2. Compared with the other participants, her engagement was Level 3. As the plot of the regression line in Figure 4 shows, there appears to be a robust correlation between rising average LMT gains and increasing levels of participation (r^2~0.6).



Level of Instructor Participation	Average of Student LMT Gain (sd)
1	0.10
1	0.14
1	0.16
2	0.18
2	0.20
2	0.29
2	0.43
3	0.27
3	0.33
3	0.33
3	0.39
3	0.43

Figure 4. Association and table of values for level of PRIMED participation and student LMT gain.

Conclusions and Future Research

We see from the lesson experiment and LMT data that there was a positive relationship between PRIMED participation and the knowledge for teaching gained by their students. While limited in scope due to the size of the study, we see that instructors implemented their intended lesson experiment curriculum with careful attention to the TRU framework and, as illustrated in the case of Sheila, their future teachers gained specialized content knowledge. The more instructors participated, the more opportunities they had to put into play a Castro Superfine and colleagues' (2013, 2014) action knowledge – an analog of knowledge of content and teaching for teacher educators (see Jackson, et al., 2018).

While certainly not evidence for a causal effect (Yoon et al., 2007), the study reported here contributes to the literature on ways to connect PD impact with undergraduate learning impact. A real challenge for the RUME community is to design and conduct large enough studies (or multiple repetitions of moderate sized studies like ours) to explore robust causal effects. Methods for addressing this challenge are part of ongoing work in educational research at all levels (e.g., Kim et al., 2018; Rosenbaum, 2005).

Student Reasoning About the Least-Squares Problem in Inquiry-Oriented Linear Algebra

Megan Wawro
Virginia Tech

Matt Park
Virginia Tech

Michelle Zandieh
Arizona State University

Zachary Bettersworth
Arizona State University

Inyoung Lee
Arizona State University

The method of Least Square Approximation is an important topic in some linear algebra classes. Despite this, little is known about how students come to understand it, particularly in a Realistic Mathematics Education setting. Here, we report on how students used literal symbols and equations when solving a least squares problem in a travel scenario, as well as their reflections on the least squares equation in an open-ended written question. We found students used unknowns and parameters in a variety of ways. We highlight how their use of dot product equations can be helpful towards supporting their understanding of the least squares equation.

Keywords: linear algebra, least squares, dot product, student reasoning, inquiry

Linear algebra courses frequently include the topic of least squares approximation. A central focus of the least squares problem is when the matrix equation $A\boldsymbol{x} = \boldsymbol{b}$ has no solution. When this occurs but some kind of solution is needed, one tries to "find an $\boldsymbol{x}$ that makes $A\boldsymbol{x}$ as close as possible to $\boldsymbol{b}$" (Lay et al., 2016, p. 362). This is consistent with a subspace orientation to the least squares problem (i.e., finding the best approximation in a subspace to a vector not in a subspace), which we leverage in our design research, as compared to a statistical interpretation. The set of least squares solutions to $A\boldsymbol{x} = \boldsymbol{b}$ are the vector(s) $\widehat{\boldsymbol{x}}$ that are solution(s) to $A^T A\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$. How can we, as instructors, help students come to understand why that equation is relevant to solving the least squares problem? Or, how can we, as curriculum designers, engage students in the guided reinvention of that equation? In this paper we pursue the research question: How do students use literal symbols and equation types as they solve an experientially real least squares problem, and what reactions do they share about the least squares equation $A^T A\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$?

The work presented in this paper is from a project (DUE-1915156/1914841/1914793) that aims to create research-based curricular materials for the guided reinvention of core concepts within an inquiry-oriented linear algebra class. This work is guided by making sense of student thinking and the complexity of mathematical ideas, which informs the refinement of the curricular materials. In pursuit of our research question, we examine written data from 13 students and analyze the variety of ways they use literal symbols and equations when solving a least squares problem in an experientially real (Gravemeijer, 1999) task setting. We also analyze the students' reactions to the least squares equation $A^T A\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$. This analysis will inform a future conceptual analysis of the mathematics as well as refinements to the task sequence.

Theoretical Framing and Literature Review

Our approach to design research is informed by what we refer to as the Design Research Spiral (Wawro et al., 2022), which is based on the design research cycle (e.g., Cobb et al., 2003), is composed of five phases, with revisions occurring between each phase based on ongoing analyses of student thinking and reflections on the mathematics. Within the first phase, the Design phase, our work is based in Freudenthal's philosophy of mathematics as a human activity (1973) and the design principles that emerged from his work in Realistic Mathematics Education

(RME) (Gravemeijer, 2020; Gravemeijer & Terwel, 2000; Treffers, 1987). RME design principles include didactical phenomenology (the means for creating the task setting of the phenomena to be organized), emergent models (a process through which students can progress from a less formal understanding of the phenomena to a more mathematized organization of the phenomena), and guided reinvention (a mechanism by which students can reinvent mathematical ideas guided by the task structure and their interactions with the instructor and their peers).

There is little literature on the teaching or learning of least squares approximation within the context of linear algebra. Turgut (2013) designed a lesson to teach least squares as a line of best fit using Mathematica. His lesson invited students to use commands in Mathematica to plot dots, form matrices from points, transpose a matrix, and take an inverse of a matrix in finding the best possible solution. A topic we view as related to the teaching and learning of least squares is dot product. Donevska-Todorova (2015) identified three definitions of the dot product within three modes of description (arithmetic, geometric, abstract-axiomatic) and created an applet to promote students' geometric understanding of the dot product. Cooley et al. (2014) developed a module to teach dot product, focusing on the cosine definition. Their task included comparing frequency vectors and determining if an author wrote two different texts. Dray and Manogue (2006) found projection to be essential in understanding dot product. They claimed the geometric approach of the dot product benefits students in many applications of physics and engineering.

As we examined students' work on the question shown in Figure 2, we were struck by the variety of ways literal symbols and equations were used as students completed the problem. In undergraduate mathematics, literal symbols are used in many ways. It is important to understand students' interpretation of literal symbols and how they are used when solving problems. For our analysis, we draw from Philipp (1992) and Drijvers (2003) for unpacking the nuance in literal symbol use. Drawing on works such as Keiran (1988), Küchemann (1978), and Usiskin (1988), Philipp uses literal symbol to describe the mathematical use of a letter; he provides seven literal symbol uses: labels, constants, unknowns, generalized numbers, varying quantities, parameters, and abstract symbols; most relevant to our work is unknown, varying quantity, and parameter. Philipp states that an "unknown involves the use of a literal symbol when the goal is to solve an equation" (p.558), such as in the role of x in $8x + 4 = 28$. Philipp's use of varying quantity is consistent with Knuth et al.'s (2005) definition of variable as "a literal symbol that represents, at once, a range of numbers" (p. 70), such as x and y in $y = 3x + 5$. Finally, Philipp describes parameters as generalized constants, such as m and b in the linear equation $y = mx + b$.

Drijvers (2003) focused on design research related to the concept of parameter, which he sees as "an 'extra variable' in a formula or function that makes it represent a class of formulas, a family of functions and a sheaf of graphs" (p. 60). Drijvers delineates four roles that a parameter can assume: placeholder, changing quantity, generalizer, and unknown. First, a *parameter as a placeholder* plays the role of a constant value that does not change; whether known or unknown, its value is fixed, and filling in different known values relate to different situations rather than variations of the same situation. Second, a *parameter as a changing quantity* represents a numerical value that takes on a dynamic character of systematic variation. It runs smoothly through a reference set, affecting the complete, global situation set rather than a single situation (e.g., p and q in $y = (x - p)^2 + q$). Third, a *parameter as a generalizer* does not stand for a specific number but rather for an exemplary number or set of numbers. It facilitates seeing the general in the particular, formulating solutions at a general level, and solving concrete cases at once by means of a parametric general solution (e.g., t in a parametric solution $x = t(1,2,3)$). Fourth, the *parameter as unknown* facilitates "selecting particular cases from the general representation on the basis of an extra condition or criterion. In such situations, the parameter acquires the role of unknown-to-be-found" (p. 69) (e.g., solve for t for a specific x in the above). Finally, these roles are not fixed and can change in the solution process.

The Task Setting

Our task sequence leverages the subspace-oriented version of the least squares problem (the best approximation to a vector not in a subspace is its orthogonal projection onto the subspace). We designed an experientially real task setting called *Delivering Mail to Gauss*, which is based on the Magic Carpet Ride sequence (Wawro, et al., 2012) in the Inquiry-Oriented Linear Algebra (IOLA) curriculum (Wawro et al., 2013). Even though it is a fantasy setting, we have found that students can immediately engage with the idea of different transportation modes, each traveling forward and backward in a single vector direction. The first Delivering Mail task asks students to use three specific travel vectors (the same vectors in Task 3 of the Magic Carpet Ride sequence) to travel to Gauss in $\mathbb{R}^3$ so that they can deliver his mail. This differs from the Magic Carpet ride task in that Gauss is now in a location outside of the span of the travel vectors. Using previous knowledge, students determine Gauss cannot be reached and the travel vectors span a plane in R^3. Students are then told their cousin has a drone they can use to deliver Gauss's mail, on the condition that they get as close as they can to Gauss using the travel vectors before they use the drone. They then determine where to travel to, how to get there with the travel vectors, along what vector the drone would travel, and what distance the drone's trip would be (Figure 1a).

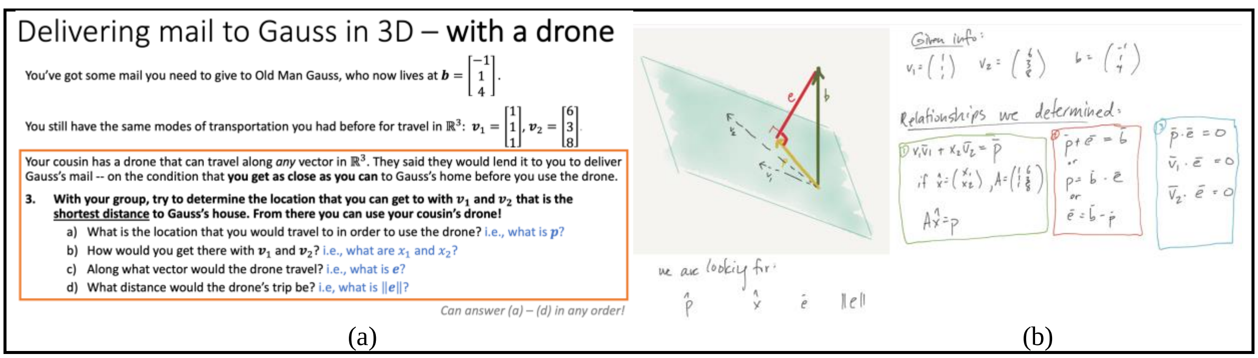

Figure 1. The setup of Task 3 and the class's shared development of known relationships to help solve the task.

There are many aspects of the problem to symbolize. Gauss's location is denoted as $\boldsymbol{b}$. The three travel vectors $\boldsymbol{v}_1$, $\boldsymbol{v}_2$, and $\boldsymbol{v}_3$ are in the first task statement, but once students realize the three span a plane, they work only with $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$. The sequence is designed to foster students' exploration of what location on the plane would be closest to Gauss, and students consistently suggest the location that creates a path *orthogonal* from the plane to Gauss (Lee et al., 2022). With an instructor's suggestions for which literal symbols to choose, the class uses vector $\boldsymbol{p}$ to denote where on the plane they should travel to and use the drone, **e** as the drone's path to Gauss, and $||\boldsymbol{e}||$ as the distance of the drone's trip. The class symbolizes the relationship between these as $\boldsymbol{p} + \boldsymbol{e} = \boldsymbol{b}$. To denote how to get to $\boldsymbol{p}$ using the travel vectors, the scalars x_1 and x_2 are used to mean how much and in what direction to travel on $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ so that $x_1\boldsymbol{v}_1 + x_2\boldsymbol{v}_2 = \boldsymbol{p}$, which can be written as a matrix equation $A\widehat{\boldsymbol{x}} = \boldsymbol{p}$ where A is the matrix with columns $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ and $\widehat{\boldsymbol{x}}$ is the vector with components x_1 and x_2. Finally, the instructor leads the class in a derivation that the dot product of two orthogonal vectors is zero, which results in the class denoting $\boldsymbol{v}_1 \cdot \boldsymbol{e} = 0$, $\boldsymbol{v}_2 \cdot \boldsymbol{e} = 0$, and $\boldsymbol{p} \cdot \boldsymbol{e} = 0$. All of these relationships are summarized in Figure 1b, which shows one instructor's written work that recorded the relationships during class.

Students then use these known relationships to solve for $\boldsymbol{p}$, $\widehat{\boldsymbol{x}}$, $\boldsymbol{e}$, and $||\boldsymbol{e}||$. Students make progress in a variety of ways. If students combine $\boldsymbol{v}_1 \cdot \boldsymbol{e} = 0$ and $\boldsymbol{v}_2 \cdot \boldsymbol{e} = 0$ into a system of equations and write it as an augmented matrix, the instructor could notate the coefficient matrix as A^T and leverage the student work towards the matrix equation $A^T\boldsymbol{e} = \boldsymbol{0}$. The final task prompts students to "Combine three of our main equations, $A\widehat{\boldsymbol{x}} = \boldsymbol{p}$, $\boldsymbol{p} + \boldsymbol{e} = \boldsymbol{b}$, and $A^T\boldsymbol{e} = \boldsymbol{0}$, to come up with one *general equation* (symbols only, no specific numbers) that would help us determine $\widehat{\boldsymbol{x}}$ for any A and $\boldsymbol{b}$. The only unknown in your *general equation* should be $\widehat{\boldsymbol{x}}$ (i.e., no $\boldsymbol{p}$ or $\boldsymbol{e}$)." Student work on this task allowed for the guided reinvention of the least squares equation $A^TA\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$ (abbreviated LSE), where $\widehat{\boldsymbol{x}}$ is the least squares solution to $A\boldsymbol{x} = \boldsymbol{b}$.

Methods

The data for this paper come from in an in-person introductory linear algebra class at a large, public, research university in the Mid-Atlantic US. The course had 27 students, of which 13 both gave consent and completed the assignments analyzed in this paper. In the university system, 8 of these students chose he/him/his pronouns (pseudonyms begin with "M"), 4 chose she/her/hers pronouns (pseudonyms begin with "W"), and 1 did not choose pronouns (pseudonym P1). Most were second-year students by credit hours and were general engineering majors. The prerequisite was a B or higher in Calculus I or a passing grade in Calculus II. The data analyzed in this paper come from student responses to two written reflections. After most class sessions, students were asked to complete a reflection by the end of the day and submit their work via an online learning management system. Students were asked to spend 5-10 minutes on a reflection, for which full credit was awarded based on effort rather than correctness. Reflection #1 (Figure 2) was given the day that the class completed their solutions to the Delivering Mail to Gauss tasks and the reinvention of $A^TA\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$ (the LSE). The purpose of this reflection was to learn more about how students were making sense of the various aspects of the least squares problem and what solution approaches they would use. Reflection #2 (Figure 3) was given the following day to learn more about how students were making sense of the least squares equation.

Create your own example of two travel vectors in $\mathbb{R}^3$ and a location for Gauss in $\mathbb{R}^3$that you cannot reach with your travel vectors. Then solve for at least two of the following: the vector closest to Gauss that you can reach, how you would get there with the travel vectors, and the distance from that location to Gauss. Show your work and/or explain your thinking

Figure 2. Reflection prompt #1.

We started Least Squares Approximation with the "delivering mail to Gauss" scenario, eventually deriving the equation $A^TA\widehat{\boldsymbol{x}} = A^T\boldsymbol{b}$ as a way to directly solve for $\widehat{\boldsymbol{x}}$. We are really curious about your reaction to the equation. In 2-3 sentences, please share with us how you are making sense of it, your thoughts, or any questions you may have.

Figure 3. Reflection prompt #2.

To analyze the data, we began by creating thick descriptions for student responses to Reflection Prompt #1. In doing so, we were struck by the variety of ways in which most students leveraged the known relationships from Figure 1 to reach a solution for the travel scenario that they created, rather than using the LSE formalized in class that day. In order to capture the nuance of students' solution processes, we decided to focus on the diversity in their use of literal symbols and equation types. We studied the related literature and found Philipp's (1992) characterization of *literal symbols* and Drijver's (2003) characterization of *parameter* to be particularly appropriate; thus, we coded the data within their frameworks (summarized in the Theory section). We also studied the literature related to students' use of various types of equations in linear algebra, and we found Zandieh and Andrews-Larson (2019) to be most helpful. Their work, which is grounded in their prior research on three interpretations of $A\boldsymbol{x} = \boldsymbol{b}$ (Larson & Zandieh, 2013), characterizes students' symbolizing while solving linear systems. We coded the data in a way compatible with their approach, analyzing the various *equations types* (e.g., vector equation, matrix equation) students brought to bear in their solution process. For Reflection #2, we engaged in open coding to make sense of the variety of student responses. The first two authors independently coded all the data, conferred with each other to resolve any differences, discussed the data with the author team, and further refined as needed.

Results

Overall, in Reflection Prompt #1, we found that students use literal symbols as unknowns in three ways: as vectors, vector components, and scalars. We found that students used literal symbols as parameters in three ways: as placeholder, generalizer, and unknown. Students also leveraged six equation types in their problem solving: matrix equation, vector equation, system of linear equations, augmented matrix, dot product equation, and quadratic equation. Because of space, we focus on a vignette from one student. We chose M7 as a paradigmatic example because of the broad range of literal symbols and equation types that he used. A limitation of our data is that it is written data only; we cannot know how the students were thinking about the various symbols they wrote. Instead, we focus on how the literal symbols seemed to function in use; for this reason, our analysis makes claims such as "$\boldsymbol{e}$ and $\boldsymbol{p}$ are unknowns" rather than "the student reasoned about $\boldsymbol{e}$ and $\boldsymbol{p}$ as unknowns." To help the reader follow the analysis, we use italics for literal symbol use and underlining for equation type within the vignette. We do not label the equations that are of the type *unknown* = *determined value,* which communicate when a student completes a solution process for the unknown vector, component, parameter, or scalar.

M7's Work on Reflection Prompt #1

At the top of his page (see Figure 4), M7 wrote the relationships $\boldsymbol{e} \cdot \boldsymbol{p} = 0$, $\boldsymbol{e} \cdot \boldsymbol{v}_1 = 0$, and $\boldsymbol{e} \cdot \boldsymbol{v}_2 = 0$, which had been established in class (Figure 1). These three equations are <u>dot product equations</u>; within them are four literal symbols: $\boldsymbol{e}$ and $\boldsymbol{p}$ are *unknown vectors*, and vectors $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ are each a *parameter-as-placeholder*. M7 shifts to a <u>system of equations</u> $e_1 + 2e_2 + 3e_3 = 0$, $e_1 + e_2 + e_3 = 0$ created from the latter two dot product equations. This introduces three new literal symbols– e_1, e_2, and e_3 –which are each *unknown components.* We note that e_1, e_2, and e_3 are the components of the $\boldsymbol{e}$; to eventually solve for unknown vector $\boldsymbol{e}$, M7 decomposed it into unknown components. M7 transitions to an <u>augmented matrix equation</u>, using it four times as he carries out row reduction. M7 expresses the solution resulting from the row reduction as a <u>system of linear equations</u> $e_1 = e_3$ and $e_2 = -2e_3$, which again use e_1, e_2, and e_3; in this instance, however, the three literal symbols are now used as *varying quantities* because the system expresses how they are related and change together. It seems that M7 next compacted this information into $\boldsymbol{e} = \begin{bmatrix} t \\ -2t \\ t \end{bmatrix}$. M7 did not explicitly write the "$\boldsymbol{e} =$", but he substituted the vector in for $\boldsymbol{e}$ twice in his subsequent work. Thus, at this point in his work, M7 used the literal symbol t as a *parameter-as-generalizer* to represent all possible solutions for $\boldsymbol{e}$.

M7 then writes the <u>vector equation</u> $\boldsymbol{b} - \boldsymbol{e} = \boldsymbol{p}$. Here, $\boldsymbol{b}$ is a *parameter-as-placeholder* and $\boldsymbol{p}$ is still an *unknown vector.* However, we see a shift in $\boldsymbol{e}$ from vector unknown to *parameter-as-placeholder*; this is evidenced by the subsequent <u>vector equation</u> in which M7 substitutes in component-wise versions of both $\boldsymbol{b}$ and $\boldsymbol{e}$, using the parameterized version of $\boldsymbol{e}$, where again t functions as a *parameter-as-generalizer*. M7 then simplifies that vector equation into $\boldsymbol{p}$ in terms of t. Next, M7 next brings in the very first known relationship he had written, $\boldsymbol{e} \cdot \boldsymbol{p} = 0$, but now that dot product equation is written with component-wise expressions in terms of t for both $\boldsymbol{e}$ and $\boldsymbol{p}$. Thus, we see a shift in the role of t to that of *parameter-as-unknown*. This use of t continues in M7's simplification of the dot product equation into a quadratic equation in t; two additional quadratic equations are written as M7 simplifies in order to solve for t. This leads to M7's solution $t = 0, \frac{1}{6}$, where t as a literal symbol is a *determined value* (i.e., the values of t that make the equation true, determined through a solution process). Choosing $\frac{1}{6}$ as an *assigned value* for t (Alaee et al., 2002), M7 gets exact solutions for $\boldsymbol{e}$ and $\boldsymbol{p}$ via substitution. M7 boxes the $\boldsymbol{p}$ vector and writes "closest vector we can reach." M7 completes his work by using a vector equation to write $\boldsymbol{p}$ as a linear combination of $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$, with the literal symbols s and t as *unknown scalars*. Although M7 again uses t as a literal symbol, we see no evidence that the two uses of t were connected in any way. M7 transitions to a system of linear equations in s and t and solves for the unknown scalars $s = -\frac{1}{2}$ and $t = 4/3$; M7 concludes by explaining how to use the travel vectors, presumably to reach $\boldsymbol{p}$, which is consistent with his algebraic solution.

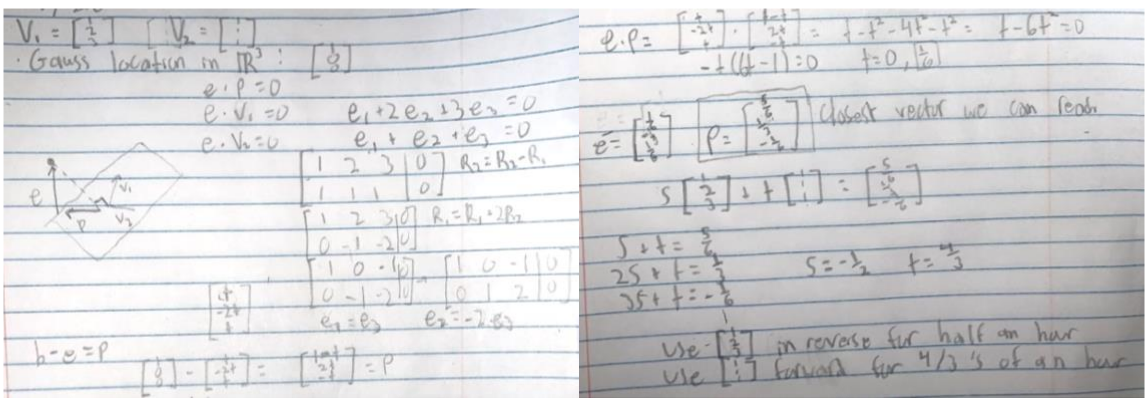

Figure 4. Student M7's written solution for Reflection 1.

We emphasize that the first augmented matrix M7 wrote corresponds to the matrix equation $A^T\boldsymbol{e} = \boldsymbol{0}$; he did not use the literal symbol A^T to notate his work, and we have no evidence he recognized the coefficient matrix as A^T. We point this out as an implicit use of A^T that grows out of the student's own problem-solving, which is important in terms of RME-inspired curriculum design and the class's use and understanding of the least squares equation $A^T A\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$.

Student work on Reflection Prompt #2

When asked about their sense-making, thoughts, or remaining questions they may have about $A^T A\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$ (Figure 3) after the following class, students shared a range of reactions about both individual parts of the equation and it as a whole.

Reactions to individual parts of the equation were typically related to the interpretation of its components. Among these, the most common topic invoked by students was that of A^T, both its properties and its function in the LSE. For example, W4 shared, "I'm wondering how $A\boldsymbol{x} = \boldsymbol{b}$ and $A^T A\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$ don't have the same solutions since it's just multiplication A^T to both sides." We note that W4 wrote $\boldsymbol{x}$ rather than $\hat{\boldsymbol{x}}$ in her LSE, helping us understand that the nuance between $\boldsymbol{x}$ and $\hat{\boldsymbol{x}}$ may not be straightforward for students. W7 wrote, "It may be because I'm still a little confused as to how transposing a matrix effects [sic] the original image, but I still don't understand how it adds possible solutions to the equation." We interpret the first part as W7 trying to make sense of what A^T means as a linear transformation, which we see as a valuable curiosity. We interpret the second part as W7 grappling with how the two equations are related and what it means to be a solution, which seems related to W4's response. We do have evidence that some students understood the utility of the transpose matrix; for example, M6 wrote "$A^T\boldsymbol{e}$ does the job of dot product each column of A by $\boldsymbol{e}$, that's why $A^T\boldsymbol{e}$ would yield the zero vector."

Other students commented on the efficiency of the LSE or contextualized their understanding on how to use the LSE within the class's work together. For example, M2 wrote "It condensed a mess of variables and diagrams into a single expression," and M8 said "The formula is quite simple to use" (M8). It appears that some students' comfort in using the equation related to their understanding of its derivation. For example, W5 wrote: "I would not know what to do with [the equation] if I didn't understand the derivation." It is unclear what W5 means by "what to do," possibly meaning use the equation to solve a least square problems or knowing what each literal symbols means in the context of least square problems. W6 wrote: "The equation makes sense to me based on how we derived it based on what we knew. However, I don't really understand how it all works together/why it all works." It is unclear what the distinction is for W6 between the LSE making sense and understanding why it works.

Discussion

The method of Least Squares is an important topic in linear algebra, although it is not always discussed in a first course possibly because of the background needed to understand all aspects involved in the SLE solution method. The first task in the least squares sequence, *Getting Mail to Gauss*, is straightforward enough to introduce in the first or second week of an introductory linear algebra course (such as after the second task of the *Magic Carpet Ride* IOLA sequence, Wawro et al., 2012). As explored in this paper and in our previous work (Lee et al., 2021), however, the solution process may bring to bear equation types and solution strategies learned across the entire introductory course. M7's work above illustrates the range of equation types and literal symbol use that this student has knowledge of and can flexibly move between in reconstructing a successful solution method.

One of the key features of the LSE is the presence of the matrix A^T. The student work in this study (not all of which we could share in limited space) suggests some connections the students were making between the LSE and A^T. While some students used A^T immediately in Reflection #1, such as M8, others such as M7 derived it through their solution process without labeling with the literal symbol A^T, such as M3, M7, and P1. The use of the array of numbers that experts think of as A^T was not problematic for students such as M7 when using these as coefficients in a system of equations or within the related augmented matrix equation. Students in this class were familiar with converting between systems of equations (or augmented matrices) and matrix equations of the form $A\boldsymbol{x} = \boldsymbol{b}$. So, converting equations such as M7's initial work into the expression $A^T\boldsymbol{e} = \boldsymbol{0}$ was not itself problematic for students; however, thinking of this array as a matrix that A, $A\hat{\boldsymbol{x}}$, or $\boldsymbol{b}$ can be multiplied by seemed to be something students wondered about. The questions some students such as W7 and W6 wondered about on Reflection #2 seemed to be about the meaning or role of A^T when multiplied by the other expressions in the LSE. Given that students in an IOLA classroom tend to be familiar with reasoning about a matrix times a vector as a transformation of that vector (Andrews-Larson et al., 2017), these students may have wondered what transformation A^T imparts on input vectors.

Our future work involves further analyzing the nuances in student solution strategies and their conceptual understanding of the LSE, using this to make adjustments to the task sequence, and developing a conceptual analysis for the mathematics in least squares approximation.

Two Vignettes on Students' Symbolizing Activity for Set Relationships

Anthony Tucci
Texas State University

Mathematicians often use set-builder notation and set diagrams to define and show relationships between sets in proof-related courses. This paper describes various meanings that students might attribute to these representations. Our data consist of students' initial attempts to create and interpret these representations during the first day of a paired teaching experiment. Our analysis revealed that neither student imputed or attributed our desired theoretical meanings to their diagrams or notation. We summarize our findings in two vignettes, one describing students' attributed meanings to instructor-provided set-builder notation and the other describing students' imputed meanings to their personally-created set diagrams to relate pairs of sets.

Keywords: Symbolization, representations, student thinking, sets, set relationships

Introduction and Literature Review

Mathematics is a unique science in which objects of analysis are inaccessible to the five senses and can only be visualized indirectly using various representations (Duval, 2006). Theories of representation abound in the mathematics education literature (e.g., Duval, 1999, 2006; Godino & Font, 2010; Goldin, 2008; Radford, 2013; Vergnaud, 1998). Previous researchers have called for increased visual representations (e.g., Arcavi, 2003) and identified privileged forms of representation for specific mathematical topics (e.g., González-Martín et al., 2011). Diverse representations provide opportunities to construct shared meanings, which invite further investigation into how students invest representations (standard or not) with meaning.

This paper investigates undergraduate students' symbolizing activity about sets and set relationships. We define *symbolizing activity* as a process of mental activities that entails students' creation or interpretation of a perceptible artifact (writing, drawing, gesture, verbalization) to organize, synthesize, or communicate their thinking. We refer to *symbolization* as the status of completing the symbolizing activity and perceptible artifacts as *symbols*. Our definition differs from Tillema's (2010) communication-focused symbolizing activity by including individuals' creation of personal representations to reflect on their thinking.

As part of our investigation into the role of set-based reasoning in students' comprehension of conditional statements (Dawkins, 2017; Dawkins et al., 2021), we created an instructional sequence for students to investigate sets using set-builder notation and diagrams. We present two vignettes detailing the various meanings students imputed to these representations during their initial exposure to these ideas. We provide the following research question to contextualize the vignettes: *What differences in thinking did students exhibit as they (a) made sense of set-builder notation and (b) created set diagrams to describe relationships between sets?*

Theoretical Perspective

One problem with studying representations in isolation from student thinking is that students can impute various ideas to the same symbol. For instance, Gray and Tall (1994) stated that mathematicians utilize algebraic notations (e.g., the numeral 6) fluidly to refer to either a process (e.g., putting together two and four pennies) or a stabilized concept (e.g., a pile of 6 pennies). Thompson (2002) showed differences between individual student meanings for a point on a graph, even after students agreed upon a group definition. Alternately, Eckman and Roh (2022) showed that students might generate one notation to reason about a process they conceive and a different convention to describe a concept they abstract from reflecting on the process.

We propose two constructs to describe the representations we investigate in this paper. First, Eckman and Roh (2022) used the term *personal expression* to describe students' imputation of meaning to a self-generated algebraic expression. In this paper, we expand the definition of *personal expression* to cover all forms of students' mathematical representation. There are two components to personal expressions: a meaning and a perceptible artifact to which the student imputes their meaning. We use the term *meaning* in the constructivist sense (Thompson, 2013; Thompson et al., 2014) that individuals construct and maintain cognitive structures through their experience. A *perceptible artifact* includes any action or product a student produces to convey their meanings (writing, drawing, gesture, verbalization), which another individual might observe with his five senses. Our definition of personal expression is related to de Saussere's (2011) notion of *signifier* and *signified*, which also informed Glasersfeld's (1995) definition of symbol.

When a student creates an expression to organize or synthesize her thinking, she creates a *personal expression*. We consider all non-student generated expressions that require the student to anticipate the expression creator's intended meaning to be *communicative expressions*. There are three components to a communicative expression: (a) the creator's intended meaning, (b) the interpreter's evoked meaning, and (c) the perceptible artifact the creator uses to convey their intended meaning. For instance, Jill might create the personal expression $S = \{x \in \mathbb{Z} | x \text{ is prime}\}$ to denote her image of the set of prime numbers. If Jill presented her personal expression to Jack, Jack would perceive $S = \{x \in \mathbb{Z} | x \text{ is prime}\}$ as a communicative expression to which he would need to assign meaning. However, Jack's evoked meaning from Jill's personal expression may not reflect Jill's intended meaning. In summary, whether a perceptible artifact is a personal or communicative expression is in the eye of the beholder. The expression $S = \{x \in \mathbb{Z} | x \text{ is prime}\}$ is personal to Jill because she created it and communicative to Jack because he must interpret it.

Methodology

The data we present in this paper come from an ongoing project to develop models of students' abstraction of logic for conditional statements (Dawkins, 2017; Dawkins et al., 2021). During the study, we conducted six paired constructivist teaching experiments (Steffe & Thompson, 2000), consisting of 8-12 sessions lasting 60-90 minutes each. We focus on the first day of the Spring 2022 teaching experiment. Our students, who chose the names Sarah and Carl, were enrolled in Calculus 3 at a large public university in the United States. The second author served as the teacher-researcher, with all other authors serving primarily as witnesses.

Students' work was collected via video recording, a shared whiteboard application, and photographs of physical board work. We analyzed the data using the principles of open coding (Strauss & Corbin, 1998). As our initial codes emerged, we realized that some findings aligned with previously proposed constructs (Dawkins et al., in preparation; Sellers et al., 2021). During axial coding, we combined our unique codes with these constructs to describe meanings students exhibited during their symbolizing activity. We synthesized our findings into two vignettes. The first vignette describes meanings that students might attribute to *communicative expressions* of set-builder notation. The second vignette describes how students might construct set diagrams as *personal expressions* to express their image of the relationship between two sets.

Results

For each vignette, we first present a theoretical model of a beneficial meaning for representing sets or set relationships. We then offer two alternative meanings from our data that students exhibited in their symbolizing activity.

Vignette 1: Students' Meanings for Set-builder Notation (Communicative Expressions)

We initially presented Sarah and Carl with pairs of sets (defined using set-builder notation) and asked them to posit relationships between the sets (see Figure 1). Our examples constituted *communicative expressions* because students interpreted our notation. In this vignette, we report on students' imputed meanings to set-builder notation while comparing set pairs α, β and α, γ.

Given the set $\mathbb{T}$ of all triangles, answer these questions about each pair of sets:

1) Is there anything in both sets?
2) Does one set contain all the members of another?
3) Can you say anything more about the relationship between the sets?
4) If you use an oval region to represent one set, how would you portray the other in relation?

$\alpha = \{\Delta ABC \in \mathbb{T}: \Delta ABC \text{ is isosceles}\}$	$\beta = \{\Delta XYZ \in \mathbb{T}: \Delta XYZ \text{ is equilateral}\}$
$\alpha = \{\Delta ABC \in \mathbb{T}: \Delta ABC \text{ is isosceles}\}$	$\gamma = \{\Delta RST \in \mathbb{T}: \angle R \cong \angle S\}$
$\alpha = \{\Delta ABC \in \mathbb{T}: \Delta ABC \text{ is isosceles}\}$	$\eta = \{\Delta JKL \in \mathbb{T}: \Delta JKL \text{ is not isosceles}\}$

Figure 1. An excerpt from Task 1. The prompt is shortened for brevity, and not all pairs of sets are shown.

A beneficial way to interpret communicative expressions for set-builder notation. We first present a theoretical meaning that did not emerge in our data but we considered beneficial for students to compare two sets appropriately (see Figure 2).

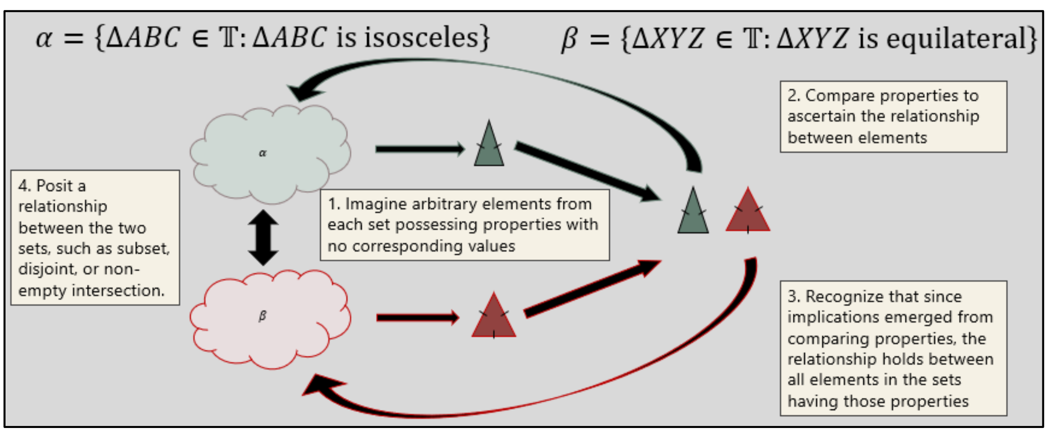

Figure 2. A productive meaning and resulting method for comparing sets α and β.

A student determining the relationship between sets α and β might first imagine arbitrary elements, ΔABC and ΔXYZ, from each set (Figure 2, step 1). These arbitrary elements contain no specific measurements for characteristics such as angle measure. The student would then compare the properties of the two elements to determine their relationship (Figure 2, step 2). For instance, the student might imagine that since the isosceles triangle has at least two equal sides and the equilateral triangle has exactly three equal sides, the equilateral triangle can be considered isosceles. The student would then infer that since every element in set β has exactly three equal sides, all equilateral triangles can be considered isosceles (Figure 2, step 3). Finally, the student would conclude that if all equilateral triangles are isosceles, then set β must be a subset of set α (Figure 2, step 4). Conventionally, we call this meaning for ΔABC or ΔXYZ an *arbitrary particular*. However, our theoretically propitious meaning was distinct from the meanings exhibited by Carl and Sarah. In the following data-driven examples, we show two meanings these students attributed to set-builder notation while comparing pairs of sets.

Meaning 1a: Particular $\boldsymbol{\Delta ABC}$. When Sarah read the teacher-researcher's communicative expressions $\alpha = \{\Delta ABC \in \mathbb{T}: \Delta ABC$ is isosceles$\}$ and $\beta = \{\Delta XYZ \in \mathbb{T}: \Delta XYZ$ is equilateral$\}$, she imagined specific triangles with corresponding values and labels unique to each triangle.

Sarah: I have a question. (Interviewer 1: Ok.) The left-hand side set (α) is congruent to the right-hand side set (β) but they're two different triangles…or are they the same triangle? Like, they are different sets of triangles, right?

(omitted dialogue)

Interviewer 2: Sarah, just to clarify, was your question in part about set α has the letters ABC and set β has the letters XYZ?

Sarah: Yes.

Interviewer 2: And so, because there are different letters, you weren't sure if the triangles were the same triangles?

Sarah: Yeah, I just got a little bit confused on that.

In this example, Sarah questioned interviewer 1 (second author) whether two triangles from sets α and β (which she considered congruent) could be regarded as the same triangle when comparing sets. Eventually, interviewer 2 (first author) asked whether Sarah's confusion emanated from denoting elements of set α with ΔABC and elements of set β with ΔXYZ, which she confirmed. In other words, Sarah comprehended that a triangle ΔABC from set α could be congruent to a triangle ΔXYZ in set β but was unsure whether ΔABC could exist within set β because the vertices of ΔABC in the communicative expression for set α were not labeled with the letters for set β. We call Sarah's evoked meaning for the expression ΔABC a *particular* triangle. We compare Sarah's meaning with our theoretical meaning in the vignette 1 summary.

Meaning 1b: Spontaneous particular $\boldsymbol{\Delta ABC}$. When Carl compared the the communicative expressions ΔABC and ΔXYZ, he imagined various possible pairings between elements in set α and set β and the relationships that might occur for each comparison.

Interviewer 1: What do you think, Carl (about the relationship between sets α and β)?

Carl: Yeah. Um, I thought that it was. I don't think of like, the sets. I thought it more like, it could, like have a good chance of being 100% the same triangle. But also, there's also a good chance that it's close, similar, but not quite. Like 70 or so percent chance.

Interviewer 1: You're talking about one specific triangle?

Carl: Yeah, like comparing ABC to XYZ.

Carl's explanation shows that he was considering two distinct situations: (1) comparing a triangle with exactly two equal sides from set α with a triangle from set β and (2) comparing a triangle with exactly three equal sides from set α with a triangle from set β. Carl's probabilistic language also indicates that he imagined how often the triangles he selected spontaneously were likely to be in both sets. We thus say that Carl's evoked meaning for the expression ΔABC was of a *spontaneous particular* and not an *arbitrary particular* triangle. We further discuss how Carl's *spontaneous particular* meaning emerged in his set diagram personal expressions in vignette 2.

Carl's *spontaneous particular* meaning ΔABC and ΔXYZ is analogous to what Sellers et al. (2021) called an *MQ4* meaning for a quantified variable. Students exhibit an *MQ4* meaning when they spontaneously select elements within a domain of universal discourse, make inferences without exhausting all elements, and may or may not repeat this process to make (potentially different) inferences about other elements.

Summary of vignette 1. In this vignette, we have shown three meanings that a student might have for ΔABC in the communicative expression $\alpha = \{\Delta ABC \in \mathbb{T}: \Delta ABC\ is$ isosceles$\}$. A student exhibiting the *arbitrary particular* meaning (see Figure 2) imagines triangles defined by the properties described in the set-builder notation and would be capable of making general comparisons between sets. Sarah's meaning of *particular* triangles allowed her to imagine elements of sets α, β and γ (Figure 2, step 1) and make rudimentary comparisons between these elements (Figure 2, step 2). However, her image of triangles with fixed values for various characteristics precluded her from discerning the appropriate relationship between the entire sets of objects (Figure 2, steps 3, 4). Carl's meaning of *spontaneous particular* triangles allowed him to imagine random pairings of elements from sets α and β (Figure 2, step 1) and compare them (Figure 2, step 2). In effect, Carl constructed relationships of likelihood, not relationships of necessity as are privileged in mathematical logic, which are essential for proving.

Vignette 2: Students' Meanings for Set diagrams (Personal Expressions)

We also invited Sarah and Carl to construct set diagrams to represent the relationships they envisioned between pairs of sets (see Figure 1, question 4). We consider the diagrams that Carl and Sarah generated (even if they exhibited the conventions of Euler diagrams) to constitute their *personal expressions* for organizing their thinking about various pairs of sets.

Regions that partition: A beneficial way to construct a set diagram. We first present a beneficial meaning that did not emerge in our data which a student might leverage to construct a set diagram to compare sets α and β (see Figure 3). First, the student would imagine the universe of discourse, $\mathbb{T}$, the set of all triangles. The student might then draw a box to metaphorically gather all triangles into an enclosed entity (Figure 3, part 1). Second, the student would consider set α, the set of isosceles triangles. The student might represent α by drawing an oval region inside the box to simultaneously gather all isosceles triangles and partition them from other triangles (Figure 3, part 2). The student would recognize that the region outside the oval denoting α constitutes the complement set to α (α^c). Third, the student would utilize the *arbitrary particular* meaning to determine that all elements of β exist within set α (Figure 3, part 3).

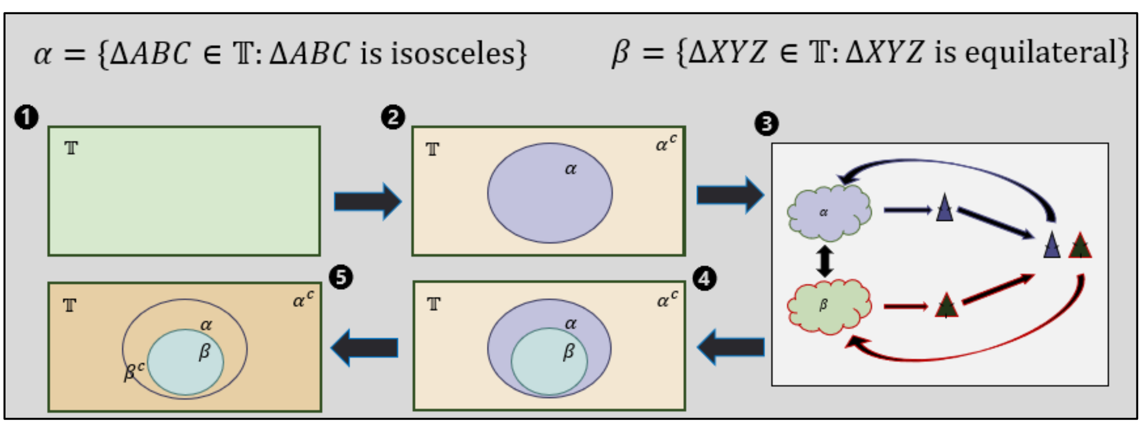

Figure 3. A productive method to produce a set diagram comparing sets α and β.

The student might then draw an oval region to represent set β within his previously created region for α (Figure 3, part 4). The student would realize that his actions (a) gather equilateral triangles from the universal set $\mathbb{T}$ into the oval region β and (b) denote the regions outside the oval for set β as the set of all non-equilateral triangles (β^c; Figure 3, part 5). We have previously used *regions that partition* to describe students' set diagrams constructed through this propitious meaning (Dawkins et al., in preparation). In the following data-driven examples, we report two other meanings that Sarah and Carl attributed to their diagrams comparing set pairs α,η and α, γ.

Meaning 2a: Regions that gather. When Sarah drew her set diagram *personal expression* to relate sets α and η (which are disjoint sets), she drew one oval region to represent α and a second, non-overlapping oval region to represent η (see Figure 4). Sarah then drew isosceles and equilateral triangles to represent the elements she imagined in set α and a scalene triangle to represent the elements she imagined in set η (see Figure 4). When the interviewer asked Sarah what she imagined the region outside α and η to represent, Sarah responded that this area was irrelevant but she could imagine the region as empty if she chose. Sarah's comment indicates that she created her personal expression to represent solely her images of α, η, and their relationship.

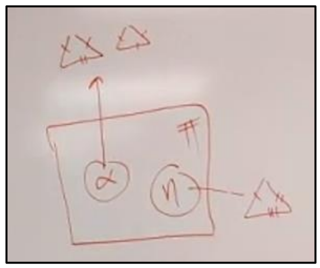

Figure 4. Sarah's set diagram comparing sets α and η (regions that gather).

We have previously defined students' diagrams to which they gave meaning solely to the inside of drawn regions as *regions that gather* (Dawkins et al., in preparation). A student who creates a diagram to express *regions that gather* typically ignores areas outside their drawn regions (i.e., no partitioning). These students use set diagrams to highlight sets of interest, not construe relationships between all the elements within the universal domain.

Meaning 2b: Regions that distinguish. While comparing sets α and γ, Carl initially concluded the two sets were equal and drew a single ovular region (see Figure 5). Carl then claimed that he could further clarify his diagram by drawing a second oval region inside the first. Carl explained that the new oval region denoted instances where he was comparing triangles from α and γ with exactly three congruent sides. He then stated that the region outside of the interior oval (but inside the exterior oval) represented instances where he was comparing triangles with exactly two congruent sides. In other words, Carl introduced a local partition to distinguish two classes of elements he perceived within his gathered set containing elements of sets α and γ. We use the term *regions that distinguish* to describe Carl's separation-of-elements-into-cases meanings he imputed within a locally gathered region of his set diagram.

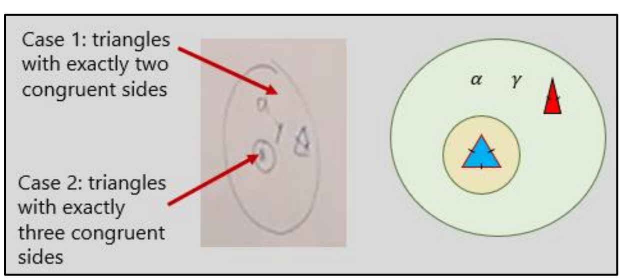

Figure 5. Carl's set diagram for comparing sets α and γ and a digital reproduction (regions that distinguish).

Summary of Vignette 2. In this vignette, we have shown three meanings that students might attribute to the regions they draw in a set diagram *personal expression*. Sarah's meaning allowed her to imagine gathering elements of a similar type, and she drew *regions that gather* to denote her grouping action. Sarah's meanings allowed her to create oval regions to represent the sets α and η and successfully determined that the sets were disjoint (Figure 3, steps 2-4). However, Sarah indicated that the regions outside the ovals were irrelevant to the task. Later in the interview, Sarah claimed that exterior regions contained non-examples of the sets but gave no indication that she considered these elements as the complement of the sets portrayed by her ovular regions (Figure 3, steps 2, 5). We also note that some students creating *regions that gather* may not include a box representing the universe of discourse (see Dawkins et al., 2021; Figure 3, step 1). Carl's meaning allowed him to imagine sorting comparisons between classes of elements, and he drew *regions that distinguish* to denote his sorting of these cases. Carl provided meaning to all areas within his outermost region (Figure 2, steps 2-4). However, Carl created his set diagrams not to partition the universe into sets possessing or not possessing properties (Figure 3, steps 2, 5) but to sort comparisons of set elements. Finally, a student imagining gathering elements into one set while simultaneously creating a complement set draws *regions that partition* to denote this partitioning action.

Discussion and Conclusion

Our research question for this paper was related to students' differences in meaning when creating *personal expressions* and interpreting *communicative expressions* for sets and set relationships. In vignette 1 we described three meanings, one theoretical and two emerging from our data, that students might possess for communicative expressions of set-builder notation presented to them by an instructor. In vignette 2 we described three meanings, one theoretical and two emerging from our data, that students might attribute to personal expressions they create to diagrammatically represent set relationships. Our results show that students can (a) invest only one portion of a conventional meaning to an expression (e.g., regions that gather, particular) or (b) aatribute meanings that allow local comparisons of element classes but fail to support claims about set relationships (e.g., spontaneous particular, regions that distinguish).

Our findings further work done by previous mathematics educators. For instance, we provided an expanded definition of Eckman and Roh's (2022) *personal expression* and proposed *communicative expressions* to describe the role of symbols in mathematical communication. We also added *regions that distinguish* to Dawkins et al.'s (in preparation) description of the meanings students attribute to set diagrams. Finally, we utilized Sellers et al.'s (2021) *MQ4 meaning* to inform our descriptions of *spontaneous particular* and *regions that distinguish,* extending their MQ framework beyond the context of interpreting quantified variables.

Our vignettes also have relevance for instructors. Vignette 1 highlights that students may attribute very different meanings to a communicative expression of set-builder notation than their instructor intended when creating the symbol as a personal expression. Vignette 2 reveals that students' imputed meanings to local regions of their personal expression set diagrams may vary across students and differ from convention. Therefore, we recommend that instructors regularly facilitate classroom discussions about personal and communicative expressions and the potential meanings the expression creators and interpreters attribute to these expressions.

What is a "Math Person?": Students' Interpretation of Identity Terminology

Jason Guglielmo
Arizona State University

Julia R. Phelps
Arizona State University

Franklin Yu
Arizona State University

Nicholas Heyer
Arizona State University

Naneh Apkarian
Arizona State University

We investigated seven undergraduate students' definitions of two terms used in mathematics education research: "identity" and "math person." Students' interpretations of these terms were compared to an existing identity framework (Cass et al., 2011; Cribbs et al., 2015). Participants' definitions for "identity" varied widely, emphasizing different aspects of personal, social, and mathematics identities. In contrast, students were fairly uniform in describing a "math person" as an individual who enjoys and/or is proficient in mathematics, which is consistent with known factors related to mathematics identity. This second finding bears relevance given the use of self-identification as a "math person" in measurements of students' mathematics identity. These results guide our development of survey items meant to assess aspects of student affect in the mathematics classroom, with the ultimate goal of providing instructors actionable insights into their classroom climate.

Keywords: Math Person, Identity, Mathematics Identity

Research has shown that the development of a strong mathematics identity is critical to students' persistence in STEM and success in their math courses (Meece et al., 1990; Boaler & Greeno, 2000; Gonzalez et al., 2020). However, *identity* and *mathematics identity* have been conceptualized and measured in different ways by different scholars (e.g., Sfard & Prusak, 2005; Cass et al., 2011). As part of a project aimed at measuring various aspects of student affect, we reviewed instruments developed to measure identity and became curious about students' interpretation of these constructs – and of the survey questions intended to measure these constructs. With an eye toward understanding the student perspective, as well as to reducing measurement error in our own work, we ask:

(1) How do students conceptualize "(mathematics) identity" and "math person?"
(2) How do students' perspectives relate to usage of these terms in prominent mathematics identity frameworks?

To begin answering these research questions, we interviewed seven undergraduate students enrolled in university mathematics courses and considered their responses in relation to the mathematics identity framework used extensively by Cribbs and colleagues (Cribbs et al., 2015; Cass et al., 2011; Godwin et al., 2016; Dou et al., 2019).

Mathematics Identity & Relevant Literature

The framework we use for mathematics identity (Cass et al., 2011; Cribbs et al., 2015) has its origins in studies of science identity (Carlone & Johnson, 2007), has been refined over time (Hazari et al., 2010), and has been positively linked to students' persistence in STEM majors and career choices (Cribbs et al., 2015; Cass et al., 2011; Verdín & Godwin, 2015; Godwin et al., 2016). In this framework, *mathematics identity* refers to how one views themselves in relation to mathematics; this is distinct from, but not entirely independent of, *personal identity* (one's individual characteristics) and *social identity* (one's characteristics as a member of a group or community). In empirical studies, self-identification as a "math person" (or "science person" etc.) has repeatedly been used as a measure of mathematics (science, etc.) identity (e.g., Cribbs et al., 2015; Gonzalez et al., 2020; Shanahan, 2008; Hazari et al., 2010; Carlone & Johnson, 2007). Three constructs have been shown to contribute to a positive mathematics identity, as measured by seeing oneself as a "math person": competence/performance, interest, and recognition (Cribbs et al., 2015). *Competence/performance* refers to a student's beliefs about their ability to understand and perform in mathematics, *interest* as a student's desire to learn mathematics, and *recognition* as how students think that others perceive them and their mathematical abilities. In this study, we explored seven students' interpretations of "identity" and "math person," and compared these to these interpretations, respectively, to the identity factors (mathematics, personal, social) and mathematics identity factors (competence/performance, interest, recognition) described above.

Studies have demonstrated, with varied methods and populations, that mathematics identity can be linked to several student outcomes. Here, we highlight a few of these findings related to students' persistence and success in STEM classes. In a large study of undergraduate calculus students, Cass et al. (2011) found that three of the factors related to mathematics identity (interest, performance, recognition) were significant predictors of students choosing careers in engineering. In another study, Boaler and Greeno (2000) conducted interviews with high school students and found that those planning to leave the discipline often lacked interest in the procedural nature of the mathematics being taught. This link between mathematics identity and retention in STEM courses has been examined in studies alongside other outcomes, such as success in math courses. For instance, Meece et al. (1990) employed surveys with middle schoolers in suburban communities and found that students' ratings of the importance of math predicted their future enrollment in mathematics courses. They also determined that students' performance expectations in their math courses strongly predicted their subsequent grades. More recent studies have further explored this relationship between students' mathematics identity and performance. For example, Gonzalez et al. (2020) demonstrated a positive correlation between mathematics identity and mathematics GPA for Black secondary students in a large-scale survey across the U.S. From these findings and others, we consider fostering a positive mathematics identity in students to be an important component of their persistence and success in STEM. This study presents a first look at understanding terms associated with mathematics identity, so that we may more accurately and sufficiently assess it in students.

Methods

In Spring 2022, we conducted IRB-approved interviews with undergraduate students at a large public research university in the southwestern United States. These interviews are part of a larger project intending to add questions to the mathematics department's end-of-course evaluations for assessing the current atmosphere in mathematics classrooms at the university. A preliminary version of such a survey included items aimed at measuring students' (1) sense of community, (2) sense of belonging, (3) sense of inclusion in mathematics classrooms, and (4) self-perceptions of ability and identity. As part of the design process, we developed an interview protocol to better understand how students interpret terms and respond to questions.

One purpose of the interviews was to gain insight into the design of the selected questions to inform the revision and refinement of the survey items. Accordingly, the interview was structured to investigate how participants interpreted the terms and questions and to understand how these interpretations informed their responses. This study employs clinical interview methodology using open-ended, think-aloud interview questions (Clement, 2000). The interview protocol consisted of two major parts. First, students were asked to define each of six terms: “sense of community,” “sense of belonging,” “sense of inclusion,” “math person,” “identity,” “classroom climate.” Second, participants responded aloud to free-response and Likert-style items from the survey, while explaining the reasoning behind their responses and their interpretations of the questions as written.

Invitations to participate were distributed via email from the instructor of record to students in all levels of undergraduate mathematics classes. Seven students participated in the interviews and were each compensated with a $15 e-gift card. These students had a wide range of experience with mathematics at the university, with enrollments from college algebra to upper-division proof-based courses. Interviews lasted between 30-60 minutes and were conducted remotely, using web-based video conferencing software.

Data analysis was conducted on de-identified transcripts of the seven clinical interviews. The transcripts were automatically generated by the video conferencing software and then verified and edited for accuracy by members of the research team. Participant responses for the first set of interview items (defining terms) were analyzed using conventional content analysis (Hsieh & Shannon, 2005). This process involved identifying themes and patterns in the students’ responses *without* using preconceived codes. Though our analysis involves comparing students’ responses to an existing mathematics identity framework (Cass et al., 2011; Cribbs et al., 2015), we decided not to use the existing framework for creating initial codes from the interview transcripts. We wanted to ground our developed codes in the key thoughts and concepts from the students’ responses, without preconceived notions of what “identity” or “math person” could mean. Our codes were then refined through several iterations with constant comparison. Final primary codes capture the essence of student responses, with secondary codes and modifiers used as needed for additional specification.

Although this coding process was implemented for all parts of the transcripts, we restrict our attention to students’ definitions of “identity” and “math person” in this study. We leverage our codes to understand how participants define these terms and compare their definitions to the factors that influence mathematics identity formation (Cass et al., 2011; Cribbs et al., 2015). In particular, we examine how these students’ definitions for “identity” relate to the personal, social, and mathematics components of identity and how their definitions for “math person” relate to the performance/competence, interest, and recognition factors of mathematics identity.

Results

Identity

We first present themes which emerged from students’ responses to the item, “What does ‘identity’ mean to you in the context of the mathematics classroom?” Note that, due to time constraints while interviewing, only five of the seven students responded to this question. Representative excerpts from each student are shown in Table 1, with key sections bolded; the right-hand column displays the codes assigned to each excerpt.

There was little to no overlap in themes between the students’ definitions of “identity.” Two students, Student1 and Student2, described “identity” in a general sense, which was decontextualized from the mathematics classroom. Student1 described “identity” as how someone views themselves (and thinks others view them), with particular focus on one's personality and interests. On the other hand, Student2 specifically called for going beyond “just who you are,” and instead defined “identity” as including one’s morals and values. Both students interpreted identity as an "inner" part of oneself but differed in whether they focused on a person's actions or values.

The remaining three students thought of "identity" specifically in the context of their mathematics classroom but were influenced by different components of the classroom. Student3 conceptualized "identity" as what one contributes to the mathematical and social environment of the classroom. They focused on the interactions that one has with their peers and TAs, as well as the effects these interactions have on establishing a hierarchy within the class (teacher > TAs > students). Student4's definition of "identity" was less about interpersonal interactions and more about one's math ability. The impact of the teacher is still significant in this definition, but only insofar as the teacher is able to foster the student's mathematics identity. Student5 also highlighted the similarities between "math person" and "identity," focusing on a person's priorities and interests related to math as central to their identity in the math classroom. However, unlike the previous two students, this definition omitted interactions with people in the classroom and instead emphasized a student's personal motivations.

Table 1. Excerpts of student responses to "What does 'identity' mean to you in the context of the mathematics classroom?" with coding. Emphasis added.

Excerpt	Coding
Student1: It's, it's who you are and what makes you different…If I can play guitar, which I'm trying to do, but I suck at it. **If I suck at playing the guitar, that adds to my identity**, because there are not as many people in the world who suck at playing the guitar. And so you keep adding that. Well, I also like video games. Well, people who suck at guitar and who play video games is even smaller in between. Well, I also like creative writing, and **it keeps getting smaller and smaller until you're your own unique person**.	How you view yourself; How others view you; Skills; Likes and Interests
Student2: Because I think of identity more of like an inner, like a personal level rather than just who are you, what are your credentials. What are, like, **what are your values, what are your morals, what do you support**? How do you, like, do you respect people?	Personality (vs. achievements); Values/morals; Respecting others;
Student3: So, I guess I would identify identity in, like, the math class as, like, like, your own personal identity. Like, **what you do, how you contribute to the classroom at all, if you do**. So, like, if you are someone that's like, "Hey, I'm really good at math. I can help you. Like, here's my phone number, like, I can help tutor you." I feel like that's, like, your sense of identity. Um, I feel like in the math class, because there is very little peer interaction, there isn't really a lot of identity."	Making Contributions (to class); Interactions (student-student)
Student4: I think identity in a math class has quite a bit to do with the teacher. Because in my, in my earlier days, like in middle school and high school, when I was doing math, **I didn't have a very good**	Teacher-dependent; Academic identity;

teacher. So, I was, my main instinct was just to think, "well, my teacher isn't good. I'm not understanding, even though they tried to explain. So, **I'm not very good at math…**So, yeah, it all boils down to, firstly, **if you're a math person**, which we addressed already. But also, your teacher and how you're, how you develop in the math class over the years.**"**	"Math person"; Developing skills
Student5: Um, I don't think [personality traits and interests are as] significant as…like it kind of, **it kind of goes hand in hand with like my definition of a math person**. Like, are you more single minded like, into like, you know, your major and your career, or are you, you know, like balancing kind of a lot of like interests and priorities? Because I know some people who will spend like hours studying for a class that I might spend a couple…you know, like, it just, it just, you know, **some people are just like really into getting everything and getting the theory and I do, I do think that like contributes to identity**.	Personality (not as important); Priorities (single-minded vs. broad interests, studying); Inconsistent definition (self); Likes and interests (concepts, theory)

These responses can be considered in light of an overall framing of identity in mathematics education literature (Cass et al., 2011; Cribbs et al., 2015). Student1 and Student2 did not contextualize their responses in terms of a mathematics classroom; instead, their responses most closely align with descriptions of personal identity (Cass et al., 2011). That is, they centered on interests and values related to the individual person. On the other hand, Student3, Student4, and Student5 contextualized their definitions within the mathematics classroom. While they also referred to aspects of personal identity, these students emphasized the social and mathematics identities that they formed in the classroom. They focused on their ability to do mathematics in the classroom, as well as the various interactions in the classroom that influence their development as a "math person." Within these responses, different components of mathematics identity were mentioned by different students: For example, Student4's response incorporates elements of competence/performance and interest, while Student5's response mostly focused on interest alone.

Math Person

In this section, we present and analyze participant responses to the item, "What does 'math person' mean to you?" Recall that "math person" is a term used to evoke a person with a positive mathematics identity (Cribbs et al., 2015). We identified more commonalities in these responses than in the identity question, with multiple students' entries receiving the same codes. Table 2 presents operationalized definitions of codes assigned to more than one student, as well as how many students (out of seven) were assigned each code. Since these codes were produced through conventional content analysis of the interview data (Hsieh & Shannon, 2005), each code may not be directly associated with the mathematics identity factors from Cribbs et al.'s (2015) framework.

Table 2. Codes for student responses to "What does 'math person' mean to you?"

Code: Description	*N*
Skills: Abilities related to successfully performing a task or action	6
Likes/Interests: Topics or activities that elicit feelings of interest or like, with or without enjoyment	5
Disinterested: Topics or activities that do not explicitly elicit feelings of interest	4
Enjoyment: Pleasure or satisfaction derived from an action or interest	4
Field of study: Reference to field(s) of study other than math	4
"Non-math person": Participant mentions "non-math" people	3
Counter-example: Participant uses a counter-example to explain a concept	3
Math is …: Subjective description of mathematics or its qualities	3
Priorities: Activities or topics that are preferentially attended to	3
Developing skills: Action of improving or expanding skills, intentionally or otherwise	2
Intelligence: Quality of being intelligent/smart, potentially in relation to others	2
Interviewee academic details: Participant gives general academic information about themselves (e.g. major or classes), with or without prompting	2
Logical: Characterized as being able to use formal/informal logical reasoning	2

A majority of the definitions of "math person" included a discussion of one's capacity to perform mathematical tasks, which we coded as *Skills*. These were sometimes explicit statements, e.g., "being good at math" as a prerequisite for being considered a "math person." Other times, students referenced skills that "math people" possessed, such as "calculating on the spot" or being able to "rearrange numbers in their head." One student who did not explicitly state the significance of skills still thought of "math people" as people who "think logically." In some capacity, all participants conceived of a "math person" as someone who thinks with and about mathematics.

Enjoyment of mathematics or mathematical thinking was also an important characteristic of "math people" for five of the seven students. This was observed in explicit statements suggesting that *Enjoyment* is essential, such as "one of the big denominators of if you're a math person is if you enjoy it." It was also implied by statements of *Likes and interests* in reference to logical or quantitative thinking, such as finding the "puzzle aspects of mathematics fun." However, one student did directly note that enjoyment was not essential, stating that "you don't have to like math to be a 'math person.'" This student's reasoning was that, after a certain point, performing mathematics becomes intuitive and does not necessarily require enjoyment (much like breathing). This is not so much a statement of lack of enjoyment as it is a statement suggesting that, after a certain level of mathematical skill attainment, enjoyment may not be a prominent factor in being considered a "math person."

Our findings with respect to "math person" were mostly consistent with a mathematics identity framework (Cass et al., 2011; Cribbs et al., 2015). The competence/performance factor can be seen in the participants' consistent focus on the *Skills* necessary to be a "math person." To them, a "math person" is someone who can perform calculations quickly or has some natural competence when it comes to mathematics. The interest factor is also clearly apparent in participants' mentions of *Enjoyment* and *Likes and interests*. However, recognition was only seen in one of the seven students' descriptions of a "math person." Student3 described a "math person" as "your person to go to" if you have a question, although they also noted that recognition by peers was not a definitive requirement for being a "math person." Overall, the seven students we interviewed did not incorporate external perceptions in their definitions.

Discussion and Next Steps

Participants' definitions of "identity" in the mathematics classroom were highly varied. Some students described only aspects of personal identity, while others referred to all three identity components (personal, social, and mathematical) in their responses. Additional research would be needed to understand this variation in response. In contrast, students were mostly consistent in describing a "math person" as someone that enjoys mathematical processes and has the skills necessary to be proficient at math. These components are closely related to the interest and competence/performance components of a mathematics identity framework (Cass et al., 2011; Cribbs et al., 2015). While students did not explicitly incorporate the recognition component into their definitions, this could be because they were doing the recognizing themselves by defining characteristics of a "math person." That is, the phrasing of the interview question could have made the recognition component of mathematics identity less salient in student responses.

We take these results as evidence that we might want to explicitly define "identity" or avoid the term in surveys altogether, and that using the term "math person" on our survey could be productive. Immediate next steps in the larger project will explore how students interpret terms for other affective constructs linked to student success and persistence in STEM, such as "sense of belonging" (Strayhorn, 2018). We will interview additional students from varied backgrounds from within the university to further enrich our understanding of these constructs. These results will be used to develop a questionnaire that captures meaningful information about the impact of a mathematics course on students' affect, while being brief enough to be appended to end-of-term course evaluations. The current study contributes towards this goal by providing insight into students' understanding of mathematics identity terminology, so that we may create more accurate and actionable items for instructors to assess and foster this form of identity in their students.

Acknowledgments

This project is supported in part by funding from the Natural Sciences DEI Seed Grant from The College of Liberal Arts and Sciences (Division of Natural Sciences) at Arizona State University (ASU). We are grateful to the student club, the Mathematical Organization for Rehumanizing Education (MORE) at ASU, for their contributions to the larger project.

Exploring Relationships Between First-Semester Calculus Students' Self-Regulation Strategies and Their Mathematics Identity and Mathematics Self-Efficacy

Kyle R. Turner
The University of Texas at Arlington

James A. M. Álvarez
The University of Texas at Arlington

This mixed-methods study examines the self-regulation strategies that first-semester undergraduates use in a first-semester calculus course through quantitative analysis of student survey responses and qualitative analysis of student interviews. The relationship between these self-regulation strategies and both mathematics identity and mathematics self-efficacy was found to be positively correlated. The strategies of metacognitive self-regulation, effort regulation, and time and study environment were found to be the most commonly used strategies by academically successful students based on a large-scale survey given to 188 first-semester calculus students as well as from interviews that occurred throughout the Fall 2021 semester.

Keywords: Calculus, Undergraduate Mathematics, Self-Regulation, Self-Efficacy, Mathematics Identity

The transition from high school mathematics to undergraduate mathematics presents challenges for many students in the United States (Clark, 2005; Gueudet, 2008, Ulriksen et al., 2017). These challenges include difficulty with foundational mathematics content, lack of self-regulation strategies, low degrees of self-efficacy, social challenges of being in a new environment, and institutional challenges of interacting with a new institutional system (Hernandez-Martinez et al., 2011 and Seymour & Hunter, 2019). High failure rates in college calculus as reported by Bressoud et al. (2015), Rasmussen et al. (2019), and Seymour and Hunter (2019) highlight the need for academic intervention for incoming college students. This intervention includes not only attending to the mathematics content understanding needed for success in first-semester college calculus, but also developing effective study strategies and self-regulation strategies employed by successful calculus students. This case study presents findings from a larger study that explores the self-regulation strategies of first-semester calculus students and how those strategies relate to their mathematics self-efficacy and mathematics identity.

To adjust to these challenges, students employ self-regulation strategies as researched by Zimmerman and Pons (1986) in a high school setting and by Wolters (1998) and Johns (2020) at the undergraduate level. In a mathematics setting, self-regulation strategies can be thought of as actions used to overcome some obstacle when working on tasks associated with a mathematics classroom. This can be in relation to specific mathematics problems and strategies used when experiencing some difficulty, or more general strategies or practices regarding tests and studying. In this report findings related to the following research questions are presented and discussed: "In what ways do students adapt self-regulation strategies from high school mathematics to college-level mathematics?" and "How does a student's mathematics identity and/or mathematics self-efficacy relate to their implementation of self-regulation strategies?"

Conceptual Framework

Zimmerman and Pons (1986) and Wolters (1998) identified categories of self-regulation strategy usage in high school students and undergraduate students respectively. The categories developed by these researchers include seeking information, keeping records and monitoring, organizing and transforming information, seeking assistance, self-evaluating, setting goals, providing rewards, changing environmental conditions, and identifying internal motivational factors such as interest, self-efficacy, emotion, attention, and willpower. Zimmerman and Pons argue that as students use the strategies and reflect on how they use the strategies, that their overall strategy usage will improve.

Johns (2020) examined the self-regulation strategies used by students enrolled in a first-semester calculus course, especially as it correlated with academic performance. In Johns' study she examined student responses to the Motivated Strategies for Learning Questionnaire (Pintrich et al., 1991) which gave a quantifiable measure of what strategies students used in a particular course setting. This data was then correlated with overall course grades for her 424 participants, and it was shown that there was a positive correlation between student course grades and the number of self-regulation strategies used.

Researchers find that positive mathematics identity and high degrees of mathematics self-efficacy contribute to students' persistence in a mathematics-based major and higher academic achievement. For example, the ways in which students view themselves as mathematics learners can be a motivating force for whether they will further their mathematics career (Cribbs et al., 2015; Gutiérrez, 2013; Ulriksen et al., 2017). Also, high measures of self-efficacy have been correlated with higher academic achievement, more frequent completion of academic goals, and academic persistence (Bandura, 1997; Hackett & Betz, 1989; Tinto, 2017; Usher & Pajares, 2009). Hernández-Martínez et al. (2011) argue that during times of transition and difficulty there is a restructuring of mathematics identity that can occur for students, such as in the transition from high school to college mathematics.

How self-regulation strategies are used and developed by undergraduates in mathematics courses has not been widely studied while attending to transition to college mathematics and connections between self-regulation strategy usage, mathematics identity, and mathematics self-efficacy. Gueudet (2008) outlined several of the challenges that arise during the transition to tertiary school, especially related to individual, social, and institutional phenomena. For the individual phenomena, Gueudet describes that undergraduates beginning the transition often lack flexibility of switching between different thinking modes, such as practical and theoretical thinking. Sonnert et al. (2020) found that high school preparation was a significant factor on retention and performance for first-year students, but as the distance from high school grows the influences lessens. Though for those first-year students it was preparation in mathematics, and to a lesser extent attitudes about mathematics, that had the largest impact on performance in a calculus class. This is attributed to the highly cumulative nature of mathematics. Self-regulation strategies play an important role in helping students to adapt to and overcome these transitional challenges.

Methodology

This report focuses on two individual student interviews for each of the six first-semester undergraduate students participants enrolled in a first-semester calculus course and participant responses to a large-scale survey. Interviews occurred throughout the Fall 2021 15-week semester. The study occurred at a large, urban research university in the Southwestern United States. All first-semester calculus courses meet two (for 80-minute lecture periods) or three (for 50-minute lecture periods) times a week for lecture. Two additional weekly 50-minute meetings engage students in a collaborative lab activity facilitated by the instructor and graduate teaching assistant (GTA) for one class meeting and traditional recitation activities facilitated by the GTA during the other meeting. Each of the courses have departmentally coordinated exams written by the course instructors, these exams are typically offered the fourth full week of the semester, the ninth full week of the semester, and the final exam during the last week of the semester. Of the five interviews, the two individual interviews occurred within a week of the first midterm and within a week of the final exam. These interviews lasted 20-30 minutes and focused on students' mathematics background, self-efficacy, and identity as well as differences between their experiences in high school and college mathematics. The other three interviews were task-based group interviews, lasting 50 minutes to an hour, occurring a week before each midterm and the final exam.

The initial surveys were sent to thirteen first-semester calculus sections which included approximately 800 students. Of those invited, 188 students completed the initial survey which included background information, the MSLQ (Pintrich et al. 1991), a survey to measure mathematical identity (Kaspersen, 2016), select questions from the Factors Influencing College Success in Mathematics (Sonnert et al., 2020), and a survey to measure the sources of self-efficacy (Usher & Pajares, 2009). Scores for each category were calculated using the scoring rubric provided with the MSLQ. Once self-efficacy, mathematics identity, and self-regulation strategy usage had all been scored, a scatterplot was created. Each score for the MSLQ strategies could range from 0 to 7, where 0 indicated that a participant never used the strategy and higher scores indicated a stronger, more frequent, use of the strategy. From the MSLQ the authors state that a score above 3 indicates an adequate use of the strategy. A weighted average was calculated from the MSLQ scores and related to both the self-efficacy scores and mathematics identity scores on a graph along with the correlation coefficients. For self-efficacy, a low score would indicate that a student is not confident in their ability to complete mathematics tasks, while a high score indicates a strong confidence in that ability. The mathematics identity score relates to how strongly a student perceives themselves in relation to mathematics. A low score would indicate that the student does not see themselves as being particularly mathematically minded, while a high identity would indicate that students see themselves as being highly mathematically minded.

To obtain an interview pool of first-time first-semester freshmen with differing measures of self-efficacy, mathematics identity, and self-regulation strategy usage on the initial survey, 38 of the students were invited to participate in a sequence of five interviews. Of these, seven accepted and began the interview sequence, with one student dropping out after the third interview. Table 1 provides information of the interview participants, including their pseudonym, major, and the highest level of mathematics course they took in high school.

Table 1: Interview Participant Information

Participant	Major	Highest Mathematics Course Taken in Secondary school
Aria	Civil Engineering	AP Calculus AB
Cyndy	Biology	Precalculus
Frank	Computer Engineering	AP Calculus AB
Jane	Architectural Engineering	Calculus
Jay	Computer Science	Trigonometry
Sunny	Computer Science	AP Calculus BC

A case study methodology was chosen to explore individual experiences of undergraduates' transitions to college mathematics and their uses of self-regulation strategies. A mix of qualitative data from the interviews and quantitative data from the initial surveys helped formulate our depiction of the students' transition. Content analysis (Stemler, 2000) methods were used to analyze interviews. For each interview an audiovisual recording was made and transcribed verbatim. Participants were given pseudonyms. To code the data, the first author used codes derived from synthesized categorizations by Zimmerman and Pons (1986) and Wolters (1998) and developed codes related to statements related to mathematics identity, self-efficacy, and differences between high school and college mathematics experiences. To ensure inter-rater reliability, the second author coded a subset of the interviews for comparison. Most codes were consistent across coding instances, and any differences were resolved.

Findings

Through the analysis of the initial survey and interviews, findings related to the relationship of self-regulation strategies to students' mathematics identity and mathematics self-efficacy were determined. First, the results of the initial survey and the quantitative data collected will be presented. Secondly, the results of the individual interviews will be presented as they inform the research questions.

From the 188 initial survey participant responses, a positive correlation between self-regulation strategy usage and mathematics self-efficacy and identity can be shown. In the following two figures (Figure 1 and Figure 2) we see the general trend of the data where self-regulation strategy usage, mathematics identity, and mathematics self-efficacy scores were determined as described in the previous section.

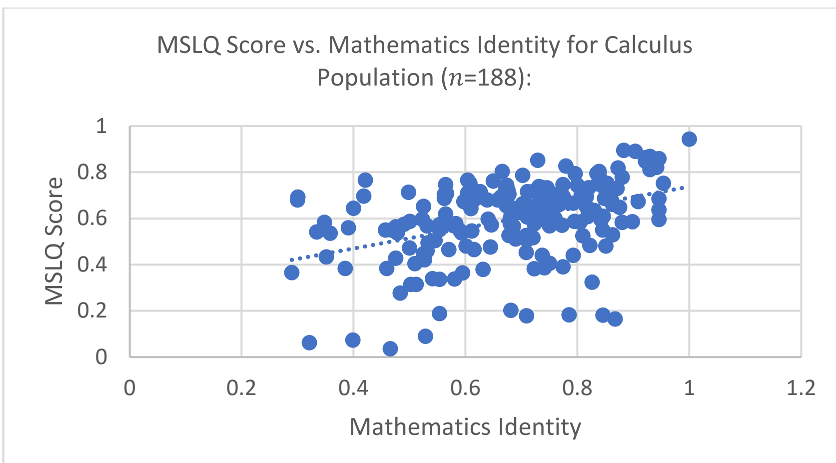

Figure 1. Population of Calculus participants' (n = 188) score obtained from Motivated Strategies for Learning Questionnaire versus Mathematics Identity score. Pearson's $r = 0.4101$

Figure 1 shows that as mathematics identity scores increase student use of self-regulation strategies tends to increase also. There is a moderately positive correlation between participants use of self-regulation strategies and their mathematics identity scores.

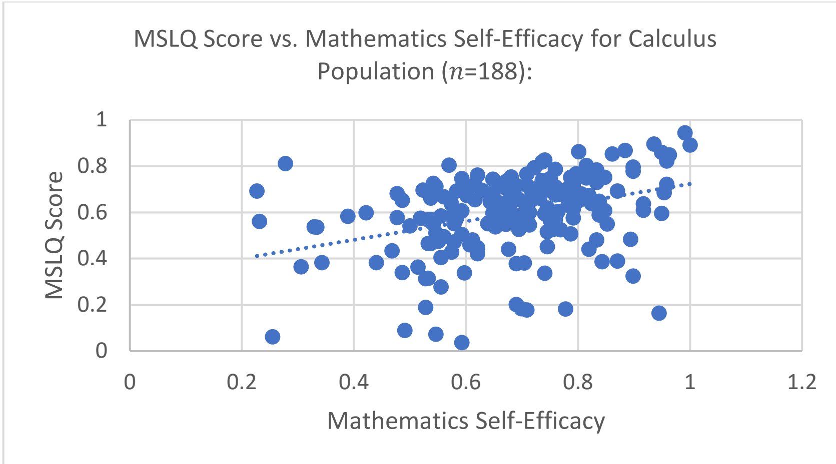

Figure 2: Population of Calculus participants' ($n = 188$) score obtained from Motivated Strategies for Learning Questionnaire versus Mathematics Self-Efficacy score. Pearson's $r = 0.3589$

As in Figure 1, Figure 2 shows a moderately positive correlation between the use of self-regulation strategies as determined by the MSLQ score and participants mathematics self-efficacy. Aside from the correlation data, data about individual participants' self-regulation strategies was found using the MSLQ. Comparing the scores from the MSLQ with participants' self-reported expected course grades it was found that three major strategies emerged as being frequently used by successful undergraduates in a first-semester calculus course. These three strategies were metacognitive self-regulation, effort regulation, and time and study environment. These strategies were also present with the academically successful interview participants as will be described later in this paper.

Along with the initial questionnaire data, data about participants' self-regulation strategy usage as it relates to mathematics identity and self-efficacy was examined through the individual interviews that occurred at the beginning and end of the semester. Within the interviews participants spoke about their general study habits in high school and how they studied for each midterm in their college calculus course. They also reported on their confidence as a mathematics student and how they saw themselves as mathematics learners. Based on their responses to the initial survey, interview participants had self-efficacy and identity scores that ranged from medium to high, but no participants with low scores agreed to be a part of the interviews. The examination of those participants with higher scores of mathematics self-efficacy and mathematics identity was used to identify what strategies students tended to employ. This analysis provides a preliminary framework of self-regulation strategies that could benefit students in their transition to undergraduate mathematics courses. From the initial questionnaire, while the three strategies of metacognitive self-regulation, effort regulation, and time and study environment were present in the interview participant responses, examining the successful interview participants' strategies also revealed they had a high frequency of organization and elaboration of course content.

From both interviews key elements emerged regarding how participants adjusted their study habits for exams from high school mathematics to college mathematics can be shown. Moving to a college setting, participants discussed how they expected to study on the calculus midterms, before having taken any mathematics midterms, and then during the final interview they discussed how they studied for the first and second midterms. The strategy most used in a high school course by these six students involved self-evaluating understanding by using test reviews or memorization tools. The next most used strategy was to seek peer assistance. Several of the participants reported that they did not expect to change their study habits significantly, but for those that did, the participants reported that they would seek external resources to further their understanding of the course content. Participants reported using more self-regulation strategies than they at first anticipated. While seeking external resources was one of the most reported additions to studying for the college mathematics midterms, most of the participants also reported adjusting their routine of studying, indicating that they spent more time studying for college exams than in high school. A couple participants, Jane and Jay, also reported adding other strategies including setting performance goals such as striving to earn a B on a particular midterm because that is what is needed to pass the course. Participants reported that this increase in strategy usage was heavily influenced by the first midterm grade and perceived difficulty of future exams; the first midterm either being lower-than-expected in Cyndy, Jane, and Jay's cases, or in the cases of Aria, Frank, and Sunny having a high midterm and resolving to keep the grade high which required additional studying.

Along with changing their strategy usage to adjust to the difficulty of the course exams, participants also discussed whether their perceptions of their mathematics identity and mathematics self-efficacy had changed. Based on the initial survey, Jane and Sunny had the highest scores of self-efficacy and mathematics identity, with all the other participants having a score indicating a medium degree of self-efficacy and mathematics identity. Cyndy and Jay reported that their confidence in their ability to work mathematics tasks was lower than when starting the course, although Jay did add that by becoming less confident it made her realize that she needed to spend more time and effort studying and preparing for exams, especially through self-evaluation of her understanding. Aria, Frank, Jane, and Sunny each reported raising their confidence levels throughout the semester, citing that their understanding of the material and the requirement of needing to know the material at a deeper level than high school improved their confidence. Jane did add that although her grade lowered, like Jay, this change in performance helped her reflect on how to better her study habits and require her to increase the effort she put into her mathematics course. Only two participants reported any change to their mathematics identity during their first semester of college. Jay reported that she did consider herself good at mathematics during the first interview, but during the final interview no longer held that belief of herself. Sunny on the other hand increased her perception of herself as a mathematics student. In general, data from the interviews and initial surveys show that these interview participants had higher rates of self-regulation strategy usage as their mathematics identity and mathematics self-efficacy increased, although in some cases like Jay, it was through the reflection that her self-efficacy had decreased that motivated her to better her study habits. Additionally, while the overall use of strategies tended to increase, in the case of Jane it was reported that she did not use certain beneficial strategies, such as seeking assistance from peers or instructors, because of her high degree of mathematics identity which led her to believe that she needed to be able to solve the problems independently to be good at mathematics.

Discussion and Conclusion

Participants in the study adapted their self-regulation strategies to the college setting by changing their study habits in response to exam performance and the increased difficulty of the course. This adjustment tended to involve some reflection about their study habits, an increase to time spent studying, or improved effort while studying which could take the form of attending to test reviews more frequently or seeking assistance from peers or instructors. Participants reported expecting a need to increase or change their high school study habits, but not to the degree that might be necessary. This finding aligns with Collier and Morgan's (2008) report that indicated undergraduate students did not expect to spend as much time per week studying in general undergraduate courses as what was recommended by the faculty that taught those courses. Almost all participants added or changed some aspect of their self-regulation strategy of setting a routine by increasing the time spent studying to adjust to the difficulty of the course, and specifically the difficulty of early exams. Participants were inclined to continue using strategies that worked for them in high school, but after recognizing the higher cognitive demand of their college course and the difficulty of their exams, participants adapted their study habits.

To inform the relationship between self-regulation strategy usage and mathematics identity and self-efficacy, we see a positive correlation between these factors as measured by the MSLQ, the mathematics identity survey by Kaspersen (2016), and the self-efficacy survey by Usher and Pajares (2009). Within the interviews we also saw that participants' discussions of their mathematics identity and self-efficacy affected their self-regulation strategies. As some participants, when their self-efficacy or identity was challenged by the difficulty of the course, were motivated to increase their use of self-regulation strategies to better their academic standing in the course. This positive correlation between self-regulation strategies versus mathematics identity and mathematics self-efficacy supports Hackett and Bets' (1989) call for promoting positive development of students' mathematics identity and self-efficacy at a young age. This also relates to Tinto's (2017) recommendation that development of self-efficacy can be accomplished through careful monitoring of first-year college students to provide social and academic support when facing difficulties.

University Students' Evaluations of Quantified Statements in Mathematics: A Survey Study

Derek Eckman
Arizona State University

Kyeong Hah Roh
Arizona State University

Erika David Parr
Rhodes College

Morgan Early Sellers
Colorado Mesa University

In this paper, we describe the results of administering a survey we created to investigate students' meanings for a universally quantified variable. Respondents with various levels of proof-course experience reviewed statement interpretations showcasing different meanings for quantified variables, indicating their preferred examples, which examples they believed to be viable, and a truth value for the statement. We developed the various interpretations from meanings described in our previous qualitative work on student quantification (e.g., Sellers et al., 2021). Our results suggest that students with a range of proof-course experience may benefit from reviewing diverse interpretations of a quantified statement. Still, students with less proof experience tended to accept more interpretations as viable or chose inappropriate truth values. In particular, we identify two non-normative interpretations most students believed were viable. We recommend proof-course instructors explicitly address these meanings in their classroom to foster student understanding of quantified statements.

Keywords: Quantification, proof education, scaling qualitative research, survey design

Introduction

Research has shown that students' interpretations of quantified mathematical statements play a crucial role in their understanding of advanced mathematical concepts in real analysis (Roh, 2010; Roh & Lee, 2017) and their proof writing and comprehension (Dawkins et al., 2021; Selden & Selden, 1995). Our previous work (e.g., Sellers, 2020; Sellers et al., 2018, 2021) has described five distinct ways students might interpret quantified variables. We have also shown that students' meanings for quantified variables can change from moment to moment, with the highest instability in meaning shown by calculus and transition-to-proof students (Sellers et al., 2017).

In this paper, we report the results of administering a survey we designed to (a) investigate the prevalence of these quantified variable meanings among collegiate students and (b) provide insight into instructional interventions that might promote students' appropriate quantification. In the survey, respondents with various levels of proof experience identified: (a) meanings they believed produced viable interpretations of a quantified statement, (b) which interpretations they preferred, and (c) a truth value for the statement. Our research questions emerged through reflection on what we might learn about students' quantification through a survey. Specifically, we investigated:

1. How does exposure to various interpretations of the quantified variable in a mathematical statement impact students' selection of the truth value for the statement? Do students' selections vary by proof-course experience?
2. Which meanings for quantified variables do students consider to be viable? Do students' selections vary by proof-course experience?
3. What meanings for quantified variables do students who select an inappropriate truth value prefer or believe to be viable after viewing the various interpretations?

Theoretical Framework

Sellers et al. (2018, 2021) propose the *Meanings for Quantified Variables* (MQ) framework to explain possible meanings students might have in a given moment for a quantified variable (see Table 1). We adopt the constructivist definition of *meaning*, grounded in the notion that individuals construct meanings in their minds through experience (Thompson et al., 2014).

Table 1: Categories of Meanings for Quantified Variables

Meaning	Mental Actions
MQ1	Checking if the predicate $P(x)$ holds for at least one value of x in X
MQ2	Checking if the predicate $P(x)$ holds for exactly one value of x in X
MQ3	Checking if the predicate $P(x)$ holds for all values of x in X
MQ4	Checking if the predicate $P(x)$ holds for spontaneously chosen values of x in X
NQ	No quantification (or absence of meaning for a quantified variable)

We describe how a student with each meaning might interpret a universally quantified statement, which we refer to as Statement 1 (S1): *For each real number x, let* $f(x) = x^4$*. Consider the following statement about the function* f*: For all real numbers x,* $\sqrt[4]{f(x)} = x$. The predicate $P(x)$ for S1 is $\sqrt[4]{f(x)} = x$, the domain of discourse X is the set of all real numbers $\mathbb{R}$, and the truth value of the statement is false. A student who uses MQ1 would check whether at least one real number satisfies the predicate $\sqrt[4]{f(x)} = x$. A student who uses MQ2 would check whether precisely one real number satisfies $\sqrt[4]{f(x)} = x$. A student who uses MQ3 would check whether all real numbers satisfy $\sqrt[4]{f(x)} = x$. A student who uses MQ4 would spontaneously choose real numbers and individually test whether each value satisfies $\sqrt[4]{f(x)} = x$. A student who exhibits no meaning for a quantified variable (i.e., NQ) might adopt an algebraic approach to investigating the predicate $\sqrt[4]{f(x)} = x$ rather than address how the quantified variable affects his interpretation of S1. A student normatively interpreting the quantified variable x in S1 would likely conclude that S1 is false by using MQ3 to identify a negative real number as a counterexample. However, other students might determine that S1 is false using MQ2, NQ, or MQ4, arriving at a normative truth value using an inappropriate quantification.

Survey Design and Methodology

Our survey instrument contained one universally and one existentially quantified statement. In this paper, we focus on S1, the universal statement. For S1, we included seven interpretations for x based on the MQ framework (see Table 2): one interpretation for each of the five meanings, and a second interpretation for both MQ1 and MQ3. In the first MQ1 and MQ3 examples, we included only values of x that satisfy the predicate $\sqrt[4]{f(x)} = x$ (which we called "E" for "examples"). In the second MQ1 and MQ3 interpretations, we included only values of x for which the predicate fails (which we called "CE" for "counterexamples").

For both quantified statements in the survey, the respondents answered questions in four distinct phases (see Figure 1). In Phase I, the students viewed and selected a truth value for the statement (options included *true*, *false*, *cannot be determined*, and *other*). The students then read a definition of "viable:" *capable of working, functioning, or developing adequately* (Merriam-Webster, n.d.). We included this definition to minimize the differences in how students might understand the term "viable" in our survey prompts.

Table 2: *Text of the Hypothetical Interpretations for S1 on the Survey*

Meaning	**Text of hypothetical interpretation for S1 on survey**
NQ	I would just plug in the function formula to the equation in the statement. The statement means that x is a real number and $\sqrt[4]{f(x)} = \sqrt[4]{x^4} = x$.
MQ1-E	I would expect to see there is at least one real number for x so that $\sqrt[4]{f(x)} = x$. If $x = 2$, then $\sqrt[4]{f(2)} = \sqrt[4]{16} = 2$. So, I have at least one real number for x so that $\sqrt[4]{f(x)} = x$.
MQ2	I would expect to see there is only one real number for x so that $\sqrt[4]{f(x)} = x$. But I found more than one real number for x so that $\sqrt[4]{f(x)} = x$. If $x = 2$, then $\sqrt[4]{f(2)} = \sqrt[4]{16} = 2$. If $x = 3$, then $\sqrt[4]{f(3)} = \sqrt[4]{81} = 3$.
MQ3-E	I would expect to see no matter what number I select for x, if x is a real number, then $\sqrt[4]{f(x)} = x$. If $x = 2$, then $\sqrt[4]{f(2)} = \sqrt[4]{16} = 2$. If $x = 3$, then $\sqrt[4]{f(3)} = \sqrt[4]{81} = 3$. I imagine that if I were to have unlimited time, I could keep selecting a different real number for x each time and see that I would have $\sqrt[4]{f(x)} = x$.
MQ1-CE	I would expect to see that there is at least one real number for x so that $\sqrt[4]{f(x)} = x$. If $x = -2$, then $\sqrt[4]{f(-2)} \neq -2$ because $\sqrt[4]{f(-2)} = \sqrt[4]{16} = 2$. Well, I will keep trying to check other real numbers to see whether I have at least one number for x so that if x is a real number, then $\sqrt[4]{f(x)} = x$.
MQ3-CE (Normative)	If I choose a real number -2 for x, $\sqrt[4]{f(x)} \neq x$ because $\sqrt[4]{f(-2)} = \sqrt[4]{16} = 2$. So there is at least one real number x such that $\sqrt[4]{f(x)} \neq x$.
MQ4-E/CE	It could be $\sqrt[4]{f(x)} = x$ or it could be $\sqrt[4]{f(x)} \neq x$. For instance, if $x = 2$, $\sqrt[4]{f(x)} = x$ because $\sqrt[4]{2^4} = 2$. On the other hand, if $x = -2$, $\sqrt[4]{f(x)} \neq x$ because $\sqrt[4]{(-2)^4} = 2$.

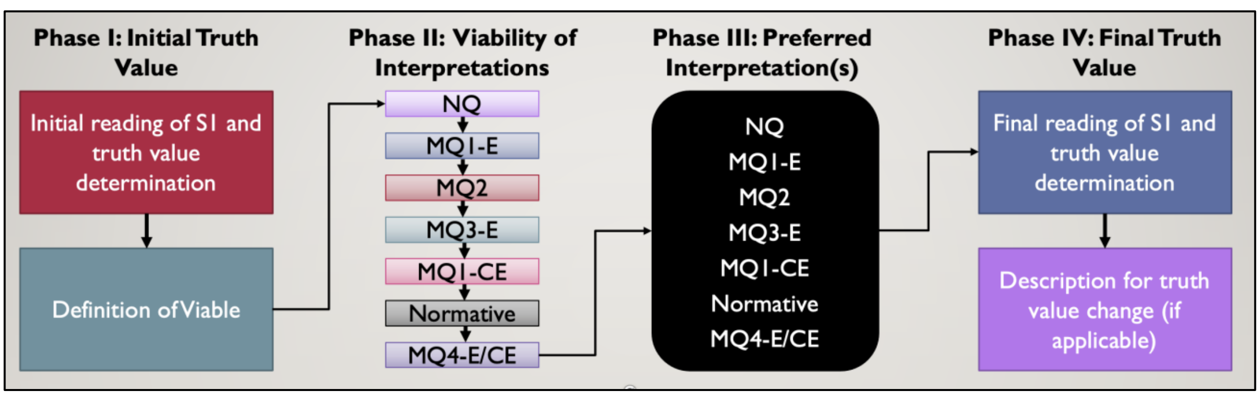

Figure 1: Visual Depiction of the Four Phases of the Survey for Statement 1

In Phase II, students read individual interpretations of the quantified statement, indicating whether they believed each example to be viable. In Phase III, students who indicated at least one interpretation was viable (a) reviewed their previous viability choices and (b) selected one or more preferred interpretations to reason about the truth value of S1. In contrast, students who claimed that no examples were viable described an alternative interpretation they considered viable. In the final phase, Phase IV, students again read the quantified statement and assigned a truth value. Students whose final truth value for S1 differed from their original truth value were prompted to explain why their choice changed.

We collected responses from 108 students enrolled in calculus courses and a proof-based geometry course at two universities in the United States. After comparing students' overall survey completion time, item completion times, and truth-value-change justifications, we deleted eight responses that appeared to be unreliable. The final sample of 100 students included 37 respondents who self-reported no proof-based course experience, 39 who reported taking one proof course, and 24 who reported participating in more than one proof course.

Results

In this section, we describe the results of our preliminary descriptive analysis of the data in relation to our three research questions regarding (a) the impact of the interpretations on students' truth value selections, (b) students' beliefs regarding the viability of the various hypothetical examples, and (c) which interpretations students who persisted in claiming S1 is true preferred or believed to be viable. We devote a subsection to each research question.

RQ1: Impact of Hypothetical Interpretations on Students' Truth Value Selections

We found a significant difference in the distribution of students' chosen truth values before and after reviewing the hypothetical interpretations, which we show in Table 3. Specifically, 69% of the 100 students initially indicated S1 is true, and 70% of the overall sample concluded that S1 is false after viewing the interpretations. This change in students' perception of S1's truth value seems to have emerged from their reflection on our survey items. For example, two students who changed their truth value from "true" to "false" explained that "I viewed instances where this statement couldn't be true" and "I did not initially think…negative numbers would not be viable solutions, as presented by multiple students."

Table 3: Initial and Final Truth Value Selections for S1 (Overall Sample of 100 Students)

Initial Chosen Truth Value	**The statement is true**	**69%**
	The statement is false	24%
	We cannot determine if the statement is true or false	6%
	Other (Please explain)	1%
Final Chosen Truth Value	The statement is true	26%
	The statement is false	**70%**
	We cannot determine if the statement is true or false	3%
	Other (Please explain)	1%

**Highlighted rows indicate the most selected truth value among respondents*

When we separated students' responses by proof-course experience, we discovered that students with little or no proof experience initially selected S1 is true in much greater numbers than those with more than one proof-based course (see Table 4). We also noted a large gain in the percentage of students who indicated that S1 is false after reviewing our interpretations (~50 percentage point increase for each group). Still, due to the near-universal initial response that S1 is true by students with no proof experience, we found that over 40% of calculus respondents still maintained that S1 is true after reviewing all seven interpretations.

Table 4: Initial and Final Truth Value Selections for S1 (100 Students Sorted by Proof-course Experience)

		0 Proof Courses ($n = 37$)	1 Proof Course ($n = 39$)	More than 1 Proof Course ($n = 24$)
Initial Chosen Truth Value	**True**	**34 (92%)**	**26 (67%)**	9 (38%)
	False	3 (8%)	10 (26%)	**11 (46%)**
Final Chosen Truth Value	**True**	15 (41%)	6 (15%)	5 (21%)
	False	**21 (57%)**	**30 (77%)**	**19 (79%)**

**Highlighted cells indicate the most commonly selected truth value among respondents. Students who selected "Cannot be Determined" or "Other" for their initial or final truth value are not included in this table.*

RQ2: Students' Determination of Viability for Individual Interpretations

We chose the order in which the hypothetical interpretations were presented to students strategically, considering that some students may not initially consider negative real numbers for values of x. We first presented an algebraic example, followed by arguments utilizing positive real numbers for x, and concluded with interpretations using negative real number values for x.

The following table, Table 5, shows the percentage of students in each proof-experience category that indicated a particular interpretation is viable. We found that at least 50% of students with no proof experience accepted 6 of the 7 interpretations as viable. Although students with proof experience tended to select fewer interpretations as viable, we noticed that a majority of students with proof experience still believed NQ, MQ3-CE (the normative interpretation), and MQ4 examples were viable. In contrast, the percentage of students who accepted the MQ1-E, MQ2, and MQ3-E interpretations decreased for each proof experience category. Our data imply that for our respondents, proof course experiences may have impacted their viability beliefs about some interpretations (i.e., MQ1-E, MQ2, MQ3-E) but not fully convinced them that other interpretations are unviable (i.e., NQ, MQ4).

Table 5: Viability Selections for S1 (100 Students Sorted by Proof-based Course Experience)

Proof Experience	**NQ**	**MQ1-E**	**MQ2**	**MQ3-E**	**MQ1-CE**	**MQ3-CE (Norm)**	**MQ4-E/CE**
0 courses (n = 37)	**27 (73%)**	**23 (62%)**	**20 (54%)**	**30 (81%)**	13 (35%)	**24 (65%)**	**20 (54%)**
1 course (n = 39)	**22 (56%)**	12 (31%)	10 (26%)	**24 (62%)**	16 (41%)	**29 (74%)**	**26 (67%)**
More than 1 course (n = 24)	**13 (54%)**	7 (29%)	4 (17%)	9 (38%)	9 (38%)	**20 (83%)**	**14 (58%)**

**Interpretations highlighted indicate more than 50% of respondents selected "viable"*

RQ3: The Preferred and Viable Interpretations of Students who Selected S1 is True

A vast majority of students in our sample concluded that S1 is false after viewing various hypothetical interpretations we provided in our survey. Still, a non-trivial minority of students

(26%) continued to insist that S1 is true (see Tables 3, 4). In this section, we examine the preferred and viable interpretations indicated by these students.

The following table, Table 6, contains two rows. The first row shows the percentage of the 26 students who insisted S1 is true that selected a particular meaning among their preferred interpretations. The second row displays the percentage of the 26 students who selected "true" that indicated an interpretation was viable. From these two rows, it appears that students who insisted that S1 is true preferred examples that only utilized positive real number values for x (i.e., MQ1-E, MQ3-E).[1] We also found that many students who indicated that S1 is true rejected interpretations that used negative values of x. For instance, no student who claimed S1's final truth value is true preferred the normative counterexample-based interpretation. Additionally, only 23% of these students claimed the normative interpretation is viable (whereas 91% of the students who claimed S1 is false stated the normative example is viable).

Table 6: Preferred and Viable Interpretations of the 26 Students whose Final Truth Value for S1 was "True"

	NQ	**MQ1-E**	**MQ2**	**MQ3-E**	**MQ1-CE**	**MQ3-CE (Norm)**	**MQ4-E/CE**
Students preferring interpretation ($n = 26$)	**12 (46%)**	**6 (23%)**	2 (8%)	**8 (31%)**	1 (4%)		3 (12%)
Students indicating interpretation is viable ($n = 26$)	**18 (69%)**	**14 (54%)**	11 (42%)	**20 (77%)**	7 (27%)	6 (23%)	9 (35%)

**Interpretations highlighted indicate the 2-3 highest (or lowest) percentages in each row*

Discussion and Conclusion

Our study aimed to gain insight into meanings for quantified variables that students preferred or believed to be viable for interpreting statements. Our survey constitutes an attempt to study these meanings, which emerged from our previous qualitative work (e.g., Sellers et al., 2017), on a larger scale. Our survey varied from our clinical interviews (Clement, 2000) in two distinct ways. First, in the survey, we gave students various statement interpretations and asked them to indicate which examples they believed were viable, while in the interviews, we modeled students' naturalistic interpretations of statements. Second, in the survey, we asked students to denote one or more provided arguments they preferred to use for interpreting the statement, while in the interviews, we assumed students' expressed ideas were their preferred interpretation.

Our first research question was related to how students' reading of various interpretations might impact their truth value choice for S1. Our results show that students selected an appropriate truth value for S1 at much higher rates after viewing the interpretations, although 41% of calculus respondents still maintained that S1 is true after reviewing our examples. This finding indicates that for many calculus students, pondering various examples of statement interpretations may not be sufficient to develop normative meanings for quantified statements.

Our second research question was related to the meanings students believed to produce viable interpretations of S1. Our results show that students with no proof experience might accept a broad range of non-normative meanings for the variable x. Additionally, our findings indicate that many students (regardless of proof experience) believe that NQ and MQ4 are viable

[1] We do not include the NQ example because 61% of students who selected S1 is false believed it to be viable.

quantifications. However, students' use of NQ or MQ4 is problematic because they might utilize these non-normative meanings to provide the appropriate truth value of S1. We thus encourage calculus and proof-based course instructors to facilitate student discussion activities to compare NQ, MQ4, and normative interpretations of quantified statements in their curricula.

Our third research question was related to students who maintained S1 is true after reviewing various interpretations of the statement. Our results show that these students preferred algebraic examples or those that only utilize positive real number values of x. These students' preference for NQ was unsurprising (to us), since we have previously reported that calculus students often exhibit NQ while interpreting statements (Sellers et al., 2017). Our finding that many students who maintained that S1 is true also believed that MQ1-E and MQ3-E are viable is a novel contribution to the quantification literature. We conjecture that these students might have relied more on examples than quantification to interpret S1. In this case, we would consider these students' rejection of MQ3-CE and MQ1-CE to be a natural consequence of their focus on interpreting S1 through examples. Specifically, these students may have believed that values of x that did not satisfy the predicate $f(x) = \sqrt[4]{x}$ were irrelevant to the interpretation process because they constituted "non-examples" of S1.

In summary, our survey results both verify and extend our previous qualitative findings. For instance, Sellers et al. (2021) described the existence of the five meanings in their MQ framework. In this paper, we extend these findings by showing (a) which meanings students prefer or believe are viable to interpret a universally quantified statement and (b) patterns in the meanings of students who believe a false universally quantified statement is true. We also provide insight into how teachers might implement Sellers et al.'s (2021) suggestion that instructors construct activities to address students' non-normative meanings for quantified variables. Our findings highlight one possible activity: asking students to compare NQ, MQ4, and normative interpretations for a universally quantified variable in a mathematical statement. In future studies, we plan to investigate further the prevalence of non-normative quantification among students and potential instructional interventions to facilitate students' construction of mathematical logic.

What is so difficult about teaching precalculus for the first time? Graduate students' perspectives on learning to teach.

Jen Crooks Monastra
University of South Carolina

Sean Yee
University of South Carolina

This study seeks to explore and understand the challenges of teaching precalculus for the first time from the perspective of a novice Mathematics Graduate Student Instructor (MGSI). This qualitative multiple-case study followed three MGSIs through a semester of teaching to understand their needs and inform efforts to support instructors. Findings indicated novice MGSIs encountered many challenges including covering course content, estimating class time, facilitating activities, maintaining student engagement, and adjusting to variation in students' preparation. However, balancing dual responsibilities of student and instructor, working with students' negative responses to engaging teaching methods, and interpreting students' performance on assessments emerged as the most difficult challenges to overcome.

Keywords: Graduate Student Instructors, Challenges, Professional Development, Precalculus

Many graduate students aspire to careers in academia (Golbeck et al., 2016) and desire to be effective instructors. Research suggests graduate teaching assistants are concerned about their teaching effectiveness, communicating with students (Feezel & Meyers, 1997), dealing with student conflict (Park, 2004), and desire support for working with undergraduate students (Boyle & Boice, 1998). This study focuses on mathematics graduate student instructors (MGSIs), defined as a graduate student who serves as full instructor of record for an undergraduate mathematics course as part of their assistantship. Thus, they present course material, assess student learning, and assign final course grades. MGSIs are commonly assigned to teach introductory mathematics courses, despite being students themselves, having limited access to professional development (PD), and limited teaching experiences (Deshler et al., 2015; Ellis, 2014; Speer et al., 2005). They may face challenges including balancing teaching with their own coursework or research, awareness of low status of teaching at a research university, difficulties getting and interpreting feedback, working with undergraduates who bring negative mathematical experiences to their classrooms, and anxiety in dealing with these challenges (Hauk et al., 2009). Further, their previous experiences and competency with mathematics likely vary greatly from the undergraduate students they teach (Deshler et al., 2015). Additionally, MGSIs may need to develop pedagogical content knowledge such as understanding common student difficulties, different ways students approach tasks, and illuminating examples to share with students (Speer, 2008).

Although many universities have developed PD opportunities and supports for MGSIs, they vary greatly in depth and breadth (Belnap & Allred, 2009). Formal PD courses can improve STEM graduate students' college teaching self-efficacy, particularly for teaching methods, course planning, and assessment of student learning (Connolly et al., 2018). Efforts to develop and improve such programs benefit from a rich understanding of MGSIs needs and teaching experiences and focusing on novice or less experienced instructors is important as universities continually use new MGSIs to provide instruction to undergraduates.

To deepen the understanding of MGSIs' needs, a larger semester-long study explored how MGSIs understand their planning and teaching for student learning and their efforts to incorporate active learning methods into an undergraduate course by examining reasons they gave for making pedagogical decisions and identifying their perceived challenges[1]. The larger study sought to address the research question: During their first semester teaching a new undergraduate mathematics course, how do MGSIs plan (design and reflect) and implement their plans, with a focus on their goals for student learning? To address this broad question, four sub-questions were created. Due to space limitations, this paper focuses on findings to only the final sub-question: *What challenges do MGSIs describe as they reflect on their planning and classroom instruction?*

Theoretical Framework

Jackson (1968) described three phases of teaching: preactive, interactive, and postactive. The preactive stage could be thought of as planning or what teachers do to prepare for class. This could include writing lesson plans, making decisions about content, selecting mathematical tasks, identifying instructional goals, or preparing materials. The interactive phase consists of the time spent in the classroom with students. Thus, it describes the time when the lesson plan is executed. The postactive stage of teaching follows the interactive stage and includes the teacher's reflective or evaluative thinking and their consideration of future lesson modifications.

However, Clark and Peterson (1986) note that many researchers do not differentiate preactive and postactive thinking when studying teacher planning. They argue that teaching is a cyclical process and that a teachers' reflections may influence their plans for subsequent classes. Thus, they conceptualized teacher planning to include both preactive and postactive thinking. Similarly, the Mathematical Association of America defined design practices as "the plans and choices instructors make before they teach and what they do after they teach to modify and revise for the future" (Abell et al., 2018, p. 89) reiterating the notion that these phases of teaching may be combined. Yet Clark and Peterson do contend that the "kind of thinking that teachers do during interactive teaching does appear to be qualitatively different from the kind of thinking they do when they are not interacting with students" (1986, p. 258) and maintain the distinction between planning and the interactive phase of teaching.

Methods

Methodological Approach

In order to deeply explore MGSIs perspectives on planning and teaching, a qualitative multiple-case study methodology was selected. Case study is defined as "an empirical method that investigates a contemporary phenomenon (the "case") in depth and within its real-world context" (Yin, 2018, p.15). The research design provided ample reflection time and space for MGSIs to describe their goals, decisions, and challenges. The site, timeframe, course, and participants defined the bounds of this case (Yin, 2018). Each case is comprised of an MGSI serving for the first-time as a full instructor of record for precalculus, an undergraduate service course in the mathematics department, as part of their teaching assistantship during fall 2019 at a large research university in southeastern United States.

Participants and Setting

All MGSIs teaching precalculus in fall 2019 were invited to participate in this study and three male MGSIs in their early twenties volunteered. All three were in their second year of graduate school, cared about their teaching, and were considering academia as a potential career track. None had experience teaching precalculus and all had served as a calculus teaching

---

[1] Supported by the University of South Carolina SPARC Grant (2020-2021)

assistant during their first year of graduate school. At the end of the study, each MGSI chose a pseudonym. Chen was an international graduate student and the other two, Willie and Patrick, were domestic graduate students. These MGSIs were actively receiving university support for learning to teach as they were provided with a peer mentor, were enrolled in a one-credit, year-long pedagogy course, and had access to lesson plans that included problem sets and teaching suggestions.

Precalculus is the prerequisite course to the calculus sequence which most STEM majors are required to complete. It is a four-credit hour course covering topics in algebra and trigonometry and is considered a service course, meaning the majority of students enrolled in the course are not mathematics majors. The course typically meets Monday through Thursday and enrolls about 38 students in each section. At this university, precalculus is a common teaching assignment for second-year graduate students.

Data Collection

To answer the research question and provide a rich understanding of MGSIs challenges and teaching experiences, data was collected throughout the fall 2019 semester and included (1) interviews, (2) lesson observations, (3) weekly journals, (4) course documents, and (5) a focus group. MGSIs were interviewed at the beginning of the semester to understand their prior teaching experiences and beliefs about teaching and student learning. They were asked to select a total of three lessons, roughly one each month, where they planned to seek student engagement. These lessons were observed and video-recorded, lesson plans were collected, and followed by a semi-structured interview (50–100 minutes) that explored the MGSIs' goals, planning and lesson design, and perceived challenges. Other forms of data included weekly journal entries (responding to 3–6 prompts), participant observations from the pedagogy course for MGSIs, their course assignments, and interviews with their peer mentors. At the end of the semester, MGSIs participated in a focus group seeking to gain insight into their overall experience as first-time instructors of record. The focus of this study was on understanding the MGSIs experience of learning to teach undergraduate precalculus.

Data Analysis

The purpose of this study was to understand MGSIs' needs by examining their thinking and teaching experiences in order to inform efforts to support their development. Thus, dramaturgical coding was chosen as the coding scheme. According to Saldaña (2016), it is useful for exploring underlying psychological constructs and "attunes the researcher to the qualities, perspectives, and drives of the participant" (p. 146). It includes six types of codes: objectives, conflicts, tactics, attitudes, emotions, and subtexts. Objectives typically referred to MGSIs goals for student learning. Conflicts, or obstacles, referred to aspects of teaching MGSIs identified as challenging or difficult and are the focus of this paper. Tactics provided insight into MGSIs' lesson design and classroom practices. The attitude codes included the MGSIs orientations about teaching and learning. Analysis of a pilot study suggested the emotion and subtext codes were not useful for answering the research questions, thus they were omitted from later analysis. A fifth category called influences was added to capture references to external influences on MGSIs planning.

Seven sources of data were coded for each MGSI: their semester-long journal, three lesson interviews, the background interview, and two written assignments from a pedagogy course. All codes were created in a hierarchical manner; each code was placed under the categories of objectives, tactics, conflicts, attitudes, or influences (level 1). To maintain MGSIs perspectives in the analysis, coding included in vivo codes (Saldaña, 2016). This paper focuses on the analysis of the conflict codes which included codes such as “run out of time” and balancing workload. Code mapping (Saldaña, 2016) included reviewing quotes from categories at levels 2 and 3 to confirm that quotes described the same concept, discussing unclear passages with a colleague, and listing, comparing, and organizing codes into categories by rearranging or combining similar codes, was utilized at four points in the analysis: after coding the first piece of data (Chen’s journal) and again after completing coding the data from each MGSI. The codes were then condensed into themes, by grouping level 2 codes into larger categories. The analysis sought to identify areas MGSIs described as problematic from their perspective. As MGSIs expressed many common difficulties, findings are reported only through cross-case analysis.

Throughout data collection and analysis, a research log was created containing memos to document the research process, reflect on lesson observations and interviews, generate future questions, discuss concerns, and contemplate next steps in the research process (Saldaña, 2016). All interviews were transcribed using software and were cleaned by the author. All coding was done in Dedoose and coding proceeded one MGSI at a time so that each instructor could be studied individually before making comparisons across cases. Tentative findings were shared with and reviewed by MGSIs for trustworthiness.

Findings

MGSIs limited teaching experience likely contributed to some of their challenges, particularly as they were trying out new teaching methods and thus struggling to facilitate activities or estimate time students would need to complete problems or tasks. Further, they were teaching the course for the first time and still grappling with determining the depth and length of time to spend on mathematical concepts. The difficulties with managing class time and course pacing could easily be attributed to their stage of beginning to learn to teach and are not elaborated upon in this paper due to space limitations. Further, MGSIs noted times in the semester, such as before breaks or near the end of the semester, when students seemed generally less engaged. MGSIs were able to manage most of these challenges with support from mentors and peers. Thus, this paper focuses on other more enduring challenges highlighted in the table.

Table 1: Summary of Challenges and Aspects of the Challenges

Phases of Teaching	Challenges
Preactive: Planning	(1) **Limited time for planning**; (2) Course content coverage
Interactive: Implementing Lesson Plans	(1) Estimating time needed for tasks or activities; (2) **Students’ responses to teaching methods** (3) Facilitating lesson logistics; (4) Maintaining semester-long student engagement
Postactive: Reflecting on Teaching Experiences	(1) **Interpreting students’ performance on quizzes or tests**; (2) Interpreting students’ course preparation

Preactive Challenges: Preparing to Teach

MGSIs are simultaneously both a student and an instructor. As a result, Willie expressed in his journal that he was “essentially working two full time jobs.” Learning to balance these responsibilities and mange workloads was a challenge for all MGSIs in this study. Throughout the semester, MGSIs found weeks where the time needed for their own coursework conflicted with their responsibilities as an instructor. Both Patrick and Chen identified this as their greatest teaching challenge in the final journal entry. Chen reflected,

> Time management is probably the most difficult in the past semester. This semester is the first time that I taught MATH 115 [precalculus]. We meet four times a week, so, I have to do a lot of lecture preparation (which I have been trying to align with homework, quiz, and exam). Even though we have the lesson plans in online material and worksheets, I still usually go over the book, look for extra material online, and compare my notes to other peoples' notes. These planning worked fine when I am not busy, however, toward the end of the semester, I find it difficult to balance planning the lesson with focusing on my own study.

Patrick identified the same challenge and stated, "there were weeks this semester where it felt as though I had to choose between doing well in my role as a MATH 115 instructor and doing well in my courses. This is a no-win situation." In the focus group, MGSIs collectively agreed they spent most of the day teaching, holding office hours, or preparing for teaching in some way and then would go home and complete their own graduate coursework in the evening or over the weekend. These MGSIs chose to spend a large amount their time on preparing to teach and wanted to be effective instructors. Willie explained,

> I feel like if you want to have a good class, it takes a lot of preparation. It's pretty much writing all those assignments and grading. You know, if you really want to be a good teacher, you're going to spend more time.

MGSIs reported that planning active learning activities tended to take more time to prepare than traditional lecture-type lessons. Experienced faculty often cite lack of time to redesign courses as a reason for not incorporating active learning (Johnson et al., 2018; Plush & Kehrwald, 2014). Thus, it may be that examples of these types of activities are more valuable to share with new instructors. To a lesser extent, MGSIs occasionally mentioned concerns about feeling behind schedule, pacing material, or selecting problems of the right difficulty level.

Interactive Challenges: Implementing Lesson Plans

A conflict MGSIs experienced with implementing lesson plans came from some students' responses to MGSIs efforts to create student engagement. MGSIs experienced conflict when their students either provided feedback indicating they disliked an activity or appeared frustrated by or not engaged in an activity. These challenges often related to lessons when MGSIs planned activities intended to engage students. MGSIs tended to reference a few students or a group of students rather than an entire class when reflecting on this difficulty. For example, Chen reflected in an interview on feedback he received from a few of his students on both a mid-course evaluation and directly following a discovery type lesson he designed to help students make meaning of asymptotes. He stated, "they don't like when I do this kind of stuff, have them struggle and conclude an idea from the lesson. A few people don't like that." Similarly, Patrick reflected on student feedback related to a jigsaw activity in his journal. He wrote, "many comments suggested that they prefer a standard lecture because the way that I explain topics is clearer and more organized" than their peers' explanations.

Beyond preferring lecture-style instruction, MGSIs occasionally encountered students who opposed non-lecture teaching methods. Willie discussed at length difficulties he encountered with one group who struggled to complete a jigsaw activity about quadratic functions. Willie shared in the interview,

> I just remember it was three red faces right in front of me. I was like, Oh no, that's not good! I tried to help. [It] just wasn't sticking. They weren't putting in effort. They just want to come into class, take notes and leave is what it felt like. They were unhappy.

Willie confirmed the students were unhappy with the *teaching method*, explaining, “I had one of them come up to me and said, can we not do this again? So yeah, she was not happy with the method.” Willie tried to provide hints to move the group along, but their progress lagged well behind other groups and their attitudes did not improve.

Although these MGSIs participated in some PD related to facilitating student-to-student interactions, MGSIs perceived success with group work varied greatly in this study. Patrick and Chen repeatedly expressed difficulties getting students to engage in group work, indicating that students tended to work alone despite their efforts to encourage collaboration. Patrick stated in his journal, “I am having trouble getting my students to interact with each other.” And elaborated in the first lesson interview,

> Maybe I can find some way to make my lessons so that they are helping each other a little more or at the very least so that it's not just silent in my classroom. Sometimes it is. A lot of times it is… I'll say you can work on these problems. You can work with people around you or people next to you. They just work by themselves mostly. I don't know if it's a matter of they just want to try it [alone] or what.

Despite the limited success, both continued to try various approaches to group work. Chen shared, “I'm not gonna give up doing group work so, but I have to like find a better way to do it.” Both suggested time of day could have impacted their students’ engagement. Many students appreciate aspects of group work yet report dissatisfaction if they prefer to work at a different pace than their group, are uncomfortable, shy or introverted, or need more clarity on a topic (Uhing et al., 2021). MGSIs perceived these types of teaching challenges as difficult to overcome, and during the focus group they expressed a consensus understanding that it is not possible to please all students.

Postactive Challenges: Reflecting on Teaching

MGSIs discussed challenges related to understanding their precalculus students, particularly their performance on quizzes or tests, but also around students’ prior preparation, and how students appeared to prepare for their current course. In this study, quizzes and tests refer to written assessments of students’ knowledge of mathematical content which MGSIs collected and graded. MGSIs were troubled that some students at times struggled to demonstrate mathematical knowledge, understand concepts, recall facts or procedures on quizzes or tests, or repeated errors that MGSIs attempted to address in their teaching despite MGSIs best efforts to include student-centered teaching methods.

MGSIs’ feelings, and perhaps efficacy for teaching, seemed to be negatively impacted by student performance on graded assessments and at times they pondered to what extent they were accountable for student learning. In some ways, this presented an emotional challenge for MGSIs as they expressed feeling responsible for student performance on quizzes and tests. Patrick wrote in his journal: “When quiz scores are lower than normal, it's hard not to feel like it's my fault somehow.” Chen stated in the third lesson interview, “I feel like as an instructor I should be somewhat responsible for how they learn.” Willie also expressed feelings of responsibility for student learning during the third lesson interview when he asked, “I mean 70 is like the minimum that I want it. So, when I get below it, I'm like, did I do something wrong?” MGSIs contemplated their responsibility for student learning. Chen expressed this in his journal when reflecting on things he could do to help students remember concepts and concluded “I don’t know if it’s the students or my fault that they don’t learn, I don’t know.” In the final journal entry Willie expressed,

> The most difficult thing for me was watching kids not do well and knowing I've tried everything I could and offered everything I could to help them. It made me feel bad as a teacher and bad for the student. However, I have to learn that I cannot help everyone!

Processing students' performance on tests or quizzes and communicating with students about low scores can be difficult for instructors. MGSIs responded to students low scores in a variety of ways including curving scores, offering extra credit, dropping quizzes, and allowing students to correct exams for points. The experience of seeing students struggle with problems on a quiz or test that had been, from the instructor's perspective, clearly covered during class was a source of conflict for these MGSIs whose goals included helping students develop mathematical thinking and procedural skills so that they could succeed in both current and future courses (Monastra & Yee, 2021). This tension may cause distress, disappointment, or discouragement for MGSIs and may have been especially salient in this study as MGSIs spent a lot of time reflecting on their goals for student learning. Further, MGSIs put a great amount of effort into their teaching and then did not always receive the benefit of large amounts of student success.

Discussion

This study's findings suggest that MGSIs need opportunities to reflect on and discuss their teaching, support and training for working with undergraduate students, and planning time. Cognitive coaching techniques (Costa & Garmston, 2018) may be helpful for promoting reflection. Graduate student PD can address a wide range of topics, yet often focuses on generic teaching skills (Park, 2004) or "administrative responsibilities and mechanical aspects of teaching" (Speer, 2008, p. 313). These topics are important and necessary, yet they may not be sufficient for supporting MGSIs. Further, their teaching does not always lead to the desired results. MGSIs may experience tension between their goals for student learning and the actual learning they see demonstrated on tests or quizzes. Acknowledging and reflecting on these tensions by pondering questions about instructors' responsibility for motivating their students may be an important area for PD. Allowing MGSIs to reflect on who should be accountable for student learning may lead to fruitful discussions.

Further, MGSIs may encounter some negative responses or pushback from their students. Student attitudes have been identified by faculty as a reason to not utilize reform materials or teaching methods (Deslauriers et al., 2019; Henderson & Dancy, 2007) and student stress can impact instructors' problem selection on assessments (Yerushalmi et al., 2010). Further, undergraduate STEM students perceive they learn more and prefer well-delivered lectures when compared to the increased cognitive effort required in active learning settings (Deslauriers et al., 2019). Discussing productive ways to respond to students' attitudes towards teaching methods, tips for creating learning environments that promote student engagement with tasks, and discussions or suggestions related to setting class norms, features of high-quality tasks for group discussion, various models of group work, and question posing techniques would appear to be beneficial for graduate student instructors. Some of these topics were addressed in these graduate students' PD, which emphasizes the point that support cannot be limited to a one-time training. Rather novice instructors need *sustained* discussion and models of teaching methods as well as opportunities to share success and struggles with implementing various teaching methods in their classrooms. Finally, PD providers and mathematics departments must be aware of the time strain some graduate students may be experiencing as time is identified as a barrier to instructors adopting reform teaching practices (Henderson & Dancy, 2007; Johnson et al., 2018). Future research into the impact of graded assessments on MGSIs self-efficacy or teacher identity and how MGSIs understand student motivation would be helpful.

Instructional interventions and teacher moves to support student learning of logical principles in mathematical contexts

This study explores how instructional interventions and teacher moves might support students' learning of logic in mathematical contexts. We conducted an exploratory teaching experiment with a pair of undergraduate students to leverage set-based reasoning for proofs of conditional statements. The students initially displayed a lack of knowledge of contrapositive equivalence and converse independence in validating if a given proof-text proves a given theorem. However, they came to conceive of these logical principles as the teaching experiment progressed. We will discuss how our instructional interventions played a critical role in facilitating students' joint reflection and modification of their reasoning about contrapositive equivalence and converse independence in reading proofs.

Keywords: logic and proof, instructional interventions and teacher moves, contrapositive equivalence, converse independence

The purpose of this study is to explore how students might learn logical principles and how instructional interventions and teacher moves might support students' learning of logic. We focus on two logical principles: contrapositive equivalence and converse independence. By contrapositive equivalence, we refer to a logical principle that a conditional statement has the same truth value as its contrapositive. By converse independence, we mean a logical principle that a conditional statement does not necessarily have the same truth value as its converse. These two logical principles are foundational for mathematical justification: the former provides a logical account that proof of a conditional statement is also a proof of its contrapositive, and the latter provides a logical account that proof of a conditional is not a proof of its converse.

It is critical for students in proof-oriented mathematics courses to know and use contrapositive equivalence and converse independence for their proof activities. However, empirical studies have reported students' challenges with using these logical principles: In Stylianides et al.'s (2004) study, many mathematics undergraduates did not use the contrapositive equivalence as a valid inference. Dawkins et al. (2021) reported a similar phenomenon in which undergraduate students with no proof experience in college conceived that the proof of the contrapositive would not provide a proof of the original conditional statement. Dawkins et al. (2021) also documented calculus students conceiving a proof of a conditional statement as proof of its converse when both the conditional and its converse are true.

While issues with student learning of these logical principles have been studied widely in proof research, these empirical studies have not focused much on how instructional interventions and teacher moves might provide support for students to learn these logical principles (Melhuish et al., 2022; Stylianides & Stylianides, 2017). In this paper, we document a case of two undergraduate students, Carl and Sarah, as a possible account for students coming to understand and might use these two logical principles. We also examined how the instructional interventions and teacher moves we designed and implemented might have played a role in students developing set-based reasoning for these logical principles. This study addresses the following research questions: (1) How might students make progress in learning to use contrapositive equivalence and converse independence by engaging in set-based reasoning? and (2) how, when, and what types of instructional interventions and teacher moves could encourage or facilitate their set-based reasoning for learning these logical principles?

Theoretical Framework

We employ Piaget's genetic epistemology as our theoretical lens for this study. From this perspective, we assume that individual students idiosyncratically organize their experiences within mental schemes (Glasersfeld, 1995; Piaget, 1971; Piaget & Inhelder, 1969). The schemes organized by an individual student's unique experience would provide space of implications for her reasoning (Thompson et al., 2014). On the other hand, individual students' ways of reasoning are not accessible to observers; we, as researchers, propose viable models of their ways of reasoning through their behaviors and utterances. We suggest and use a triad of relationships a student might need to construe when validating a proof-text paired with a conditional statement to be proven (**Error! Reference source not found.**):

- What the student knows: this may include mathematical propositions, logical principles, or any relationship that the student conceives from the given conditional
- What the student construes from the given conditional to be proven: a student might posit a relationship that the given conditional construes (to them).
- What the student believes the given proof-text attempts to prove: A student might posit a relationship that the given proof-text construes (to them).

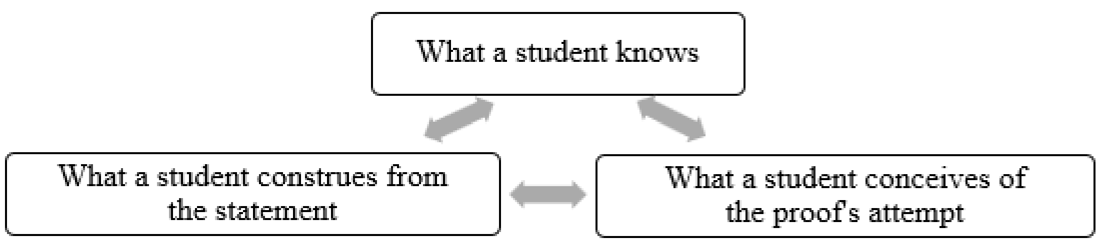

Figure 1. Three relationships a student may construe while reading a proof-text paired with a statement

The three relationships a student construes would likely support her reasoning when examining if the proof-text proves the statement to be proven. However, students may not find compatibility among the relationships they have construed. In such cases, instructional interventions and teacher moves could play a critical role in supporting students in connecting these relationships (e.g., Ellis et al., 2019; Mata-Pereira & da Ponte, 2017). Using this triad as an analytic tool, this paper provides empirical evidence that instructional interventions and teacher moves could leverage students' learning of contrapositive equivalence and converse independence.

Research Methodology

As part of a more extensive study aiming to develop constructivist models of students' abstraction of logic for proof of conditional statements, we have conducted exploratory teaching experiments (Steffe & Thompson, 2000) since 2018. The exploratory aspect of the experiments allowed us to repeat six iterations of the design-implementation-analysis cycle over five years to refine the instructional tasks and our models of students' ways of reasoning about logical principles.

This paper documents our findings from our sixth iteration of the teaching experiments conducted at a large public university in the United States. Two undergraduate students, Carl (engineering major) and Sarah (mathematics major), were recruited from calculus 3 at the beginning of the semester in the Spring of 2022. We selected Carl and Sarah out of 14 students who completed the screening survey (Roh & Lee, 2018) as they met our selection criteria. Their survey responses indicated they would have sufficient mathematical knowledge to comprehend conditional statements and proof-texts in our designed tasks yet need to learn logical principles to validate mathematical proofs. Both students also reported they learned proofs in geometry in high school but had not yet taken any proof-oriented courses in college.

The exploratory teaching experiment was organized once a week for 12 weeks for 75-minute interviews. For the first (intake) and last (exit) interviews, we conducted clinical interviews (Clement, 2000) by meeting each student individually to assess their use of logic to validate proofs of conditional statements. We conducted exploratory teaching interviews for the rest of the ten interviews (Sellers, 2020). We met with both students and implemented the tasks we designed to help students leverage set-based reasoning. The tasks for the teaching interviews consisted of 4 tasks: (1) set theory tasks (defining sets by shared properties); (2) truth conditions tasks (evaluating truth values of conditional statements); (3) what-does-it-prove tasks (reading and comparing proof-texts paired with a conditional statement), and (4) abstraction task (comparing various proofs across different mathematical contents to abstract general proof frames for conditional statements). With these tasks, we tried to create a student-centered learning environment to encourage students' reflection and modification of their reasoning.

Results

At the intake interviews, Carl and Sarah exhibited the opposite of the normative mathematical logic regarding contrapositive equivalence and converse independence. Specifically, they both responded that a proof of the contrapositive of a given conditional does not prove the statement. In contrast, a proof of the converse of a given conditional proves the statement when both the original conditional and its converse are true. Their responses at the intake interviews indicate the absence of these logical principles in the students' reasoning, or at least the intake interview tasks did not evoke the students to use these logical principles. However, their reasoning about logic shifted during the teaching interviews in which we implemented the what-does-it-prove (WDIP) tasks (Days 5-8). Carl and Sarah first made sense of the contrapositive equivalence and later began to make sense of the converse independence. We describe how contrapositive equivalence became these students' knowledge base for proof by contrapositive, yet created resistance to develop converse independence. We also document how our instructional interventions designed to leverage set-based reasoning and teacher moves facilitated students' reflection on mathematical proof and their eventual recognition of converse independence.

Teacher Moves Leveraging Student Progress in the Contrapositive Equivalence

On Day 5, the first day for the WDIP tasks, the interviewer presented Theorem 1 ("For every integer x, if x is a multiple of 6, then x is a multiple of 3") with three associated proof-texts, Proof 1.1 (direct proof), Proof 1.2 (disproof of converse), and Proof 1.3 (proof of the contrapositive). Carl and Sarah immediately attended to the first and last lines of Proof 1.1 and said that Proof 1.1 would prove Theorem 1. Afterward, these students frequently examined if the first line and last line of other proof-texts matched the if-part (the premise) and the then-part (the conclusion) of the theorem to be proven, respectively. These students' attention to the first and last lines of the proof-texts enabled them to find the compatibility among what relationship they know about the premise and conclusion of the given theorem, what relationship the given theorem describes, and direct proof attempts to prove the given theorem.

On the other hand, these students' tendency to check the matches between the first line of a proof-text and the premise of the theorem statement may have hindered them from discerning why proof of contrapositive indeed proves the given theorem, even though proof of contrapositive does not start with the if-part of the given theorem statement.

Sarah: I said it [Proof 1.3] proves something different. I guess it [Proof 1.3] proves the complements of the original one that if x is not a multiple of 3, then x is not a multiple of 6, which [is] base[d] off of how we were seeing the complement, remember? That could possibly be true [inaudible].

Carl: Yeah. I said the same thing […] It's, yes, if we're allowed to say that if A is a subset of B, and B's complement is a subset of A's complement.

In the dialogue above, Sarah and Carl used set languages, such as subsets and complement sets. Carl used letters A and B to name the truth sets for the premise and conclusion of Theorem 1 and used these letters to interpret what Theorem 1 says and what Proof 1.3 proves in terms of subset relationships. Sarah then claimed that what Proof 1.3 attempts to prove is the contrapositive of Theorem 1 and could also be true. Carl agreed to interpret Theorem 1 and Proof 1.3 in terms of subset relationships if they were allowed to say the set relationships $A \subseteq B$ and $B^c \subseteq A^c$. However, the students' use of set language itself did not indicate their use of contrapositive equivalence. They responded that both Theorem 1 and its contrapositive are true in this case but drew two different diagrams to represent what Theorem 1 construed to them and what they believed Proof 1.3 attempts to prove. Sarah drew a diagram to represent what Theorem 1 meant to her: the truth set P of the premise of Theorem 1 is a subset of the truth set Q of the conclusion of Theorem 1. She also drew another diagram for Proof 1.3, in which Q^c is contained in P^c (**Error! Reference source not found.** left).

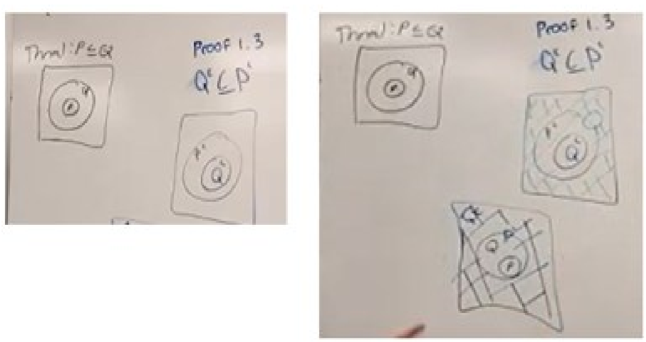

Figure 2. Sarah's diagrams for Theorem 1 & Proof 1.3: (left) initial; (right) after the teacher intervention

At this point, the interviewer intervened with Carl and Sarah by inviting them to use only one diagram for both Theorem 1 and Proof 1.3. This teacher intervention enabled Sarah to use her diagram for Theorem 1 to shade the region corresponding to the complements of P and Q. (i.e., If $P \subseteq Q$, then $Q^c \subseteq P^c$). By Instructor's request, Sarah was also able to use her diagram for Proof 1.3 to describe Theorem 1 (i.e., If $Q^c \subseteq P^c$, then $P \subseteq Q$). Sarah's revised diagrams (**Error! Reference source not found.**, right) are indicative of her progress in the conceptualization of contrapositive equivalence (P $\subseteq Q$ iff $Q^c \subseteq P^c$). After looking at Sarah' revised diagrams, Carl agreed with Sarah and illustrated his diagram, which was similar to

Sarah's diagrams. But he also added another case in which if two sets A and B are equal, then A's complement and B's complement are also equal (If $P = Q$, then $Q^c = P^c$). Figure 3 illustrates our model of Sarah's reasoning in which she began to use contrapositive equivalence as her new knowledge to comprehend a proof of contrapositive as a proof of the original conditional. From that point, the contrapositive equivalence became robust knowledge for Carl and Sarah for the rest of the teaching experiment. Here, we see the teacher intervention supported these students to use what they came to know (contrapositive equivalence) to connect

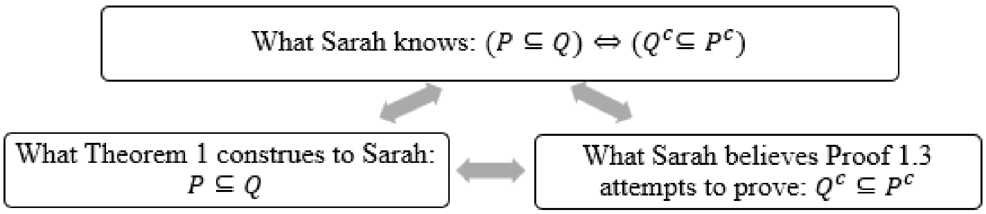

Figure 3. A model of Sarah's way of reasoning with contrapositive equivalence

what relationship Theorem 1 construed to them ($P \subseteq Q$) with what they believed Proof 1.3 attempts to prove ($Q^c \subseteq P^c$).

Teacher Moves Leveraging Student Progress in Converse Independence

On Day 6, the interviewer presented Theorem 2 (for any integer x, if x is a multiple of 2 and 7, then x is a multiple of 14) with two associated proof-texts: Proof 2.1 (proof of converse) and Proof 2.2 (direct proof). Carl and Sarah responded that Proof 2.1 proves Theorem 2 despite the reversed order because they believed Theorem 2 and its converse are both true. To be more specific, Carl explained that he knew the set of all multiples of 2 and 7 (P) is the same set as the set of all multiples of 14 (Q), i.e., $P = Q$, and to him, Theorem 2 interprets the subset relationship $P \subseteq Q$. Carl also believed Proof 2.1 proves the reversed subset relationship $Q \subseteq P$. While Theorem 2 and Proof 2.1 form different subset relationships, he could infer Theorem 2 from Proof 2.1 by substituting P to Q and Q to P in the subset relationship $Q \subseteq P$. He said that since he already knows $P = Q$, by using his knowledge, he could infer Theorem 2 from what Proof 2.1 proves.

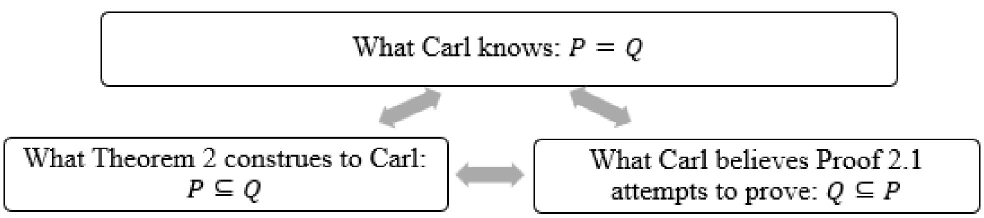

Figure 4. A model of Carl's reasoning about why Proof 2.1 proves Theorem 2

On Day 7, the interviewer presented Theorem 4 (Given any quadrilateral ABCD, if ABCD is a kite and parallelogram, then ABCD is a rhombus) with Theorem 4.1 (proof of converse) and Theorem 4.2 (direct proof). Carl continued claiming, and Sarah agreed, that although Proof 4.1 proves the converse of Theorem 4, it also proves Theorem 4 because both Theorem 4 and its converse are true. We infer that these students meant the two subset relationships $P \subseteq Q$ and $Q \subseteq P$ are indistinguishable to them when $P = Q$. In our model, they conceived that Proof 4.1 proves the converse of Theorem 4. But since they already knew the premise and the conclusion of Theorem 4 represents the same truth sets ($P = Q$), they went further to infer that Proof 4.1 proves Theorem 4 as well.

On Day 7, Carl claimed, and Sarah agreed, that they should be allowed to use what they know without justification. He compared proof of converse with proof of contrapositive. Although Proof 1.3 does not justify contrapositive equivalence, Carl accepted that Proof 1.3 (proof of contrapositive) proves Theorem 1 because he knew contrapositive equivalence. Carl then claimed with an analogy that we should also accept Proofs 2.1 and 4.1 (proofs of converse) even though these proofs do not provide justification for $P = Q$, since he already knew these sets were equal. Furthermore, Carl claimed, and Sarah agreed, that proof does not necessarily justify explicitly what they already know. This is similar to how one may apply a known theorem without reproving it. The distinction between the ways mathematicians cite prior knowledge and how Carl wanted to cite prior knowledge is quite subtle, and we see Carl's reasoning as subjectively rational. The more central question was: how would Carl and Sarah justify $P = Q$ instead of saying they already know it?

On Day 8, the interviewer presented Proof 4.4 () as an instructional intervention, which resembled our model of Carl's reasoning on Day 7. As a version of proof of converse, Proof 4.4 explicitly stated the equal set relationship that "we already know" without justification. Both students responded that Proof 4.4 would prove Theorem 4 directly because it explicitly stated $P = Q$ in the proof-text and thus provided warrants ($P = Q$) to support Proof 4.1 ($Q \subseteq P$) infers Theorem 4 ($P \subseteq Q$).

Proof 4.4: Let P and Q be subsets of $\mathbb{Q}u$ defined as follows:
$P = \{ABCD \in \mathbb{Q}u: ABCD\ is\ a\ kite\ and\ paralleogram\}$;
$Q = \{ABCD \in \mathbb{Q}u: ABCD\ is\ a\ rhombus\}$.
From Proof 4.1, we proved $Q \subseteq P$.
And we already know $P = Q$.
Then $P \subseteq Q$.
Thus, given any quadrilateral $\blacksquare ABCD$, if $\blacksquare ABCD$ is a kite and is a parallelogram, then $\blacksquare ABCD$ is a rhombus.

Figure 5. Proof 4.4: A model of Carl's reasoning in accepting Proof 4.1 (proof of converse) as a proof of Theorem 4

While the interviewer acknowledged that the students already knew $P = Q$, she invited them to state what it would mean for two sets P and Q to be equal. Students' responses to this instructional intervention uncovered the absence of meaning for equal sets in these students' reasoning: They were not sure how to say two sets are equal. Carl merely suggested that two sets are equal ($P = Q$) when their complements are equal ($P^c = Q^c$) (see **Error! Reference source not found.**, left). Sarah then suggested combining Theorem 4 and its converse (see **Error! Reference source not found.**, right) as a meaning for equal sets.

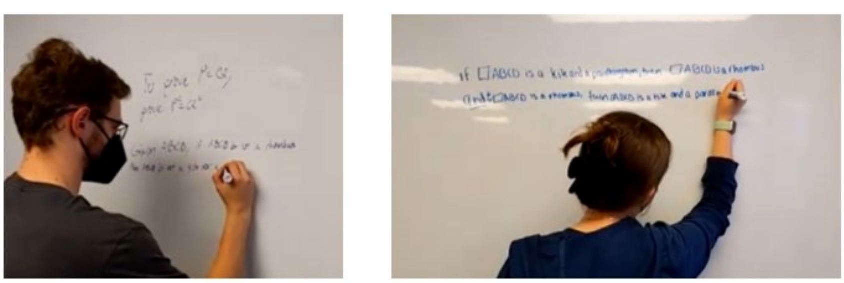

Figure 6. Students wrote their meaning of equal sets: Left: Carl; Right: Sarah

After the interviewer invited Carl and Sarah to state their meaning of equal sets, Sarah shifted her interpretation, revealing a sense of circularity. In particular, her interpretation of equal sets by this conjunction of a conditional and its converse helped her to realize the absence of justification for $P = Q$ in Proof 4.4. When Carl asked if "we are given $P = Q$ from Proof 4.4 or not," Sarah responded to Carl that "No, Proof 4.4 isn't even really proving $P = Q$. It's just saying it is." When Carl asked again if that ($P = Q$) is "given or inferred," Sarah again responded to Carl that "it [Proof 4.4] never says [justifies] $P = Q$." From this student dialogue, we could see Sarah's reasoning had evolved regarding the converse independence. While engaging in the sequence of activities and responding to the interviewer's prompts, she concluded that we should use only what we had already proved without justification again. Since they already justified contrapositive equivalence by diagrams (Figure 2), Sarah believed that they could say Proof 1.3 (proof of contrapositive) proves Theorem 1 even though Proof 1.3 does not justify the contrapositive equivalence. However, she contended that "Proofs 2.1 and 4.1 (proofs of converse) do not necessarily prove their original theorems because the theorems ask "if P, then Q" ($P \subseteq Q$) but the proofs instead prove "if Q, then P" ($Q \subseteq P$). To prove the theorem to be proven, the proofs would have to prove $P = Q$ so we can assume $P \subseteq Q$ *and* $Q \subseteq P$." While Carl did not accept Sarah's claim on Day 8, he exhibited his acceptance of converse independence at the exit interview. Specifically, Carl determined, "Proof γ (proof of converse) proves $B \subseteq A$ but doesn't really prove Theorem γ ($A \subseteq B$) [because] Proof γ lies on the reader inferring $A = B$. Basically, if proof γ added an extra line, proving $A = B$, then it would be equal to it. Then it would prove the theorem. [but] I don't think they do it."

Discussion

In this paper, we documented how Carl and Sarah generalized contrapositive equivalence and converse independence across proofs of conditional statements as they were engaging with the WDIP tasks. The interviewer's prompting to use only one diagram to interpret two subset relationships helped the students make the line of inference between Proof 1.3 (proof of contrapositive) and Theorem 1 explicit, such that they affirmed it by their "prior knowledge" regarding the contrapositive equivalence. Later, Carl used this idea to justify why proof of converse proves the original conditional. For him, proof of contrapositive and proof of converse both relied on his prior knowledge, which he called "prove indirectly." Indeed, in one case, his prior knowledge was logical knowledge about the generalizable contrapositive relationship; in the other, it was local mathematical knowledge that the situation described by Theorem 4 related two equal sets of quadrilaterals. By introducing Proof 4.4, the interviewer's move of reflecting the form of Carl's justification back to the students allowed them to move forward in critiquing the justification. However, to see the conflict, which is what mathematicians usually call "circularity," Sarah needed to interpret set equality as the conjunction of two subset claims. This made it clearer how asserting $P = Q$ without proof was tantamount to asserting $P \subseteq Q$ without proof. Understanding the logic of the relationships between proofs and theorems is quite challenging. Still, we see how these instructional moves supported Carl and Sarah in apprehending the structure of their own arguments to evaluate them more precisely. We are pleased with how our interventions allowed these students to wrestle deeply with these matters of justification, though more work is needed to explore this arena of learning.

Students’ Inferences Using a Conditional Statement in Probability: The Relationship between Independence and Covariance of Random Variables

Megan Ryals
University of Virginia

Chris Hellings
University of Virginia

Hui Ma
University of Virginia

The purpose of this study was to investigate how students in a probability course interpret a theorem and how they apply the theorem when asked to determine whether two random variables are independent given the value of the variables’ covariance. We considered how responses of students with prior training in logic compare to other students, as the theorem is a conditional statement. We used a quasi-experimental design to investigate the impact of two instructional treatments, using isomorphic colloquial statements and using Euler diagrams. Participants largely gave conventional truth values for variants of the conditional statement prior to instruction, but many of them used the converse and/or did not use the contrapositive when given covariance values and asked to determine whether two variables were independent. Our results do not consistently show a significant difference in students’ choices based on their prior logic training or either treatment.

Keywords: Probability, Conditional Statements, Logic, Covariance, Independence

Students are frequently presented with conditional statements in undergraduate mathematics courses that do not place a large emphasis on proof; consider as examples the Intermediate Value Theorem and the Divergence Test for Series in Calculus and the Existence and Uniqueness Theorems in Differential Equations. Challenges arise as students with no formal training in logic contend with deciding when and how to apply these tests and theorems while instructors sometimes make assumptions that logical inference is more intuitive than it is. While studying students’ use of formal mathematical logic has long been of interest for the training of students majoring in mathematics, it has taken more time for researchers to begin exploring how students’ interpretations of conditional statements in courses like calculus might impact their success (Case, 2015; Durst & Kaschner, 2020; Sellers et. al, 2021).

In this study we consider how Probability students interpret and use the following theorem about random variables: “If X and Y are independent random variables, then $\mathrm{Cov}(X, Y) = 0$” (Casella & Berger, 2002, p. 171). The statement’s converse, “If $\mathrm{Cov}(X, Y) = 0$, then X and Y are independent” is logically false. (Covariance is a measure of a linear relationship, and variables may be clearly related without being linearly related.) In a probability course, students may be asked to use their knowledge about the independence or covariance of two random variables to make inferences about the other, and more importantly, to recognize in which situations they can do so.

Our study differs from the majority of prior work on students’ understanding of conditional statements in two ways. First, our goal is not to help students redevelop conventional rules of logic to then use more broadly. Rather, we are providing students with the truth values of a statement and its three variants (subsequently referred to as the contrapositive, converse, and inverse) and we want to know which analogies and connections might be useful in helping students use this particular conditional statement to make accurate inferences about independence. Secondly, because of the nature of these problems, students have the option to entirely bypass the use of logical inference. While calculations may be cumbersome, covariance can be calculated directly and independence determined using the definition of independence. That is, students may choose to avoid using the logic of conditional statements altogether to answer the problems we give them. We therefore pose the following questions:

1. *How do students use covariance values to determine whether two random variables are independent?*
2. *Are their choices influenced by prior formal logic training?*
3. *Are their choices influenced by connections to isomorphic colloquial examples and/or the use of Euler diagrams?*

Review of Literature and Theoretical Perspective

An important and consistent finding in prior studies of students' interpretations of conditional statements is that students very often interpret conditional statements as biconditionals (Hoyles & Küchemann, 2002; O'Brien et. al, 1971; Wason, 1968). This presents as students assuming inverse and converse statements are true even though they are not. Possibly more significant is the finding that even the same student often does not make the same logical inferences consistently; instead, their inferences depend on the context, particularly when it is a familiar one. (Dawkins & Cook, 2017; Durand-Guerrier, 2003).

The results above must be interpreted in light of which "reasoning domain" the researchers used (Sylianides et. al, 2004). Logic can be taught using meaningful everyday (colloquial) statements, meaningless everyday statements, mathematical statements, or formal syntax (Hub & Dawkins, 2018). Claims have been made that students have less difficulty interpreting verbal and mathematical statements than abstract or symbolic ones (Case, 2015). Moreover, it has been hypothesized that everyday statements may be used to help students develop logical principles. Epp (2003) argues "it is helpful to introduce each principle with examples of sentences whose "natural" interpretation agrees with the one used in standard logic" (p. 895). Stylianides et. al (2004) found evidence to support this. Specifically, students who initially identified a contrapositive statement as false changed their minds after seeing an isomorphic statement in the verbal domain.

However, formal logic conventions do not align with the way conditional statements are used in everyday language. Epp (2003) provides the following example. A parent may say, "You can go to the movie if you finish your homework" when what she intends is "You can go to the movie if and only if you finish your homework," but the latter rarely gets stated. "If you don't finish your homework, you cannot go" is implied. So while they only state a conditional, the intention is biconditional. It is not surprising that students would interpret conditional statements in mathematics similarly. We interpret the theorem relating independence and covariance as a "generalized conditional statement" (Durand-Guerrier, 2003). There is an implicit universal quantifier within the antecedent, "X and Y are independent random variables," so mathematicians interpret the conditional as "$For\ all$ pairs of random variables X and Y, if X and Y are independent, $\mathrm{Cov}(X, Y) = 0$." Accordingly, mathematicians assign a positive truth value to the statement and its contrapositive and negative truth values to its converse and inverse. Students often, and reasonably so, read conditional statements as "open statements" which have no quantifier and no truth value (Durand-Guerrier, 2003).

Some authors have posited that explicit training in logic and/or exposure to more mathematics should improve students' ability to make correct logical inferences. Durst and Kaschner (2020) for example, show that students often label statements such as "If the limit of a sequence is 0, the corresponding series converges" as "Sometimes True, Sometimes False." They argue that explicit training in logic would assist students in adopting the conventions of formal logic. However, there has been no clear relationship established between current performance and either prior exposure to either mathematics or logic instruction (Attridge et. al, 2016; Cheng et. al, 1986; Inglis & Simpson, 2008).

Our position is that students, in identifying some statements as "sometimes true," have viable reasons for doing so. These students are not conforming to conventional rules of logic but may, in fact, be being more specific. Additionally, while adhering to these conventions may be essential for success in mathematics, we question whether this should be a goal for engineering students. Engineers are trained to become comfortable with uncertainty and this training leads to a reasonable and necessary discomfort with absolutes (Cardella & Atman, 2005; Gainsburg, 2006). Recognizing this, we narrow our focus to identifying analogies that students may use to convince themselves of when independence and covariance may be used to determine the other.

Recently Dawkins and colleagues have argued for developing in students a "subset meaning for conditional truth" (Dawkins & Cook, 2017; Hub & Dawkins, 2017). Their work suggests that given a conditional statement, students initially struggle to determine whether the set of elements that satisfy the *if* are contained in the set of elements that satisfy the *then*, or vice versa. Hub and Dawkins make the case that using Euler diagrams, which provide an illustration of this subset relationship, may facilitate the development of the subset meaning which will then help them move towards consistently making normative logical inferences. For example, a student who places set P within set Q can recognize in the visual representation that elements outside Q are also outside P.

Methods

Data Collection

The data was collected during in-class instruction and testing in the spring of 2022 in a semester-long Applied Probability course for engineering and computer science students at a large public institution in the United States. Prerequisites for the course include multivariable calculus and an introduction to programming. All students from the four sections who were present during this lecture were invited to participate and 72 students provided consent. Of these 72 students, 53 had previously taken or received credit for Discrete Mathematics, which provides an introduction to logical inference and proof techniques.

The second and third authors each taught two sections of the course on the same day when they covered the relationship between covariance and independence of random variables. Each instructor taught one "control" and one "treatment" section, though the treatments differed. After the initial presentation of the theorem in each section, the instructors asked each student to determine whether each of the following statements below (subsequently referred to as the inverse, converse, and contrapositive) were true or false and collected their responses prior to any discussion.

a. If X and Y are not independent, then $Cov(X,Y) \neq 0$.

b. If $Cov(X,Y) = 0$, then X and Y are independent.

c. If $Cov(X,Y) \neq 0$, then X and Y are not independent.

The instructors then explained briefly why statement (c) was true but statements (a) and (b) were false. Specifically, they shared an example of two random variables that were dependent but had no linear relationship (thus having a covariance of 0) and briefly reiterated that covariance is specifically a measure of the *linear* relationship between the variables.

At this point in the lesson, instruction in the control and treatment sections diverged. In the Control sections, which closely resembled how instructors of this course have presented this lesson in past semesters, the instructors completed 2 examples where they first determined whether two random variables were independent and then found the covariance of those variables. In the first example, the variables were independent and therefore the statement of the theorem could be applied directly to decide that the covariance must be 0. In the second, the variables were determined to be dependent, so the covariance had to then be calculated.

Instructor 1 presented the Treatment 1 students with the colloquial statement: "If it is raining, there are clouds" and asked them to determine whether the other variants of this statement, such as "If it is not raining, there are no clouds" were true. This was completed as a whole class discussion and subsequently the instructor made a direct comparison between the truth values of the rain/clouds statements and variants of the theorem.

Instructor 2 presented an Euler diagram illustrating the universal set of all pairs of random variables. (Note that in our conditional statement, the elements of sets P and Q are *pairs* of random variables, which is a potential complication for students in the process of abstraction.) In the diagram, an oval representing the pairs of independent random variables was completely contained within an oval representing the pairs of random variables with a covariance of zero. The class then discussed how a situation could be in the outer oval without being in the inner oval, but it was impossible to be in the inner oval without also being in the outer oval.

At the end of class for all four sections, students individually provided open-ended responses to two problems in which they first computed covariance of two random variables and then were asked to determine whether those variables were independent and justify their answers. In the first example, the covariance was 0 so independence had to be determined using the definition of independence. In the second example, the covariance was not 0 so dependence was guaranteed. We will subsequently refer to these examples as the "In Class Converse" problem and the "In Class Contrapositive" problem, respectively.

We also collected data on a midterm exam and the final exam. The midterm contained a similar converse problem and the final exam a similar contrapositive problem. The midterm and final exam were given 12 days and 6 weeks after the in-class instruction, respectively and there was no significant intervention between assessments.

Analysis

The first and third authors first open coded responses to the two in-class problems. When coding the midterm and final exam problems, we built on and refined the coding schemes from the in-class problems since they were very similar to the in-class problem 1 and 2, respectively. At this stage we were attending to correctness as well as the type of justification provided. The second author then used the coding scheme to code all 4 problems and we refined the coding scheme to reach agreement on approximately 95% of responses across the 4 problems.

For ease of comparing groups by treatment and by exposure to prior logic instruction, we opted to complete a second round of coding to condense the number of codes for each type of problem. For the contrapositive problems, we considered whether the student used the fact that a covariance other than 0 implies variables are dependent (which we labeled "using the contrapositive"). For the converse problems, we asked whether students used the fact that covariance was 0 to (incorrectly) claim that the variables were independent (which we labeled "using the converse"). This resulted in a binary response for each student for each of the 4 problems that we then used in the comparisons discussed below.

Results

Prequiz Truth Values

The truth values that students assigned after being presented with the theorem but prior to instruction were largely in line with conventional logic. Of the 72 participants, 59 of them (82%) stated the inverse was false and (though not the exact same group of students) 59 also claimed the converse was false. 64 students (89%) selected true for the contrapositive statement. 49 students (68%) gave conventional truth values for all three statements. Prior logic training did not appear to impact responses; 68.4% of students who did not have credit for Discrete Math gave conventional truth values for all three statements while 67.9% of those with credit for Discrete Math did the same.

Types of Responses

For the in-class and midterm converse problems, we focused on whether students used the fact that covariance was 0 to (incorrectly) claim that the variables were independent (which we will subsequently refer to as "assuming the converse"). 38% of students used this argument on the in-class converse problem and 31% used it on the midterm. Only 25% used the definition of independence on the in-class problem to correctly conclude that X and Y were dependent. However, the response of 17% of students in class and 10% of students on the final exam was that independence could not be determined since the covariance was 0. These students made a conventional logical inference, although they failed to recognize that independence can be determined directly through use of the definition of independence. This highlights another challenge of introducing and asking students to use this conditional statement; students may focus on the application of the theorem and neglect viable and necessary alternatives. We saw improvement in using the definition of independence on the midterm; 40 of the students (56%) used the definition of independence on the midterm problem to reach the correct conclusion that X and Y were dependent. The remaining students used incomplete or incorrect arguments, some of which referenced the definition of independence and some which did not.

On the in-class contrapositive problem, 90% of students used the covariance being a value other than 0 to (correctly) claim that X and Y were dependent. In contrast, only 44% of students used this argument on the final exam problem. On the final exam problem, 33% of students "bypassed" the theorem and used the definition of independence correctly. This appears to coincide with the increase in students using the definition of independence correctly on the midterm converse problem. 13% of students provided multiple justifications; specifically, they stated that X and Y must be dependent because the covariance is not 0 and also used the definition (either by stating $P_X(x)P_Y(y) \neq P_{X,Y}(x,y)$ for all x, y or by providing an example.) We grouped these students with those who did not use the contrapositive in our analysis below.

From Covariance to Independence

We might expect students who claimed the converse was true on the prequiz to be more likely to use the covariance of 0 as justification to claim independence on the in-class converse problem. (We highlight the cells in Table 1 below where responses on the prequiz and in-class problem are consistent from our perspective.) However, students who said the converse was false on the prequiz were actually slightly more likely to use covariance being 0 as justification for independence in the example problem than students who had said the converse was true in the prequiz.

Table 1. Converse Prequiz Truth Value versus In Class Problem Approach

Prequiz Response	Used Converse	Did Not Use Converse	TOTAL
Converse: False	22	37	59
Converse: True	5	8	13
TOTAL	27	45	72

A smaller percentage of Treatment 2 students assumed the converse on the In Class Problem than Control 2 students. In contrast, a smaller percentage of Control 1 students assumed the converse than Treatment 1 students. However, these differences were not statistically significant. We built a binary logistic regression model for the response on the In-Class Converse problem for each instructor using Previous GPA, prior logic experience, and treatment as independent variables. For each instructor, p-values for all three variables were each at least 0.1. Trends on the midterm Converse problem closely resembled those on the in-class problem except that on the midterm, treatment for Instructor 1 was a marginally significant predictor ($p = .042$) with Control students less likely to assume the converse.

There was greater consistency between the truth value students selected on the prequiz and the approach to the in-class problem for the contrapositive than for the converse (see Table 2). Specifically, 58 of 72 students claimed the contrapositive was true and used covariance being nonzero to decide X and Y were dependent. However, of the eight students who declared the contrapositive was false on the prequiz, seven of them used covariance being nonzero as their sole justification for the variables being dependent. Furthermore, six students claimed the contrapositive was true but did not use the covariance value in determining independence.

Table 2. Contrapositive Prequiz Truth Value versus In Class Problem Approach

Prequiz Response	Used Contrapositive	Did not Use Contrapositive	TOTAL
Contrapositive: False	7	1	8
Contrapositive: True	58	6	64
TOTAL	65	7	72

Treatment 2 students were more likely than Control 2 students and Control 1 students more likely than Treatment 1 students to use the contrapositive on the In Class Problem. On the final exam problem, Treatment 2 and Control 2 students performed comparably and Control 1 students again used the contrapositive more than Treatment 1 students. These results were not significant when using binary logistic regression and neither GPA nor prior logic training were statistically significant predictors for whether students used the contrapositive.

Discussion and Limitations

Students in this study were more likely to provide conventional truth values for variants of a conditional statement than they were to apply those only when appropriate to determine whether two random variables are independent. Students who provided conventional truth values were not more likely than others to use the contrapositive or avoid using the converse. This may partially explain why prior logic training was not a statistically significant factor impacting problem response. We posit that many students are able to identify contrapositive and converse statements and have learned conventional truth values for the same, but do not hold the same meanings for “true” and “false” as those in the mathematics community. This may help explain why one of the control groups outperformed the treatment group. Each treatment focused on helping students reach agreement with the conventional truth values of the contrapositive and converse statements. Yet, our data suggests that this is not the primary issue. The examples used in instruction with only the control sections accomplished something the treatments did not; they made explicit that the theorem could not be used to solve all problems and that alternative methods to calculating covariance or determining independence are available.

We saw a marked increase in using the definition of independence from in-class to midterm/final exam on both converse and contrapositive problems. It is natural as an instructor to view this shift positively for the converse problems and somewhat negatively for the contrapositive problems. It may be that some students did not have confidence in their ability to apply the theorem correctly during exams and therefore decided to always calculate covariance and determine independence directly. Alternatively, it is possible students simply didn’t think to use the theorem. Students also may have been less likely to use the definition of independence on the in-class problems because of availability bias (Tversky & Kahneman, 1973); they had discussed the theorem more recently than the definition of independence in class, but between class and the midterm and final exam had more time to review. Other explanations are possible of course and this is one question that should be explored in the future with student interviews.

A primary limitation in this study is the single source of data (student written responses) and our inability to perfectly dichotomize students by their understanding of the conditional statement and its implications. For example, a student who chooses to use the definition of independence when the covariance is 0 does not necessarily believe the converse is false. The student may, in fact, answer this way with little to no knowledge of the theorem or logic principles. As another example, some students provided multiple justifications to one of the problems and we do not know why. They could have been simply checking or confirming their work with a second method. Alternatively, students who use the contrapositive correctly may simply be reiterating a rule they’ve been taught but do not necessarily believe it is always true. Future studies may follow up these types of responses with interviews and slightly modified problems so that students can be more carefully classified. We are particularly interested in the 22 students who claimed the converse was false but then used covariance being 0 as justification for X and Y being independent on the in-class converse problem.

Another limitation is using credit for Discrete Math as a proxy for whether the student had received prior instruction in logic. We cannot guarantee that some of the students who did not have credit for Discrete Math had not taken other courses in logic. Moreover, we did not capture performance in Discrete Math but only whether credit had been achieved.

Finally, the instruction was limited to one 50 minute class period, not by choice but because of the restrictions imposed by the course schedule. This once more highlights the common challenge of how to best prepare students who are not math majors for courses that rely on an understanding of logical implication but do not have time allotted for explicit logic instruction.

Analyzing the Reasoning Types potentially Required by Tasks in an Open-Source Introductory Statistics Textbook.

Joash M. Geteregechi
Ithaca College

This study examined the tasks in the exercise sections of a popular open-source statistics textbook in order to characterize the types of reasoning the tasks are likely to elicit from readers. To achieve this, I examined the narrative sections of the book alongside the solved examples to determine the extent to which the kind of guidance provided was relevant in solving the tasks in the exercise sections of the book. Findings show that although most tasks could be solved by closely following the procedures and methods in the book (imitative tasks) there were other tasks that could elicit more nuanced forms of reasoning (creative mathematical reasoning tasks). These tasks were more prominent on the tail ends of the exercises section than on the beginning parts. Implications of these findings are discussed.

Keywords: Creative mathematical reasoning, Task analysis, Mathematics textbooks, Imitative reasoning.

Mathematics textbooks are among the most important resources for the teaching and learning of mathematics at the college level (Geteregechi & Waswa, 2020). Both instructors and students rely on mathematics textbooks to meet various learning needs such as self-study, practice, among others (Van Steenbrugge et al., 2013). Although it is difficult to exclusively characterize the role of textbooks in students learning of mathematics (Tarr et al. 2008), researchers (e.g., Stylianides, 2009) have reported that textbooks have a significant influence on how students make sense of and learn mathematics concepts.

One of the most important aspects of student learning is the kinds of reasoning that they engage in. Instructors often want to understand students' ways of thinking so they can better support their learning. However, what is often ignored is the sources that may inform students' thinking. In this paper, I argue that textbooks play a significant role in informing students' ways of thinking and thus there is need to examine the opportunities they present. Although there are many studies on the kinds of opportunities that mathematics textbooks provide for their readers (Thompson et al., 2012), not many such studies focus on how the narrative section of the texts influence the kinds of reasoning that students use for future task solving including tasks found in the exercise sections of the texts. I define the narrative section as the parts of a textbook where the readers learn the intended concepts and ideas. For most textbooks, the narrative section comprises of descriptions, illustrations, solved examples, among others. Exercise sections, on the other hand, comprise of the tasks intended to be completed by the readers of the text.

Most studies examining mathematics textbooks focus on calculus and geometry textbooks hence leaving a dearth of research in other important areas such as statistics. Furthermore, not many studies examine tasks from the perspective of the kinds of reasoning they are likely to elicit from readers. The term reasoning is often used without a clear definition of what it is and how to characterize it which means many studies on textbook analysis do not provide ways to characterize the potential of tasks to elicit specific kinds of reasoning. In this study, therefore, I sought to answer the following research questions:

1. What kinds of reasoning can be expected from tasks in a popular introductory open-source statistics textbook?
2. How are these tasks distributed within the exercises section of the book?

Related Literature

Most studies analyzing opportunities for reasoning in mathematics describe general characteristics associated with higher order thinking. Dolev and Even (2015), for example, examined the extent to which tasks in mathematics textbooks required students to provide justifications for claims made. The study compared six textbooks with a focus on geometry and algebra strands. Their findings indicated that geometry tasks tended to have more opportunities for justifying than algebra tasks across all textbooks. Similarly, Otten et al. (2014) examined the reasoning-and-proving opportunities available in secondary geometry textbooks and reported that although there were numerous reasoning and proving opportunities in both the narrative section and the exercises section of the books, these opportunities were not an object of focus in these books. While these studies provide insights into the kinds of tasks in textbooks, they rarely classify tasks themselves based on the reasoning types they are likely to elicit. This is due, in part, to the fact that the studies did not approach the analysis with a specified definition of reasoning. Thus, this study uses Lithner's well defined framework on reasoning to characterize tasks according to the kinds of reasoning they are likely to elicit. There are, however, some studies that have used specified definitions of reasoning in conducting their analysis. For example, Sidenvalli et al. (2015) analyzed the reasoning types required by secondary mathematics textbooks and compared them to the types of reasoning actually used. The study reported that most tasks (80%) could be solved by imitating the procedures given in the book. Studies such as this are rare for college-level textbooks especially ones that focus on statistics concepts.

Frameworks

Lithner (2008) defined the term reasoning as "the line of thought adopted to produce assertions and reach conclusions in task solving" (p. 257). Argumentation is the part of reasoning that one uses to ground the truthfulness or otherwise of assertions. Argumentation could be based on intrinsic properties (relevant and correctly applied mathematical features in a given situation) or non-intrinsic ones. If one is trying to tell which fraction between 7/8 and 8/9 is bigger, for example, an intrinsic property would be the quotient while a non-intrinsic one would be a focus on the magnitudes of the numbers themselves (e.g., 9 is bigger than 8 so 8/9 is bigger). Lithner (2008) categorized mathematical reasoning into two broad categories namely imitative reasoning (IR) and creatively founded mathematical reasoning (CMR). IR is analogous to rote learning and is further categorized as memorized imitative reasoning (MIR) or algorithmic imitative reasoning (AIR). MIR involves complete recall of a solution to a problem and is common especially in tasks requiring proofs of mathematical claims and theorems. AIR, on the other hand, involves following certain solution procedures/algorithms to a certain class of problems without a deeper understanding of the process.

Reasoning is classified as CMR, if it meets the following conditions:

1. Novelty. A new (to the reasoner) reasoning sequence is created or a forgotten one is recreated.
2. Plausibility. There are arguments supporting the strategy choice and/or strategy implementation motivating why the conclusions are true or plausible.

3. Mathematical foundation. The arguments are anchored in intrinsic mathematical properties of the components involved in the reasoning. (Lithner, 2008, p. 266)

CMR is further classified as local or global. Local CMR can be thought of as an improved form of AIR. Local CMR happens when someone makes non-trivial modifications to parts of an already known solution strategy or algorithm in solving a new task. Global CMR happens when a solver has no known solution strategy or algorithm and thus engages in CMR throughout the task. Using these classifications of reasoning, I define tasks accordingly. A task that requires imitative reasoning is called an IR task while a task that requires CMR is labelled a CMR task. CMR tasks are further classified as global or local while IR tasks can be algorithmic (AIR) or memorized (MIR).

In making the above classification of tasks, I recognize the fact that different solvers may experience the same task differently depending on several extraneous factors. A task may be a local CMR task for one person while being a global CMR task for another. Since the focus of this study was to examine the tasks themselves, the study only considered the guidance provided in the narrative section of the book and the extent to which such guidance would likely elicit different kinds of reasoning among readers of the book.

Method

Data and Setting

The text analyzed in this study is the fourth edition of *OpenIntro Statistics* by David Diez, Mine Centikaya-Rundel and Christopher Barr. I chose this book because it is one of the most popular open-source books being used as the main text or as an additional reference "at community colleges to the Ivy League" (OpenIntro, n.d). The book is divided into nine chapters each with several sections. Each section has one exercise set with several exercise tasks for readers to complete. I randomly sampled four tasks from selected sections within chapters five, six, seven, and eight. I chose these chapters because their primary focus was on statistical inference, which according to previous studies, is one of the areas that many students struggle in (Makar & Rubin, 2018). Chapter five had three sections with a total of 26 tasks while chapter six had five sections with a total of 38 tasks. Chapter seven on the other hand had five sections and a total of 46 tasks. For chapter eight, only one section focused on inference (i.e., inference for linear regression) and had six tasks. Previous studies (e.g., Author, 2020) have shown that for many textbooks, more cognitively demanding tasks tend to appear towards the end of the exercises. Since I were not sure whether this is the case for the book that I analyzed, I wanted to ensure our sample had at least one task from all parts of the exercises (i.e., initial, middle and last). To achieve this, I used stratified sampling where I split the questions into the first 25%, middle 50% and upper 25%. I then used simple random sampling to select one task from the first stratum, two from the second, and one from the last. Some selected tasks had several parts (like a, b, c etc.) that were related and built on one another. Whenever such a task was selected in the random sampling, I purposefully chose the last one in the series since it was likely to incorporate all the others in some way. In the end, I had 54 tasks in the sample, representing 47% of all tasks within the target sections of the book.

Within the narrative of the text, I focused mainly on the solved examples, guided practice items, and the solved case studies. I also brushed through the other parts of the narrative section (e.g., introduction and motivation) for descriptions of procedures and methods of solving certain kinds of tasks. This information was useful in characterizing the reasoning forms that the tasks in the exercise section of the book might elicit.

Analytic Procedures

To analyze the data described above, I used a modified version of Lithner's framework as provided in Mac an Bhaird et al. (2017). As described earlier, argumentation is an important component in any attempts to characterize reasoning. However, since the aim in this study was to characterize exercise tasks according to the kinds of reasoning they are likely to elicit from their readers and not the reasoning of specific students, I thought that examining the model solutions alongside the argumentations given in the book would be more meaningful. This is because the solutions in the book provide a model that readers may use with varying degrees of modification when solving the exercise tasks. While I recognize that a reader can use knowledge gained elsewhere to solve problems in the book, I believe that for most readers, the methods described in the book would play a significant role in their task solving process. Indeed, Mac an Bhaird et al.'s (2017) noted that the solved examples provided in math textbooks and lectures play a key role in students' task solving processes. I then solved the sampled tasks from the exercise sections by following the methods given in the book whenever possible while keeping track of the number and nature of any required modifications on the book methods. I defined modifications as any alterations on the book methods without which a successful solution would be impossible. Trivial alterations such as a different problem context and numerical values were not considered modifications. Another expert also worked on the problems separately then we met to discuss. The interrater agreement on the modifications was 94%. I labelled tasks that required no modification of procedure in the book as IR tasks and those that required at least one modification or that did not have a procedure in the book as CMR tasks. I classified CMR tasks as local CMR if they required only one modification and global CMR tasks if they required at least two modifications or if there was no algorithm or procedure for solution in the book.

Results

To concretize the analysis described above, I start by using a task (see Figure 1) drawn from a section called "Confidence Intervals for a Proportion" under the chapter titled "Foundations for Inference".

> **5.14 Coupons driving visits.** A store randomly samples 603 shoppers over the course of a year and finds that 142 of them made their visit because of a coupon they'd received in the mail. Construct a 95% confidence interval for the fraction of all shoppers during the year whose visit was because of a coupon they'd received in the mail.

Figure 1. A task from Inference for Single Proportion

We were able to solve this task by closely following the solution model to one of the guided exercises (see Figure 2) in the book. Although the problem does not provide a percentage value for the success rate (in this case percentage of shoppers who made a visit because of a coupon), this is considered trivial given that most readers of the book would be college or high school students. The rest of the solution requires using different numbers and substituting them in the formulas appropriately. The critical value associated with the new confidence interval can be confusing to some readers but the process of finding it was provided elsewhere in the book and could be applied in this new situation.

GUIDED PRACTICE 5.15

In the Pew Research poll about solar energy, they also inquired about other forms of energy, and 84.8% of the 1000 respondents supported expanding the use of wind turbines.[9]

(a) Is it reasonable to model the proportion of US adults who support expanding wind turbines using a normal distribution?

(b) Create a 99% confidence interval for the level of American support for expanding the use of wind turbines for power generation.

Solution:

[9](a) The survey was a random sample and counts are both ≥ 10 ($1000 \times 0.848 = 848$ and $1000 \times 0.152 = 152$), so independence and the success-failure condition are satisfied, and $\hat{p} = 0.848$ can be modeled using a normal distribution.
(b) Guided Practice 5.15 confirmed that $\hat{p}$ closely follows a normal distribution, so we can use the C.I. formula:

$$\text{point estimate} \pm z^{\star} \times SE$$

In this case, the point estimate is $\hat{p} = 0.848$. For a 99% confidence interval, $z^{\star} = 2.58$. Computing the standard error: $SE_{\hat{p}} = \sqrt{\frac{0.848(1-0.848)}{1000}} = 0.0114$. Finally, we compute the interval as $0.848 \pm 2.58 \times 0.0114 \rightarrow (0.8186, 0.8774)$. It is also important to *always* provide an interpretation for the interval: we are 99% confident the proportion of American adults that support expanding the use of wind turbines in 2018 is between 81.9% and 87.7%.

[10] No, a confidence interval only provides a range of plausible values for a parameter, not future point estimates.

Figure 2. Sample guided practice exercise and solution

A reader solving the task in Figure 1 can provide a similar sequence of argumentation as given in the guided practice and other parts within the text. For this reason, I categorized the task as an AIR task. Next (Figure 3) I consider an example of a CMR task.

5.11 Waiting at an ER, Part I. A hospital administrator hoping to improve wait times decides to estimate the average emergency room waiting time at her hospital. She collects a simple random sample of 64 patients and determines the time (in minutes) between when they checked in to the ER until they were first seen by a doctor. A 95% confidence interval based on this sample is (128 minutes, 147 minutes), which is based on the normal model for the mean. Determine whether the following statements are true or false, and explain your reasoning.

(a) We are 95% confident that the average waiting time of these 64 emergency room patients is between 128 and 147 minutes.

(b) We are 95% confident that the average waiting time of all patients at this hospital's emergency room is between 128 and 147 minutes.

(c) 95% of random samples have a sample mean between 128 and 147 minutes.

(d) A 99% confidence interval would be narrower than the 95% confidence interval since we need to be more sure of our estimate.

(e) The margin of error is 9.5 and the sample mean is 137.5.

(f) In order to decrease the margin of error of a 95% confidence interval to half of what it is now, we would need to double the sample size. (Hint: the margin of error for a mean scales in the same way with sample size as the margin of error for a proportion.)

Figure 3. A sample CMR task

Although there were several solved examples and guided exercises in the narrative section of the text, none of them was presented in a way that can be directly used to answer the task in Figure 3 (part d). The examples provided step by step procedures for creating confidence intervals but did not provide ways of assessing the effect of sample size on the margin of error. As a result of this, I concluded that a solver would have to reuse the procedure for creating confidence intervals in a different way that goes beyond a mere plugging in of numbers. Specifically, a solver will need to think about the procedure in a reverse manner since the confidence interval is already provided. These two modifications meant that the task was further classified as a global CMR. In an analogous manner, I examined all sampled tasks within the chapters focusing on statistical inference. I summarized the results in Table 1.

Table 1. Classification of Task Types by Chapter and Distribution

Chapter	IR Tasks			CMR Tasks					
				Local CMR			Global CMR		
	First 25%	Mid. 50%	Upper 25%	First 25%	Mid. 50%	Upper 25%	First 25%	Mid. 50%	Upper 25%
Foundations of inference	5	3	1	0	1	1	0	0	1
Inference for Categorical data	4	6	2	0	1	1	0	1	1
Inference for numerical data	7	6	2	1	2	1	0	0	1
Linear Regression	2	2	1	0	0	1	0	0	0
	18	17	6	1	4	4	0	1	3

The general trend prevalent in Table 1 is that the text has more IR tasks than CMR tasks. Out of the 54 sampled tasks, 41 (76%) were found to be IR tasks. These tasks tended to appear more at or below the 50th percentile. Indeed, out of the 41 IR tasks, 35 (85%) appeared at or below the 50th percentile. This trend appears to be reversed for CMR tasks, especially for global CMR ones. Three out of 4 global CMR tasks were all found at or above the 75th percentile of tasks. Similarly, for local CMR tasks, 8 out of 9 tasks were at or above the 50th percentile.

Discussion

This study sought to explore the kinds of exercise tasks in a popular open-source statistics textbook based on the kinds of reasoning the tasks are likely to require for successful solution. As noted earlier, most studies on textbook analysis are based on calculus and geometry strands and do not use well specified definitions of reasoning. Thus, this study addresses this gap by using a well-specified framework for mathematical reasoning to characterize mathematical tasks based on the kinds of reasoning they are likely to elicit from readers. The study targeted one of the most challenging parts of statistics (inference) within a popular open-source textbook used in several colleges for introductory statistics courses.

In general, the study found that the processes described and/or implemented within the narrative sections of the book could be followed with little to no modifications for successful solution of most tasks within the exercise sections. This means that opportunities for engaging in deeper thinking were limited at least in the exercise sections. This finding should not be taken to mean that there are no opportunities for deeper thinking in the textbook. In fact, the narrative section did have examples that provide opportunities for deeper thinking but only of the reader attempts them before looking at the solution provided. Nevertheless, there were several tasks that provided opportunities for deeper thinking in the sense that solvers would have to engage in creative reasoning for successful solution. These tasks require major modifications to the procedures described in the book and a reader would need to think deeply about the concepts for successful solution. This finding is similar to those reported by Sidenvalli et al. (2015) which indicated that mathematics textbooks tended to have more imitative reasoning tasks than creative reasoning tasks.

In regard to the distribution of the tasks within the exercises section, I found a general trend in which imitative reasoning tasks appeared at or below the 25th percentile while creative reasoning tasks appeared at the tail end (above the 75th percentile). A possible explanation for this trend could be that the authors intended readers to practice with basic concepts and factual tasks before they could engage with more cognitively engaging ones.

One possible implication of this study is for instructors using the text as a resource in their classrooms. When assigning exercises, it would be helpful to have students complete at least one task from the initial, middle and the last parts of the exercise sections. Depending on the goal of assigning the exercises, it might also be helpful for instructors to modify the tasks in some way before assigning them to the students.

One limitation of this study is the lack of student voices in characterizing the reasoning likely to be elicited by the tasks. Nevertheless, the fact that the study examines the tasks in relation to the narrative section still provides useful information because the arguments provided in the narrative section are likely to be repeated by students solving the tasks.

Navigating AB705 and a Pandemic: An Investigation of Students' Experiences With Placement and Advising

Alicia Hernandez Charles E. Wilkes II
San Diego State University San Diego State University

Recent state policies have pushed for more diversity in the STEM pipeline. One proposed solution is the California Assembly Bill (AB705) (California Community College, 2018), which requires students to take and pass gateway math courses within their first year at community colleges. In theory this policy seems like a solution, however pragmatically there is a lot to be learned about its implementation and consequences for students. In this paper, we address the research question: What are students experiences with placement and advising at a local two-year college. We conducted a descriptive qualitative case study (Yin, 2009) that draws upon s student outcome data and focus groups. We focus on 5 STEM majors' experiences. Findings suggest most students passed their gateway math courses within a year, however students described negative placement and advising experiences: receiving deficit-oriented suggestions from counselors and limited counselor availability. We discuss implications in the paper.

Keywords: Gateway Mathematics Courses, Placement, Advising, Guided Self Placement (GSP)

Introduction

California Assembly Bill 705 (AB705) was created to increase the diversity of students pursuing STEM (California Community College, 2018). AB705 requires that students enroll and complete transfer-level mathematics courses, such as college algebra, trigonometry, or pre-calculus by the end of their first year. In order to meet state mandates, institutions were forced to adjust structures and procedures, while still navigating various levels of students' preparation. Despite AB705 being well intentioned, one potential consequence is that the increase in students taking STEM courses sooner, has not led to a decline in student failure rate in these courses. In fact, the failure rate in these courses is the same or in some cases higher. This creates a paradox of sorts, as administrators see the increase in "throughput" as a positive, while instructors see the unchanging or higher failure rates as a negative result. This paradox raises concerns about what issues are underlying the implementation of the state mandate. In this paper we describe students' experiences with placement and advising at a local two-year college. Specifically, we consider the role of counselors in placement and advising students. It is important to note that the study took place during the pandemic. We highlight the pandemic because it is an additional layer of complexity that potentially impacts student placement and advising. As a result, this paper has two purposes: understanding students' experiences with placement and advising and highlighting the challenges of ensuring that students are appropriately placed in gateway mathematics courses. The research question that guides this paper is How do students feel about their placement and advising compared to how they did in the course they were placed into?

Literature Review

Several researchers have investigated gateway mathematics courses at two-year colleges. For example, one thread of inquiry researchers have tried to understand is student placement and the subsequent role that advising plays in the placement process. By gateway mathematics courses, we mean courses that are credit-bearing and transferable to four-year institutions (e.g., College Algebra, Precalculus). With respect to student placement and advising, there are several key findings worth highlighting. First, Kosiewicz and Ngo (2019) using self determination theory, found students who have autonomy to select their courses are successful in enrolling and passing those courses. This finding is important as it highlights the value and importance of student agency. In contrast, other research using Behavioral Decision Theory (BDT) has found that students often do not make good decisions on which course to take (Payne, Bettman, & Johnson, 1992). The tension between findings that show students successfully enrolling and passing their course, alongside studies that show students do not make good decisions raises the question: Under what circumstances is it possible for students to exercise their autonomy and agency in course selection so that they can be successful?

There is literature that points to the idea of directed self placement (DSP) meaning that students have some autonomy, but also have guidance in the placement process. Tovar (2015) highlighted how crucial it is for counselors and students to develop a good relationship with one another in order to allow counselors to have a positive impact on supporting students to take and pass courses throughout their college career. Based upon this literature it seems it is possible that students can be placed in the correct courses and pass them. By correct courses we mean courses that students are prepared to take and likely to pass. It also seems that key individuals such as counselors play a pivotal role. However, one area that needs further study is understanding how students navigate having more agency and autonomy in selecting courses as a result of state mandate. Additionally, we need more understanding of the role that counselors in particular play in this process to ensure that students are placed in the appropriate course. Our study attends to these questions by focusing on students' experiences with placement and advising during the implementation of AB705.

Theoretical Framework

Self Determination Theory

Self determination theory (SDT) is a framework at the macro level utilized to comprehend personal intrinsic motivation and how social circumstances can influence individual intrinsic tendencies to not only grow, but also develop (Ryan and Deci, 2005). Moreover, social determination theorists have found that when a student is in an educational environment that captures three psychological needs, autonomy, competence and relatedness, student academic achievement is enriched (Kosiewicz and Ngo, 2019). Autonomy refers to the students using their own interest to decide how to take action.

In this study, we will focus on students' autonomy in order to understand how students decide to place themselves into their courses. From a SDT perspective, we expect that students' individual autonomy will make them feel like they were placed into the correct course. On the other hand, BDT suggests that students underestimate their abilities because of factors such as personal experience, demographics, and psychological features (Kosiewicz and Ngo, 2019). As a result, students tend to make suboptimal decisions. Our study intends to explore and highlight student experiences when it comes to placement and advising using both SDT and BDT. The implementation of AB705 removes the high stakes of a placement test in order to properly place students into their respective courses. Furthermore, this removal gives students more autonomy as additional measures such as high school GPA, high school courses and high school grades are taken into consideration when placing students into courses. Since students are aware of these additional measures that are being considered, they realize their current skills and abilities and use their autonomy to ultimately decide which math course they want to take.

Social Capital Theory and "Cooling Off"

Social capital theory is a framework that considers all the resources such as social networks and interpersonal relationships created and maintained by individuals when support is being sought (Bourdieu, 1986). Additionally, Tovar (2015) found that counselor and student communication impact not only how students interact with faculty members, but also their acclimation to social and academic environments in college. This highlights the importance of fruitful interactions and relationships between students and counselors. One may deduce that a lack of developing and nourishing this relationship between students and counselors may be detrimental to a student's overall experience navigating college. Using social capital theory as a framework, we hypothesize that counselors are supportive and helpful in advising students, and predict that as a result of this support, students will have positive experiences with counselors. It is important to note that although counselors are meant to act as agents of the institution who are supposed to provide students with the help, guidance, and support they need to be successful in their academic endeavors, Bahr (2008) emphasizes that counselors are subject to "cooling off" students. Bahr (2008) defines the "cooling off" process as the progressive detachment of a student from his or her personal academic goals. Furthermore, Bahr (2008) explains that this is executed by counselors using factors from students such as level of preparation, skills and abilities in order to lead them down a lesser path of achievement rather than the path students intend to take. In our study, we intend to explore the role counselors have on students and how student experiences with advising affect placement.

Collectively we leverage SDT to understand the ways students exercise their autonomy with respective placement and advising. BDT is used to capture if students are not appropriately placed and/or do not pass their course to understand what mechanism might contribute. Lastly, we use "cooling off" as a lens to describe how counselors place and advise students.

Methods

Context

Focus groups and interviews were conducted at Southern Hispanic Serving Institution (SHSI). When collecting the data, courses taken by students and taught by instructors at this institution were college algebra and precalculus with trigonometry. This HSI has diverse students with 90% racial-ethnic minorities and the Hispanic population making up 70% of the population. Furthermore, the most common demographic for instructors at this institution was female professors, followed by male professors and female assistant professors.

Data

The data used for this study comprised student interviews and student outcomes. Student interviews were done in the format of focus groups. There was a total of 19 students interviewed across gateway math courses. Student interviews focus on students' experiences navigating placement and advising with a focus on counselors. We define counselors as fine non-department university staff who work with students on course selection. The last data used in this paper is student outcome data. Student outcome data contained the courses students took for Fall and Spring and whether the student passed a course. This data included only gateway mathematics courses. It is important to note that we define *passing* as a student who does not need to take the course again. For example, if a student earned a C in College Algebra, then they would not need to retake College Algebra.

Data Analysis

Analysis of the qualitative data was done using MAXQDA software. Interview transcripts were coded using open coding with a focus on advising and placement. In the first round of coding, the first author coded the student transcripts. After coding the first and second author met to discuss first level codes. That is, segments of the data that focused on placement and advising. In the second round of coding the first author developed subcodes to further unpack the first level codes. The first author then met with the second author to confirm the subcodes. Lastly, the first author looked across the coded transcripts for similarities and differences between and among students' transcripts.

Findings

In this section we provide data on students' course trajectory to get a sense of the courses students took and the letter grade they received, which indicates whether they passed. Next, we address the research question: *How do students feel about their placement and advising compared to how they did in the course they were placed into?*

After the passing of AB705, the SHSI created an assessment called Guided Self Placement (GSP) that considers additional measures such as high school transcripts, last math course taken, etc., in order to help students be successful in their respective placed courses. In some cases, if a students' assessment determines that they are going to require additional help to be successful in their math course, the student needs to enroll into a support course for the math course they were placed into. Regarding placement, most of the nineteen students interviewed in focus groups believed they were placed into the correct math course. Additionally, students who felt they were not due to either the difficult transition to online classrooms during a pandemic and/or lack of proper foundation to be successful in their placed course. Despite students feeling that they were placed into the correct course, multiple students described having negative experiences while trying to get placed into the proper course. There were two categories of negative experiences students had with placement, interactions with counselors and counselors not having adequate time. Below I provide student examples to illustrate students' negative experiences with placement.

Counselor Suggestions Through Deficit Orientation

Kali is a student who enrolled into Precalculus with Trigonometry after taking the SHSI's Guided Self Placement (GSP). When consulting a counselor about her math placement, the counselor questioned Kali's ability to be successful in the course by saying "oh a lot of people take Applied Calculus I first because they think it's easier, are you sure you want to take Precalculus with Trigonometry?" This comment shows how counselors partake in the "cooling off" process described by Bahr (2008). Kali stated that the counselor's comment, "...kind of rubbed me the wrong way." Kali's reaction to the comment highlights how although it may seem like counselors have the students' best interest at heart, they may not properly convey that. As a result, a weak relationship is developed between Kali and this counselor, which limits the social capital Kali has access to. Having limited access to social capital can be detrimental to student experience, but regardless of what she was told, Kali felt like she was placed into the correct course. This shows that through her own agency and autonomy, Kali decided Precalculus with Trigonometry was the correct fit for her level of preparation. Lastly, she was able to prove the counselor wrong by receiving a passing grade.

After taking Intermediate Algebra I and II, Saul is a student who decided to reach out to his math instructor to receive guidance on which class to take next. He ended up enrolling in

Precalculus with Trigonometry. When Saul decided to consult with a counselor to get advice, the counselors completely disregarded what Saul said and did not give him advice to help him take the proper steps toward achieving his academic goals. Instead, the counselor advised Saul to change his major, which leaves Saul in a tough position since he knows what major he wants to pursue and decided to attend this SHSI in order to save money. This interaction highlights how counselors accomplish “cooling off” by not listening to students and suggesting them to stray away from their academic goals. Furthermore, it highlights the importance of listening to a students’ wants and needs, and having the counselors receive the proper professional development to ensure those needs are met. Even having a negative experience with advising, Saul used his own agency and autonomy to ultimately enroll in and pass the Precalculus with Trigonometry.

While only two experiences are highlighted in this section, these experiences are powerful because they highlight the counselors' deficit perspective on student trajectories in STEM (e.g., Change of Major). Since only two students were able to personally interact with counselors, this shows the limited availability of counselors. We will say more about limited counselor availability in the next section and how it affects student placement and advising.

Limited Counselor Availability

Nicole is a student who was placed into Analytic Geometry and Calculus II. The path to getting the correct placement was not easy. Nicole had to talk to her high school teacher for guidance because her discrete math class did not transfer credit to the SHSI, but the material covered in the discrete math course should place her in a higher level of math. After speaking to a counselor about her misplacement, Nicole was placed into Analytic Geometry and Calculus II. This particular experience highlights the lack of coordination between high schools and local community colleges. Furthermore, it shows that students rely on former math instructors for guidance on which math course to take when they transition into college, which shows Nicole utilized her autonomy to ultimately decide what course she wanted to be in. Nicole states in her interview that getting counseling is a bit hard. As a result, she relies on the SHSI’s student plan that was made with a counselor in order to help her choose the classes she needs to achieve her academic goals. Although it was difficult to receive advising, through her own agency and autonomy, Nicole enrolled into and received a passing grade in her placed course.

Evie is a student who enrolled into College Algebra with support after filling out the SHSI’s GSP. When the GSP assesses that a student is going to need support to be successful in the course they place into, the student is required to enroll into the support course. Evie took initiative and decided to reach out to counselors to get advice on which courses to take. She states, “Well, I went to the counselor and um, I just, I did-they didn't have time to do a counseling meeting um at the time. So, it was just some lady in the front. She just could see me for five minutes.” Evie not being able to access helpful resources such as counselors shows that Evie’s social capital is limited. Additionally, it shows a need for properly trained counselors for students to be able to receive the proper resources to be successful. Overall, despite not being able to access counselors, Evie utilized her autonomy to ultimately enroll into College Algebra with support and received a passing grade.

Domi is a student who enrolled into Precalculus after using the SHSI’s GSP. When attempting to reach out to counselors about which math course to enroll into, Domi did not receive a response. As a result, Domi attempted to enroll into Calculus, but due to not meeting the prerequisites was unable to. After this experience, Domi reached out to a friend who told him to fill out the GSP. The path Domi had to take in order to be properly placed into his math course is common for students. Additionally, not being able to access counselors during a time of need shows that there are more students needing help than counselors can attend to. Although Domi was unable to seek support from institutional agents (e.g., counselors, faculty/staff), he utilized his autonomy to reach out to others in order to ultimately make a well-informed decision on which course he should enroll in. Additionally, Domi's experience highlights the power of GSP as it helps students place themselves in their math courses. Overall, although Domi had to reach out to resources other than counselors, he still felt like he was placed into the correct course and received a passing grade.

Discussion

The purpose of this study was to investigate students' experiences with placement and advising at a two-year college in the aftermath of passing AB705. In our study, we noticed that fifteen out of the nineteen students passed the gateway mathematics courses they were placed into within a one year time frame. Furthermore, we found that most students felt like they were placed into the correct mathematics course. Although this was the case, students described having negative experiences when interacting with counselors. These experiences were grouped into two categories, Counselor Suggestions Through Deficit Orientation and Limited Counselor Availability. These findings highlight points made in the literature about counselors "cooling off" students, and not developing positive relationships with students, which can limit the access to resources within a students' social capital. An important resource students mentioned being helpful was being a part of the First Year Experience (FYE), which gives students direct access to counselors who can dedicate themselves fully to them. On the other hand, students who did not have a resource such as FYE had a more difficult time accessing counselors. As a result, although not focused on this paper, there seems to be a lack of counselors needed to ensure that students are able to obtain and access the resources they need, which brings attention to limitation of resources available in a students' social capital. Other work might also attend to the ways in which counselors are trained, as several interactions between counselors and students highlighted the deficit lens. It is important to note that this study was conducted during the pandemic, which may have contributed to the experiences students described. However, the concerns raised are very significant while learning to navigate a pandemic.

Limitations

While our study focused on student experiences with placement and advising, our study did not allow us to interview many students. In addition, student focus groups were conducted over Zoom, which may have contributed to why students may have resisted being interviewed as they were just beginning to use the platform. Collecting data over Zoom may not give diverse perspectives. Moreover, we also recognize that when this data was collected students were learning how to navigate the world in a pandemic, which could heavily influence their responses and experiences at the SHSI. As a result, we must acknowledge that the self-reported data we gathered may be subject to bias. These limitations highlight the importance of further research of student experiences with placement and advising during a pandemic.

Participatory Equity in One Undergraduate Linear Algebra Class

Jessica L. Smith
Vanderbilt University

Inquiry and active learning instructional methods have largely been regarded as equitable and beneficial for students. However, researchers have highlighted math classrooms as racialized and gendered spaces that can negatively impact marginalized students' experiences in such spaces. In this study, I examine the development of one argument, and whose ideas are solicited and leveraged, in an inquiry-oriented linear algebra course with an eye toward participatory equity. I found that gender related most to the inequity of participation in argumentation and that only men participated in generalizing activity. This study adds to the growing literature addressing equity in inquiry and active learning math settings.

Keywords: Inquiry-oriented instruction, Participatory equity, Argumentation, Linear Algebra

Researchers have found active learning to be beneficial for students (Esmonde, 2009; Freeman et al., 2014; Laursen et al., 2014; Rasmussen et al., 2020; Yackel & Cobb, 1996) and link active and cooperative learning environments to higher student achievement and success in STEM courses compared to traditional, lecture-based teaching methods (Freeman et al., 2014; Theobald et al., 2020; Zakaria & Daud, 2010). These student-centered approaches generally involve argumentation; however, argumentation can take many forms depending on who contributes and connects between ideas in the arguments. While many of these approaches have been linked to positive outcomes, researchers have also found whole-class and small-group discussions in mathematics classes to be gendered and racialized spaces, which can create negative mathematical experiences for women and students of color (Boaler, 2008; Ernest et al., 2019; Hand et al., 2012; Jackson & Cobb, 2010; Leyva et al., 2020; Reinholz et al., 2022; Wilson et al., 2019). Some students might have their mathematical methods consistently explored more often or more thoroughly, while others might feel as though their ideas are overlooked. The emphasis on certain ways of participating in mathematical activity involve cultural assumptions and expectations about what is normal and acceptable (Boaler, 2002; Nasir & Cobb, 2007).

Studies examining students' success, achievement, or growth in active learning mathematics classrooms often omit the gendered and racialized experiences that transpire in these classrooms. Much of the research detailing the latter tend to background the mathematics. This study fills a gap in the research by analyzing argumentation in an inquiry-oriented linear algebra course while attending to racialized and gendered interactions. My goal is to illuminate ways in which certain interactions in student-centered classrooms, such as who gets called on or whose ideas get taken up, can lead to racialized and gendered experiences in mathematical practices, such as argumentation. One research question guided this analysis: *In the context of an inquiry-oriented linear algebra class, how are arguments being developed and whose ideas are solicited and leveraged during this development?*

Theoretical Background: Equitable Participation and Argumentation

Equitable Participation

Leyva et al. (2020) theorize the ways in which mathematics classrooms are racialized and gendered by locating classroom events at the intersection of societal discourses about ability in STEM and explicit and implicit institutional logics related to access and authority (e.g., use of certain mathematics courses to prevent students from entering certain majors). With this lens, they highlight the ways in which students experience a range of classroom events that provide different opportunities and support to students in math class that vary systematically by race and gender. Reinholz and Shah (2018) refer to equity related to who is allowed to participate in classroom practices, such as discussions, as participatory equity. Ernest et al., 2019 describe participatory equity as concerning “the fair distribution of both participation and opportunities to participate in core aspects of the learning process” (p. 155). Reinholz and Shah (2018) explain that participating in mathematical discussions is part of the learning process, which can present a variety of settings for inequities. They explain that while it might not be intentional, women and students of color tend to be systematically given easier tasks and fewer opportunities to participate in doing mathematics.

Argumentation

I use Toulmin’s (1958/2003) model of argumentation not only to examine the mathematics being discussed by students and the instructor but also to organize the instructor’s prompts for contributions and responses to those contributions. Toulmin originally used this model to examine “argumentation in the traditional sense of one person convincing an audience of the validity of a claim” (Conner et al., 2014, p. 404). Mathematics education researchers (e.g., Andrews-Larson et al., 2019; Conner et al., 2014; Rasmussen & Stephan, 2014) have shifted the way this model is used, to examine the development of ideas through argumentation. An argument is a series of statements involving a combination of claims, data, warrants, rebuttals, and backings as defined below (Conner et al., 2014; Toulmin, 2003).

- *Claim*: statement to be validated
- *Data*: evidence validating the claim
- *Warrant*: statement connecting data to the claim
- *Rebuttal*: statements asserting when the warrant would not be valid
- *Backing*: “support that give warrants authority” (usually unstated) (Andrews-Larson et al., 2019, p. 4)

Data or warrants can become a *Data/Claims* or *Warrant/Claims*, respectively. For instance, if a claim that once needed validation becomes data to validate another claim, it is a Data/Claim.

Methods

Study Context, Participants, and Data Sources

This study focuses on a single instructional unit (systems of linear equations) in one undergraduate linear algebra class at a public institution in the Southeastern United States. According to institutional data, this university is categorized as a primarily Black institution. The class was taught using a hybrid format, where some students were in-person and some online via Teams. Students could decide each day how they wanted to join the class (in-person or online). The class used OneNote, a platform where the instructor and students could see the tasks, insert text or images, write notes, and see what each group did every class (making sharing group work easier in the hybrid format). The instructor for this course, Dr. Pi (all names are pseudonyms), used inquiry-oriented instruction to teach most, if not all, of the topics. All gender and race data were self-reported by students via survey. The participants were students enrolled in the course who consented to participate, which included four women, eight men, and no students self-identifying in any other gender categories; six students self-identified as Black, two as two or more races, one as Asian, one as Hispanic or Latinx, one as White, and one preferred not to respond. The data sources were video and audio recordings of whole class discussions (across 12 days), records of the chat in Teams, and field notes.

Data Sources and Analysis

Equitable participation analysis. To examine the equitable participation in the arguments described below, I coded students' contributions using Reinholz and Shah's (2018) EQUIP observation codes. The unit of analysis was a *sequence* of talk. A sequence begins when a student initially speaks and ends when another student speaks, thus starting a new sequence of talk. Because of the reliance on another student speaking, sequences vary in length depending on how long the instructor and student are speaking. If two students are going back and forth in conversation, then each time a student speaks starts a new line of code. For this study, I used Author's (2019) modified EQUIP codes. I generally focused on Dr. Pi's Solicitation Method and Evaluation. I counted the number of sequences involved in argumentation and the number of sequences involving contributions from women and from men. I used these numbers to calculate equity ratios (Reinholz & Shah, 2018), which compare the percentage of sequences involving women or men to their percentage in the population. An equity ratio of one means the ratio of a group's contributions in discussions (in this case, argumentation) was proportional to their representation in the class. An equity ratio less than one means a group is underrepresented in argumentation, where an equity ratio greater than one means an overrepresentation.

Argumentation analysis. I identified 12 different arguments taking place throughout the systems unit, which was eight class days long. For a discussion to be identified as an argument, students had to make vocal mathematical contributions. The arguments were large in grain size, where I allow for subarguments in the development of arguments (Conner et al., 2014). I identified the arguments by topic using my knowledge of the tasks and what happened in class. I identified all mathematical whole class discussions in the video data and selected which ones I wanted to further analyze based on observed trends, which will be described later in this section. After transcribing, I did the argumentation analysis first, which involved identifying the different arguments. I then examined the overall flow of ideas, later adding the evidence provided by students and Dr. Pi. I then labelled the different contributions as components in the arguments. In the 12 arguments I identified, I noticed some important trends that were relevant to the research question as they directly related to equitable or inequitable participation in argument development. The trend highlighted in this paper is that no women contributed to any arguments after the second half of the fourth day. This happened to be when the class started moving toward general activity (Gravemeijer, 1999), in which they generalized knowledge they had developed about solution sets so far in the unit. Instead, women only participated in situational activity in which students worked with systems in the context of a meal plan.

Findings

EQUIP Findings

Equity ratios were calculated based on a population of 8 people (due to consent), 2 women and 6 men. There were 98 sequences of talk throughout the unit, 5 (5%) from women and 93 (95%) from men. The 5 sequences involving women were all made within the first 4 (of 8) days of the systems unit, when the task sequence intended for mostly situational activity. Women had 5% of the total sequences but comprised 25% of the total population, as compared to men having 95% of the sequences while comprising 75% of the population (shown in Table 1). This produces an equity ratio of .2 for women and 1.267 for men. Thus, men were participating in argumentation far more than their representation in class, where women were involved in argumentation much less than their representation. Overall, men spoke more in general and, when women did speak, it was earlier in the unit, pointing to more contributions from women during situational activity than generalizing activity. When I examined the solicitation method by gender, I found that women were called on and not called on two times each (50% of the time for each code) (shown in Table 2). Table 2 shows men spoke most of the time without being called on (66.7%), but also spoke a fair amount being called on (29.4%). Sometimes men were called on was because they had previously spoken without being called on and Dr. Pi later asked them to elaborate or made a connection back to their idea. Women were also only solicited to give contributions answering a "what" type question, where men were solicited to give answer what, how, and/or why questions.

Table 1. Sequences and equity ratios by gender.

Gender	% Of Sequences	% Of Population	Equity Ratio
Women (2)	5%	25%	.2
Men (6)	95%	75%	1.267

Table 2. Solicitation method by gender.

Gender	Called On	Not Called on	Called on Volunteer	Called on Group
Women (2)	2 (50%)	2 (50%)	-----	-----
Men (6)	30 (29.4%)	68 (66.6%)	2 (2%)	2 (2%)

I found that the groups by race that participated in arguments almost proportionally to their representation in the class were the Asian student (equity ratio of 1.2 shown in Table 3) and the Black students (.82). The four Black students consisted of two women and two men. One man, Noel, had about 83% of the sequences within this group. He was both called on and not called on about equally as often. It could be argued that the White student had an equity ratio relatively close to 1 (.72). Alberto, who identified as multiracial, contributed considerably more than his representation in the class. He contributed to arguments more than three times his representation in the class. He was often not called on and had some of the longest sequences of talk. Lastly, the Hispanic/Latinx man, Jorge, was involved in argumentation much less than his representation in the class. He was generally called on and often had short sequences of talk.

Table 3. Sequences and equity ratios by race/ethnicity.

Race/Ethnicity	% Of Sequences	% Of Population	Equity Ratio
Black (4)	41%	50%	.82
Asian (1)	15%	12.5%	1.2
Hispanic/Latinx (1)	3%	12.5%	.24

White (1)	9%	12.5%	.72
2 or More Races (1)	32%	12.5%	2.56

Argumentation Findings: Contributions from only men during generalizing activity

The selected argument (shown in Figure 2) was chosen because it highlights and is representative of the type of generalization that occurred in the class, where students were generalizing knowledge about solution sets of systems by drawing on what they learned previously in the meal plans task. It lasted about 16 minutes and took place on the sixth day of the unit. Students were discussing a task in which they match four different systems to images of what their graphs would look like before solving the system or using technology to graph. In particular, students were discussing which graph out of six choices corresponded with System 1, $\begin{cases} x+y+z=210 \\ 5x+7y+10z=1500 \\ x+y+z=500 \end{cases}$. Dr. Pi started the discussion by looking at and reading out each group's choices for which graph matches:

> "*So y'all say that system one, the third equation will be parallel to equation one, but intersects equation two* [Data/Claim 11]. *So, we believe it's graph E* [Claim 12] … *They said for D, E, F* (shown in Figure 1)*, that they have no common points of intersection* [Data 10] ... *But due to the way systems three and four equations were made, they had connection either to D, E, or F."*

All the groups agreed that System 1 has no solution (Data/Claim 1); thus, System 1 corresponds with D, E, or F (Data/Claim 2). Dr. Pi then explained what the same group said about two of the equations, "*we know that* $x+y+z=210$ *and the money equation,* $[5x+7y+10z=1500]$ *do intersect,*" (Rebuttal 3, Data/Claim 11) with which the class agreed. The group also said that "*the scalars of* $x+y+z=210$ *and* $x+y+z=500$ *are the same and would probably lie on the same plane or be parallel to each other*" (Data/Claim 3). This was revoiced by Dr. Pi and other students, notably Noel who pointed out which planes in the graph were parallel.

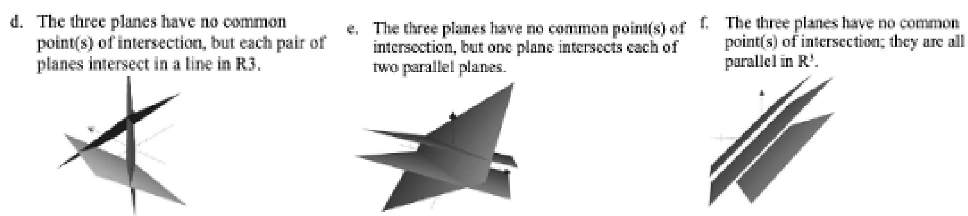

Figure 1. Options D, E, and F as possibilities for the graph of System 1.

This argument was driven by students' ideas. Dr. Pi voiced some of the argument by reading out each group's decision and explanation and drew in students to explain their reasoning or reason with other students' ideas. Dr. Pi did not make many connections during this argument, but rather engaged students in sensemaking about their own and others' decisions and making connections between those. In the end, students articulated what it means for a system to have no solution: there are no intersections between any of the three planes, or there is no common intersection between all three planes. Dr. Pi emphasized the latter as correct, and Aaron concluded E represents System 1.

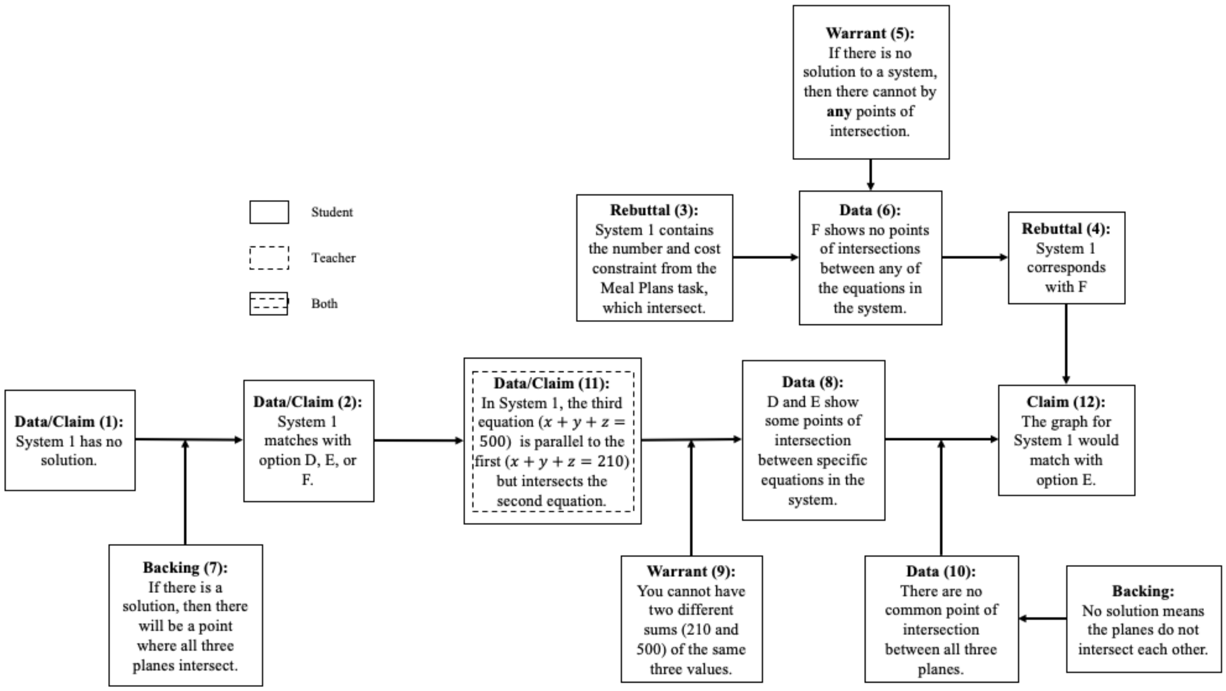

Figure 2. Map of the argument: Contributions from only men during generalizing activity.

Argument with EQUIP. Recall that this argument was selected because it is representative of the generalizing argumentation in which students engaged later in the unit. Also recall that no women verbally contributed to this type of argumentation during this unit, which I noticed during the argumentation analysis but confirmed through the EQUIP analysis. The EQUIP analysis showed that many of the students who did participate in developing this argument spoke without being called on, which could contribute to women not participating because men tend to dominate open discussions (Reinholz et al., 2021; Author, 2019). There was one instance in which Dr. Pi called on a group to see if they wanted to change their answer, which still elicited a response from a man. These findings of more men participating when Not Called On or Called On Group are consistent with findings from Author (2019).

Dr. Pi started the discussion by reading out different groups' ideas, so several argument contributions were provided by students but voiced by Dr. Pi. He started with a group's idea that System 1 has no solution because two of the equations are parallel planes, so System 1 must match with D, E, or F. To further think about this, the class looked at a graph of the system that a group developed to find which two planes were parallel. When discussing the colors of the planes, Alberto said, "*Leave the color identification to the girls.*" Dr. Pi made an uncomfortable noise in an effort to push back a bit on this comment. Alberto added that he said this "*because* [he is] *colorblind.*" This presented a moment when the women in the class could have felt uncomfortable and framed as less capable than the men, or like they do not belong. Alberto was suggesting that men need to make more mathematical contributions while the women can be left to decide colors. There were no women attending in-person in class that day and students joining virtually always had their cameras off, so it was hard to tell women's reactions. This comment created a slight disruption in the class discussion before Dr. Pi continued.

At one point after reading the groups' decisions, Dr. Pi asked if the group from Breakout Room 1 wanted to change their answer. Aaron spoke on behalf of the group and explained that he still thinks System 1 matches F because there should be no intersections when a system has no solution. Alberto interjected, without being called on, that a solution to a system would be somewhere *all three planes* intersect, not just two of them. In the end, Dr. Pi leveraged Alberto's contributions leading Aaron to agree that System 1 matches with E. In this argument, Alberto, Noel, and Aaron had the largest number of talk sequences. Alberto had 33% of the 15 sequences of talk, Aaron had 26.67% of the sequences, and Noel had 20% of the sequences, so they comprised 79.67% of the sequences of talk were contributed by three students in the class. This tended to be the trend throughout the generalizing arguments, where only a few students, always men, contributed most of the arguments. Alberto, who made a comment that suggested women's role in a mathematics classroom is to identify colors on a graph, was ultimately positioned as making the mathematically correct contribution that was publicly accepted by the authority figure, Dr. Pi. Not only were women not part of the development of the argument, but they were also learning mathematics in a context where a fellow student (a man) who made a sexist comment regularly played a central role in the mathematics that was developed.

Discussion

In this paper, I found that the data showed that the most distinct participation inequities in this class related to gender more than race. Women contributed between zero and three times per class, while provided between 4 to 30 sequences. Women's overall representation was substantially less than what would be considered equal, let alone equitable. Women participated in argumentation during situational activity and not formalizing activity. This could be related gender stereotypes in which women are framed as procedural and algorithmic thinkers as opposed to creative and abstract (Leyva, 2017). This could also be related to a larger stereotypical narrative in society (and STEM classrooms) around what women can and cannot do. Furthermore, this could contribute to similar outcomes between women enrolled in inquiry courses and women enrolled in non-inquiry courses (Johnson et al., 2020), as abstraction and generalization are core components of inquiry-oriented instruction. The current study adds to literature highlighting the nuance and complexities of active learning and discussions in mathematics classrooms.

Additionally, Alberto tended to dominate discussions and, because he usually spoke without being called on, there was limited space for other students to contribute. Instructors can sometimes implicitly, and unintentionally, allow students to drive the mathematical discussion, even when the other students provide more mathematically sound arguments (Black, 2004). Alberto also publicly commented during whole class discussion, saying Dr. Pi and Noel should "*leave color identification to the girls*." This was a multi-faceted situation in that Alberto felt comfortable enough in the class to make this comment but there are also implications for how this could have affected women in the class. It was normal for Dr. Pi and students to make jokes during class, but these jokes generally did not reference anyone's gender or race. This comment implied that men's role is to do the mathematics and women can take on a more superficial role (e.g., identify colors). Despite making this comment, Alberto spoke more than most students in the class and had his mathematical reasoning heavily publicly featured in almost every argument. These findings together point to the need for further examinations into the nature of interactions in inquiry and active learning classrooms, even when there appears to be strong argumentation taking place. Exploring these interactions can reveal inequities taking place when using a type of instruction thought to be the most equitable.

Identifying Tensions in a Small Group Work on an Open-Ended Modelling Task

Yuriy Rogovchenko
University of Agder, Norway

Svitlana Rogovchenko
University of Agder, Norway

We analyze students' cooperative small group work on an open-ended mathematical modelling task. Introduction of new ideas and techniques challenged traditional students' views on mathematics and conventional solution routines. This caused tensions in the student activity system pointing towards primary and secondary contradictions. To identify contradictions, their discursive manifestations were used.

Keywords: mathematical modelling, activity theory, contradictions, discursive manifestations of contradictions

The role of mathematics in life sciences has been continuously growing over past decades. Biology eventually replaced physics as the principal research partner for mathematics, and "after a century's struggle, mathematics has become the language of biology" (Steen, 2005, p. 22). An emergent need for professionals combining the knowledge of biology and mathematics stimulated changes in biology education, "the need for basic mathematical … literacy among biologists has never been greater" (Gross, Brent & Hoy, 2004, p. 85). New demands on the education of future biologists created major challenges for both disciplines calling for the reform of undergraduate biology education which "is burdened by habits from a past where biology was seen as a safe harbour for math-averse science students" (Steen, 2005, p. 14). New educational trends promoted interdisciplinary integration suggesting that "concepts from biology should be integrated within the quantitative courses that life science students take, and quantitative concepts should be emphasized throughout the life science curriculum" (Gross, Brent & Hoy, 2004, p. 86). Higher education institutions were encouraged to create strong interdisciplinary curricula integrating life sciences, mathematics, physics, and information science (Steen, 2005). In applications, mathematical modelling (MM) is often used to describe real-world problems in mathematical terms and analyze the real system gaining a deeper insight allowing to understand the future and take necessary actions. Motivated by the idea that MM can serve as a "didactical vehicle both for developing modelling competency and for enhancing students' conceptual learning of mathematics" (Blomhøj and Kjeldsen 2013, p. 151), in this paper we analyze the work of biology undergraduates on an open-ended MM task.

Design of the Study

An extra-curricular MM project for the first-year undergraduate biology students at a large Scandinavian university was designed to engage students into solution of biologically meaningful tasks. A group of twelve volunteer students (nine female and three male) met for five four-hour sessions where they were introduced to fundamentals of mathematical modelling (both theory and worked out examples) and worked on similar tasks in small groups of three to five students. Only two students had previously taken mathematics courses and ten were enrolled at the same time in a regular first-semester compulsory mathematics course. Our main goal was to demonstrate applications of different mathematical ideas and tools in life sciences and increase students' motivation for learning mathematics. Students' work on MM tasks was as a cooperative learning understood as "students working together in a group small enough that everyone can participate on a collective task that has been clearly assigned … without direct and immediate supervision of the teacher" (Cohen, 1994, p. 3). In the very first session students were introduced to basic ideas of modelling and a model of a modelling cycle illustrated with relevant examples. To get an idea of students' initial preparedness for mathematical modelling tasks, they were asked to work on an open-ended task 'Rabbits on the Road' (Harte, 1988, pp. 211–213).

> Driving across Nevada, you count 97 dead but still easily recognizable jackrabbits on a 200-km stretch of Highway 50. Along the same stretch of highway, 28 vehicles passed you going the opposite way. What is the approximate density of the rabbit population to which the killed ones belonged?

The work of two groups of students was video recorded and transcribed. The data set also includes answers to two self-administered questionnaires on a 5-point Likert scale on students' perception of mathematics and its relevance for biology. For more details about the activity, selection of tasks, and organization of students' work we refer to Rogovchenko (2021).

The research question we address in this paper is: *What contradictions arose during a small group work of biology undergraduates on an open-ended modelling task and how they were manifested*?

Activity Theory and Contradictions

Activity theory (AT) provides a versatile tool for inquiry into various aspects of interactions in a teaching and learning process. The main unit of analysis in AT is the activity system composed of six core elements. A mediational triangle is formed by a subject (an individual or a group of individuals) dealing with an object (a desired outcome) via mediating tools or artefacts (material and conceptual). The object embodies the meaning and purpose of the system, and the analysis of the system is based on point of view of the subject. The activity of the subject is directed towards the object and is transformed into outcomes through the tools. The base of the triangle represents the contextual characteristics of the activity system. It is composed of the community (individuals and groups that share with the subject an interest in the same object), the rules (explicit or implicit) that regulate the actions of the subject towards an object, and the division of labor (horizontal and vertical) stipulating the division of tasks between the community members. The model of the activity system we use in this paper is represented in Figure 1. With the main focus on the student group, the six core elements of the activity system are contextualized as follows. The subject is a student group acting towards the object which is related to desired outcomes (engaging in a MM activity; learning new practices; gaining new skills, solving assigned problems). To achieve the goals, tools (instruments, mediating artefacts) are used including MM tasks; problem-solving strategies; mathematical symbols, concepts, procedures, and results. The object and tools can eventually change impacting in turn the activity. A wider community includes the MM project group, fellow students, family, friends, educational officials, academics influencing the activity system. The system is regulated by the rules -- social-mathematical norms, university regulations, class culture, educational pedagogy, expectations of peers. The division of labor defines the roles and responsibilities of community members along with their expectations of each other's roles.

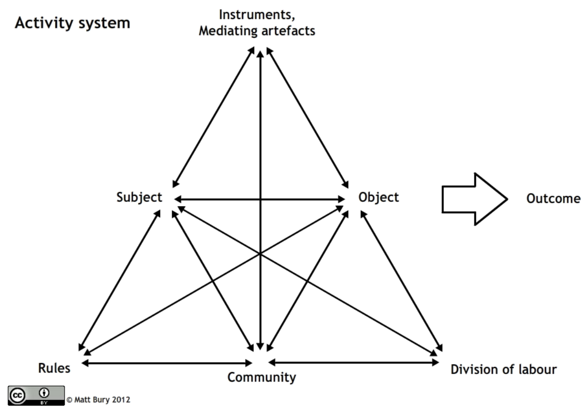

Figure 1. A model of the second-generation activity system. Adapted under CC-by-SA-3.0, Bury (2012).

Contradictions and Their Discursive Manifestations

Each activity system continuously evolves through collective actions; it is not isolated and interacts with other activity systems. In activity systems, "equilibrium is an exception, and tensions, disturbances, and local innovations are the rule and the engine of change" (Cole & Engeström, 1993, p. 8). External influences are appropriated by the system and modified into internal factors which impact the system's development. The third generation of AT identifies contradictions as "historically accumulating structural tensions within and between activity systems" emphasizing "the central role of contradictions within an activity system as sources of change and development" (Engeström, 2001, p. 137). Contradictions should not be perceived as system's deficiencies but rather as opportunities for transformations that change the activities. Implementation of new teaching approaches, ideas and tools disturbs activity systems and creates tensions which manifest contradictions in the system that should be resolved to improve the quality of education. The process of using contradictions to promote learning and change is referred to as expansive learning and should be understood as "construction and resolution of successively evolving contradictions" (Engeström & Sannino, 2010, p.7). Our recent research discusses tensions arising in the modeling project analyzing two activity systems for students and for the project team (Rogovchenko, 2023).

Contradictions are the systemic phenomena which develop in time; they cannot be identified directly. Contradictions should be "approached through their manifestations" (Engeström & Sannino, 2018, p. 49), and we use the term 'tensions' for the latter. Tensions signal internal contradictions in the activity system both within its core elements (primary contradictions) and between these elements (secondary contradictions). In a network of interacting systems tensions may point towards tertiary and quaternary contradictions (Engeström, 1987) which are out of the scope of this paper. Engeström and Sannino (2011) introduced a methodological framework for the identification and analysis of discursive manifestations of contradictions distinguishing four main types described in Table 1. We use this tool to analyze the transcripts of students' small group work on a MM task.

Table 1. Types of discursive manifestations of contradictions (adapted from Engeström & Sannino, 2011, p. 375).

Manifestation	Features	Linguistic cues

Dilemma	Expression or exchange incompatible evaluations	“On the one hand […] on the other hand”, “yes, but”
Conflict	Arguing, criticizing	“no”, “I disagree”, “this is not true”
Critical conflict	Facing contradictory motives in social interaction, feeling violated or guilty	Personal, emotional, moral accounts, narrative structure, vivid metaphors
Double bind	Facing pressing and equally unacceptable alternatives in an activity system	“we”, “us”, “we must”, “we have to”, pressing rhetorical questions, expressions of helplessness

Methodology

Our research focus is mainly on the student group whose traditional views on mathematics and conventional solution routines were challenged in the project when new ideas and techniques of MM were introduced. It was expected that tensions in the activity system would arise, in particular, in relation to student engagement, understanding of a modelling task, comprehension of the mathematical content, and approaches to solution of a modelling task. Since tensions in the system were anticipated, deductive thematic analysis of the data was conducted to identify the presence of contradictions in our activity system. The list of tensions-related themes was generated, and the search for discursive manifestations of contradictions was made by the authors based on the descriptions and linguistic cues in Table 1. Full session transcripts were analyzed for two groups working on the task, the transcripts of a 42-minutes long recordings with 5,076 words and 7,874 words respectively. The word count includes speaker labels (Student 2 or Teacher), time stamps (01:00 or 01:26-01:38), and short comments of transcript writers (“inaudible” or “students work silently”). The initial screening of full transcripts was made, and eight episodes were selected for the analysis in this paper. Separate coding was used for identifying four types of discursive manifestations of contradictions (as in Table 1) and four types of tensions related to (i) student engagement, (ii) understanding of a modelling task, (iii) comprehension of the mathematical content, and (iv) approaches to solution of a modelling task. Tensions that were identified were in turn coded in relation to core elements of the student activity system and associated primary or secondary contradictions. Both authors independently coded each of the eight episodes; the count of discursive manifestations and tensions is shown in Tables 2 and 3.

Table 2. Discursive manifestations of contradictions identified by the authors.

Manifestation	First author	Second author
Dilemma (D)	3	4
Conflict (C)	4	5
Critical conflict (CC)	6	6
Double bind (DB)	7	6

Table 3. Tensions identified by the authors.

Tension	First author	Second author
Engagement (E)	2	2

Understanding of the task (U)	8	9
Comprehension of the mathematical content (MC)	2	2
Approaches to solution (A)	6	7

The disputed issues were reviewed again, the authors discussed the codes applied in the episodes and negotiated common meanings coming to the agreement.

Analysis

Eight episodes were selected from the transcripts to illustrate tensions identified through discursive manifestations of contradictions. For each episode we provide the codes used in the analysis of students' work.

Episode 1

Student 1: Eh, and then we have to assume how many cars are running over a rabbit then.
Student 3: Oh, God…
Student 2: Not everyone runs over a rabbit!
Student 1: No, it is not so! And that is not even a half either, it is maybe five percent. (C, A)
Student 2: Right.
Student 1: Five percent is one out of 20.
Student 3: But one out of 20 sounds like quite a lot of rabbits then. (D, A)
Student 1: Yes.
Student 3: So, one out of 20 is not so wrong. Take five percent then.
Student 1: Five percent.
Student 3: We just have to put… we just have to put something like this. (DB, A)
Student 1: But no! We have 97 dead [rabbits]. But if we assumed that they died in the last 24 hours, then we divide it by the number of cars. Then we find that percentage. (DB, A).

Episode 2

Student 5: Can't we just divide the number of individuals in the area and find out how many are there in each square meter?
Student 1: But we don't know what the area is, we only know the stretch. We don't know how wide it is. (DB, U)

Episode 3

Student 3: No, but let's just assume, as she says, that we have 20 miles that way and 20 miles that way, then we have 20 miles on the stretch.
Student 1: Yes.
Student 3: But then there is still a very large area, for only 20,000 rabbits. (D, U)
Student 1: Yes, I think, I don't know if this is what they mean by density.]So, density.
Student 3:]No.
Student 1: There is no point in calculating density per hypothetical square kilometer. (C, A)
Student 2: You never know how big it is as well…
Student 1: So, I do not know if that's what they mean by density, or if it is just a part of the population they're looking for. It is like 'What is the approximate density of the rabbit population?'

Student 3: To obtain density, we have to have the whole area; we can't use just a stretch. You must have something like a square. (DB, A)

Episode 4

Student 4: Yes, you have to say how many remain alive, that is something.
Student 2: Yeah. Not all [rabbits] who jump over there die.
Student 2: No, and there were only 28 cars, and you don't know for how long the bodies have been laying there. (C, U)
Student 4: No, that's exactly it. ‘Easy recognizable,’ then it's like that, then it's like they have just been ran over, so you can see what they are. (C, U)

Episode 5

Student 4: No, you find kilometers per rabbit. Ninety-seven, what did you get?
Student 3: Hm?
Student 4: Ninety-seven divided by two hundred
Student 3: That's half a rabbit per kilometer
Student 4: Yes, approximately one half
Student 2: So, half a rabbit dies per kilometer
Student 4: Yes, per kilometer
Student 3: Every two kilometers there is a dead rabbit.
Student 4: Yeah, but that’s hell is not right, it's not logical at all! (CC, U)

Episode 6

Student 3: Since he] drives two hundred kilometers an hour
Student 2: What if we just round it [velocity] up to a hundred?
Student 4: Sure.
Student 3: It makes it much easier to round up to a hundred.
Student 4: Yes, but we have, we have this bizarre thing, so it will be the same anyway. (CC, U)
Student 2: Hmmm, this was a frustrating task. You think it's a math problem, but then you know nothing. So, you can't solve it. (CC, U)
Student 4: Yes, we have to, we have to [solve it] somehow. Find our own numbers. (DB, U).

Episode 7

Student 1: Won't it be too many, because it gets a bit more complicated when you start pulling so many different factors into
Student 4: Yeah, but it is only getting … The answer will just be better and better (D, U)
Student 1: That's about it.
Student 4: Then there will be fewer factors that will screw us up. (CC, U)
Student 2: Just assume something about all the factors in the end!
Student 1: I wonder if it is possible to solve this task here. (CC, U)
Student 4: Sure, it is.

Episode 8

Student 4: I'm really just looking forward to getting an answer, because this was really annoying! (CC, U)

Student 2: Hmm, but I think I will be just as annoyed then, because there is no correct answer. But it will be fun to hear what can be assumed. (C, U)

Conclusions

Activity theory acknowledges that contradictions can potentially transform the activity system, but this may not necessarily happen. Contradictions are present in each activity system; they may originate from multiple perspectives, cultural and historical traditions, different interests of members of an activity system. Experiencing problems, conflicts, disturbances that originate from the contradictions in the activity system, individuals or groups of individuals attempt to change the system to alleviate tensions. Nevertheless, resolution of contradictions by individual actions alone is not possible, significant changes in the activity system require cooperative actions leading to the development of a historically new form of activity. Ultimately, "an expansive transformation is accomplished when the object and motive of the activity are reconceptualized to embrace a radically wider horizon of possibilities than in the previous mode of the activity" (Engeström, 2001, p. 137).

In our MM project, primary contradictions were observed within the subject (engaged learners vs passive participants), tools (new methods of population dynamics vs student's traditional mathematics toolkit), rules (student-oriented learning in MM sessions vs teacher-centered pedagogy in regular classes), object (scientifically based understanding of phenomena vs intuitive interpretation of the reality), division of labor (lack of scaffolding vs increased volume of the independent student work). Secondary contradictions were manifested between the rules and object (students' engagement with extra-curriculum modelling tasks vs the need to perform well in the exam; instructor's wish to infuse teaching innovations in students' learning vs curriculum and time constraints), between the tools and division of labor (new thinking required by MM tasks vs learners' expectations how the learning of mathematics should be organized), and between the community and object (creating numerate mathematicians and students' conventional perceptions of mathematics and their previous bad experience with it).

Although the work on an open-ended modeling task was challenging for students, they mentioned the work with assumptions as the best thing in the project: "It made me think in a different way than usual and it was exciting. Making assumptions was new to me." "The assumptions. To understand what assumption is important and which is not." We observed that students interest in mathematics was gradually increasing, and they were opening up for new ways of learning the subject. Students' answers prompted that the use of MM in teaching biology undergraduates stimulates their interest in mathematics and its interdisciplinary applications: "It was interesting to try to solve problems without knowing all about them." "It was social and challenging; it was also very interesting to experience new educational methods." Students' positive feedback on the project indicates possibilities for the expansive learning in the activity system which can transform students' learning of mathematics by enriching the standard curriculum with biologically meaningful mathematical tasks.

Acknowledgments

The research reported in this chapter originates from a collaborative project between two Norwegian centers for excellence in higher education, the Centre for Research, Innovation and Coordination of Mathematics Teaching (MatRIC) and the Centre for Excellence in Biology Education (bioCEED). The authors gratefully acknowledge the unfailing support of colleagues at both institutions.

A Student's Application of Function Composition when Solving Unfamiliar Problems: The Case of Zander

Lorna Headrick
Arizona State University

Function composition is highly useful for making sense of many fundamental ideas in calculus and related areas of mathematics. However, of the large body of research investigating students' understandings of function, very little has been centrally focused on function composition. In an effort to contribute to the existing findings pertaining to function composition, this interview-based study involved an exploration of a first-semester calculus student's use of function composition when solving unfamiliar problems. The student's responses revealed potential evidence of his understanding of function composition, function as an action or process, and covariational reasoning.

Keywords: Function Composition, Function, Covariational Reasoning

Introduction and Literature Review

Functions serve a fundamental role for modeling dependence relationships between variables in every area of mathematics and physical science. Thus, it is not surprising that the idea of function is heavily emphasized in mathematics curricula, and has been heavily studied in mathematics education research (early examples include Breidenbach et al., 1992; Carlson, 1998; Vinner & Dreyfus, 1989). Function composition has also been mentioned as an area of importance, but often briefly or in passing. To date, few studies in mathematics education related to the idea of function have had function composition as their central focus (a few exceptions include Bowling, 2014; Engelke et al., 2005; and Kimani, 2008). However, applications of function composition can be found in many important ideas studied in calculus, including the limit definition of derivative, related rates problems (Engelke, 2007), and the chain rule (Clark et al., 1997; Cotrill, 1999; Engelke, 2007). Thus, function composition is an area worth studying further, particularly in the context of students' experiences prior to and during calculus.

Many of the existing studies pertaining to function composition have been based on the primary theoretical frameworks used to explain students' understandings of function more generally. Among the most common are Breidenbach et al.'s (1992) characterization of students' perspective of function in terms of specific actions or procedures to compute a result, or an "action" view of function, versus a general process that associates input with output values, or a "process" view of function (empirical studies using this framework have included Ayers et al., 1988; Bowling, 2014; and Engelke et al., 2005). Other frameworks used in function composition studies have included Carlson et al.'s (2002) framework for covariational reasoning (Bowling, 2014), a framework to study the impact of representational context (e.g., symbolic, tabular, graphical, word problem) on a student's conception of functions in a problem (Kimani, 2008), and Sfard's (1992) framework for function in terms of operations or in-progress activities, referred to as an "operational" view of function, or in terms of a single object that could be operated upon, referred to as a "structural" view of function (Kimani, 2008).

Several findings from existing studies pertaining to function composition have been focused on students' reasoning relative to the above frameworks. For example, studies employing the action and process framework have found that a process view of function can play an important role in student success with unfamiliar function composition problems, which the students would not be able to rely on a memorized procedure to solve (Ayers et al., 1988; Bowling, 2014; Engelke et al., 2005). Across multiple studies, another common finding is that students are often more comfortable solving function composition problems with functions defined symbolically than problems with graphical, tabular, or applied (word problem) contexts (Engelke et al., 2005; Kimani, 2008), which could be linked to the symbolic substitution approach to function composition commonly presented in high school curricula (e.g., Bowling, 2014). These studies have provided insight into how students' understandings of function might inform their approaches to solving function composition problems.

In addition to the above findings based on existing frameworks, a few studies have resulted in findings related to students' reasoning specific to function composition. One such finding was that, when solving related rates problems involving variables which the students found difficult to relate directly, students found a "middle variable" to be helpful for identifying familiar functions that could be composed to relate the primary variables of interest (Engelke, 2007). This finding suggests a possible extension of existing function frameworks to account for reasoning involved in function composition. In an effort to continue extending existing frameworks, this study was intended to address the question: In what ways does a calculus student apply their understanding of function composition, variable, and function to solve unfamiliar problems?

Theoretical Perspective

The analysis for this study involved a characterization of the types of functions and relationships between values a student might construct. For this work, two main frameworks for explaining students' understanding of function were leveraged: action and process view of function (Breidenbach et al., 1992) and covariational reasoning (Carlson et al., 2002; Castillo-Garsow et al., 2013). Each of these frameworks are described in more detail below.

Action and Process View of Function

Someone using an action view of function perceives a function as a specific set of computations or other describable, repeatable activities to get a particular result from given information. With an action view, a function is the method by which a result can be related to the given information (often both the result and given information are numerical values). For instance, someone with an action view of function might associate $f(x) = 3x + 2$ with the series of computations: 'multiply x by 3 then add 2'. On the other hand, someone using a process view of function perceives a function as an association between values which could be specified in different ways and is not tied to a specific rule. With a process view of function, someone might associate $f(x) = 3x + 2$ with an assignment of every real number (each of which would be a value of x) to a number that is 2 units greater than the number 3 times its value. With a process view, someone might imagine the rule of assignment according to the equation above, a graph, a computer program, a verbal description, an applied context, or a variety of other ways.

Covariational Reasoning

A commonly adopted perspective of covariational reasoning for modeling students' understandings of function is that of Carlson et al. (2002). Re-framed to account for the idea of function as a dependence relationship, Carlson et al. (2002) defined covariational reasoning as imagining a situation with multiple variables that change together such that the value of one variable depends on the value of the other. Underlying the idea of variable according to this perspective is an idea of quantity as conceiving of a feature of an object which one can imagine measuring (e.g., Thompson, 2011). The situation in which one might imagine a quantity could be a tangible, real-world situation, or it could be more abstract. For example, someone could quantify their distance from a wall in a number of feet, or they could quantify the x-coordinate of a point in the Cartesian plane as the horizontal distance of that point from the origin, measured in some specified unit used to scale the graph.

Carlson et al. (2002) characterized students' covariational reasoning into five stages of mental activity (MA1 – MA5). A description of the first three (used in this study), framed in terms of constructing a dependence relationship between variables is as follows: (a) MA1: identifying two varying quantities and noting that the value of one depends on the value of the other, (b) MA2: a qualitative description of the direction of change in one variable with respect to the value of the other; and (c) MA3: a description of an amount of change in one variable with respect to the value of the other. Castillo-Garsow et al. (2013) proposed two additional forms of covariational reasoning: chunky continuous covariation, through which someone imagines the variables' values changing in completed chunks or intervals, and smooth continuous covariation, through which someone imagines the variables' values changing gradually, smoothly, or through each moment in time. In addition to the forms of covariation above, in some situations, someone might conceive of a fixed quantity, or, in an algebraic context, associate a symbol with a fixed value (which they may or may not imagine as a quantity).

Methods

Data Collection and Task Design

The researcher (author of this paper) conducted a semi-structured interview with a first-semester calculus student, Zander, attending a large, public university in the Southwestern United States. Zander's calculus course involved a research-based curriculum, which could have impacted his understanding of function, covariation, and function composition differently from traditional calculus curricula. While solving the interview tasks, Zander was asked to think aloud. As he described his thinking and solution approaches, the researcher sometimes asked follow-up questions to further inform hypotheses about his thinking. Scanned images of any written work from the interview were also collected for further evidence of Zander's thinking.

The interview tasks were designed to be unfamiliar to most students, so that a solution would probably not be immediately available from experiences with similar problems. The researcher anticipated that a student's reasoning about the task context and solution attempts would give rise to some form of function composition, while also providing opportunities to generate hypotheses about their understanding of function and types of covariational reasoning.

Data Analysis

The author intended to leverage existing frameworks (as described in the theoretical perspective) and generate new explanatory models for students' applications of function composition in solving the tasks. In alignment with this goal, the author analyzed the interview using a process similar to that described by Simon (2019). Analysis consisted of three primary phases: (a) generating hypotheses about a student's thinking at specific moments in the interview; (b) generating hypotheses about a student's thinking over the course of the interview; and (c) modeling the student's understanding of function in the context of the interview.

Results

To illustrate the multiple types of function composition Zander appeared to use during the interview, data will be reported from two tasks in contrasting representational contexts.

The Equation Task

Let x be a variable that takes on real numbers, and let f be a function defined by $f(x) = x^2$. Suppose that y is a variable related to x through the relationship $y = 5x$. If y increases from -20 to 20, what will happen to the value of $f(x)$?

Figure 1. The Equation Task Prompt

The equation task was designed with the hypothesis that most students will imagine the equation $y = 5x$ as a way to directly relate a value of x to a value of y and the equation $f(x) = x^2$ as a way to directly relate a value of x to a value of $f(x)$, though the nature of the relationships students construct could vary widely. The prompt provided numerical information with which to associate y and requested that the student state a conclusion about $f(x)$. No equation or other function definition was provided to relate a value of $f(x)$ with a value of y, posing a potential challenge for many students in finding a relationship between y and $f(x)$.

Zander's Response to the Equation Task

Zander first responded to the equation task by stating an equation of the form $x =$ [expression containing y], but shortly afterward, indicated that the equation ultimately would not matter and gave a more general description of how he imagined the value of $f(x)$ might change with the value of y.

Zander: so x is equal to y divided by five I think, and—but y is from minus twenty (inaudible) but it does not really matter at the end because, uh, x squared, because it's, uh, x squared, so I think the value of y, I mean the value of f x will increase, when you go from minus twenty to twenty for y.

Zander's initial response suggested some details about his goal for solving the problem he appeared to perceive in the task and the way in which he might describe two variables he imagined, y and $f(x)$, changing simultaneously. However, there was almost no evidence as to why Zander had initially stated that "x is equal to y divided by five". Upon probing for further evidence, Zander's response revealed that writing an expression for x in terms of y was most likely part of a strategy that would allow him to compute—or imagine computing—a specific value of $f(x)$ from a specific value of y.

Zander: So, like, the…I think (inaudible) a function we're supposed to plug in the value of x, and then we're supposed to get another answer which is like our value of y or it could be something else too. So, in this we're like given two things. First of all, it's a function which is f x equals to x squared, so if we have a value of x, we just plug it in for, I'm talking about f x equals to x squared, and then we'll get our y, right? So if we plug in one, it'd be one. Plug in two, it'd be four. So, but (inaudible) to figure out what our y will be, uh, I mean our x will be, we are given another equation, which is that y equal to five x. So, I think from this equation, y is equal to five x, we're supposed to figure out what our x will be, and then we can plug in that x into f x equals to x squared and then we can figure out uh, another, like the, another function (inaudible) y for that one.

From Zander's statement at the beginning of the above excerpt, he appeared to be imagining a situation in which he would consider a specific value of x, perform a calculation, and obtain a specific value of y resulting from that calculation. It is not completely clear from Zander's overall response how he imagined the relationship between x and y to yield the equation $x = y/5$; however, given what appears to be a computational use for the equation with specific values of x and y, it is plausible that Zander imagined manipulating the equation using a "solving" or "switching" procedure. More evidence would be needed to confirm this. Zander also mentioned an overarching strategy for figuring out a value of $f(x)$ from a value of y that involved two separate calculations: a calculation that would give him a value of $f(x)$ from a value of x, and a calculation that would give him a value of x from a value of y.

The Cylinder Task

A chemist pours a liquid into two empty, differently-sized cylinders. The smaller cylinder has a radius of 2 cm, and the larger cylinder has a radius of 3 cm.

(a) If the chemist pours the same volume of liquid in both cylinders, and the height of liquid in the smaller cylinder is 11 cm, what is the height of liquid in the larger cylinder?

(b) If the chemist pours the same volume of liquid in both cylinders, as the height of liquid in the smaller cylinder increases from 0 to 11 cm, how does the height of liquid in the larger cylinder change?

Figure 2. The Cylinder Task Prompt

The cylinder task is loosely based on a problem from the Precalculus: Pathways to Calculus workbook (Carlson et al., 2020). This task was designed in anticipation that if a student wanted to relate the height of liquid in the smaller cylinder and the larger cylinder numerically, they would need some intermediate value (which they could imagine as fixed or varying) they could individually relate to both heights. Then, they could use the intermediate value to compose the relationships, forming a relationship between the height of liquid in each cylinder. One anticipated intermediate value would be the volume of water in each cylinder, since the task context specifies that the volume would be fixed, and it might occur to many students to leverage the formula for the volume in a cylinder with respect to radius of the base and height: $V = \pi r^2 h$ (this formula was not provided in the task context, but was given to a student upon request).

Zander's Response to the Cylinder Task

Zander appeared to engage in two primary forms of function composition in his response to the cylinder task, both of which involved a relationship between the volume of liquid in each cylinder and the height of liquid in each cylinder. The first composition involved computing a single value for the volume of liquid in the smaller cylinder, substituting the result into the formula for volume in a cylinder with respect to radius of the base and height of liquid in the cylinder, and solving for the height of liquid in the larger cylinder. Zander's computation of a single value for the volume in each cylinder and solving for the corresponding height in the larger cylinder enabled him to achieve the goal of getting a numerical answer. The type of function composition he appeared to use in this instance could be regarded as grounded in an action view of function (Breidenbach et al., 1992) and a fixed-value understanding of the volume and height of liquid in each cylinder. However, his description of the relationship between the height in each cylinder shortly before this series of calculations suggests that he imagined the height and volume as variables with which he could make a general, qualitative comparison. In fact, his first inclination for finding the height of liquid in the larger cylinder was to use the relationship between the radii of the cylinders to form a mathematical analogy with which to compare the heights.

Zander: Um so first of all, I'd say that the height of the liquid in the larger cylinder is going to be less than what it is for the smaller one, because the radius is less, which means that for the first one, it is like kind of small, so it will fill up more. And the second one is a larger cylinder, it has a radius of three, so basically its base is bigger, so it could fill in the same volume but in like less height, that is what I'm trying to say here.

Following his description, Zander tried to use a proportion to express the comparison mathematically and ultimately calculate a value for the height in the larger cylinder, but he was not confident that the equation he wrote would result in the correct calculation.

Zander: I'd say, when our radius was two, our height was eleven, and then that'd be, is equals to when our radius is three, what is going to be our height. I'm not really sure if this is like in a ratio or not, but it should be because after all it's like a cylinder, it's just different size. The volume is going to be the same, the amount of liquid poured is the same so, this should be like in a ratio with each other.

When asked why he decided to set up a proportion, Zander's response suggested he was trying to guess what equation he could set up to calculate the desired value: the height in the larger cylinder. He noted that there was little information given in the problem overall that he could use to achieve this goal. Thus, the interviewer asked him what other information would be useful for him to know, and after only a short pause, he stated that it would be useful to know the formula for the volume in the cylinder.

Interviewer: Um, what information would be useful for you to have, that would allow you to figure out the height of water in the larger cylinder?

Zander: (inaudible) Radius. Uh, I think for this, we need to know the formula for the volume of the cylinder. If we do know the formula of the volume, I don't remember it that well, maybe it is—I don't know, I don't remember.

Once the interviewer gave him the formula for the volume in the cylinder, he made a statement that suggested he imagined the formula as a way to express a dependence relationship between the enclosed volume, height, and radius of a cylinder.

Zander: Yeah, so our pi is always constant, so if you're making comparison, it does not really matter. We are only dependent on two things for the volume. The first one is our radius, and the height.

Following his use of the volume formula to calculate the height of liquid in the larger cylinder, Zander rejected the proportion he initially had set up, concluding that it would not be possible to have a greater height of liquid in the larger cylinder than in the smaller cylinder (he had calculated a greater height from his initial proportion, whereas the volume formula produced a smaller value for the height in the larger cylinder).

The second form of function composition Zander used emerged when prompted to describe how the height of liquid would vary in the larger cylinder. Zander described a comparison of two graphs he imagined: one for the height of liquid in the smaller cylinder with respect to volume, and the other for the height of liquid in the larger cylinder with respect to volume.

Zander: Our x is going to be the volume and our y is going to be the height…so if the volume is increasing for the smaller one, our height is also going to, height is going to increase in both of these, so we do know that the graph is going to be like linear in this, it'd be increasing, but at a different rate for the smaller one, it would increase at like a really high rate so our slope is going to be really high; however for the larger one it's not.

Following his description of the graphs and a discussion about how he conceptualized the "rates" he was comparing, Zander described what first appeared to be evidence of a smooth continuous conception (Castillo-Garsow et al., 2013) of the covariation of each height with respect to volume. After further discussion, the researcher concluded that Zander was most likely employing a chunky continuous conception of covariation, since he stated that the slope of the graph should be the same over any size of interval for the volume.

Zander: So like we can, in this equation, we can find out our, like, height at every single moment as volume changes, so as of here, our volume was one thirty eight point one six, and we figured out that our height would be four point eight, so we can increase that volume to one forty and then we can figure out our height. This is what we can do. Then we could like have a slope at this point, and I hope that this slope is the same for the, every single interval in there, otherwise it won't be linear.

Conclusion

In response to both tasks, Zander frequently alternated between computing specific values and using algebraic manipulation procedures, and making general descriptive comparisons between what he seemed to imagine as variables. Zander appeared to imagine the functions as a means of relating the direction of change in two variables (Carlson et al., 2002). Thus, it appears that Zander leveraged a process view of function (Breidenbach et al., 1992). However, whether he used an action or process view of function in particular parts of his solution depended on his goal at that point in his thinking process. When his goal was to calculate a specific value or define an algebraic equation, he described a series of computations between individual values, suggesting he employed an action view of function in these situations.

In addition, Zander appeared to engage in several types of function composition. One form of function composition involved a series of computations and substitutions to compute one specific value given another (i.e., computing the height of liquid in the larger cylinder from a known height of liquid in the smaller cylinder). A second form of function composition involved algebraic manipulations to link together two equations, followed by a two-step sequence of computations to relate several numerical values, one-at-a-time, input to the first equation to corresponding numerical values output by the second equation (i.e., using the equation $x = y/5$ and subsequently the equation $f(x) = x^2$ to compute values of $f(x)$ from values of y). Finally, a third form of function composition involved a sequence of covariational relationships through which he appeared to imagine a chunky continuous, or possibly even smooth continuous variable (Castillo-Garsow et al., 2013) in relation to another by comparing his visualization of two graphs (i.e. comparing volume-height graphs he constructed in response to the cylinder problem).

Zander provides an example of how one student can use several different forms of function composition, covariation, and function to solve unfamiliar problems. His case suggests that the type of function composition that might be deemed applicable in a problem situation depends on the experiences with covariation and function someone associates with a problem's representational context and the goal someone has for a solution at particular points in the solution process.

Magnitude Bars and Covariational Reasoning

Irma E. Stevens
University of Rhode Island

In this report, I examine the recommendations made by researchers to use magnitude bars (or dynagraphs) with students to support their reasoning about quantities. More specifically, I look at implications of an undergraduate pre-service secondary mathematics teacher's reasoning when using tasks with magnitude bars designed to support students' meanings for geometric formulas in dynamic contexts. I illustrate the ways in which a student reasoned, ways that both resonated with researchers' recommendations but also introduced unanticipated difficulties that resulted from the introduction of the magnitude bars. Specifically, I show two different ways of comparing magnitudes a student illustrated in the Painter Problem-using amounts of change reasoning and length comparison reasoning. The results of this study contribute to the literature on using magnitude bars to support students' reasoning by illustrating the different ways in which a student can reason with magnitudes.

Keywords: Pre-Service Teachers, Covariational Reasoning, Dynamic Geometry, Representations

In RUME 2017, Stevens, Paoletti, Moore, Liang, and Hardison (2017) provided principles for designing tasks that promote covariational reasoning—in which students reason about two quantities changing in tandem (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). Among their considerations to use quantities that are not monotonic, to use shapes strategically, and to use different representational systems, the authors suggest to "use varying segment magnitudes to represent a quantity's magnitude in a situation" (p. 933). In this report, I first (i) review how and why these researchers and others have argued for using dynamic magnitudes to support students' reasoning (ii) describe the methods of a study with pre-service secondary mathematics teachers (hereafter, PSTs) that considered the aforementioned design principles from Stevens et al. (2017), (iii) describe the results of the study by illustrating one PST's reasoning, and (iv) discuss how analysis of the larger study included insights into the affordances and limitations of using varying segment magnitudes that do not have any numerical values or units labeled (hereafter, magnitude bars). Specifically, the results section includes how magnitude bars were able to support students' covariational reasoning but also provided additional sources of confusion about what quantities were being represented. In sum, this report is of a study that aims to answer the question, "What role does the use of magnitude bars play in students' reasoning about relationships between quantities in dynamic geometric contexts?".

The Cases for Varying Magnitudes

This section is a summary of researchers' justifications for using dynamic magnitudes to support students' mathematical reasoning. It includes recommendations from researchers who consider the role of technology in reasoning and are interested in students' cognition.

Varying bars as a way for students to construct productive meanings for graphs

As mentioned in the introduction, Stevens et al. (2017) proposed the following task design principle for designing tasks that promote covariational reasoning—using varying segment magnitudes to represent a quantity's magnitude in a situation. Specifically, the authors stated that using the magnitude bars instead of prompting for a graph immediately offers researchers "insights into students' reasoning while minimizing the influence of the ways of thinking they have developed for graphs (e.g., iconic translations, issues of function/dependency, ways of thinking based on figurative thought)" (p. 933). They also described how the magnitude bars served to help scaffold students into constructing graphs by placing the magnitude bars orthogonally and constructing a multiplicative object (i.e., a point on the graph in this case) and then an emergent trace of all the instantiated pairs (see also a similar use of dynagraphs from Antonini, Baccaglini-Frank, & Lisarelli (2020). This emphasis on using different representations to support productive meanings for graphs relates to the task design principle of Marton's Variation Theory (Kullberg et al., 2017; Marton, 2015) that Johnson (2022) described, though she recommended specifically using different forms of the same type of graph to support students' meanings for rate (building of literature such as Johnson (2012)). Liang & Moore (2021) extend the idea of partitioning magnitudes and its role in students' covariational reasoning. They noted how students' partitioning activities can be rooted in figurative thought by illustrating cases in which students struggled to relate partitions constructed in situations with partitions constructed in graphs intended to represent relationships between quantities from those situations. Thus, collectively, these authors have concluded that magnitude bars can be used to support productive meanings for graphical representations via covariational reasoning but also note the importance of attending to how partitions of magnitudes relate across representation systems.

Varying bars as having semiotic potential for function

Hollebrands, McCulloch, & Okumus (2021) considered the theory of semiotic mediation to discuss the design idea that a tool (such as the dragging tool in dynamic geometry tasks) has semiotic potential that a teacher can exploit to "guide students to produce *mathematical signs* (definition, proof, mathematical conclusion, generalization, etc.). Here semiotic potential of an artifact relates to the "mathematical meanings related to the artifact and its use" (Bartolini Bussi & Mariotti, 2008, p. 754). For example, they described how dynagraphs elicited students' understandings of the notion of function, referencing, the work of Antonini, Baccaglini-Frank, & Lisarelli (2020). *Dynagraphs* are like magnitude bars where students drag the bar representing the independent variable and can observe the effects of the bar representing the dependent variable, but unlike magnitude bars, they are typically placed on a number line with values labeled. In summary, these authors argued that interacting/dragging the bars in the dynagraphs has the semiotic potential for students to find patterns and generalizations related to ideas of function.

Magnitude bars as a way for students to understand measurement

The idea of motivating ideas about measurement through motion stems from Piaget and colleagues (1960). They and other researchers (e.g., Curry, Mitchelmore, & Outhred, 2006; Kamii, 2006) have reported that students start to conceptualize a length or magnitude via motion (e.g., stepping, sweeping, and pointing motions across straight paths). Moreover, Barrett et al. (2012) proposed a hypothetical learning trajectory that intends to build on this meaning for the quantity by introducing the iteration of single units (eventually without gapping, overlapping, or inconsistent unit size.). These researchers, although not explicitly mentioning magnitude bars, describe an image of movement associated with a length quantity to support students in learning about measurement.

Magnitude bars as a way for students to compare quantities

Lastly, the idea of comparing two magnitude bars to each other at different lengths shows up in the literature as well. These researchers have discussed how comparing dynamic magnitudes can support students at various levels. Yeo (2021) described how "dragging mathematical objects plays a critical role to mediate and formulate fraction understandings" (p. 1) And at the undergraduate level, Beckmann & Izsák (2020) described how a variable-parts perspective (in which the unit measurement varies and is then multiplicatively compared to the output measurement) can be considered when representing measurements graphically to support learning about average rate of change, the Fundamental Theorem of Calculus, and Trigonometry. These researchers highlight how the multiplicative comparison of dynamic magnitudes can support the learning of several different mathematics topics from the elementary to the undergraduate level.

Methods

In part of a semester-long teaching experiment (Steffe & Thompson, 2000), three undergraduate students in a preservice secondary mathematics education program at a large public university in the southeastern U.S individually interviewed with a teacher-researcher and observer(s) to reason about formulas via dynamic geometric objects. Each student participated in 12-15 teaching sessions. Due to space constraints, I discuss only one students' work (Lily) on a single dynamic geometric context (called the Painter Problem), one that she worked on over the course of six total sessions, resulting in about six hours of video data. I video-recorded and screen-captured students' work on a tablet and scans were made of student work.

The overall goal of the teaching experiment was to analyze the mental operations needed to support students in constructing productive meanings for formulas (see Stevens (2019) for full details), but this report focuses specifically on the role of magnitude bars in their reasoning by attending to the ways in which Lily reasoned with magnitude bars in the Painter Problem. To do so, I attended to the descriptions Lily provided for her reasoning when discussing magnitude bars, focusing specifically on (i) what quantities (if any) she was referencing in the situation when describing the magnitude bars (ii) what the goals were for Lily when she was reasoning with the magnitude bars and (iii) what mental operations she was describing when trying to achieve those goals. In particular, I look at students' covariational reasoning—the mental actions involved in reasoning about changing quantities. Of note in this proposal are directional covariational reasoning (i.e., as one quantity increases/decreases another quantity increases/ decreases), and amounts of change reasoning (i.e., as one quantity changes by equal amounts, another quantity changes by increasing/decreasing/equal amounts) (see Carlson et al., 2002).

Task Design

As mentioned, the tasks used in the teaching experiment as a whole considered the design principles outline in Stevens et al. (2017), and the Painter Problem involving a dynamic rectangle described here is no exception. The context of a dynamic rectangle varying in one dimension to discuss area in relation to width has been used by several other researchers (e.g., Ellis, 2011; Kobiela, Lehrer, & VandeWater, 2010; Matthews & Ellis, 2018; Panorkou, 2020). In this version, the students are given a dynamic geometric sketch in which they can drag the bottom right corner to the right or left. They can also press the "Paint" button to watch the rectangle sweep out to the right (maintaining the constant height of the paintbrush used to create the painted area) and "Reset" to move the bottom right point back to the beginning location (thus removing the rectangle). The novel addition to this varying rectangle in the Painter Problem is the inclusion of magnitude bars. Doing so meets the task design principle of using varying magnitudes from Stevens et al. (2017). In Part II of the problem (Figure 1), the students were told that the orange bar represented the length that a painter had swept out the roller (i.e., the width of the rectangle) and that they were to decide which, if any, of the purple bars represented the area of the rectangle. The top purple magnitude bar was an appropriate bar to represent the area of the rectangle because it has a linear relationship with the orange bar, whereas the bottom purple bar increases at an increasing rate with respect to the orange bar.[1]The students could move around the dots, which they used to mark specific widths of the rectangle and endpoints of the magnitude bars. Other design principles from Stevens et al. (2017) were also met. For example, the choice to allow the student to move the rectangle to the right or left by dragging the points met the design principle of not providing monotonically increasing quantities. The choice to keep the rectangle shape was strategic in that it provided students with a proportional relationship (other tasks considered different relationships between a length dimension and (surface) area). And lastly, throughout the interviews, students were asked to represent the relationship between quantities using different representations (with a formula being the focus of the teaching experiment), meeting that design principle.

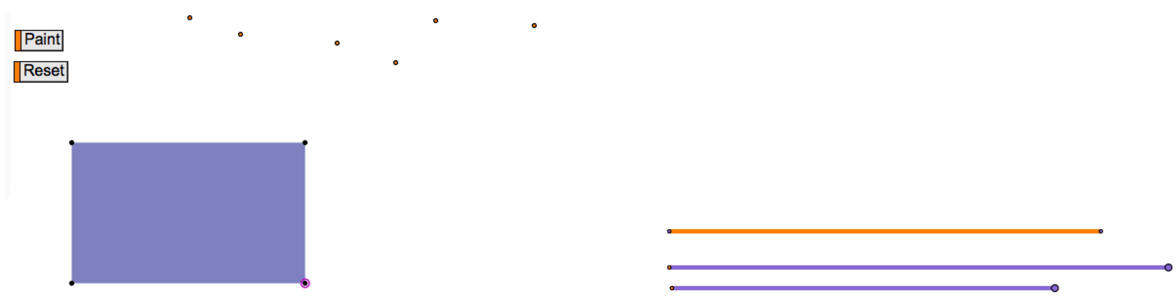

Figure 1. The Painter Problem Part II.

Results

In this section, I describe how Lily reasoned with magnitude bars while considering the relationship between the area and height of a dynamic object, the rectangle in the Painter Problem. Specifically, I attend to her descriptions of (i) the quantities she constructed with the dynamic geometry software (ii) the quantities she constructed with the magnitude bars, and (iii) the quantities she represented in her formulas.

For some context, in the Painter Problem Part I (i.e., prior to the introduction of magnitude bars), Lily had made three conclusions. First, she concluded that the area painted increased as the length that roller swept out increased (a directional covariational relationship as defined by Carlson et. al (2002)). Second, she knew to multiply the length and width to get the area of the rectangle (specifically, her formula was $A=bh$). Lastly, Lily had referenced the idea that "multiplication makes bigger".

Reasoning with the idea that multiplication makes bigger

When Lily started the Painter Problem Part II, she immediately chose Bar #1 (the top purple bar) as appropriate because "the value of the area is bigger than the value of the base, and I think,

[1] In Part III of the problem, the students were allowed to determine a number of partitions that would populate along the length of the rectangle. They could also see measurements of the length and area based on their chose unit sizes. The results of this part of the Painter Problem are not discussed in this section. See Stevens (2019) for details.

it can't-I don't think the area can be smaller than the base." She then discussed three different cases of the magnitude bars (which she called "segments") (Figure 2): when the purple segment (area magnitude) was less than, equal to, or greater than the orange segment (length magnitude). Since there were cases in which Bar #2 was not longer than the orange bar, and since multiplication makes larger means that the purple bar should always be longer than the orange bar to represent the multiplicative relationship between length and area, then Bar #2 could not be appropriate. Bar #1 satisfied her condition because its magnitude was always greater than the orange bar. Thus, Bar #1 was Lily's choice.

(a) *(b)* *(c)*

Figure 2. Lily's three cases for Bar #2 in the Painter Problem Part II: (a) area less than length (b) area equal to length and (c) area greater than length.

Lily felt unsatisfied with her justification for Bar #1, worried she was overgeneralizing the rule that "multiplication makes bigger". Thus, she decided to test various numerical values with her formula $A=bh$ to decide if it was a viable generalization. Her results are in Table 1.

Table 1. Lily's list of numerical calculations using A=bh to compare A (which should correspond to the value of the purple bar) and b (which corresponds to the value of the orange bar).

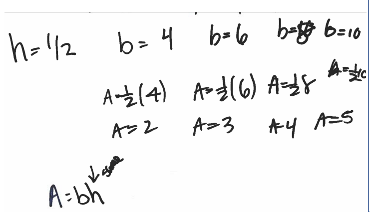
	Painter Problem Part II		
	(Cases) If…	(Conclusions) Then…	Numerical Example
1	$h = 1$	$b = A$	$b=3, h=1 \Rightarrow A=3$
2	(unspecified)	$A < b$	$b=6, h=½ \Rightarrow A=3$ $b=2, h=½ \Rightarrow A=1$
3	$b > h$	$A \leq b$	$b=6, h=½ \Rightarrow A=3$ $b=2, h=½ \Rightarrow A=1$ $b=6, h=1 \Rightarrow A=6$
4	$b < h$	$A \geq b$	$b=.5, h=4 \Rightarrow A=2$ $b=.5, h=1 \Rightarrow A=.5$
5	h is a constant	"If the area starts smaller, it should stay smaller. But if the area starts bigger than the base, then it should stay bigger."	$h=½ \Rightarrow$ "It would always make the area half the base."

As a result of Lily's reasoning with numerical values, she stated that she could no longer rule out Bar #2 as a potential viable candidate based on "my discovery that the area can be smaller than the base, the value of it" (Case 2). But after constructing Case 5, she decided to rule out Bar

#2 again because "[*dragging the corner of the rectangle back and forth*] I don't think [the area bar] should be less than [the base bar] and then greater than [the base bar]." Beyond saying "I don't think" and referencing the idea that "multiplication makes bigger", however, Lily struggled to relate her conclusion to the rectangle in the dynamic situation.

Reasoning with Amounts of Change

In a follow-up session, I asked Lily to consider the case where both purple magnitude bars were always bigger than the orange bar (essentially considering the case where the orange magnitude starts at its location in Figure 1c and extends to its maximum length). After some time, she stated that for equal changes in the base (she specifically stated, "like plus two, plus two, plus two" while dragging the corner of the rectangle in small chunks to the right), the purple magnitude bar should indicate a "constant increase in area." After some effort, and some additional numerical calculations to support her conclusions (see Figure 3), Lily reasoned using amounts of change; namely, that for the rectangle situation, for equal changes in the base, the amount of area increased by a constant amount. When she made that conclusion, she had no difficulty in deciding that Bar #1 was appropriate. That is, she could identify the magnitude bars as "increasing at a constant amount" (for Bar #1) and "increasing by increasing amounts" (for Bar #2). For example, for Bar #2, she described the situation as adding two "square units" for the first change in length and then four "square units" for the second successive equal change in length. Her discussion of the values was consistent across the situation and the magnitude bars; she associated an increasing number of boxes in the situation with a magnitude bar with increasing changes in magnitude (for the same successive change in the orange magnitude).



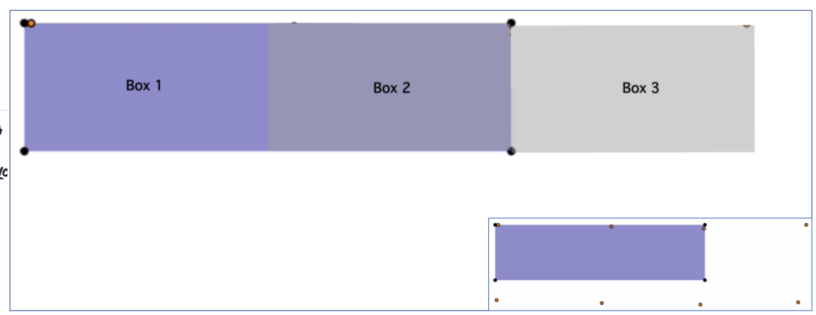


Figure 3. (left) Lily's numerical amounts of change calculations and (right) Lily's amounts of change in the situation after focusing on magnitudes. Bottom right corner shows Lily's markers for amounts of change and main figure shows post hoc edits for the reader to indicate the three boxes corresponding to her amounts of change in area.

Discussion and Implications

Researchers have already identified several reasons to include dynamic magnitude bars when introducing students to topics ranging from graphical representations to functions to fractions to trigonometry to the Fundamental Theorem of Calculus. These recommendations stem from ideas that the bars provide a means for comparison (via segmenting, iterating, counting, making multiplicative comparisons, etc.) and that the dynamic nature of the segments supports means for constructing length as a quantity or for observing patterns and generalizing.

In the results of this study, I reported on how the introduction of the magnitude bars supported Lily in covariational reasoning. Lily did not need the magnitude bars to make the conclusion about a directional covariational relationship between quantities. That is, already in Part I, she claimed that as the length the paint roller has swept out increases, the amount of paint increases. However, given the nature of the initial prompt (i.e., to describe the relationship between the two quantities), there was no intellectual need to compare the quantities beyond a directional covariational relationship. Further inquiry was needed but magnitudes are not the only option. If, for instance, she was asked to create a graph, the graph, whether intentional or not, would have been either straight or curved, giving the researcher a natural place to motivate a discussion about rate of change (e.g., Stevens, & Moore, 2016). Or given a formula, the student could be asked to discuss the form of the equation (y=kx, y=mx+b, $y=x^2$, y=sin(x), etc.) to motivate discussions of rates of change. But both of these methods of prompting reasoning about rates of change rely on perceptual features of the representation (i.e., the straightness of the line, the arrangement of the letters) and steps away from the quantities at hand. In doing so, students can turn to relying on conventions they have learned (e.g., shape thinking (Moore & Thompson, 2015)) to justify responses. Instead, by providing students with magnitude bars that represent different relationships between quantities and asking the students to indicate which one is appropriate, students are intellectually motivated to identify differences between the bars that go beyond the directional covariational relationship. For Lily, that prompted her to consider amounts of change covariational reasoning. That is, she considered equal changes in length on both the sketch of the situation and the orange magnitude bar representing that length, observed the resulting equal changes in area, and then identified which of the two magnitude bars also had equal changes. The larger teaching experiment showed similar gains by other students, with more or fewer struggles revolving around the use of numerical values to support their reasoning (see Stevens, 2019). Thus, this study contributes to the knowledge about magnitude bars by illustrating that they can provide a way for students to reason covariationally about amounts of change that do not rely on their understandings of graphs or equations.

Though Lily demonstrated amounts of change reasoning with the magnitude bars, she also demonstrated that it should not be assumed that students will necessarily reason quantitatively. Namely, Lily also compared each purple bar's magnitude to the orange bar's magnitude at specific points. This reasoning was not productive for her because she started relying on generalizations she recalled about mathematical operations (i.e., multiplication makes bigger) rather than attending to how the magnitudes were representing the growing rectangle. Thus, this study also contributes to the knowledge about magnitude bars by illustrating that students' ways of reasoning about the magnitude bars may not result in conclusions that they can relate to the quantities they are being asked to consider in the situation.

In conclusion, the results of this study show that magnitude bars have the potential to support student's covariational reasoning about formulas without relying on numerical values or understandings of different representation systems. I call for the research community to consider how different ways of reasoning with magnitude bars could be productive when learning different mathematical ideas. For example, although Lily's first way of reasoning about the bars did not support her in making a conclusion about the amounts of change relationship between quantities she was asked about, perhaps her comparison of quantities' values would be productive for different mathematical goals.

A Linear Algebra Instructor's Ways of Thinking of Moving Between the Three Worlds of Mathematical Thinking Within Concepts of Linear Combination, Span, and Subspaces

Avery Madden
University of Oklahoma

Sepideh Stewart
University of Oklahoma

Jeffrey S. Meyer
CSU, San Bernardino

Linear algebra is an important topic for many STEM students and presents unique challenges for teaching and learning. In this study, we analyzed one mathematician's instructional materials and spoken language. Our theoretical framework is based on Tall's (2008) three worlds of mathematical thinking and Harel's (2008) ways of thinking. The goal of the study was to examine the complexities of a mathematician's ways of thinking while moving between the three worlds of mathematical thinking, while orchestrating the important aspects of linear combination, subspaces, and span.

Keywords: subspace, linear combination, span, ways of thinking, three worlds of mathematical thinking

Literature Review

Establishing the current state of linear algebra education research, a survey paper by Stewart, Andrews-Larson, and Zandieh (2019) highlights the students reasoning on the topics of span (e.g., Wawro, Zandieh, Rasmussen, & Andrews-Larson, 2013) and subspaces (e.g., Britton & Henderson, 2009). However, most studies focus on these topics and student comprehension, leaving a gap in the investigation of teacher understanding. Furthermore, the survey paper helps indicate extensive research into linear combinations and span, but less so in subspace.

When discussing Subspace, the idea of "Span" and "Spans" is inevitable. These two words are quite similar but mean different things invoking a type of polysemy, which can create challenges for the learning of subjects when it occurs in mathematics (Kontorovich, 2018). This issue overlaps with the understanding of subspace, something that research has documented as a challenge for student understanding (Britton & Henderson, 2009). Specifically concerning subspaces, one study showed that students prefer to use geometric intuition to understand subspaces (Wawro, Sweeny, & Rabin, 2011). Furthermore, students struggled with understanding how many subspaces are in a given space (Fleischmann & Biehler, 2018). Similar struggles exist in learning the concept of linear combination. When researching undergraduates' ability to determine if something is linearly dependent or not, instead of utilizing the characteristics of linear combination, the students preferred to use matrix operations (Aydin, 2014). Navigating these challenges presents important considerations for an instructor's teaching methods.

Looking to how this information is communicated, a teacher's knowledge base is an important aspect of education. A teacher's knowledge base and its relation to student understanding is a deep facet of education that has been studied (Tallman & Frank, 2020). This knowledge base may be accessed through the educator's ways of thinking (Harel, 2008). In their view Tallman and Frank (2020) find for a given topic, "this study provides support for the notion that mathematical ways of thinking comprise a fundamental aspect of teachers' professional knowledge base" (p. 92). A teacher's knowledge base has overlap with how they present information. In the literature, there has been an increasing interest in examining this topic in how an instructor conveys information to students and conducts procedures in the classroom. For example, Stewart, Troup, and Plaxco (2019) discussed an instructor's reflections on his lectures and movements between different mathematical worlds. The study concludes that the instructor was able to give careful attention to the needs of the students after consulting with his own reflections and knowledge base.

Emerging studies have begun examining how digital resources can be used to help students understand linear algebra topics. Previously, introducing drawings into linear algebra education has been a topic of study. Gueudet-Chartier (2004) argues that "the concreteness that seems to lack in linear algebra could be more efficiently provided by the use of drawings" (p. 500). Research into the learning of span has shown that visualization can be helpful in making students more flexible in their reasoning of the topic (Wawro, Rasmussen, Zandieh, Sweeney, & Larson, 2012; Wawro, Rasmussen, Zandieh, & Larson, 2013b; Cárcamo, Fortuny, & Gómez, 2017). Further, it has been shown that using GeoGebra to assist students in understanding subspace, specifically the zero vector is beneficial (Caglayan, 2019). These studies suggest that linear algebra concepts can be enhanced by visualization tools. Similar studies were conducted on students showing that these students benefited from a more embodied representation (Hannah, Stewart, & Thomas, 2013).

Theoretical Framework

The theoretical framework for this study will utilize Harel's (2008) ways of thinking and Tall's three worlds of mathematical thinking (2010). Harel (2008) introduced the notion of a mental act as actions such as interpreting, conjecturing, justifying, and problem solving, which are not necessarily unique to mathematics. These several types of mental acts are the foundation of ways of thinking defined as "a cognitive characteristic of a mental act" (p. 269). These ways of thinking have the characteristics of being able to abstract, generalize, structure, visualize, and reason logically. Tall (2010) describes the embodied world as "our operation as biological creatures, with gestures that convey meaning, perception of objects that recognize properties and patterns… and other forms of figures and diagrams" (2010, p. 22). In his view, "The world of operational symbolism involves practicing sequences of actions until we can perform them accurately with little conscious effort. It develops beyond the learning of procedures to carry out a given process (such as counting) to the concept created by that process (such as a number)" (2010, p. 22). The formal world "builds from lists of axioms expressed formally through sequences of theorems proved deductively with the intention of building a coherent formal knowledge structure" (2010, p. 22). Using the above frameworks, the goal of this narrative study is to examine the complexities of a mathematician's ways of thinking while moving between the three worlds of mathematical thinking while orchestrating the important aspects of linear combination, subspaces, and span.

In analogy with Tallman and Frank (2020), we consider moving between the embodied, symbolic, and formal worlds as a characteristic of mental acts and, as such, a way of thinking. It is through Tall's three worlds lens of mathematical thinking that we evaluate the teaching moves of the instructor.

Methods

This qualitative narrative study (Creswell, 2013) took place in the Fall of 2021. The participants in this research consisted of a mathematician and co-author. The mathematician, thereafter, referred to as the instructor, specialized in geometry, linear algebra, and number theory. The teaching material of note is part of a first-year linear algebra course from a university located in the southwest region of the USA taught by the instructor. There were 30 students enrolled in this course. In addition, a mathematics educator, and a research undergraduate assistant from another university in the USA were part of the research team. The data consisted of (a) the instructor's notes (which he authored) on linear combinations, span, and subspaces (in this order) that was available to students (Figure 1), (b) his notes on the blackboard (Figure 2a & b), and a GeoGebra interactive example (Figure 2c), (c) two of his recorded video lectures, and (d) students' weekly reflections and homework. The data analysis for this study consisted of transcribing the second lecture, finding pertinent sections in the notes related to the lecture concepts, and coding the different themes. These different components of analysis were done with the instructor as part of the research team. Harel's (2008) ways of thinking and Tall's three worlds of mathematical thinking (2008) were employed as a framework to analyze the data. We identify and analyze the instructor's one specific way of thinking, namely, the disposition of moving between languages as well as Tall's (2008) three worlds of mathematical thinking (embodied, symbolic, formal). The data from students' work is in the process of being analyzed for future research.

Results

The instructor intentionally ordered his lecture with the goal of building on intuition with more embodied understandings before generalizing to reach into new topics. The instructor gave a variety of connections between topics to aid in understanding. In his lecture, he reminds students of the definitions in the notes and refers to them. Descriptive ways of how to understand and apply these concepts are placed on the board. In the first and second lectures, diagrams of two- and three-dimensional space are drawn on the board to emphasize embodiment (Figures 2a & b).

Linear Combination and Span: the language and movements between the three worlds

We noted the instructor used a variety of informal and geometric language to support the concepts and their definitions. In the notes, the instructor used words like "reach", "line", and "parallelogram" to describe linear combination and span (Figure 1). He repeatedly used the informal language of "mixture" to refer to linear combinations. For example, he asked, "Which vectors? The collection of how many mixtures? Some mixtures? … All mixtures. Right, …all mixtures you can make with these not some, not half, not a few, but all mixtures right." Here the instructor relies on language to give meaning to linear combinations as his way of thinking about the topic. An instance of the instructor's disposition to attend to language is when they anticipated and addressed student confusion stemming from the polysemy "span." Figure 2b breaks the topics of possible linear combinations "span the noun" and spanning sets making subspaces "span the verb" into two categories and highlighting the most crucial pieces of the definition. Harel (2008 considers 'anticipating' as a mental act. This certain mental act motivated the teaching act described above. The instructor further clarifies the distinction between an object and the relationship between two objects: "Right, that's very different than the noun right this is just a set (gestures to W = Span(S) this is like a true false kind of thing (gestures to S spans W) it either does or doesn't span." During the lecture (see Figure 2b), the instructor said: "I would call span the mixture set associated to any collection of vectors, okay and then we could talk about uh span the verb you know if if you know if given a set of vectors right if it's mixture set is the subspace in question, we would say it spans the subspace." Following, the core mixture questions (Figure 1) are set up in such a way as to help internalize what is important about the concept and give these characteristics of linear combinations meaningful language while also pushing towards the concept of span. During the first lecture, some examples with matrix representations are written on the board to assist in symbolic understanding (Figure 2a).

During the second lecture, the word "mixtures" is used. This way of thinking about the concept of linear combinations involves changing the language to give the term linear combination additional "meaning". The instructor poses the question, "So let's say what's the noun associated to this, what is the noun given a collection of vectors, what can we make with it? ... Yeah …so we can make mixtures." The instructor utilizes the movement between the mathematical worlds of thinking throughout the lecture. In one such example (Figure 2), the instructor moved from the formal to embodied and acknowledged the possibilities of movements to symbolic: "the span of those guys it equals the line, and you can see that visually and if we wanted to, we could verify that symbolically". For the topic of span, the notes provided a definition of span with emphasis on the word "all" this is done to emphasize any possible linear combination is made up in this set. Meanwhile, the embodiment of the definition invokes the use of visualizing a line that represents all linear combinations of a single vector. This is further extended to the notion of two vectors and a plane. In analyzing the concept of span, in the first lecture, the instructor drew two vectors, proceeded to analyze their linear combinations visually via a parallelogram, and then moved to the symbolical representation (Figure 2a). Next, he showed symbolically how to create an arbitrary vector in R^2 as a linear combination of the original vectors. Performing examples in this order suggest that the instructor comes from a place of visualizing the span first and symbolizes in the matrix form. Visualization continues to be included in the second lecture, with vectors being drawn on the board and displayed in GeoGebra (Figure 2b & c).

Subspace: the language and movements between the three worlds

In the notes (Figure 1), the instructor provided a nonstandard formal definition of subspace relying on the concept of span. His notes continued to discuss a "quick" way to determine if a region is a subspace by checking if it is closed under scaling and addition, but he phrased it in geometric language as "line containment" and "parallelogram containment", respectively. In the first lecture, the notion of subspace, having a set of "mixtures" and then a spanning set, are all written on the board (Figure 2a). With these components, the same language of the notes is used where a plane is drawn on the board in a projected three-dimensional space. The use of line test and parallelogram test are employed with the inclusion of passing through the origin.

During the second lecture, the instructor used GeoGebra as an activity and demonstration to discuss single vectors, zero vectors, and span vs. spans. With the focus changing to subspace, a GeoGebra three-dimensional model is placed on the top of the board, where the instructor manipulated different vectors and created a variety of subspaces (Figure 2c). After the group activity, an example from the class dialogue continued as follows:

"So, let's see, A plus B spans the line well that's a very good point again what is A plus B?... So there's there's also there's all sorts of relationships here so so you could say A plus B spans but A plus B goes by another name D. So, there's all sorts of algebraic relations between these things."

Vectors represent quantities we see in the world around us every day. One of the most fundamental ideas associated to quantities is *mixing quantities*. This core idea will be central to everything going forwards.

The idea of mixing vectors is made mathematically precise through two natural operations: scaling and addition. To reason about them verbally, I will discuss them in the context of cereal, where a vector represents one serving size of a given cereal (as in Example 2.2). *Can you reason about them in other contexts?*

Definition 2.8. If $\mathbf{v}, \mathbf{w} \in \mathbb{R}^2$, then a **linear combination** of them is a vector of the form $x\mathbf{v} + y\mathbf{w}$, for real numbers $x, y \in \mathbb{R}$.

More generally, a linear combination of vectors $\mathbf{v}_1 \ldots \mathbf{v}_n \in \mathbb{R}^m$ is an vector

$$x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n, \qquad \text{where } x_1, \ldots x_n \in \mathbb{R}.$$

CORE MIXTURE QUESTIONS

If $S = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\} \subset \mathbb{R}^m$ is a collection of vectors, then we seek to understand:

1. *Reach.* What are all the possible vectors that can be made by mixing vectors in S?
2. *Redundancy.* Is one of the vectors in S already a mixture of the other vectors in S?
3. *Realization.* Given a vector $\mathbf{w} \in \mathbb{R}^m$, can $\mathbf{w}$ be made by mixing vectors in S, and if so, how?

To begin, let us start with the question of *reach*. In this situation, we have fixed vectors but can select any and all serving sizes for them. The collection of all possible mixtures which can be made with S is made precise by the notions of *span* and *subspace*.

Definition 2.12. If $S = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\} \subset \mathbb{R}^m$, their **span** is the collection of *all* linear combinations of $\mathbf{v}_1 \ldots, \mathbf{v}_n$. Symbolically,

$$\operatorname{span}\{\mathbf{v}_1, \ldots, \mathbf{v}_n\} = \{x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n \mid x_1, \ldots, x_n \in \mathbb{R}\}.$$

Definition 2.16. Any subset $W \subset \mathbb{R}^m$ which is the span of a collection of vectors is a **subspace**.

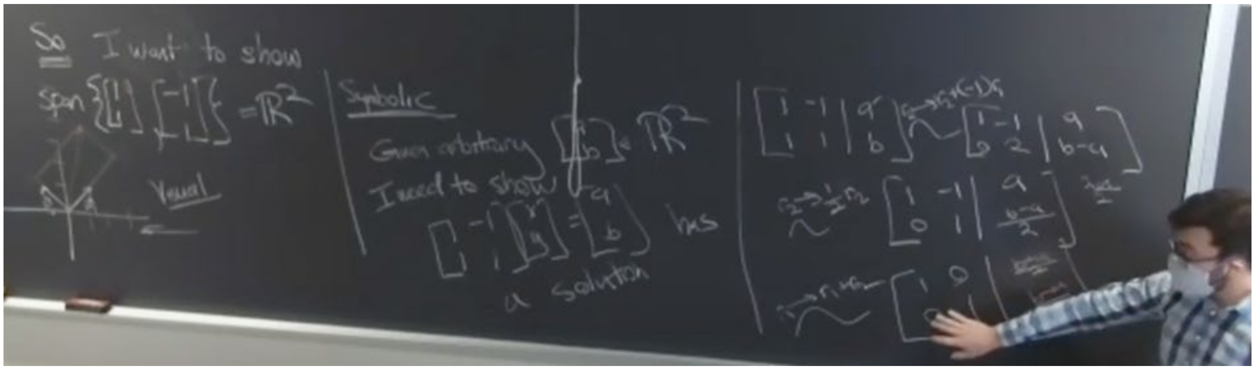
Observe that for our purposes, a span and a subspace are essential the same thing. The reason why we might use the language of one instead of the other is the following: a span means we explicitly know the mixing set S while for a subspace, we know such an S exists, we just do not necessarily know what it is.

The containment properties of span can help us determine *which subsets of* $\mathbb{R}^m$ *are subspaces*.

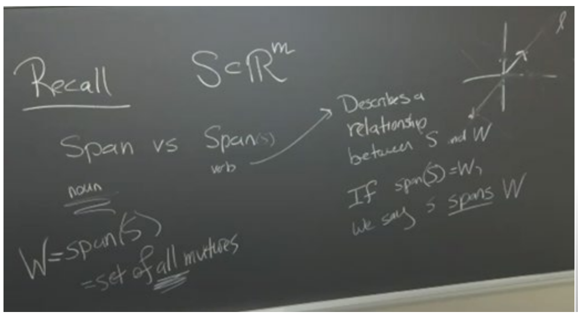
Computational Quick Check 2.17 (Subspaces)**.** If $W \subset \mathbb{R}^m$ is a subset, then W is **not** a subspace if you can find either:

1. **(Line Failure.)** A vector $\mathbf{v} \in W$ for which the line $\operatorname{span}(\mathbf{v})$ is *not* contained in W, or
2. **(Parallelogram Failure.)** Vectors $\mathbf{v}, \mathbf{w} \in W$ for which the mixture parallelogram associated to $\mathbf{v} + \mathbf{w}$ is not contained in W.

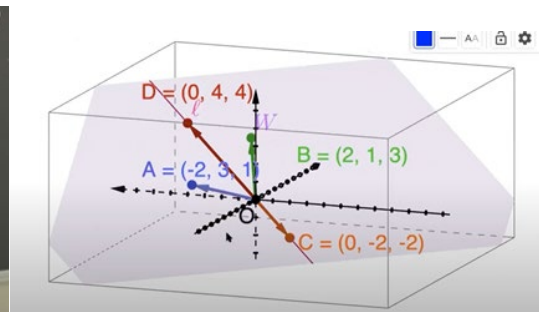
Figure 1. Linear combinations, Span, and Subspaces from the instructor's notes.



(a)



(b)



(c)

*Figure 2****.*** *The instructor is writing on the board during lectures one and two and engaging students via GeoGebra.*

During this episode, the instructor focused on how the zero vector and the zero-subspace fit into 3D space. Here is a sample of subsequent discussions:

Instructor: [I]s a single vector a span? No, right, so we have to go back to our precise definition. So, a single vector is not a span right, but a line here is a span. What other things in somehow depicted here are spans of something?

Student 1: Like a point.

Instructor: Uh which point?

Student 2: Any point on the line.

Instructor: Is Anything on the line, Is any point a span? This is a span? (Gestures at a drawing point of a line on board). This is a subspace? No because right a single point cannot be a subspace unless there's one exception.

Here the instructor is connecting the different ideas about what a single vector can generate while also asking them to recall special cases. This response is supported by the picture of a line placed on the board earlier in the lesson (Figure 2b). "Does this guy span the trivial subspace, zero? Some people say no. No! As they take mixtures of this is bigger, it's bigger it's not equal." Here the instructor used geometric language of relative size to support the idea that the span of a non-zero vector cannot be the trivial subspace.

Discussion and Conclusions

Upon analyzing the data in this study, we observed the instructor relied heavily upon reasoning in many representations, which impacted his choices in instruction. We observed how this informed his selection of demonstrations and his attention to language.

We also found that these ways of thinking impacted the choices that he made in instruction. He consistently moved from embodied to symbolic to formal worlds, and back again. His choice of language moved from informal to geometric to formal, and returned to informal. This was observed in both his prepared lecture and his spontaneous responses to questions. The weaving of formal language with informal and familiar language made the topics more accessible. The lecture began using descriptive geometric words such as “sweep out”, “stretch” and “reach” to articulate how these objects look. The instructor used informal terms during the lecture to familiarize informal terms like “mixtures”, “span the noun”, “span the verb”, when talking about these concepts. In their responses to questions, students also used this informal language, indicating that the familiarization may have been effective. The prepared and distributed notes allowed students to focus on active participation within the class. The lecture weaved through multiple understandings of each concept allowing for engagement with familiar concepts, language, and embodied objects, only to then progress to understanding the mathematical machinery of the subjects before being exposed to their deeper meaning. Here the use of language is crucial again as the lecture begins using descriptive words such as “sweep out”, “stretch” and “reach” to articulate how these objects look.

Furthermore, the use of GeoGebra during the lectures supports this meaning by seeing all the different possible combinations of vectors and having students identify what they created. The instructor gives meaning to span and subspace in similar ways by providing a definition and then constructing a visual representation of the topic. The instructor employed the use of language to illustrate how the zero subspace looks, citing that adding anything besides zero would be “bigger” than the zero subspace. He made a clear distinction between the words span and spans when a discrepancy appeared about what a singular vector can make. Following these results, our future research will include an analysis of students’ weekly surveys and some of their homework.

Synthetic vs. Analytic Formalism of Matrix Representations in Linear Algebra: What it Means to Diagonalize a Linear Transformation

Günhan Caglayan

New Jersey City University

The contributed report highlights linear algebra students' understandings of the matrix representations of certain linear transformations defined on with respect to given bases in a DGS-MATLAB assisted pedagogical environment. The research focused on the diversity of strategies that students utilized specifically in the process of diagonalizing linear transformations in a series of in-depth qualitative interviews within a framework of modes of description and thinking in linear algebra (Dreyfus, Hillel & Sierpinska, 1998; Sierpinska, 2000). Data analysis revealed three main categories: (i) synthetic-geometric mode manifested as the visual alignment strategy in which students visualized each image vector as a multiple of the corresponding preimage vector; (ii) analytic arithmetic mode prevailed in the process of expressing the image vectors in terms of the preimage vectors; (ii) analytic structural mode was observed in the process of determining the diagonal form of the linear transformation with reference to the transition matrices and the commutative diagram.

Keywords: matrix representation of linear transformations; transition matrices; diagonalization; eigenbasis; dynamic geometry software; modes of description and thinking in linear algebra

Theoretical Background and Motivation for the Study

The pedagogy of linear algebra has been a focus of research interest for many years (Dogan-Dunlap, 2010; Dorier, 1991, 1995, 1998; Dorier, Sierpinska, 2001; Gueudet-Chartier, 2006; Harel, 1987, 1989, 1990; Parraguez & Oktac, 2010; Pavlopoulou, 1993; Robert & Robinet, 1989; Rogalski, 1994; Sierpinska, 1995, 2000; Sierpinska, Dreyfus & Hillel, 1999; Sinclair & Gol Tabaghi, 2010; Thomas & Stewart, 2011; Zandieh, Wawro & Rasmussen, 2017). Hillel (2000) characterized linear algebra students' understanding of matrices and linear operators to be at the interoperational level of thinking – although they were expected to communicate at the transoperational level of thinking. Hillel (2000) further posited the requirement that at the trans-level linear algebra learners should be able to: (i) determine the matrix representation of a linear transformation relative to a given basis; (ii) determine the coordinate representation of a vector in a vector space relative to a basis; (iii) think about these representations (coordinate representations of vectors and matrix representations of linear transformations) as "objects of inquiry in their own right;" (iv) think about "the general conditions under which a vector or a linear operator can have a particularly desirable representation" (p.206).

Harel and Kaput (1991), and Harel (1985, 1990) formulated the concreteness principle, as a fundamental approach for the teaching and learning of linear algebra, originated from Piaget's (1977) idea of conceptual entities. According to this principle, "for students to abstract a mathematical structure from a given model of that structure the elements of that model must be conceptual entities in the student's eyes; that is to say the student has mental procedures that can take these objects as inputs" (Harel, 2000, p.180). Concreteness principle requires that "students build their understanding of a concept in a context that is concrete to them" (p.182). He recommends MATLAB as a tool that would help students visualize vectors and matrices as concrete mathematical objects, in accordance with the concreteness principle. Aligned with the concreteness principle (Harel, 2000) and in search for a desirable matrix representation for a linear transformation as brought forward in Hillel (2000), this study focuses on students' questioning of the essence of diagonalization of linear transformations in a DGS-MATLAB-assisted learning environment.

Modes of Description and Thinking in Linear Algebra

Representations are central to the teaching and learning of linear algebra. Harel (1989) established, among other things, that geometric representations contribute significantly in linear algebra students' concept image formation (p. 57). The present report is guided by the theoretical viewpoint that identifies three modes of description (language) with the corresponding three modes of thinking as demonstrated by linear algebra students (Dreyfus, Hillel & Sierpinska, 1998; Hillel, 1997, 2000; Sierpinska, 2000): (i) Geometric description (synthetic-geometric mode of thinking): point, line, plane, geometric transformation (translation, reflection, rotation, projection), vector as a directed line segment (arrow with a head and tail); (ii) Arithmetic description (analytic-arithmetic mode of thinking): n-tuples, matrices and operations on matrices including the inverse of a matrix, the adjoint of a matrix, partitioned matrices, systems of linear equations and their solutions; (iii) Algebraic description (analytic-structural mode of thinking): theory of vector spaces, subspaces, inner product spaces, linear transformations.

Context and Method

Qualitative-descriptive interview data were collected over three years in a university in the United States, as part of a research project which was designed for the purpose of enhancing mathematics and mathematics education majors' content knowledge of advanced mathematics, with particular focus on geometry-linear algebra connections using DGS-MATLAB technology. The data for the analysis of matrix representations of linear transformations concept came from the videotapes of interview sessions in a computer lab that included a total of sixteen math majors who successfully completed a one-semester long linear algebra course, who were interviewed by the author individually on separate days. The university linear algebra course math majors took had covered the first eight chapters of Ron Larson's "Elementary Linear Algebra" textbook. Math majors were familiar with the MATLAB and DGS as they had already used them during the preceding interview sessions on linear algebra topics; they were not provided any training or instructional help during the interviews.

Table 1. Interview tasks: Find the matrix A' for $T: \mathbb{R}^3 \to \mathbb{R}^3$ relative to the basis β'.

Linear Transformation $T: \mathbb{R}^3 \to \mathbb{R}^3$	Basis β'
$T(x,y,z) = (x+z, -x+3y+z, 2z)$	$\beta' = \{(2,1,0),(1,0,1),(0,1,0)\}$
$T(x,y,z) = (3x+2y+z, 2z, 2y)$	$\beta' = \{(1,-5,5),(-3,1,1),(1,0,0)\}$
$T(x,y,z) = (x+2y-2z, -2x+5y-2z, -6x+6y-3z)$	$\beta' = \{(1,1,3),(1,0,-1),(1,1,0)\}$
$T(x,y,z) = (2y, x-y, z)$	$\beta' = \{(-1,1,0),(2,1,0),(0,0,1)\}$
$T(x,y,z) = (3x+2y-3z, -3x-4y+9z, -x-2y+5z)$	$\beta' = \{(1,-3,-1),(3,0,1),(-2,1,0)\}$

Sample Interview Outline: Why did you decide to begin with the standard matrix A for T? How would you (What does it mean to) obtain the matrix A' for T relative to basis β'? Visually? Analytically? How are matrices A and A' related? What are your thoughts about the types of the matrices A and A' in relation to each other? What made you embrace the visual approach? The analytic approach? Is T diagonalizable? What does it mean for a linear transformation to be diagonalizable.

The qualitative interviews were based on a semi-structured interview model (Kvale, 2007) in the course of which the interviewer followed-up with probes and questions on the interviewees' responses. Math majors were asked to respond to a variety of interview questions with primary focus on the matrix representations of linear transformations in a manner leading to students' questioning of the essence of diagonalization. During the interviews, math majors were asked to think aloud, to clearly indicate their problem solving procedure, and to explain their reasoning in detail. Math majors were granted access to scratch paper along with MATLAB and DGS to facilitate and clarify their explanations during the interviews. All interview tasks were designed in such a way that they could be explored via both analytic and synthetic approaches, in accord with the guiding theoretical framework used in the study. Table 1 outlines the linear transformations along with an interview outline that were used during these interviews. Though it was optional, all math majors were very eager and passionate about using MATLAB and DGS, primarily for checking their work, visualizing analytic approaches, testing conjectures, or providing examples and counter-examples.

Analysis of data, which consists of videotaped qualitative interviews along with MATLAB-DGS work and inscriptions, was carried out using thematic analysis (Boyatzis, 1998). The thematic analysis was primarily used to describe how research participants came up with a diversity of innovative and creative ways for understanding and making sense of matrix representations of linear transformations and their connections to other important concepts of linear algebra. After transcribing all interview videos, using thematic analysis, the author reviewed the interview videos along with the original transcripts line by line to gain access to the modes of description and thinking adopted by students as they explored matrix representations of linear transformations and their relationship to other core concepts of linear algebra, in accordance with the research objective. The last cycle of data analysis process consisted of a holistic review of the corpus of data multiple times, in accordance with constant comparative methodology (Glaser & Strauss, 1967).

Results

Overall, students provided a diversity of synthetic and analytic strategies in their exploration of the diagonal form of linear transformations. This section considers the visual alignment approach (synthetic-geometric mode), the expressing of the image vectors in terms of the preimage vectors approach (analytic-arithmetic mode), and the transition matrix approach (analytic-structural mode), respectively. In each interview task, students were asked to find the matrix representation A' for the given linear transformation $T: \mathbb{R}^3 \to \mathbb{R}^3$ relative to a specifically chosen nonstandard basis β'. Because most of the time all sixteen students began each task by retrieving the standard matrix A for T, the analysis that follows primarily focuses on what happened next.

Synthetic-Geometric Mode: The Visual Alignment Approach

Upon obtaining the standard matrix A for T, six out of sixteen students consistently embraced the synthetic-geometric approach in an organized attempt to arrive at the matrix A' for T relative to β'. Typical student approach was to first introduce A along with the basis vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$, respectively on the DGS. Second step was to obtain the *matrix-applied* basis vectors $A\mathbf{v}_1, A\mathbf{v}_2, A\mathbf{v}_3$, denoted by $\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$, respectively on the DGS (Figure 1). Upon noticing the parallel relationships $\mathbf{v}_1 \parallel \mathbf{u}_1, \mathbf{v}_2 \parallel \mathbf{u}_2, \mathbf{v}_3 \parallel \mathbf{u}_3$, visually, students in this category immediately focused on the scale factor $\lambda_1, \lambda_2, \lambda_3$, for each parallel vector pair, which, they mentally straightforwardly determined as $\lambda_1 = 1, \lambda_2 = 2, \lambda_3 = 3$, respectively. The final step was to simply write down the diagonal matrix $A' = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$.

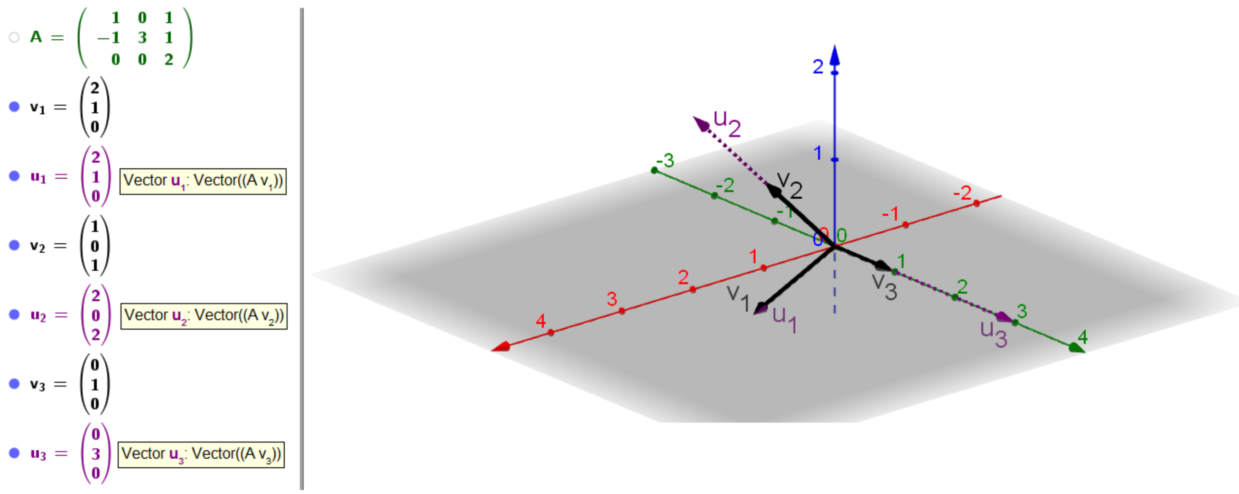

Figure 1 Typical student synthetic-geometric approach for Task 1.

Students' synthetic-geometric description of the parallel vector pair (i.e., the basis vector $\mathbf{v}_i$ and the matrix-applied basis vector $A\mathbf{v}_i$) relationship appeared to have functioned in two steps: (i) when $\mathbf{v}_i$ and $A\mathbf{v}_i$ were aligned in the same octant, the corresponding eigenvalue λ_i was given by the ratio of the length of $A\mathbf{v}_i$ to the length of $\mathbf{v}_i$; (ii) when $\mathbf{v}_i$ and $A\mathbf{v}_i$ were aligned in opposite octants, the corresponding eigenvalue λ_i was given by the negative ratio of the length of $A\mathbf{v}_i$ to the length of $\mathbf{v}_i$. Upon the interviewer's probing whether T is diagonalizable, S1 responded: "*Well in this case A' is a diagonal matrix so I would say yes T is diagonalizable*." S2, who embraced the visual approach like S1, was more specific in her explanations: "*Only because all these* [pointing to the image vectors] *are multiples of these* [pointing to the preimage vectors] *the linear transformation is diagonal*." In the synthetic-geometric approach, students simply focused on each image vector as a multiple of the corresponding preimage vector, without considering the remaining two preimage vectors. This was what made the linear transformation diagonal.

Analytic-Arithmetic Mode: Expressing the Image Vectors in Terms of Preimage Vectors
Six students consistently embraced the analytic-arithmetic mode. Among these six, three students directly applied the linear transformation to each vector of the given nonstandard basis, whereas the other three applied the standard matrix representation of the linear transformation to the coordinate vector representation of each basis vector. This was the slight difference in the thinking of these two groups of students.

Expressing $T\mathbf{v}_1, T\mathbf{v}_2, T\mathbf{v}_3$ in terms of $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$. In Task 2, for instance, S3 first evaluated the *linear transformation-applied* basis vectors $T\mathbf{v}_1 = T(1,-5,5), T\mathbf{v}_2 = T(-3,1,1), T\mathbf{v}_3 = T(1,0,0)$ and obtained the corresponding image vectors $(-2,10,-10), (-6,2,2), (3,0,0)$. Simply by comparing the preimage-image vector pairs was she then able to retrieve the eigenvalues as

$\lambda_1 = -2, \lambda_2 = 2, \lambda_3 = 3$, respectively via mere inspection. This was enough for her to deduce the desired matrix representation as $A' = \begin{bmatrix} -2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$.

Expressing $A[\mathbf{v}_1]_\beta, A[\mathbf{v}_2]_\beta, A[\mathbf{v}_3]_\beta$ in terms of $[\mathbf{v}_1]_\beta, [\mathbf{v}_2]_\beta, [\mathbf{v}_3]_\beta$. Among the three who embraced this *representation* approach, only one student felt the need to specify the coordinate vector representation notation $[\mathbf{v}_1]_\beta, [\mathbf{v}_2]_\beta, [\mathbf{v}_3]_\beta$ where β denoted the standard basis. The other two students, without being specific, still were able to interpret it as the representation of the vector *object*. S4, who embraced the representation approach for Task 3, explained: "*I'd first apply A to each basis vector*." Upon juxtaposing the three image vectors (written as 3×1 column matrices $\begin{bmatrix} -3 \\ -3 \\ -9 \end{bmatrix}, \begin{bmatrix} 3 \\ 0 \\ -3 \end{bmatrix}, \begin{bmatrix} 3 \\ 3 \\ 0 \end{bmatrix}$), respectively, she first suggested $A' = \begin{bmatrix} -3 & 3 & 3 \\ -3 & 0 & 3 \\ -9 & -3 & 0 \end{bmatrix}$ as the matrix representation of T relative to β'. Upon the interviewer's probing how she knew whether her suggestion was the desired matrix representation, she responded: "*I compare each column to the standard basis vectors… No, that's not right. I am supposed to be comparing them to the nonstandard basis vectors and it looks like each column is a factor.. I mean multiple of each basis vector so I am changing my answer to a diagonal matrix*." This way, S4 obtained $A' = \begin{bmatrix} -3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix}$ as the desired matrix representation.

Analytic-Structural Mode: The Transition Matrix Approach

Among the four consistently adopting the transition matrix approach, two students emphasized the matricial relationship by drawing a commutative diagram. Except for one student, S5, all students began each task by first writing the transition (change of basis) matrix as $P = \beta'$. S6, for instance, began her exploration of Task 4 by setting $P = \beta'$ while explaining: "*Okay I remember this very well.. this is the nice case.. P is the transition matrix from β' to β so I don't have to do anything I remember this very well*." With reference to her commutative diagram, she proposed the matricial equation $P^{-1}AP = A'$ and verified her proposed diagonal form $\begin{bmatrix} -2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ on MATLAB (Figure 2a). Likewise, Figure 2b demonstrates S7's MATLAB procedure based on the transition matrix approach in her exploration of Task 2.

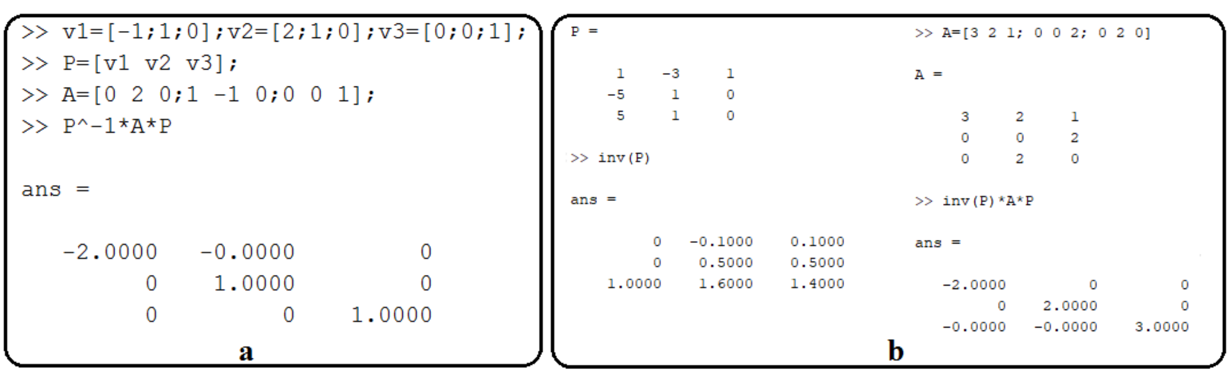

Figure 2 Transition matrix approach.

Difficulties Observed within the Three Modes of Description

This section highlights some of the difficulties students encountered in their exploration of the matrix representations of linear transformations in all three modes of description.

Retrieving the zero eigenvalue from the matrix applied eigenvector. This difficulty occurred in the synthetic-geometric approach in the exploration of Task 5. All six students who embraced the visual approach successfully graphed the given basis vectors along with the matrix-applied basis vectors. Obviously, $\mathbf{v}_2$ and $\mathbf{v}_3$ were both parallel to $A\mathbf{v}_2$ and $A\mathbf{v}_3$, respectively, in the same direction, with corresponding eigenvalues 2, and 2, respectively (Figure 3). It took quite some time for all students to realize that 0 was indeed the eigenvalue corresponding to $\mathbf{v}_1$. S8, for instance, felt the need to switch to the analytic-arithmetic mode to resolve his confusion regarding $\mathbf{v}_1$. In his first attempt, he used the matrix approach by writing $A\begin{bmatrix}1\\-3\\-1\end{bmatrix}=\begin{bmatrix}0\\0\\0\end{bmatrix}, A\begin{bmatrix}3\\0\\1\end{bmatrix}=\begin{bmatrix}6\\0\\2\end{bmatrix}, A\begin{bmatrix}-2\\1\\0\end{bmatrix}=\begin{bmatrix}-4\\2\\0\end{bmatrix}$. Inconclusive, he switched to the transformation notation by explicitly writing $\begin{cases}T\mathbf{v}_1 = 0\mathbf{v}_1 + 0\mathbf{v}_2 + 0\mathbf{v}_3\\ T\mathbf{v}_2 = 0\mathbf{v}_1 + 2\mathbf{v}_2 + 0\mathbf{v}_3\\ T\mathbf{v}_3 = 0\mathbf{v}_1 + 0\mathbf{v}_2 + 2\mathbf{v}_3\end{cases}$. This way of writing enabled him to obtain the diagonal matrix $A' = \begin{bmatrix}0 & 0 & 0\\0 & 2 & 0\\0 & 0 & 2\end{bmatrix}$ while explaining: "*now it looks like a matrix.. a diagonal matrix with eigenvalues on the diagonal*." In theory, all students seemed to accept the possibility of having 0 as an eigenvalue, however, when it came to visualize or algebraically work it out, difficulties arose, as also shown in the present report.

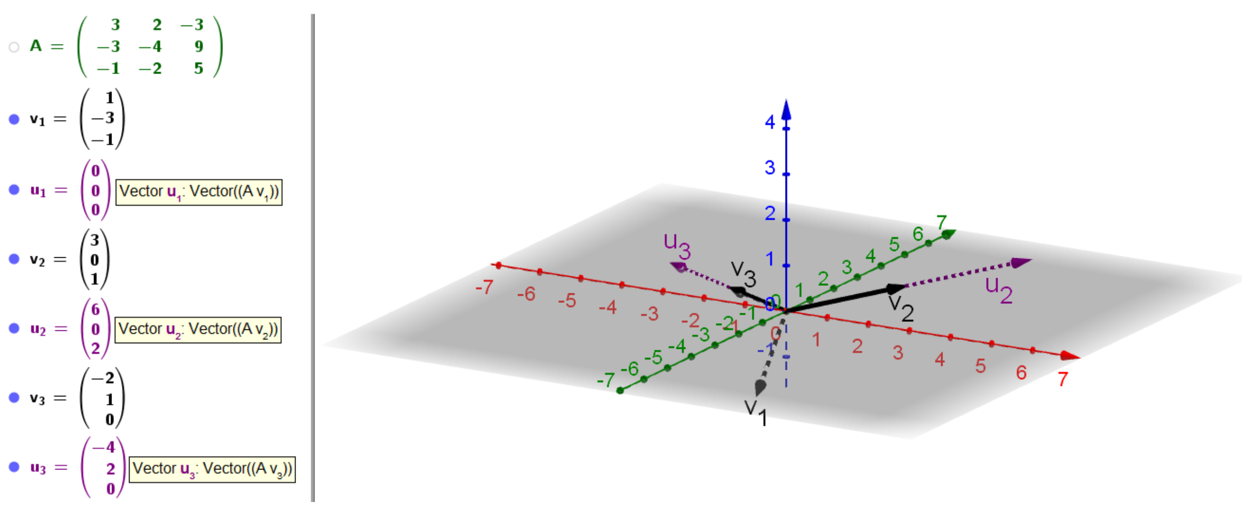

Figure 3 Typical student synthetic-geometric approach for Task 5.

Retrieving the negative eigenvalue from the matrix applied eigenvector. This difficulty occurred in the synthetic-geometric approach in the exploration of Task 3. Upon graphing the basis vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$, and the *matrix-applied* basis vectors $A\mathbf{v}_1, A\mathbf{v}_2, A\mathbf{v}_3$, respectively, S9's first reaction was that that $\mathbf{v}_2$ and $\mathbf{v}_3$ were eigenvectors of A corresponding to the same positive eigenvalue $\lambda = 3$ (Figure 4a). Regarding $\mathbf{v}_1$, S9's first conjecture was that, rather than being a scalar multiple of $\mathbf{v}_1$, $A\mathbf{v}_1$ was perhaps a linear combination of $\mathbf{v}_2$ and $\mathbf{v}_3$. Upon using some techniques such as rotating the view, hiding the *xy*-plane, changing the scale by zooming in/out, hiding $\mathbf{v}_2$ and $\mathbf{v}_3$, etc., she ultimately came to the conclusion that $A\mathbf{v}_1$ was indeed "*three times* $\mathbf{v}_1$ *but pointing in opposite directions so the eigenvalue must be -3 and not 3* (Figure 4b)."

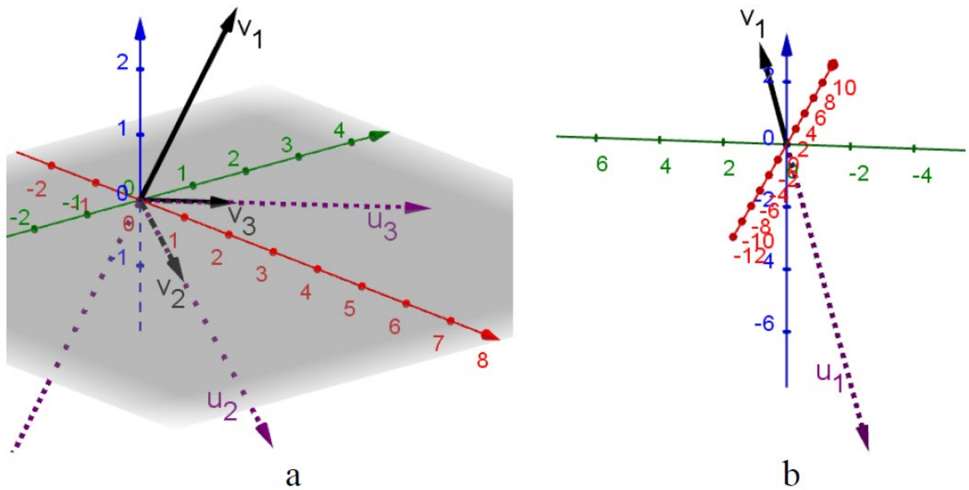

Figure 4 S9's synthetic-geometric approach for Task 3.

Issues within the analytic-arithmetic mode. S10, who embraced the analytic-arithmetic mode in Task 2, used a combination of *representation approach* and *object approach* by explicitly writing $\begin{cases} A\mathbf{v}_1 = \cdots = -2\mathbf{w}_1 + 10\mathbf{w}_2 - 10\mathbf{w}_3 \\ A\mathbf{v}_2 = \cdots = -6\mathbf{w}_1 + 2\mathbf{w}_2 + 2\mathbf{w}_3 \\ A\mathbf{v}_3 = \cdots = -3\mathbf{w}_1 + 0\mathbf{w}_2 + 2\mathbf{w}_3 \end{cases}$ (where $\mathbf{w}_1, \mathbf{w}_2, \mathbf{w}_3$ denoted standard basis vectors for S10) which enabled him propose an incorrect matrix A'. Only after switching to the analytic-structural mode was he able to obtain the correct diagonal matrix representation as a result of computing $P^{-1}AP = \begin{bmatrix} -2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$ (in a manner similar to S6 and S7's approaches described above but without using MATLAB). It can be postulated that S10's willingness to make use of the standard basis vectors within the analytic-mode is perhaps what caused the emergence of an incorrect matrix A'.

The issue was not the fact that she managed to obtain the correct answer at the end; the issue was, rather, that it took S11 quite longtime to solve three sets of systems of equations. S11, who embraced the analytic-arithmetic mode in Task 3, began with the *representation approach* by explicitly writing $\begin{cases} A\mathbf{v}_1 = \cdots = -2\mathbf{w}_1 + 10\mathbf{w}_2 - 10\mathbf{w}_3 \\ A\mathbf{v}_2 = \cdots = -6\mathbf{w}_1 + 2\mathbf{w}_2 + 2\mathbf{w}_3 \\ A\mathbf{v}_3 = \cdots = -3\mathbf{w}_1 + 0\mathbf{w}_2 + 2\mathbf{w}_3 \end{cases}$. However, she failed to see the eigenvalue-eigenvector relationships, which led her to write and solve three sets of systems of linear equations (each with three unknowns and three equations).

Issues within the analytic-structural mode. S5, who embraced the analytic-structural mode in Task 3, began by defining the inverse of the transition (change of basis) matrix as $P^{-1} = \beta'$ (as opposed to the others who defined the transition matrix as $P = \beta'$). This way, she obtained $A' =$

$P^{-1}AP = \begin{bmatrix} 13 & -20 & 0 \\ 8 & -13 & 0 \\ 4 & -8 & 3 \end{bmatrix}$. Upon the interviewer's probing how she knew this was the correct matrix representation for T, she switched to the analytic-arithmetic mode (based on pure *representation approach* unlike S10 who blended *representation approach* and *object approach*) and obtained another incorrect matrix for T due to the involvement of the standard basis vectors like S10. Inconclusive, she felt the need to switch to the synthetic-geometric approach via which she ultimately was able to obtain the correct matrix representation as $A' = \begin{bmatrix} -3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 0 \end{bmatrix}$.

Conclusion and Discussion

This report delved into mathematics students' interpretations of a classical problem in linear algebra, diagonal matrix representations of linear transformations with respect to eigenbases. All three modes of description in linear algebra appeared to have been adopted by the students; in some cases, students felt the strong need to switch between modes or utilize multiple modes of description. All students insistently questioned the meaning of having an eigenbasis such that the matrix representation for T relative to the given eigenbasis is diagonal. Using these multiple modes of description also enabled students acknowledge the importance of adopting a nonstandard basis with respect to which certain linear transformations revealed diagonal matrix representations. Some difficulties arose within each mode of description; notwithstanding, students addressed these difficulties by (i) paying close attention to the diagonalization structure; (ii) delving into the fundamental linear algebraic structures within and between modes description; and (iii) pondering deeply upon the desirableness of the diagonal matrix representation of the linear transformation under consideration.

The Need for Conditional Reasoning Tasks with Mathematical Content

Lara Alcock
Department of Mathematics Education, Loughborough University, UK

This theoretical report argues that conditional inference is central to undergraduate mathematics, and that there is potential for using and adapting conditional inference tasks from cognitive psychology to study ways in which reasoning develops (or does not develop) with mathematical expertise. Specifically, developing mathematical expertise might improve conditional reasoning in mathematics only, or it might improve conditional reasoning in a way that transfers to abstract and/or everyday contexts; alternatively, it might develop conceptual understanding, so that people become better at conceptually valid mathematical inferences but more vulnerable to invalid responses typically seen in tasks with everyday content. This report argues that, to test and distinguish these possible developmental mechanisms, we need new conditional inference tasks with mathematical content. It also describes the first stage of a project designed to develop (and later use) such tasks, initial outcomes of which will be reported at the conference.

Keywords: logic, reasoning, conditional, if-then

Introduction

Conditional reasoning is central to undergraduate mathematics, especially in upper-level courses. Students learning to understand and construct proofs need to work in mathematically valid ways with conditional (if-then) statements. They need, for instance, to make standard interpretations in relation to implicit quantification. Mathematically experienced people tend to infer universal quantification, reading "If 3 divides x, then 6 divides x" as (something like) the proposition "For all $x \in Z$, if 3 divides x, then 6 divides x" and thus interpreting the statement as false (Hub & Dawkins, 2018; Solow, 2005). Less mathematically experienced people might not infer universal quantification, and reasonably claim that the truth value of "If 3 divides x, then 6 divides x" is undetermined because it depends on the value of x (Durand-Guerrier, 2003).

Importantly for this report, students also need to recognise that some inferences from conditional statements are valid and some are not. Four standard inference types – *modus ponens*, *denial of the antecedent*, *affirmation of the consequent*, and *modus tollens* – are illustrated below.

Modus Ponens (MP)
If x is less than 2, then x is less than 5;
x is less than 2;
Therefore, x is less than 5.

Denial of the antecedent (DA)
If x is less than 2, then x is less than 5;
x is not less than 2;
Therefore, x is not less than 5.

Affirmation of the consequent (AC)
If x is less than 2, then x is less than 5;
x is less than 5;
Therefore, x is less than 2.

Modus Tollens (MT)
If x is less than 2, then x is less than 5;
x is not less than 5;
Therefore, x is not less than 2.

With universal quantification assumed, MP and MT inferences are valid under the mathematically normative material interpretation of the conditional, in which a conditional statement is false if and only if its antecedent is true and its consequent is false (Velleman, 2006). DA and AC inferences are not valid, but endorsing them is natural if the conditional "if A then

B" is interpreted as the biconditional "A if and only if B" (Blockowiak, Castelain, Rodriguez-Villagra & Musolino, 2022).

In cognitive psychology, conditional inference has been studied extensively via tasks that systematically vary content across the four inference types (Oaksford & Chater, 2020). Some research uses everyday content with statements like "If Jenny turns on the air conditioner, then she feels cool" (De Neys, Schaeken & d'Ydewalle, 2005). Other research uses abstract content with imaginary letter-number pairs and statements like "If the letter is A then the number is 1" (Evans, Clibbens & Rood, 1995). Participants are typically asked whether or not they endorse inferences of the four types. With variations depending on factors such as believability of the conditional statements (Evans, Handley & Bacon, 2009) and availability of counterexamples (Cummins, 1995; De Neys, Schaeken & d'Ydewalle, 2003), people often endorse inferences that are not normatively valid.

Departures from normatively valid interpretations need not be problematic in everyday life, where we tolerate ambiguity and rely on context to infer intended meanings (Evans & Over, 2004). Indeed, reasoning research is much occupied with developing models that describe human reasoning more accurately than does normatively valid logic (Oaksford & Chater, 2020). However, departures *are* problematic in mathematics, which makes strict distinctions between inferences available from true conditional statements like "If x is less than 2, then x is less than 5", and those available from true biconditional statements like "x is even if and only if $3x$ is even". Failure to recognise invalid inferences can lead to making or accepting invalid mathematical arguments (Inglis & Alcock, 2012; Selden & Selden, 2003), so mathematicians care greatly about valid conditional reasoning.

Wider society cares about valid reasoning too, and mathematical education is valued partly because there is widespread belief that it develops logical reasoning skill in general (Inglis & Attridge, 2016). This is known as the *theory of formal discipline* and it is certainly plausible. Mathematics has clean conceptual boundaries (Vinner, 1991): a number either is or is not less than 2. So logical relationships in mathematics are clear-cut in a way that everyday ones are not. Consequently, studying mathematics – especially at advanced levels – might help people to become sensitised to logical structures and to transfer this understanding to general contexts. Empirical evidence on this process is, however, minimal and mixed, as described below.

Conditional Reasoning and Mathematics

Research indicates that, as the theory of formal discipline predicts, post-compulsory mathematical study does develop conditional reasoning toward normatively valid interpretations. However, it does so unevenly and imperfectly. Research in the UK (Attridge & Inglis, 2013) and in Cyprus (Attridge, Doritou & Inglis, 2015) found that among 16-18 year-old students, those studying mathematics intensively became better able to reject invalid DA and AC inferences in abstract conditional inference tasks. However, they still endorsed just under half of DA inferences and more than half of AC inferences (Attridge & Inglis, 2013). These students also became slightly more likely to reject normatively valid MT inferences (Inglis & Attridge, 2016), a finding in line with work showing that individuals with higher general intelligence scores and higher overall conditional inference scores tend, if anything, to endorse fewer MT inferences than those with lower scores (Inglis & Simpson, 2009; Newstead, Handley, Harley, Wright & Farrelly, 2004). This means that mathematical study seems to shift students away from naïve interpretations of conditionals but not toward a material interpretation; the shift is better understood as toward a *defective* interpretation in which a conditional statement is viewed as irrelevant when its antecedent is false (Attridge & Inglis, 2013).

Indeed, although individuals might tend to endorse conditional inferences in line with particular interpretations, this does not mean that they apply those interpretations consistently (Evans, Handley & Bacon, 2009). Reasons relevant to pedagogical design are evident in detailed qualitative research in undergraduate mathematics education. For instance, it would be a mistake to think that students considering conditionals with mathematical content are necessarily thinking about logic. Their reasoning might instead be built on content-specific and pragmatic factors (Dawkins & Cook, 2017), so that they benefit from experience designed to focus their attention on assigning truth values consistently across contents (Dawkins & Norton, 2022; Dawkins & Roh, 2022; Hub & Dawkins, 2018). Similarly, it would be a mistake to think that students understand the connections within and between conditional statements and the truth tables often used in teaching. Instead, they might treat the components of both statements and tables as separate entities, which prevents them from effectively reasoning about negation and about conditions under which statements would be false (Hawthorne & Rasmussen, 2015)

We see the impact of imperfect conditional reasoning in undergraduate students' evaluations of mathematical arguments: secondary students and undergraduates often fail to distinguish arguments for the converse of a conditional statement from those for the statement itself (Dawkins & Roh, 2022; Hoyles & Küchemann, 2002; Selden & Selden, 2003). Professional mathematicians do not make that mistake: they reliably identify and reject arguments that prove a converse (Inglis & Alcock, 2012). However, their conditional reasoning remains intriguingly imperfect. They do not, for instance, perform as well as might be expected on the Wason selection task (Wason, 1968). This task involves cards with a number on one side and a letter on the other: participants are shown cards labelled D, K, 3 and 7 and asked which should be turned over to determine whether the rule "every card that has a D on one side has a 3 on the other" is violated. Inglis and Simpson (2004) found that mathematicians largely avoided the common error of selecting D and 3, but fewer than half gave the normatively valid answer D and 7. This task involves evaluating the truth of a conditional rather than making inferences from a conditional that is assumed to be true, but the result is in line with the findings on mathematics students: mathematicians neglect the case corresponding to MT (if not-3 then not-D).

Unsurprisingly, given these findings, there is no standard way of teaching conditional inference. Mathematicians explicitly teach logical reasoning in textbooks (e.g., Houston, 2009; Velleman, 2006) and in introduction-to-proof courses (Davis & Zazkis, 2019), but there is debate on how to do this. Some, for instance, believe that teaching should leverage everyday reasoning and previous mathematical knowledge, others that everyday content muddies the waters and that mathematical education should focus on abstract logical structures (Alcock, 2010; Epp, 2003; Hawthorne & Rasmussen, 2015). Books designed to support students at the transition to proof offer short explanations of truth values in relation to conditional statements, perhaps emphasising the difference between a conditional statement and its converse and explaining why we consider a conditional to be true when its antecedent is false (e.g., Houston, 2009; Solow, 2005; Velleman, 2006). But they do not usually explain any research on everyday reasoning or acknowledge that professional mathematicians apparently need not be perfect logicians. If we wish to support students in developing mathematical expertise, there is pragmatic reason to investigate what that development might look like and where it ends up.

Possible Mechanisms and the Theory of Formal Discipline

Of theoretical interest is that although the theory of formal discipline seems to be partially valid, the mechanism by which it operates remains largely unexamined. The mechanism suggested in the Introduction requires that studying mathematics sensitises people to logical structures and that this understanding transfers to other contexts. This appears not to be fully correct: Inglis and Attridge (2016) suggested that mathematics students' lower endorsement of all three of DA, AC and MT inferences might result from their greater experience of error checking, which leads them to be more productively skeptical about all conditional inferences (see also Inglis & Simpson, 2004). But the larger point stands: if mathematical expertise makes people more productively skeptical, then those with more expertise should perform in similar ways across tasks with all types of content. However, mathematical study could promote different reasoning in mathematics without promoting transfer. If so, people with more mathematical expertise should perform more normatively on mathematical tasks but not on tasks with everyday content. In that case, abstract tasks make an interesting and potentially intermediate possibility: the evidence so far has used exactly these tasks, showing that mathematics students become better at rejecting DA and AC inferences (Attridge & Inglis, 2013). Performance with abstract content might represent the best that we can expect in terms of valid reasoning, or performance might be even better with meaningful mathematical content.

Alternatively, mathematical expertise might be less about sensitivity to logical structures or general skepticism, and more about deeper conceptual understanding: greater familiarity with mathematical examples, definitions and theorems might enable people to "understand the terrain" (cf. Goldenberg & Mason, 2008; Michener, 1978) and avoid errors by thinking about mathematical situations as they would about "real" situations. If so, people with more expertise might exhibit patterns of mathematical reasoning that reflect those seen for everyday content. For instance, conditional inference is known to be affected by believability. Individuals are less likely to endorse inferences of all four types when a conditional is less believable (Evans, Handley & Bacon, 2009). Similarly, conditional inference is affected by counterexample availability. For a causal conditional "If p then q", people are less likely to endorse DA and AC inferences if there are many *alternatives* that might cause q in the absence of p; they are less likely to endorse MP and MT if there are many *disablers* that might intervene to prevent p from causing q (De Neys, Schaeken & d'Ydewalle, 2005). People can usually think of several alternatives and disablers for "If the brake was depressed, then the car slowed down", for instance (Cummins, 1995). If greater expertise makes mathematics more "real", then it should be possible to manipulate believability and counterexample availability in mathematical content so as to induce everyday-like response patterns. This might support an account in which mathematicians do not really need formal discipline because expertise is primarily a matter of content knowledge.

These possible mechanisms for the theory of formal discipline – or for its relative unimportance – are not currently distinguishable because research has not examined conditional reasoning with mathematical content. Cognitive psychologists have almost exclusively used tasks with abstract or everyday content, even when studying mathematics students (Morsanyi, McCormack & O'Mahony, 2018) or investigating the theory of formal discipline (Attridge & Inglis, 2013). Research in mathematics education has been small-scale (Hub & Dawkins, 2018) or not systematically related to all four inferences (Hoyles & Küchemann, 2002). To understand how mathematical expertise develops conditional reasoning, and to relate that development to research in cognitive psychology, we need tasks with mathematical content.

From Theory to Empirical Research

The talk for this report will present the theoretical argument given above and describe the development of two new conditional reasoning tasks with mathematical content. (The larger project of which this work forms part will use these alongside tasks with abstract and everyday content to study how conditional reasoning develops with mathematical expertise.) The new tasks will both comprise conditional inference items of the form shown in the Introduction. One (MCB) will have basic mathematical content familiar to all educated adults; inferences will likely be from conditional statements such as "If x is less than 2, then x is less than 5". The other (MCA) will have advanced content familiar only to people with upper-level undergraduate mathematical experience; inferences will likely be from conditional statements such as "If $f: R \rightarrow R$ is differentiable at a then f is continuous at a". Both tasks will be structured using a standard *negations paradigm*, systematically varying negated elements across antecedents and consequents of conditional statements (see Attridge & Inglis, 2013; Evans, Handley, Nielens & Over, 2007).

Specific content for the MCB and MCA will be developed in Fall 2022. Mathematicians experienced in teaching proof-based courses will learn about factors known to affect everyday and abstract conditional inference; they will take these into account when generating potential items. This will not necessarily be straightforward for mathematical content. For believability, there are obvious possible manipulations: switching a true conditional like "If x is less than 2, then x is less than 5" for its false converse "If x is less than 5, then x is less than 2" might interfere with performance in predictable ways; switching it for a conditional with no obvious truth value, like "If x is less than 2, then y is less than 5" might render it more like an abstract task. For counterexample availability, the picture is more complex. It might be straightforward to affect DA and AC inferences: alternatives to "If x is less than 2, then x is less than 500" should be more accessible than alternatives to "If x is less than 2, then x is less than 5", for instance (see Hamami, Mumma & Amalric, 2021, for related results in geometric contexts). But the absolute nature of truth in mathematics makes it difficult to manipulate disablers that might affect MP and MT inferences: nothing could interfere to prevent x being less than 2 from "causing" x to be less than 5, and there is no readily inferable cause in "If x is less than 2, then y is less than 5". It will be interesting to see whether and how mathematicians attempt to address these issues, as well as whether and how they deal with implicit quantification.

With potential items in place, the mathematicians will collaboratively narrow down the list with the aim of constructing MCB and MCA tasks that mimic the systematic variation in tasks with everyday and/or abstract content. This will be accomplished using a Delphi-like process in which the mathematicians review, revise and prioritise one another's suggestions; individual interviews will capture the reasoning behind their suggestions, revisions and prioritisations. Later, the items will be tested with undergraduate participants to establish the extent of their comparability with standard abstract/everyday tasks. The talk for this report will present the outcomes of the Delphi process and the interviews: it will exhibit the items developed and present a qualitative analysis of the mathematicians' input in light of the theory outlined in this report.

Re-envisioning a Value Framework for Examining Transformational Communities of Practice in Mathematics Education

Paula Jakopovic, Ph.D.
University of Nebraska at Omaha

Kelly Gomez Johnson, Ed.D.
University of Nebraska at Omaha

Communities of practice (CoPs) provide a structure that allows individuals with a common goal or purpose to come together to engage in collective learning (Wenger-Trayner & Wenger-Trayner, 2015). The COMmunity for Mathematics Inquiry in Teaching (COMMIT) Network was developed to support regional Math CoPs, called COMMITs, composed of undergraduate mathematics faculty interested in using active learning and inquiry teaching approaches in their courses. For the past three years, we have utilized the value framework, presented by Wenger et al. (2011), to better understand the layers of value faculty experience as they engage in COMMITs and the broader network. In doing so, we have identified modifications to the original model from Wenger et al. that may further interrogate and articulate the layers of value that can be used to help advance and sustain CoPs longterm. We present our theoretical adaptation in the following report.

Keywords: Community of Practice, STEM Faculty, Theories of Change, Value Creation Framework

In recent years, mathematics faculty at institutions of higher education have begun to focus on the use of evidence-based teaching practices, such as active learning and teaching with inquiry, to help support undergraduate student success. Despite mounting research that backs the use of such practices (e.g., Chen & Yang, 2019, Cook-Sather et al., 2016; Freeman et al., 2014; Healey et al., 2014, 2016; Werder & Otis, 2010), many math faculty still engage in traditional lecture style instruction, which is often less effective in supporting student success (Jaworski & Gellert, 2011). Attempting to integrate innovative teaching techniques in isolation can make sustained implementation challenging (Banta, 2003), therefore communities of practice (CoPs) offer a pathway to connect like-minded faculty and create a support system for instructional change. CoPs are defined as "groups of people who share a common concern or a passion for something they do and learn how to do it better as they interact regularly" (Wenger-Trayner & Wenger-Trayner, 2015). They help the group to identify common goals, develop and share resources and ideas, and engage in shared learning to foster transformational change.

Our research team is part of a grant funded project focused on supporting regional CoPs of undergraduate mathematics faculty as they attempt to implement active learning and teaching with inquiry strategies into their courses. The project developed the COMmunity for Mathematics Inquiry in Teaching (COMMIT) Network as a way to loosely connect each region to help the regional CoPs (COMMITs) mature and shift toward sustainability. We identified the value creation framework developed by Wenger et al. (2011) as a tool with which to examine the role of the COMMITs and the broader network in supporting faculty members in their efforts to implement instructional innovations in their courses. We have also examined value-add from the COMMIT level through regional leaders, to determine the facets of the COMMITs and the connecting network that best support all participants (including the leaders themselves) in their pursuit of instructional change. Our preliminary findings support the use of the value framework as a mechanism for exploring this work (Gomez Johnson, Jakopovic, von Renesse, 2021; Gomez

Johnson, Jakopovic, Rech et al., 2021). However, through our data analysis we have established several modifications to the original value framework that we hypothesize will more effectively describe the patterns emerging within value-added data at the CoP and network level. In this report, we share our use of the value creation framework, as well as our proposed modifications and the rationale behind the changes.

Teaching with Inquiry and the Role of Communities of Practice

There is an established body of research that shows how active learning and instructor effectiveness can positively impact students' learning, attitudes, and educational experiences (Freemen et al., 2014; De Vlieger et al., 2016; Laursen & et al., 2019). Incorporating active learning teaching strategies in STEM classrooms can impact students' academic success, overall attitude toward content, and their retention rates in STEM courses (Bowen, 2000), as well as lesson the achievement gap for students from historically underrepresented groups in STEM (e.g., people of color, women) (Freeman et al., 2014; Haak et al., 2011; Hrabowski & Henderson 2017; Laursen et al., 2014; Theobald et al., 2020). Active learning classrooms situate students as partners in the learning process with the instructor rather than acting as passive observers (Cook-Sather et al., 2016; Healey et al., 2014, 2016; Werder & Otis, 2010).

A survey by Rassmusssen et al. (2019) found that many mathematics departments in institutions of higher education report believing that active learning is "very important" or "somewhat important," however these beliefs translated to programmatic implementation only 15% of the time. Garnering buy-in from mathematics faculty can be challenging, as active learning practices challenge the historically accepted cultural norms of mathematics teaching. CoPs have the potential to serve as a vehicle for change (Gehrke & Kezar, 2017). Like other areas of social change, this requires disruption to systems that have been historically inequitable and act against and across existing boundaries (Hooks, 1994). For mathematics education, participation in praxis—engagement in reflection, learning, practice, and action—reduces the gap between theory and practice for faculty. In CoP structures, this allows members to defy norms about who belongs in a community or field, what is pursued, how it is organized, and how it works (Drane et al., 2019; Freire, 1968/2000; Hooks, 1994). CoPs can also give a voice to counter-narratives and people who have been historically excluded from stories and spaces (Solórzano & Yosso, 2002). Given the organic nature of CoPs, they transform and evolve at key points in their development or cease to be sustained if they no longer serve a useful purpose to individual members (Stuckey, 2004). For this reason, attention to the value-added aspects of participation at the COMMIT regional and network levels is important to not only examine long-term sustainability impacts, but CoP creation and implementation factors as well.

Theoretical Framework

We established our research design to study the COMMIT Network project as a community-based approach to instructional and institutional change using situated learning theory (Lave & Wenger, 1991; Wenger, 1998) as the theoretical perspective. Rather than focusing solely on the traditional conception of teacher/pupil learning, situated learning theory conceives of learning as something that occurs as individuals engage in CoPs and social networks (Lave & Wenger, 1991). CoPs involve intricate levels of interaction that can make examining the factors leading to the success or failure of these communities a challenging endeavor. The value creation framework positions CoPs within "a dynamic process in which producing and applying knowledge are tightly intertwined and often indistinguishable" (Wenger et al., 2011, p. 21). As Figure 1 illustrates, the original framework includes five cycles, or layers, of value creation—immediate (in the moment resources, information, connections), potential (for the future), applied (piloted implementation), realized (actualized implementation), and transformative (broad dissemination to others) value. One cycle does not necessarily lead to the next and the importance of the various cycles can differ for different stakeholders and at different points in the life of the CoP. Strategic and enabling value layers attend to the programmatic processes, structures, and ways of evolving and sharing value with others that support these five cycles.

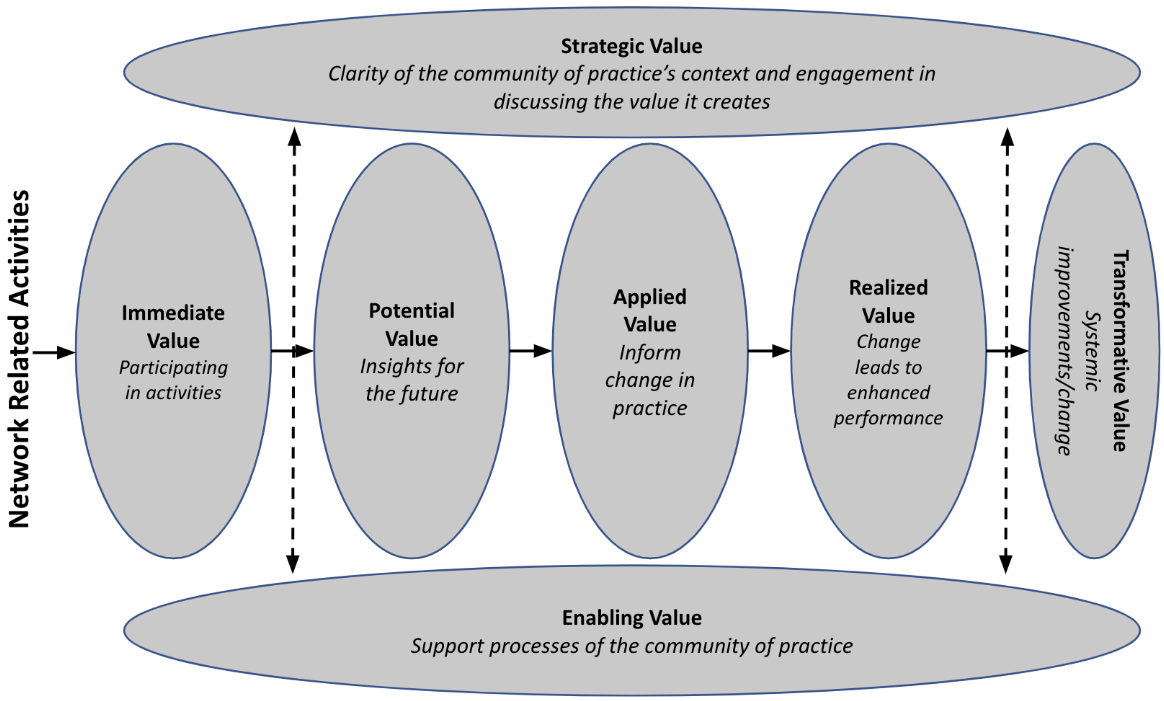

Figure 1. Value creation framework (Wenger et al., 2011).

The value framework in its original form has been utilized in a range of studies around CoPs. For example, Booth and Kellogg (2015) used the value framework specifically to examine value cycles within online CoPs. They identified labels for each type of value as follows: immediate value - productive activities, potential value - knowledge capital, applied value - promising practices, realized value - "return on investment" (i.e. seeing the payoff/benefit of the new knowledge implementation in practice). Clarke et al. (2021) applied the value framework to develop "ground narratives" that allowed them to identify themes within the broader community. In our project, we sought to better understand how the larger network of COMMITs might help to engage stakeholders and expand faculty engagement in the COMMITs. Therefore we adopted the value framework to investigate the experiences of COMMIT participants and leaders and follow the trajectory of the COMMITs themselves, within the context of the larger network. Through our ongoing analyses we gradually began to re-envision the framework. Specifically, we encountered nuances of the value layers emerging as we shifted away from looking at the value of individual participants and toward identifying the value the COMMIT Network afforded regional leaders and their CoPs. In the following sections, we present the findings from our research that support the need for the hypothesized revision to the value framework at the network level value.

Research Methodology

Data analysis is an ongoing, recursive process that involves the examination, interpretation, and reinterpretation of data and findings (Patton, 2002; Richards, 2009). Design based research positions theory development and refinement within the complex, social contexts within which interventions are examined (Brown, 1992; Tabak 2004). In this section, we report on the findings from our research as a way to illustrate both the need for and envisioning of the hypothesized value framework revisions, as this process is intrinsically embedded into the iterative nature of qualitative research design.

Context

Our research on the COMMIT Network is part of a project funded by a National Science Foundation grant (No.1925188). The authors of this report are researchers on the grant leadership team, initially tasked with gathering and analyzing data to better understand how the COMMIT, supported by the network, could recruit, develop, and retain mathematics faculty use of active learning and inquiry-based teaching practices. During the initial two years of the grant, our research focused on identifying the layers of value that individual COMMIT faculty members self-reported after engaging in COMMIT events and activities. At the end of Year 2 of the grant, we gathered additional data from members of the regional COMMIT leadership teams in an effort to expand our examination of value beyond individual participants to the regional COMMIT and COMMIT Network levels.

Participants and Data Collection

Midway through Year 2 of the project, we surveyed individual CoP participants representing a total of five regional COMMITs in the Math COMMIT Network to gather a first round of data. Participants in this initial data set included responses from 156 faculty members who participated in COMMIT workshops and events in their region. The participants included faculty from a broad range of institution types. Coverage of survey responses represented faculty from K-12 schools (4%), two-year colleges (10%), doctoral granting institutions (18%), and predominantly undergraduate institutions (68%). We created an online survey that included a combination of multiple choice and open-ended follow up questions for participants to identify the value, if any, they found through engaging in COMMIT activities and to what extent they planned to use ideas from these events in their teaching practice.

At the end of Year 2, we used social network analysis to identify leaders within each of the regions (Gomez Johnson et al., 2021b). We then gathered a second phase of data, conducting a total of 19 semi-structured interviews with COMMIT leaders representing eight of the regions in Spring 2021. The interviews focused on the experiences of leaders as individuals, as well as representatives of their regional COMMIT. We collected and analyzed the interview data to help us begin to understand the collective value these CoPs identified as a result of engaging in the COMMIT Network. The analysis of this second data set became the area of focus in our re-imagining of the value framework, as we shifted from talking about the value found by individuals within their group to the value the COMMITs found within the Network. The analysis of this second data set led us to uncover more complex, nuanced sub-layers of value that were not completely captured within the original value framework.

Data Analysis

Our initial analysis of the COMMIT participant surveys involved first deductively coding the open-ended survey prompts for instances where faculty identified any immediate, potential, or transformative value they found by engaging in COMMIT activities. In the second round of coding, we used *a priori* codes where we identified responses that aligned with one of the Four Pillars of inquiry based teaching: 1) students engage deeply with coherent and meaningful mathematical tasks, 2) students collaboratively process mathematical ideas, 3) instructors inquire into student thinking, and 4) instructors foster equity in their design and facilitation choices. (Laursen & Rasmussen, 2019). We determined that these four codes did not completely capture the essence of all participant responses, therefore we conducted a third round of descriptive coding (Miles et al., 2014; Saldaña, 2021) where we identified additional emergent codes in the data. These codes included resource sharing, ideas for technology integration, forms of assessment, evolving beliefs about teaching mathematics, and the usefulness of the COMMIT Network. Participants regularly self-reported finding immediate (in the moment), potential (for future use), and transformative (worth sharing with others) value around these five topics (Gomez Johnson, Jakopovic, von Renesse, 2021). Reflecting on this first set of findings, we determined that, for this data set that focused on the experiences of individual participants, the five layers of value that are described by Wenger et al. (2011) appropriately captured the essence of participant responses.

With the semi-structured COMMIT leader interviews, we began in a similar fashion, coding in a first pass deductively for evidence of the five layers of value. As we coded for transformative value, we identified the need for a distinction between enacted transformative value (dissemination and change that has taken place) and the "potential to transform" (future possibilities to promote teaching with inquiry to the broader community). Therefore, we inductively added a sixth code. This came about due to leaders' reflections on the value they identified the COMMIT Network providing to their regional COMMITs (versus identifying the value-add for individual participants). At times, leaders shared the ways in which they envisioned taking steps toward transformative action in their COMMIT, but these were phrased as future aspirations and ongoing goals rather than work currently happening within the region (Jakopovic & Gomez Johnson, 2021).

Reframing the Value Creation Framework

As we reflected on this need for an additional code to more accurately capture the essence of value creation at the CoP level, we realized there is a potential connection between the unit being studied (individual participant or COMMIT leader/representative) and the ways in which "transformative value" manifests itself. With faculty participants, their descriptions of "potential value" encompassed the ways in which their participation in the COMMIT Network and regional COMMITs might influence their future, individual teaching practice. Their responses also included ideas as to how they might "transform" teaching by sharing this information with close colleagues or peers. When we analyzed the COMMIT leader interviews, however, they identified opportunities where the Network provided ideas and supports that have the potential to create transformative value within and across COMMITs. For example, one regional leader explained,

> I think we have a lot to offer. I think especially because we might be ahead, at least in the idea of [our cultural renaissance], There is a huge focus on respecting [our] culture. Even in the aspect of math, that can be shared in the broader network nationwide and reaching

> out to Native American/first nations to collaborate and share ideas. [Our region] has had this ability because of the renaissance of [our] culture happening in the 70s, we are a little further along that we can share, not even inquiry based, but also focus on the place where you are and the people you are teaching.

A leader from a different region shared similar comments with regard to ways their COMMIT had the potential to support other COMMITs, stating, "We have been trying to learn from the others in the network and what they are doing. It is nice to figure out what they are doing. It has been inspiring for us. We hope to contribute like that in the future. I would hope that it's reciprocal." These recurring observations based on our coding and analysis evolved as we made further shifts from studying individuals to COMMIT leaders and have led us to hypothesize a reimagined visualization of the value creation framework, as shown in Figure 2.

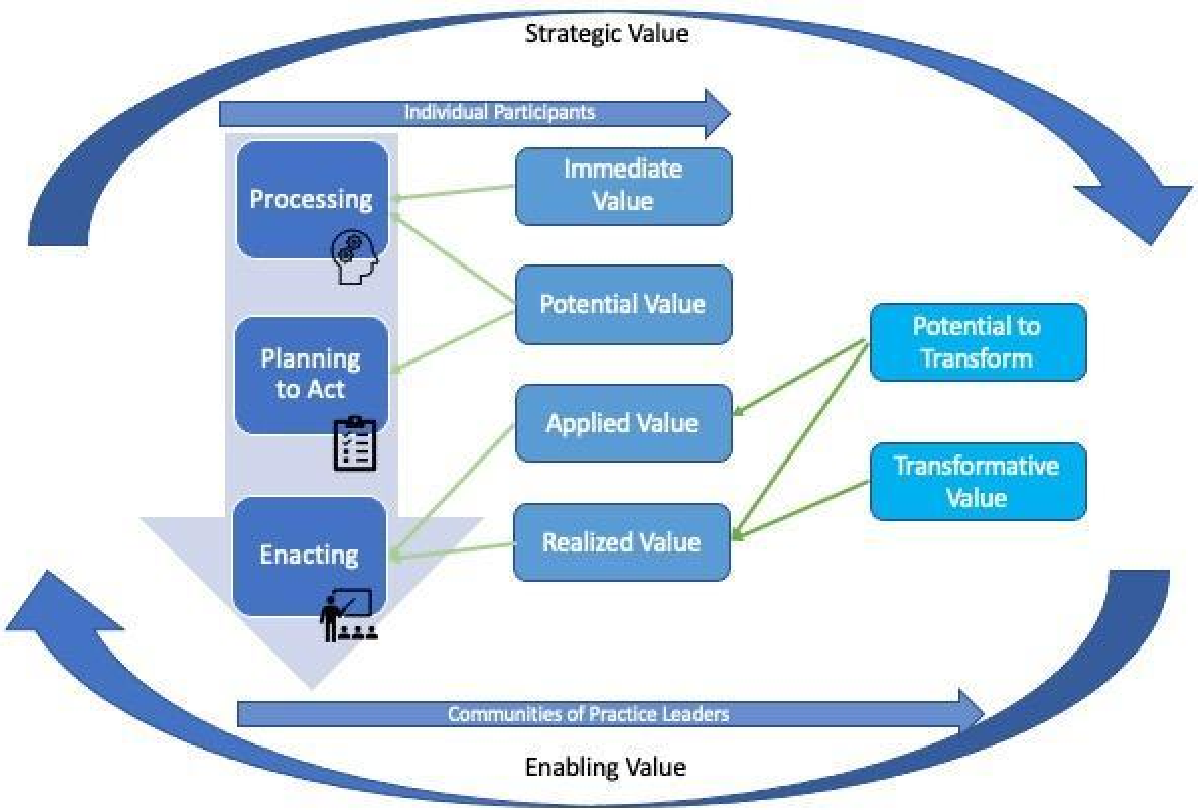

Figure 2. Value creation for community of practice leaders.

We realized that the ways in which value is created through the COMMIT Network for faculty participants is different from that of COMMIT leaders. In the figure above, we attempt to articulate our vision of this hypothesis. The five layers of value creation all lead participants to process and consider new ideas, to make plans and imagine acting on the new information, and eventually to enact these plans in their practice. For individual faculty members, this most often encompasses the first four layers of value: immediate, potential, applied, and realized. They consider new ideas, plan for them, and then implement them in their mathematics courses. They may consider sharing these ideas with others, yet in our findings this typically happened due to the support of their COMMIT and the larger COMMIT Network through established structures like regular meetings, book clubs, and online workshops.

In our consideration of the value COMMIT leaders experienced in their COMMITs and in the Network, however, we overwhelmingly saw more evidence of their plans to share at the regional and network level in addition to the ways they identified their COMMITs as currently acting to share and transform with other COMMITs in the Network.

Implications and Conclusion

To date, we have found the value creation framework first established by Wenger et al. (2011) to be an invaluable tool for studying the potential impacts of STEM CoPs on instructional transformation, particularly at the individual participant level. CoPs are meant to meet the needs of individual participants in a specific area or domain, however, evolution and sustainability are often a challenge once their needs are met (Wenger et al., 2002). Knowing the contextual factors impacting CoPs, we recognize that the ways in which value is defined shifts when moving from studying individual participants to regional COMMITs and broader network levels. Our goal moving forward is to continue refining the model based on new and additional data analysis, to more clearly define how leaders interact with their COMMITs and drive not only transformation of practice but also sustainability of the community as a resource. We believe this work can inform others who are studying COMMITs and sustainability, particularly in subject-specific areas, such as mathematics and more broadly STEM education.

Additional studies in different contexts and subject areas can contribute to our developing understanding of CoP sustainability within the framework of value-add. For example, research is currently underway with other STEM CoPs to further examine if and how this work may be similar or different based on variables such as geographic location, participant demographics, etc. This additional research within this project and other STEM projects is needed to help generalize our findings and proposed model. Our team plans to continue our investigation in this area, with future work focused on considering how strategic and enabling value (see Figure 1) may also need to be reimagined when shifting from the value a regional CoP can provide individuals to the value the CoP can find within a broader network structure.

Characterizing a Teacher's Ways of Thinking about Teaching the Idea of Sine Function

Abby Rocha
Arizona State University

Over the past thirty years, researchers have developed constructs to investigate teachers' knowledge base and how it relates to their teaching. These constructs include Mathematical Knowledge for Teaching (MKT), Mathematical Meanings for Teaching (MMT), and Key Pedagogical Understandings (KPUs). In this report, I describe each of these constructs, their uses, and how they are related. I then describe a recently introduced construct, Ways of thinking about Teaching an Idea (WTTI) (Carlson, Bas-Ader, O'Bryan, & Rocha, in press) and illustrate the usefulness of this construct for investigating a teacher's mathematical understanding of sine function and how this understanding is related to the teacher's instructional goals and actions.

Keywords: Mathematical Knowledge for Teaching, Meanings, and Ways of Thinking

Introduction

Mathematics educators have asked the question, "what do teachers need to know to teach students?" for quite some time. In the late 1800s, debates about teachers' knowledge primarily focused on teachers' experience with the subject matter (Shulman, 1986). A century later, emphasis on teachers' subject matter knowledge lost traction as new policies concerning teachers' evaluation and testing were implemented. During the 1960s and 1970s, research programs shifted their focus to teachers' pedagogy with little regard for teachers' content knowledge. Shulman (1986) described the education community's disregard for teachers' content knowledge as the "missing paradigm problem" and responded by proposing that researchers "blend properly the two aspects of teachers' capacities" (p.5) and begin focusing on teachers' pedagogical content knowledge, a type of knowledge that "goes beyond knowledge of subject matter per se to the dimension of subject matter knowledge for teaching" (p.6). Following Shulman (1986), teachers' knowledge in the context of teaching became a focus of mathematics education research. This area of research on teachers' knowledge is now known by many as *Mathematical Knowledge for Teaching (MKT)*(Thompson & Thompson, 1996).

Mathematical Knowledge for Teaching

In the last three decades, researchers have turned their attention to teachers' MKT to improve the quality of mathematics teaching and learning in the United States. While the literature on teachers' MKT is vast, various research groups' foci and ontological stances differ significantly.

A Practice-Based Theory of MKT

Ball and colleagues (e.g., Ball, 1990; Ball & Bass, 2003; Ball, Hill, & Bass, 2005) sought to answer the question, "what do teachers do in teaching mathematics, and in what ways does what they do demand mathematical reasoning, insight, understanding, and skill?" (Ball, Hill, & Bass, 2005, p. 17). Ball's work on teacher knowledge began in 1990 when she studied 252 pre-service teachers' understanding of division with fractions. In this study, most teacher candidates could correctly complete the procedures of dividing fractions. However, few were able to describe a situation that represented the division of fractions accurately to students (Ball, 1990).

Following Ball's (1990) findings of teachers limited mathematical understandings, Ball and Bass (2003) proposed focusing on the mathematical work of teachers, including how and where teachers use their mathematical knowledge in practice. Ball and Bass' analyses revealed that the mathematical knowledge needed for teaching differs from that of mathematicians and other practitioners of mathematics. Namely, mathematics teaching requires teachers to have knowledge of (1) the work involved in problem-solving, (2) how to "unpack" their mathematical understandings, and (3) how to help students in making connections across mathematical domains (ibid). These empirical analyses lead to Hill, Schilling, and Ball's (2004) proposal that teachers' MKT is multidimensional, and Shulman's (1986) original category of subject matter knowledge be subdivided to include teachers' *common content knowledge (CCK)* and *specialized content knowledge (SCK*).

In the past twenty years, these researchers have explored the multi-dimensional nature of teachers' knowledge when teaching and classified teachers' MKT into five types of specialized knowledge (Ball, 1990; Ball & Bass, 2003; Ball, Hill, & Bass, 2005). These researchers have also identified positive links between teacher knowledge and student performance (Ball, Thames, & Phelps, 2008; Hill & Ball, 2004; Hill, Ball, & Schilling, 2008; Hill, Schilling, & Ball, 2004, Hill et al., 2008).

A Piagetian Theory of MKT

While Ball and colleagues (e.g., Ball, 1990; Ball & Bass, 2003; Ball, Hill, & Bass, 2003; Hill, Rowan, & Ball, 2005) primarily focused on identifying how teachers must know mathematics to teach it, Silverman and Thompson (2008) focused on the nature of teachers' MKT and how it develops. Silverman and Thompson (2008) made two propositions, (1) teachers' MKT is grounded in personally powerful understandings of mathematical concepts, and (2) teachers' MKT is created through the transformation of those concepts from an understanding having pedagogical potential to an understanding that has pedagogical power.

Mathematical understandings are personally powerful if they carry throughout an instructional sequence, are foundational for learning other ideas, and play into a network of ideas that do significant work in students' reasoning (Thompson, 2008). According to Silverman and Thompson (2008), *Key Developmental Understandings (KDUs)* (Simon, 2006) are an example of mathematical understandings that are personally powerful. A KDU is an individual's understanding of an idea that is critical to their learning of other related ideas (Simon, 2006). We say an individual has developed a KDU for a mathematical idea if they (1) make a conceptual advance or have "a change in [their] ability to think about and/or perceive a particular mathematical relationship" (Simon, 2006, p. 362) and (2) develop an understanding for the idea through their own activity and reflection on their activity.

Silverman and Thompson (2008) propose that "developing MKT involves transforming [personal] KDUs of a particular mathematical concept to an understanding of: (1) how this KDU could empower their students' learning of related ideas; (2) actions a teacher might take to support students' development of it and reasons why those actions might work" (p. 502). More concretely, the development of MKT involves transforming teachers' KDUs into *Key Pedagogical Understandings (KPUs).* A KPU is a mini theory that a teacher has regarding how to help students develop the meanings she intends (Byerley & Thompson, 2017). As such, these researchers developed a framework to describe the process by which teachers' MKT-their KDUs and awareness of their KDUs- develop.

Comparing Research on Teachers' MKT

There are two distinguishing characteristics in research programs focused on teachers' MKT. The first involves the focus of each program. Ball and Colleagues' investigations primarily focused on what teachers do in their teaching and the knowledge required to engage in these teaching actions (Ball & Bass, 2003). In contrast, Silverman and Thompson (2008) focus on the cognitive mechanisms that enable teachers' behaviors. These researchers seek to uncover the nature of teachers' knowledge and how it develops. According to Silverman and Thompson (2008), the second distinguishing feature of MKT research involves their ontological stance that an individual's knowledge is constructed and is idiosyncratic. Ball and colleagues (e.g., Ball 1990, Ball & Bass, 2003, Ball, Hill, & Bass, 2005) describe teachers' knowledge in the sense of a truth about a reality external to the knower. In comparison, Silverman and Thompson describe teacher knowledge in the sense of Piaget and von Glasersfeld (1995)- as schemes and ways of coordinating them that explain how a person might act when teaching. Moreover, Silverman and Thompson describe a teacher's knowledge base in terms of her individual cognitive structures and thought patterns. Silverman and Thompson use the phrase *Mathematical Knowledge for Teaching (MKT)* to describe teachers' schemes or meanings for the ideas they teach and hold at a reflected level.

Mathematical Meanings for Teaching

In 2016, Thompson proposed using the construct *Mathematical Meanings for Teaching* (MMT) rather than MKT to make explicit that he was using the word *knowledge* to describe an individual's schemes or meanings for an idea. An individual's meaning is the space of implications resulting from assimilation to a scheme (Thompson, 2016). Thus, to say an individual has a *meaning* for a word, symbol, expression, or statement means that the individual has assimilated that word, symbol, expression, or statement to a scheme. A scheme is a mental structure that "organize[s] actions, operations, images, or other schemes" (Thompson et al., 2014, p. 11). When defining *Mathematical Meanings for Teaching*, Thompson (2016) extended the construct *mathematical meaning* to account for characterizations of teachers' actions related to teaching. As such, a teacher's mathematical meanings for teaching an idea include (1) the meanings (schemes) the teacher uses while teaching or thinking about teaching, and (2) the teacher's image of the meanings (schemes) they want students to develop for the idea.

The construct *Mathematical Meanings for Teaching* differs from the construct *Mathematical Knowledge for Teaching* in two distinct ways. First, Thompson's use of the word *meaning* connotes something personal (i.e., meanings existing in the mind of the knower) to readers rather than *knowledge*, which seems less personal and disjoint from the knower (Thompson, 2016). Second, and arguably most important, the construct *Mathematical Meanings for Teaching* is used to describe the *status* of an individual's understandings relative to teaching. Although Ball and Thompson defined teacher's MKT differently, both researchers used the construct MKT to describe teacher knowledge as a target for teachers to *achieve*, not a *state* of teacher's knowledge. For instance, Ball, Hill, and Bass (2005) use the example of multiplying two integers to demonstrate that a teacher's sole ability to compute 35 x 25 correctly is insufficient knowledge. These researchers argue instead that teaching involves knowledge of an effective way to represent the meaning of the algorithm to multiply. In this example, Ball, Hill, and Bass (2005) state what teachers must be able to do and know, but they do not make explicit the ways of thinking that enable the teacher to do or know. As a second example, Silverman and Thompson (2008) outline a framework for developing teachers' knowledge that supports conceptual teaching of a particular mathematical topic. This framework frames teachers' MKT as something that must be attained as opposed to a status of teachers' knowledge that may be advanced.

The Affordances of Attending to Teachers' MMT

Attending to teachers' mathematical meanings for teaching an idea has many affordances. Investigations into teachers' meanings enable researchers to focus their attention on the mathematical conceptions teachers have and the implications of these understandings on students' learning. In particular, focusing on teachers' MMT enables researchers to shift their focus from the behaviors that a teacher exhibits while teaching to the cognitive mechanisms, meanings, and ways of thinking that enable these behaviors. This shift in focus to teachers' meanings allows mathematics educators to explain why teachers act as they do and how we can improve their teaching (Thompson, 2013; 2016).

As one example, Thompson (2013) described his observation of a ninth-grade teacher's lesson on the point-slope and point-point formulas. In this example, the teacher can write an equation of a line through a point when provided the slope. However, when provided two points and asked to write an equation of a line through the two points, the teacher is unable to do so. Thompson's (2013) efforts to make sense of and characterize the instructor's meaning for constant rate of change led to him uncovering that the instructor's difficulty resided in her schemes for variation, slope, division, and rate of change. As one example, the instructor expressed a meaning for slope as "rise over run" where rise and run represented "two things changing in chunks" (Thompson, 2013, p. 81). With this way of thinking, the instructor could not determine the y-intercept as her "chunk" did not place her at *x=0*.

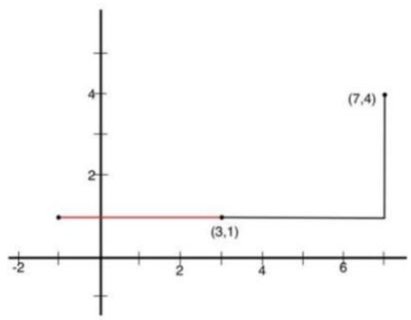

Figure 1. An example provided in Thompson (2013, p. 81)

By investigating instructors' meanings for ideas, we, as mathematics educators, are positioned to enhance our understanding of teachers' practice and develop ways to improve it.

While few mathematics educators have investigated teachers' MMT, the results of the few are alarming. Thompson and colleagues (e.g., Thompson, 2016; Byerly & Thompson, 2017; Yoon & Thompson, 2020; Thompson & Milner, 2018) have repeatedly uncovered the unproductive nature of U.S. mathematics teachers' mathematical meanings for teaching. Yoon and Thompson (2020) have also shown that U.S. teachers' meanings for foundational mathematical ideas are less productive than their South Korean counterparts. The South Korean teachers' conveyance of productive meanings implies that it is reasonable to expect U.S. teachers to be able to construct and convey mathematical meanings in this way (ibid).

One approach for improving US students' mathematical understandings is to support US teachers in advancing their mathematical meanings. Musgrave and Carlson (2017) have demonstrated that teachers' meanings for a foundational mathematical idea can become more productive if these teachers are engaged in interventions designed to support teachers' development of coherent mathematical meanings. "A focus on MMT would also foster the field's conceptualization of bridges among what teachers know (as a system of meanings), how they teach (their orientation to high-quality conversations), what they teach (meanings that an observer can reasonably imagine that students might construct, over time, from teachers' actions), and what students learn (the meanings they construct)" (Thompson, 2013, p. 82).

The Need for a New Construct

Although attention to teachers' mathematical meanings for teaching an idea is needed to support teachers' development of coherent mathematical meanings; researchers who have investigated teachers' MMT have claimed that teachers' development of strong mathematical meanings does not necessarily lead to their conveying these meanings to students (Carlson, O'Bryan, & Rocha, 2022; Rocha, 2021; Tallman & Frank, 2018; Tallman, 2021). Instead, scholars have proposed that teachers' *ways of thinking* are critical to their ability to develop, advance, and convey coherent meanings to students (Carlson, O'Bryan, & Rocha, 2022; Carlson et al., in press; Musgrave & Carlson, 2017; O'Bryan & Carlson, 2016; Rocha & Carlson, 2019; Rocha, 2022; Tallman, 2015; Tallman & Frank, 2018). As one example, these researchers have proposed that quantitative reasoning is a critical *way of thinking* that supports teachers' in (1) developing coherent mathematical meanings, (2) conveying coherent and consistent meanings to students, and (3) designing activities that create opportunities for students to engage in quantitative reasoning (ibid).

The nature of a teacher's decentering actions has also been identified as a mechanism for advancing teachers' MMT and their ability to convey coherent meanings to students while teaching (Carlson & Bas Ader, 2021; Carlson et al., in press; Rocha & Carlson, 2019; Teuscher, Moore, & Carlson, 2016). In particular, researchers have argued that decentering or setting aside one's thinking to understand what students understand (Steffe & Thompson, 2000) is useful for explaining and characterizing teachers' responses and interactions with students while teaching (Carlson & Bas Ader, 2021; Carlson et al., in press; Rocha & Carlson, 2019; Tallman & Frank, 2018; Teuscher et al., 2016). As one example, Teuscher et al. (2016) propose that a teachers' ability to decenter is related to the nature of their interactions with students and the development of their mathematical meanings for teaching. Teuscher et al's., (2016) empirical study revealed that teachers' explanations advanced to become more conceptually oriented as the instructors made their speaking and listening to others a specific object of focus and reflection. In 2019, Rocha and Carlson corroborated Teuscher et al.'s (2016) proposal by providing empirical evidence of the reflexive relationship between teachers' meanings and their decentering actions. Rocha and Carlson's' (2019) analysis of an instructor's teaching revealed that the teacher's actions to decenter advanced her MMT by providing the teacher with more refined images of a student's ways of understanding the sine function.

It is relevant then to describe mechanisms for advancing teachers' MMT in ways that support their development of ways of thinking and decentering actions that support the instructor in developing images of students' thinking about an idea and leveraging those images while teaching. Carlson et al. (in press) have classified images of teaching that include ways of thinking about students' ways of learning an idea as a *way of thinking about teaching that idea*. In the next section I illustrate the alignment of these images with an instructor's instructional goals and actions.

Ways of Thinking about Teaching an Idea

The construct *Ways of Thinking about Teaching an Idea (WTTI)* was introduced by Carlson et al. (in press). These researchers leveraged Harel's construct of *way of thinking* to describe a "habitual form of reasoning that governs the application of a variety of specific mathematical schemes" (Thompson et al., 2014, p. 12). A teacher's *Way of Thinking about Teaching an Idea* (WTTI) includes:

1. How the teacher reasons about and understands the idea (the teacher's MMT which includes the ways of thinking the teacher engages in when reasoning about the idea) (Thompson, 2016).
2. The teachers' images (second order models) of students' thinking about and learning that idea (Steffe et al., 1983; Thompson, 2000).
3. The teachers' image of ways of thinking students may engage in to develop and refine their understanding of an idea (ways of learning an idea) (Carlson et al., in press; Silverman & Thompson, 2008).

Carlson et al., (in press) claim that a teacher's WTTI becomes more connected and refined as the teacher engages with students, while attempting to model students' thinking. Repeated efforts to do so typically results in refinements of a teacher's MMT and their images of students' way of learning an idea. The construct WTTI is useful for describing the relationship between teachers' MMT, their ways of thinking about learning an idea, and their actions while teaching. Researchers have demonstrated links between a teacher's MMT and how a teacher interprets and responds to students' questions (decenter) (Carlson et al., in press; Rocha & Carlson, 2019; Tallman, 2015, 2021). Based on these claims of the symbiotic relationship between a teacher's MMT and their decentering actions (Carlson et al., in press; Rocha & Carlson, 2019; Tallman, 2015, 2021), there is a need for research to investigate teachers' decentering actions and the impact of these actions on advancing teachers' MMT and ways of thinking about learning and teaching an idea.

An Example: A Way of Thinking about Teaching Sine Function

A teacher's WTTI is a status of their current meanings and ways of thinking about teaching and learning. As such, a teacher's WTTI can be more or less productive for teaching. Below I present an example of a precalculus teacher's current ways of thinking about teaching sine function. The data presented comes from a clinical interview with an instructor, Uri, who (1) was in his second semester of teaching pre-calculus using a research-based curriculum, and (2) regularly attended a weekly professional development seminar designed to support instructors in engaging in conceptually oriented teaching (Thompson & Thompson, 1996).

During the clinical interview, Uri was asked to describe how he wants students to reason about what the values in the table below (see Figure 2) represent. Uri responded by stating that he wanted students to understand that "sine is a function that relates an angle measure with the height [of the terminal point] above the horizontal diameter". Uri further conveyed that he wanted students to view the value of $\sin(\theta)$ as a means of representing the terminal point's height measured in units of the circle's radius. For example (see Figure 2), when prompted to explain the meaning of the point (337° , -0.391) Uri expressed that "the table of values is a snapshot, like if we were to pause an animation, at these instances in angle measure, then this [-0.391] would be the corresponding height above the vertical diameter in radius lengths."

As Uri described the meanings for $\sin(\theta)$ he wanted students to develop, he also conveyed that he wanted students to view sine as representing how the terminal point's height above the horizontal diameter varies with the measure of an angle. When Uri was asked if his prior teaching of sine function has informed his preparation for teaching the same topic during the current semester, Uri conveyed that his previous students' conception of the value of sine as a multiplicative comparison between the terminal point's vertical distance and the circle's radius supported his students' later learning of right triangle trigonometry. In particular, Uri expressed that his former students’ conception of the output of the sine function as a multiplicative comparison of two quantities’ values supported them in recognizing where the commonly applied trig ratios (SOHCAHTOA) come from.

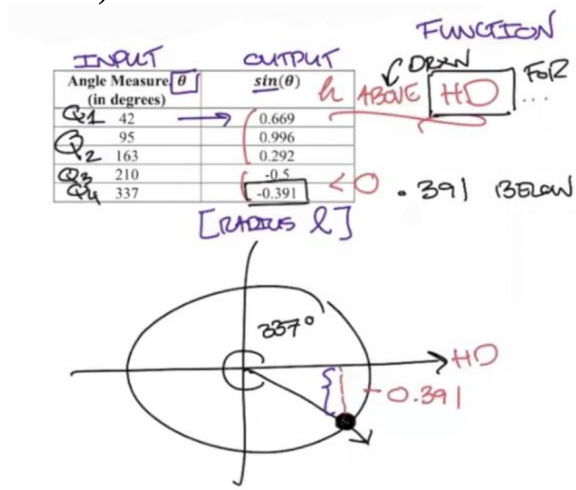

Figure 2. Uri’s Description of Sine Function

Uri’s description of the meanings he hopes to support students in developing for sine function provides a window into Uri’s way of thinking about teaching sine function. In this example, Uri expressed (1) a meaning for sine function that he intended to support students in developing, (2) ways of thinking (quantitative and covariational reasoning) that he anticipated would support students’ development of this understanding, and (3) images of student thinking and ways of learning that appeared to influence his instructional goals and actions.

Discussion and Conclusion

In the past thirty years, researchers have used the constructs Mathematical Knowledge for Teaching and Mathematical Meanings for Teaching to describe teachers’ knowledge base while teaching. While research on teachers’ knowledge base is vast, scholars’ use of these constructs varies greatly. The constructs MKT and MMT differ in the nature of the phenomena they describe. Researchers have used the construct MKT to describe a knowledge base as a target for teachers to achieve. In contrast, the construct MMT has been used to describe the current state of teachers’ mathematical understandings relative to teaching. While many researchers have advocated for more attention to teachers’ MMT, a sole focus on advancing teachers’ MMT is insufficient for explaining a teachers’ instructional planning and actions. Instead, a focus on a teacher’s *ways of thinking about teaching an idea* (that includes teachers’ MMT) may provide a more powerful lens for studying a teacher’s instructional goals and teaching of a specific idea. This report provides an example of how a teacher’s *ways of thinking about teaching* the idea of sine function are related to his instructional goals and actions. In particular, this report highlights the critical role a teacher’s mathematical meanings for teaching sine function and ways of thinking about learning and teaching sine function have in the instructor’s planning for teaching. The example provided in this report provides empirical support for Carlson et al.(in press) call for the design of professional development seminars focused on developing and advancing teachers’ WTTI. Seminars with this focus may support instructors’ enactment of teaching practices that focus on understanding and advancing student thinking and learning. As such, further exploration of the role of teachers’ WTTI on their enacted teaching actions and mechanisms for developing and advancing teachers’ WTTI are needed.

Explicating the Role of Abstraction During Analogical Concept Creation

Michael D. Hicks
Virginia Tech

Kyle Flanagan
Virginia Tech

Matt F. Park
Virginia Tech

Recent research has explored the potential for students to create new mathematical concepts by analogy with previously known concepts. However, there is more to be understood about the intricate processes of analogical reasoning that students leverage when creating new concepts. In this paper, we describe an initial theory explicating the role of abstraction during analogical concept creation. First, we introduce the abstracted domain to operationalize abstraction during analogical reasoning. We then describe two mechanisms of analogical concept creation through which abstraction may occur while reasoning about a ring-theoretic analogue to subgroups: (1) comparative analogy, and (2) inductive analogy. To broaden the interpretive scope of the theory, we further apply the mechanisms to scenarios involving meta-analogical reasoning and pedagogy. Implications for research and teaching mathematics with analogy are discussed.

Keywords: Abstract algebra, Abstraction, Analogical reasoning,

Analogical reasoning typically involves the comparison of two previously given or known concepts in search of relational similarity between the two (Gentner, 1983; Holyoak & Thagard, 1989). This forms the basis for many pedagogical analogies that are used in mathematics courses (Greer & Harel, 1998). For example, the concept of projection of a vector onto a general subspace is often presented with analogous references to spatial examples of a geometric vector projected onto a two-dimensional Euclidean plane, the goal being to ground students' knowledge of the abstract concept within a more accessible one.

While pedagogical analogies are often leveraged as a tool for reinforcing previously introduced concepts rather than creating new ones (e.g., Cobb, Yackel, & Wood, 1992), recent research has explored the potential for students to create new mathematical concepts, thereby expanding the scope of productive pedagogical analogies in undergraduate mathematics classrooms to allow for students to establish new mathematics for themselves. For example, it has been shown that students can explore, define, and create new concepts in ring theory by analogy with known concepts in group theory rather than simply reinforce their previous understandings (e.g., Hejný, 2002; Hicks, 2022; Stehlíková & Jirotková, 2002). This expanded view of pedagogical analogies in mathematics broadens the horizons for what pedagogical analogies can accomplish in advanced mathematics classrooms. However, to promote more productive pedagogical analogies in advanced mathematics, we must first better understand the intricate processes of analogical reasoning that students leverage when creating brand new (to them) concepts by analogy.

One avenue for deepening our understanding of analogical concept creation is to explore the role of abstraction within the process of analogical reasoning. Prior research in mathematics education has touched on the presence of abstraction in analogical reasoning (e.g., English & Sharry, 1996), although this research has not focused as heavily on cases in which students are generating new concepts or defining structures through analogy, focusing instead on developing conjectures to be verified (e.g., Lee & Sriraman, 2011). As such, the focus of this report is to develop an initial theory for explicating the role of abstraction during analogical concept creation. We are guided by the following overarching question: What is the role of abstraction during analogical concept creation?

Theoretical Underpinnings

The typical framework of analogical reasoning strives to capture very specific or 'perfect' representations of analogy rather than interpret potentially imperfect reasoning. In contrast, our proposed theory builds off the Analogical Reasoning in Mathematics (ARM) framework (Hicks, 2020) to interpret analogical activity that is specific to mathematics and may not align with usual or perfect cases of analogical reasoning. Analogies are viewed as series of mappings between a (typically) known source domain and a (typically) unknown target domain (Gentner, 1983), while analogical reasoning is the search for underlying structural relation between domains. A key component of the ARM framework is the adoption of the Actor-Oriented (AO) perspective (Lobato, 2012) to interpret analogical reasoning which allows for non-standard and idiosyncratic cases of analogical reasoning. During novel concept creation by analogy, immediate analogies are often impractical and instead require effort to refine the analogy. Thus, we draw upon the notion of *progressive alignment* (Gentner & Hoyos, 2017) to describe the process of developing an analogy through multiple analogical inquiries. In other words, we allow for the possibility for analogies to be incomplete at a given moment in time and consider them to be 'under construction' during analogical reasoning. Finally, for the purposes of this paper, we adopt Mason's (1989) notion of mathematical abstraction as a "delicate shift of attention" (p. 2), as well as acknowledging mathematical abstraction as a process closely linked to relational property recognition (e.g., Dreyfus, 1991; Ohlsson & Lehtinen, 1997; Piaget, 1985; Skemp, 1987). More specifically, Dienes (1967) indicated that "the essence of abstraction is to draw out common properties from different types of situations" (p. 201).

Developing the Theory: An Example of Student Thinking

To assist with presenting our proposed model of abstraction through analogical reasoning, we interlace the description of the general model with an example of analogical concept creation in abstract algebra. This particular example is based off of previously collected data of students' analogical reasoning in which the goal was to develop a ring-theoretic analogy to subgroups. Hence, the source concept is the subgroup concept, while the target concept is an analogous concept for rings.

To operationalize abstraction during analogical reasoning, we introduce the concept of the *abstracted domain*. We define the abstracted domain to be the domain to which the desired abstracted characteristics are mapped. Thus, the abstracted domain acts as a 'shell' of a concept or structure and forms the basis for future potential analogies. Figure 1 displays a possible abstracted domain for subgroups and subrings in which the notion of a 'sub-structure' would behave as a shell for future analogous concepts (such as subspaces of topological spaces.) The abstracted domain may vary in scope depending on the original concepts and domains being investigated.

The abstracted domain may not exist in every case of analogical reasoning. For example, a student may engage in a pure analogical comparison of two entities and construct a new concept without ever abstracting from the original structure by attending solely to surface level or superficial features. Instead, we claim that the abstracted domain exists only when abstraction activity arises during analogical reasoning. In alignment with ARM, we accept that the abstracted domain may be vague during its creation and may never be fully realized. Through progressive alignment, the abstracted domain may be refined over time as further inquiries are made. Our initial theory proposes two mechanisms through which the abstracted domain is developed: (1) comparative analogy and (2) inductive analogy.

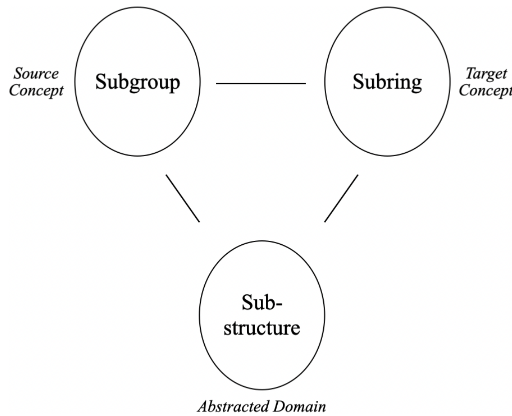

Figure 1. A possible abstracted domain associated with subgroup/subring.

Comparative Analogy

The first mechanism for developing the abstracted domain is *comparative analogy*. This process begins with a typical approach to analogical reasoning in which an analogy is either formed (or in the middle of being constructed) between the source and target domain. To illustrate this mechanism, we leverage an example of one student who had constructed an analogy to subgroups in the context of rings by directly mapping the subgroup structure and then making modifications to fit the ring context. After exploring the ring-theoretic analogy to subgroups, the student began to inspect his resulting analogy and reflect upon what he considered to be the key aspects of the two concepts of subgroup and the newly created concept of subring. During his reflection, some evidence of an abstracted concept appeared. In the following quote, the student is making observations about the subset similarity:

Student: My idea is just a set and a subset. Like that, it lives inside of it.
Interviewer: So you have this set and a subset idea? And that also carried over to this kind of context?
Student: Yeah, so we would say this would imply S is, maybe let me draw a little ring [draws subset symbol with a small "o" over it]. Like, subring.

Thus, after having developed the concept of 'subring' and directly comparing to subgroups, this student began to recognize a broader concept of a 'set and a subset' that 'lives inside of it' that could potentially describe a larger class of analogous structures. The left figure within Figure 2 displays the process of comparative analogy in the context of comparing the subgroup concept and the new subring concept to establish the abstract concept of 'sub-structure'. The box in Figure 2 indicates that it was the analogy between the source and target that produced the abstracted domain.

Inductive Analogy

While comparative analogy requires a comparison of two concepts to create the abstracted domain, our second mechanism involves the development of the abstracted domain before the target concept is established. We refer to this second mechanism as *inductive analogy*. In contrast to comparative analogy, inductive analogy may occur with only one known concept to begin with (e.g., subgroup), as well as a possible awareness of other contexts (e.g., the subject of ring theory.) Knowledge of the original concept is then leveraged to develop the abstracted domain. A target concept is then created by making inferences about how the abstracted domain may be mapped onto the target. Consider the following quote by another student who was in the process of creating the subring concept by analogy:

> Yeah, well that's pretty much the definition for groups, if we have some group G and some operation *. Then if H is a subset of G and H is a group under that same operation, then we say H is a subgroup of G. **So, I literally just took the exact same thing from group theory and applied it to rings**.

We view the last sentence as partial evidence that this student had identified the abstracted concept of a sub-structure based on the subgroup concept.[1] Afterward, the new sub-structure concept is then mapped to the context of rings to form what the student eventually described as a 'subring'. The visual on the right of Figure 2 displays the mechanism of inductive analogy wherein the source concept of subgroup is leveraged to create the concept of 'sub-structure' before subring. We note that it is possible that multiple source domains are leveraged as the 'base case' for the abstracted domain. In those cases, progressive alignment may occur through multiple instances of comparative analogy preceding the induction and the creation of the new target structure.

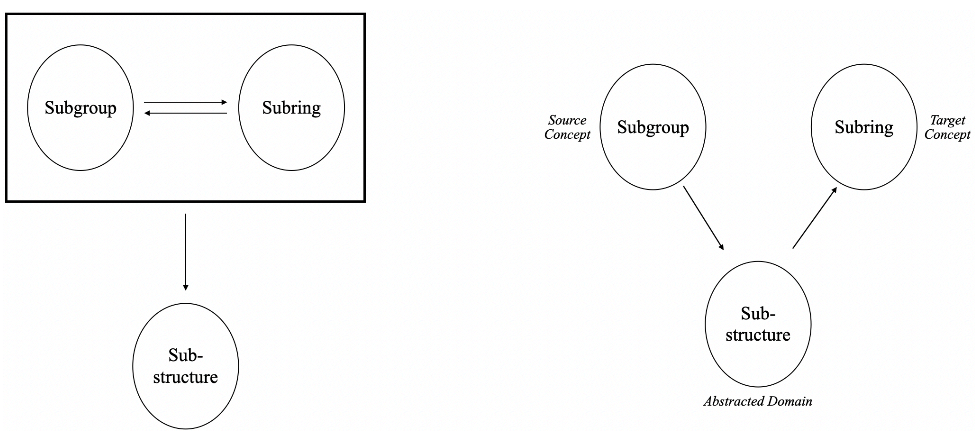

Figure 2. The mechanisms of comparative analogy (left) and inductive analogy (right).

In this section, we have introduced the mechanisms of comparative and inductive analogy to describe ways through which abstraction may occur during analogical concept creation. In the section that follows, we broaden the scope of this initial theory and apply it outside of the context of interpreting students' analogical reasoning between two structures in abstract algebra by looking more deeply at how this theory might inform purposeful analogical concept creation, and how this theory might be applied to pedagogy.

Further Applications of the Theory

Identifying Strategies for Purposeful Analogical Reasoning

In the absence of prior opportunities to reason by analogy in advanced mathematics, the students in the above examples may have been reasoning by analogy about advanced

[1] We choose this example to clearly display reasoning with one domain rather than comparing across two domains. However, we recognize that the student may have been carrying the subgroup concept itself into the ring context without having created the abstracted sub-structure concept.

mathematics in a manner that was brand new to them. Overtime, learners may develop *meta-analogical awareness* (Modestou & Gagatsis, 2010) and, by extension, learn to purposefully and strategically reason by analogy. In particular, the increased awareness of one's own analogical reasoning can widen the range of strategies for analogical concept creation. For example, purposeful reasoning by analogy is a known strategy used by research mathematicians when defining new concepts (Ouvrier-Buffet, 2015). In this section, we describe how the mechanisms of comparative and inductive analogy clarify what one case of purposeful reasoning might entail when defining a new concept. To show this, we describe a hypothetical example of a student purposefully defining topological subspaces by analogy with several known algebraic concepts.

Consider a student who possesses an understanding of several algebraic structures and has recently learned of the definition of a topological space (i.e., a set X along with a collection of subsets containing X, the empty set, and is closed under arbitrary union and finite intersection.) Their experience in algebra suggests that given any particular algebraic structure, one can construct an additional one. Thus, upon becoming aware of the context of topology, an inductive analogy can be invoked to begin considering the meaning of a topological subspace. First, the student understands that subgroup, subring, subalgebra, or algebraic sub-structures in general are modeled by taking a subset of the collection of elements with respect to the structure in some way (i.e., the subset must be closed under the algebraic operation(s) of the over-structure.) In this way, the student may have already created an abstracted domain relevant to algebraic sub-structures. The student may then inductively analogize the notions of both 'subset' and 'respect the structure' from algebra within topology to establish the concept of a topological subspace. For this mathematically experienced student, it may be straightforward to argue that because an algebraic substructure is modeled with subsets, a topological substructure should be modeled by subsets as well. However, the student can also begin investigating what it means for a substructure to 'respect the structure' in the context of topology. In this way, purposeful inductive reasoning has provided an opportunity for rich exploration for this student to begin thinking about how a topological subspace may be defined.

After having established some notion of topological subspace (whether it is complete or not from the student's perspective), suppose now that the student encounters the definition of a topological subspace in a textbook or in a class lecture. The student may now reason by comparative analogy while also being informed by the findings from the prior inductive analogical reasoning. As an algebraic structure is a set along with various operations and a topological space is a set along with a collection of open subsets, the student may try to draw an analogy between operations and collection of open subsets. While the subset analogy was perhaps trivial, the student may not be immediately sure of the analogy of the restriction of the operations within a topological space. The modeling of topological spaces purely in the language of sets may motivate them to understand n-ary algebraic operations as sets as well. Particularly, an n-ary operation could be modeled as a subset of the $(n+1)$-fold cartesian product of the underlying set, and the restriction to a substructure can be realized by considering the restriction to the substructure to be the sequences that only contain its elements. Thus, they are drawing a comparative analogy between a subset of the cartesian product of a set with itself and a subset of the power set of a given set. In negotiating a satisfactory definition of a topological subspace, they are drawing on comparing different kinds of sets: they are attempting to understand the notion of topological subspaces by drawing comparisons between the cartesian product of set and the power set construction.

Applications to Pedagogy

Students may engage in analogical reasoning in any classroom setting. While the prior examples linked our proposed theory to interpreting student thinking and analogical reasoning, our final example links our proposed theory to teaching and curriculum design. In particular, we assert that increased attention to comparative or inductive analogy can assist teachers with identifying affordances or obstacles to promoting analogies in specific ways as well as consider the timing for productively introducing an analogy. In this section, we consider an example in undergraduate linear algebra. An important analogy that helps link many of the concepts in this course is the three-way analogy between systems of linear equations, matrices (or matrix-vector equations), and linear transformations (Larson & Zandieh, 2013). Every system of n linear equations in m variables can be represented with a matrix-vector product using an $n \times m$ coefficient matrix (or an $n \times (m+1)$ augmented matrix), and vice versa. Similarly, every linear transformation $T\colon \boldsymbol{R}^m \to \boldsymbol{R}^n$ has a standard $n \times m$ matrix representation, and vice versa. This ability to transform between systems of equations, transformations, and matrices leads to many analogous theorems and properties in linear algebra, including the infamous Fundamental Theorem of Invertible Matrices.

One concept that is closely tied to this analogy is matrix multiplication, as matrix multiplication corresponds to compositions of linear transformations. Cook et al. (2018) conducted a textbook analysis on 24 introductory linear algebra textbooks, analyzing how matrix multiplication was presented in each text. They identified three overarching sequences for when and how matrix multiplication was introduced, and characterized these sequence rationales utilizing Harel's (1987) classification of linear algebra content sequencing. Pedagogically, the choice of which of these sequences is used for course design influences what analogical reasoning students engage in during class. Students' potential analogical reasoning in two of these sequences is provided. It is important to emphasize that neither sequence is considered better, but rather these examples demonstrate that pedagogical choice can influence students' analogical reasoning, and this framework provides a way to understand that reasoning.

Many of the common undergraduate linear algebra textbooks for large universities begin by introducing systems of linear equations and immediately transition into basic matrix operations, such as (typically in this order) addition, scalar multiplication, and multiplication (e.g., Larson, 2016; Poole, 2014). Textbooks with this structure often fall into the sequence where matrix multiplication is first defined using the matrix-matrix product AB determined by the dot products of row and column vectors, and the justification for the definition's rationale is postponed until much later in the course. Under this course design, after students have been provided with the definitions for matrix addition and scalar multiplication, it is possible that students may engage in inductive analogical reasoning, where these definitions induce the creation of an abstracted domain encompassing matrix operations as component-wise operations. Though this would lead to the 'incorrect' definition, it should be noted that this is reasonable analogical reasoning; hence, it should not be surprising that students are perplexed when the actual definition is presented.

Another common sequence for matrix multiplication includes first defining matrix multiplication with the matrix-vector product Ax as a linear combination of column vectors, which follows an introduction to systems of linear equations and linear transformations (e.g., Lay et al., 2015). Since the three-way analogy has already been introduced to the students, when some students see the full definition of the matrix-matrix product AB, they might construct a comparative analogy using any two (or all three) of those domains. In particular, some students may construct or refine an abstracted domain about 'how vectors are transformed.' In addition, prior to seeing this full matrix-matrix product definition, some students might engage in inductive analogy, hypothesizing what the actual definition is, being informed by the matrix-vector product definition. However, it is entirely possible that students will not engage in either of these forms of analogical reasoning.

Implications for Theory and Future Research

In this paper, we set out to describe an initial theory intended to explicate the role of abstraction during the process of analogical concept creation. To this end, we described two mechanisms through which abstraction may occur and illustrated several scenarios in which these mechanisms assist with interpreting or predicting possibilities of students' thinking. These mechanisms contribute to the literature on analogical reasoning in mathematics education, especially with respect to analogical concept creation. In particular, we greatly expanded the scope of possible scenarios presented by English and Sharry (1996) and Lee and Sriraman (2011) by both operationalizing and clarifying what abstraction during analogical reasoning might look like.

In addition to the examples presented in this paper, this theory can be applied to various other contexts, demonstrating even further potentially far-reaching implications. For instance, one can frame both problem-solving strategies (Weber & Leikin, 2016) and problem-solving analogies (English, 2004) in this theory. When an individual has solved two different problems with an analogous problem-solving strategy, there is a possibility that this individual will retroactively engage in comparative analogy, constructing an abstracted domain containing a 'problem-solving heuristic or strategy.' Moreover, an individual may also be in the process of solving a problem and is looking for ways to complete the problem. In this scenario, the individual could engage in inductive analogy, by reflecting on how a previous problem-solving technique could apply to the current problem, and constructing an abstracted domain for the general problem-solving strategy. This can also apply to proof-writing and proof-constructing strategies (e.g., Zazkis, Weber & Mejía-Ramos, 2015). Furthermore, researchers have demonstrated the value of example-based reasoning in mathematics (e.g., Lockwood et al., 2016; Lynch & Lockwood, 2019). It is possible that two or more examples give rise to comparative analogy, where the abstracted domain is an analogous property, concept, or new mathematical definition. Additionally, after an individual has meaningfully engaged with one example, and is about to engage with a subsequent example, this person may engage in inductive analogy. Prior to working out the details, the individual may construct an abstracted domain containing certain potentially relevant properties, which help the individual to predict how the example may work.

Though this paper has outlined the central components of this theory about the role of abstraction in analogical concept creation, and demonstrated its implications to various facets of mathematics education research, we have several future goals for expanding on and refining the theory. First of all, two mechanisms for this theory were introduced, comparative and inductive analogy; however, we acknowledge that these mechanisms do not always function entirely separate from one another. The example of the algebraically mature student engaging with topology explicates how one might engage in inductive analogy and then comparative analogy, and we would like to further delineate how these mechanisms interact. Second, we would like to more specifically explore how this theory is connected to theories of abstraction. In particular, we recognize that the construction of an abstracted domain aligns closely with Piaget's reflective abstraction (Beth & Piaget, 1966; Piaget, 1977, 2001). To what extent these two mechanisms entail reflecting and reflected abstractions versus empirical or pseudo-empirical abstractions is worth further exploration.

Proving as cooperative communication: Using Grice's maxims and implicature to understand proof comprehension in undergraduate mathematics education

Keith Weber
Rutgers University

Paul Dawkins
Texas State University

Elise Lockwood
Oregon State University

In this exploratory theoretical analysis, we apply Grice's maxims for cooperative communication to make sense of the ways that proofs are written and understood. We argue that proving can sometimes be productively viewed as a form of cooperative communication. Grice's maxims place expectations on the prover and provide norms for how proofs should be written. The reader's expectation that the prover is adhering to these norms allow for the possibility of implicature—that is, the prover can imply statements to the reader that are neither explicitly said nor logically necessary. We use this analysis to better understand the practice of proving and to suggest a future line of empirical research.

Keywords: Linguistics; Grice's Maxims; Proof; Proof Comprehension

A central goal of research in undergraduate mathematics education is to design instruction to enculturate students into the process of proving. We would like students to use proof for the same reasons that mathematicians do (e.g., deVilliers, 1990) and to understand and learn from the proofs that they read (e.g., Conradie & Firth, 2000; Mejía-Ramos et al., 2012). Unfortunately, these goals are often not achieved in undergraduates' advanced mathematics courses, with many students emerging from these courses unable to read or write proofs successfully and, more generally, lacking a sense of what proof is about (e.g., Stylianides et al., 2017).

There has been substantial research into helping students understand what type of reasoning is permissible in a proof. For instance, there has been work into helping students realize that inferences must be based on deductive, rather than empirical, argumentation (e.g., Brown, 2014), to learn new proving techniques such as proof by induction (e.g., Harel, 2001), and about the nature of modus ponens reasoning (e.g., Dawkins & Norton, 2022). This research is important and has substantially increased our understanding of pedagogical issues related to proof. However, we argue that this work alone is not sufficient to enculturate students into the practice of proving. Knowing what types of reasoning is allowable in a proof underdetermines how proofs should be written and read. There are permissible moves in a proof that are almost never carried out in mathematical practice (e.g., introducing variables or making explicit assumptions that are never used again in the proof). There are formal violations of logic and syntax that frequently appear in proofs (e.g., abuses of notation). There are norms of proof writing that are independent of logic (e.g., not using the first-person pronoun "I" and not including information about the wrong turns made in the proving process). Some mathematicians have complained that their students are "tone deaf" with respect to proof and do not have a feel for the game (Weber, 2012). Elsewhere, we have speculated that part of enculturating students into proof is helping them learn the linguistic norms of proving along with the values that they uphold (Dawkins & Weber, 2017). These kinds of rules of the game that are not captured by the grammar or direct meaning of proof might be appropriately categorized as part of the pragmatics of proving. Pragmatics refers to the use and contexts of use. This is an understudied arena of proving practice, which might reflect how proving is often understood as decontextualized and depersonalized (Balacheff, 1988). We argue that proofs still communicate through shared rules.

The goal of this theoretical report is to use Grice's maxims for cooperative communication to better understand how proofs are written and read in mathematical practice (Grice, 1975, 1989). We first document that in mathematics education, proof is often treated as an adversarial form of communication. We argue that it would behoove mathematics educators to also view proof as a form of cooperative communication. Next, we review Grice's maxims for cooperative communication. Critical to this paper is Grice's notion of implicature: when we assume that a speaker is communicating cooperatively with us, we can infer many things that the speaker did not explicitly state. Then we explore the consequences of applying Grice's maxims to proof in mathematical practice and undergraduate mathematics classrooms, showing how proofs invite or even expect implicatures. There are ideas that one can from a proof that are neither explicitly stated nor logically necessary. Finally, we suggest a line of empirical research based on our theoretical explorations.

Proof as a cooperative form of communication

Proof as an adversarial form of communication in mathematics education research

Frequently, proof is framed as a semi-adversarial form of communication: the prover is trying to persuade a skeptic to accept a claim that the skeptic doubts and the skeptic will not (and should not) be swayed easily. Mason (1982) described proving as convincing an enemy and Volminik (1990) defined a proof as an argument that would convince a reasonable skeptic. More recently, Dutilh Novaes (2020) wrote that "a good proof is one that convince a fair but 'tough' opponent" (p. 50). When students are reading proofs, they are encouraged to take a skeptical stance, with Brown (2014) arguing that the capacity to retain doubt is critical to understanding proof. Similarly, Inglis (2022) argued that developing one's inner skeptic when considering proofs may be a critical part to becoming a mature mathematician.

Inglis (2022) referred to the dialog between a prover and their skeptical audience as "semi-adversarial" because neither the skeptic nor the prover engages in a "win-at-all-costs" strategy. A reasonable skeptic must grant sensible premises and not repeatedly ask for supporting evidence in bad faith. A reasonable prover should not use rhetoric to mislead the skeptic. Both the prover and the skeptic share the communal goal for identifying the flaw in a proof, should one exist, or otherwise verifying that the proof is airtight (Dutilh Novaes, 2020). Nonetheless, to achieve these shared aims, the reader is asked to take an adversarial role, only granting inferences if it is epistemologically necessary to do so. In short, according to the adversarial account of proving the audience of the proof of a theorem acts as a gatekeeper who checks that the proof passes a high standard of muster, lest a false theorem enter into their collection of mathematical facts (or, in the case of a referee, in the mathematical community's accepted statements).

Proof as cooperative communication

Mathematicians do not always view other mathematicians' proofs adversarially, or even with skepticism. Indeed, when mathematicians read proofs in the published literature, they often do not check proofs for correctness; they presume the proofs are correct (Mejía-Ramos & Weber, 2014; Weber & Mejía-Ramos, 2011). As one mathematician described things, "when I was reading a proof in a journal or a proof that was handed to me by a mathematician friend and they were pretty sure it was true, my assumption would be that the steps are probably correct and that I need to work hard to make sure I understand and can justify each step" (Weber, 2008, p. 448). The point here is that while proofs in the literature and proofs from trusted peers can contain mistakes, mathematicians often do not read the proof scouring for errors. They do not assume unclear statements in a proof are wrong, but rather work to justify these steps. We believe students are in a similar position when they read proofs in a textbook or hear proofs in a lecture.

Grice (1975, 1989) characterized communication as cooperative if the interlocutors are working together to actively achieve a particular goal. Proving can sometimes best be understood as a collaborative communication in which the prover is trying to help their audience see how their theorem can be reached from shared premises by a series of deductive inferences that their audience accepts as clear, indubitable, and not admitting exceptions. Of course, proofs in textbooks and in journals often contain inferences that are neither clear nor obvious. Hamami (2021) explained the situation as follows: The prover hands her audience a proof P. Some steps in P will not be clear to a reader. To address this, a reader will expand P to a longer proof P^*, such that each step in the proof is either an accepted statement or an immediate consequence of a known rule of inference. An accepted statement might be a definition, a result that is established elsewhere in the literature, or a statement that the reader had personally proven in the past. A known rule of inference might be an axiom or the application of a previously proven theorem.

As a brief clarification, while mathematicians sometimes seek out a proof as an end in itself (c.f., Paseau, 2011), they frequently use proof as a means to achieve other epistemic goals (deVilliers, 1990). Possessing the expanded P^* consisting of a series of indubitable inferences can help achieve epistemic aims of proof such as conviction and explanation highlighted by de Villiers (1990) and others (e.g., Hanna, 1990). For instance, if a mathematician harbored significant doubts about the truth of an assertion, seeing how the statement could be reached by a series of indubitable inferences could increase their confidence that the statement was true.

Grice's maxims and implicature

Grice's maxims

When interlocutors are engaged in a cooperative conversation, they are trying to achieve a shared goal. When a speaker offers a contribution to a cooperative conversation, Grice (1975, 1989) argued that the speaker is expected to follow the Cooperative Principle and make contributions that will efficiently facilitate the achievement of these goals. Grice offered four conversational maxims specifying how contributions should be made: The maxim of quality (be truthful); the maxim of quantity (offer the right amount of information); the maxim of relation (be relevant); and the maxim of manner (be clear). These maxims can be regarded as norms or obligations that constrain what contributions a speaker can make in a conversation (in the sense of Herbst et al., 2011 and Yackel & Cobb, 1996). When we apply these maxims of proof, these will yield norms about how proofs should be written (in the sense of Dawkins & Weber, 2017).

Implicature

In a cooperative conversation, a listener presumes that a speaker is following the Cooperative Principle in general and Grice's maxims in particular. Grice's (1975) key insight was that this enables the listener to make inferences that are neither explicitly stated nor deductively implied by the speaker's utterances. To illustrate, consider the following conversational exchange:

Man (speaking to a passerby on the road): My car has run out of gas.

Passerby: There is a gas station around the corner.

The explicit contribution from the passerby is the location of a gas station. Grice (1975) argued that the passerby is also making an implicit contribution, namely that (the passerby believes) the gas station is open. The reason this implication is possible is because the man assumes that the passerby is following the Maxim of Relation (and the passerby assumes this). The man and the passerby are working toward the shared goal of helping the man resolve his problem of finding fuel for his car. If the gas station around the corner were closed, the existence of the gas station would not be useful for achieving this goal. Therefore, by stating the location of the gas station, the passerby is implying that this is open. Grice (1975) referred to *implicature* as the act of making this type of implication and *implicatum* as what is being implied. As we view the situation with proof, Grice's maxims place norms upon the prover. The recipient of the proof makes the presumption that the prover is following Grice's maxims, which allows for the recipient to infer ideas that were neither explicitly stated nor logically necessary consequences of what appears in the proof. These ideas are implicatum. The shared assumption of cooperative communication allows the prover to convey implicata without explicitly stating them.

Grice's Maxims, Norms, and Implicature and proof

In this section, we present norms and their associated implicatures for proof presentation for each of Grice's Maxims. In our presentation, we will discuss norms that the maxims impose on the prover and the implicata that a reader may gain.

The Maxim of Relation

The Maxim of Relation asserts that contributions to a conversation should be relevant to the goals of the conversation. Any contribution in a proof P should be relevant to obtaining a chain of indubitable inferences that lead to the conclusion.

> *Norm of proof writing:* Any assumption, deduction, or variable introduced in a proof should be useful in the final chain of argumentation establishing the theorem.
> *Associated implicatum:* If a statement or variable appears in a proof, the reader can expect that it will be built upon at a later stage in the proof.

In other words, proofs do not contain digressions. The prover should not include "logical dead-ends" in a proof and the reader can expect that none will be included. Strictly speaking, from a formalist perspective, adding unused assumptions and including extraneous true statements or valid deductions in a proof does not render it invalid. Nonetheless, this is rarely done. One consequence is that when the prover makes an assumption in the proof, the prover is implying that this assumption will be useful for establishing the theorem. One consequence of the implicatum is that one can understand a proof by seeing why assumptions are necessary or how statements are built upon (e.g., Mejía-Ramos et al., 2012). This consequence only follows based on the expectation that the prover is following the norm above.

The Maxim of Quantity

Grice (1975) summarized the Maxim of Quantity by saying, "make your contribution as informative as required (for the exchange) [and] do not make your contribution more informative than is required" (p. 45). Applying this notion to proof, the prover is aiming to give the reader sufficient information in the proof P so the reader can produce an expanded chain of indubitable inferences P^*, but no more. This suggests some interesting norms and implicata.

> *Norm of proof-writing:* In a conditional statement, "If A, then B" or "Since A, then B", the truth-value of B is tracked by the proof value of A.

Associated implicatum: If "Since A, then B" appears in a proof, there is a general principle for how the truth of A necessitates the truth of B.

Grice (1989) discussed the nature of conditionals more generally. Suppose one asserts, "If John walks to the party, he will be late." Technically speaking, this statement would be true if the speaker knew that John would be late regardless of how he reached the party. However, making such as assertion would be violating the Maxim of Quantity, as the simpler statement "John will be late" would be simpler and more informative. Similarly, if the speaker knew that John would be driving to the party, the statement would be (vacuously) true, but making the assertion would be violating the Maxim of Relation, as John's timing if he were walking would not be relevant in this situation. Hence, when the speaker asserts that "If John walks to the party, he will be late," the implicature is that the speaker is certain neither of how John is getting to the party or whether John will be late, but the speaker believes that the truth of the antecedent implies the proof of the conclusion.

A similar analysis follows from statements such as "if A, then B" or "since A, then B" in a proof. A prover should not proffer such a statement if B could easily be seen in the absence of A, since it would be simpler and more informative to simply state B. Further, to understand the proof, the reader should try to find a chain of reasoning from A to B. There is evidence that this phenomenon is borne out in practice. Some mathematicians will reject statements like "if 13 is prime, then 1013 is prime" in proofs even though they are true because they are not informative. Some will infer that there is a relationship between 13 being prime and 1013 being prime (such as adding 1,000 to a prime number will yield a prime number) and reject the statement not because it is explicitly false, but because the implied warrant is invalid (c.f., Weber & Alcock, 2005). There is further empirical support for this statement. In pedagogical setting, mathematicians do not think it is appropriate to make a statement of the form "If A, B, and C, then D" unless A, B, and C are all relevant to the truth value of D (e.g., Lai et al., 2012). Presumably, this is because, if C was unnecessary, it would be simpler and more informative to state "If A and B, then D."

Norm of proof-writing: The prover will provide enough information in *P* for the reader to expand without extraordinary effort.

Associated implicata: New steps in the proof may require justification, but the justification should not be based on sophisticated ideas outside the proof or be exceptionally difficult.

Recall the passerby who told the stranded motorist that there was a gas station around the corner. The passerby probably would not instruct the man where to look for the gas station after he turned the corner if gas station was clearly visible. The passerby would only provide this information if the location of the gas station was not obvious (e.g., if it were behind a strip mall) and would not be found by a routine search of the area. Similarly, justifications for statements within a proof are only provided if the reader could not find them through ordinary effort. What is interesting here is that the implicature is based on what the passerby did *not* say. If the location of the gas station would not be obvious to the stranded motorist, the Maxim of Quantity would dictate that more direction would be provided. Since the passerby did not provide that information, the location of the gas station should be clear when the motorist walked to it.

There are a few remarks worth noting. First, the ability for the reader to justify steps within a proof *P* is clearly audience dependent, so how a prover follows this norm depends on the audience. A proof appropriate for a professional number theorist would not be appropriate for a student in a transition-to-proof course, and vice versa. Second, what the readers are capable of doing "without extraordinary effort" is a nebulous concept. At least in pedagogical settings, mathematicians seem to disagree on how much detail a proof should provide (Lai et al., 2012). Research has revealed that students do not appreciate that it is their responsibility to justify some of the steps in a proof (e.g., Weber & Mejía-Ramos, 2014). Nonetheless, when a prover chooses *not* to provide detail for how a particular step can be established, the prover is conveying information about the existence of a type of justification for the step—namely it is a justification that can be formed routinely without extraordinary effort.

In addition to the knowledge of the intended audience, we expect that the application of this maxim is also sensitive to the intended purpose within the proving context. If the proving context is focused on developing an axiomatic system or proving the properties of an axiom system, the prover may adhere to stricter rules regarding what the reader should have to expand on their own. This again portrays how the context of proving influences the rules at play in the cooperation between the prover and reader.

The Maxim of Manner

The Maxim of Manner asserts that speakers try to say things as clearly and orderly as possible. Suppose that you are asked to prove a statement of the form "A if and only if B". Suppose you have a subproof that A implies B, say $A \to A_1 \to B$, and you have a subproof that B implies A, say $B \to B_1 \to A$. You could, in principle, write a logically valid proof as follows.

1. Assume A
2. Assume B
3. Since A, A_1
4. Since B, B_1.
5. By (3), B
6. By (5), A
7. Since $A \to B$ and $B \to A$, A if and only B.

Of course, no one would write the proof in such a confusing manner.

> *Norm:* Proofs are ordered to make the chain of arguments clear.
> *Implicature:* The justification for how a new line follows in a proof will depend on previous statements in a proof.

Mirin and Dawkins (2022) have illustrated how when a proof involves a string of identities (i.e., showing A=D by showing A=B, B=C, and C=D), mathematicians are sensitive to the order of these identities. They will think norms are being broken and proofs are deficient if the identities are not ordered in the most sensible manner.

> *Norm:* Name objects in proofs according to convention to convey their role or status in the proof.
> *Implicature:* The name of an object will help the reader keep track of its role in the proof or its quantificational status.

The names assigned to mathematical objects is taken to be logically irrelevant. Nevertheless, there are strong norms for how things are usually named. For instance, input variables are frequently named x and bounds on output estimates are usually named ε. Quantification is often encoded using indices and superscripts. A reader who notes that a set indexed by the natural numbers would be justified in drawing the implicature that the set is countable or finite. It would also be strange to denote an object G^* if the variable name G was not used elsewhere in the proof. The superscript is only used to distinguish various objects bearing the label G. As ** stated, one would never give the name "6" to a group. Strictly speaking, these naming conventions bear no logical status and the proofs would remain valid were they not followed. Nevertheless, they are strong conventions of naming because the notation affords implicatures that aide readers in constructing the line of inference intended by the prover.

Discussion and future research

In this paper, we have argued that both in the advanced mathematical classroom and in mathematical practice, it is often productive to frame proof as a cooperative form of communication. We have asserted that Grice's maxims for conversation are useful in two respects. First, Grice's maxims suggest norms for proof writing that place expectations on the prover for how proofs are written. Second, the presumption that the prover is following these norms allow for implicature; the reader of a proof may infer things that are neither explicitly stated nor logically necessitated by the proof text being read.

We believe that this has pedagogical consequences. Much of advanced mathematical instruction (and undergraduate mathematics education research) focuses on the type of reasoning that is admissible in a proof. We agree that this is essential, but argue that this is not enough to fully enculturate a student into the practice of proving. We suggest more effort can be put into instruction as to norms about how proofs are written and how they can be read. There is an intimate relationship between the form of mathematical proofs and the proving practices they express. As Schleppegrell (2004) explained, "It is important for students to develop academic register options in different disciplines because particular grammatical choices are functional for construing the kind of knowledge typical of a discipline" (p. 137).

We also believe that our exploratory theoretical analysis suggests a further line of research. We have made a number of speculative claims about norms for proof writing and opportunities for implicature. Such claims can be empirically tested with breaching experiments by showing both mathematicians and students situations in which those norms were violated, or showing mathematicians and students situations in which our proposed norms were followed and asking them if they believed that the implicata likely held. Mathematicians' responses to such situations would reveal if our speculative claims were accurate and provide us with a richer sense of why these proving norms were operative. Differences between students' and mathematicians' responses could help us unpack one way in which students might not yet have a feel for the game of proving.

(Re)defining Developmental Mathematics: A Critical Examination of the Research Literature

Claire Wladis

University of Alabama

Katie Taylor
University of Alabama

Derek Williams
Montana State University

Although "developmental math" is widely discussed in higher education circles, exactly what developmental math encompasses is often underdeveloped. In this theoretical report, we use a sample of highly cited works on developmental math to identify common characterizations of the term "developmental math" in the literature. We then interrogate and problematize each characterization, particularly in terms of whether they serve equity-related goals such as access to college credentials and math learning. We close by proposing an alternative characterization of developmental math and discuss the theoretical implications. We see this as a first step towards conversations about how developmental math could be conceptualized.

Keywords: Developmental Math; Equity; Time Capital; Postsecondary; College Level

Developmental math has been a regular focus of education research for decades. Understanding these courses is important as they disproportionately enroll students from historically marginalized backgrounds (e.g., Chen, 2016) and many students in these courses never complete their required math sequence (Bailey et al., 2010). We posit that despite the heavy focus on developmental math in higher education research and policy, the way that "developmental math" is defined or characterized in the research literature often runs contrary to equity concerns and begs the question of what developmental math actually is. Using definitions drawn from a comprehensive literature search, we consider how developmental math has been defined in the research literature, with the aim of problematizing some common characteristics of these definitions. We refrain from initially defining developmental math explicitly so as to let the term itself drive our sampling and analytical procedures. We devote the majority of this report towards developing a framework for understanding characteristics used to define developmental math and the different conditions each characteristic privileges. We close with a discussion about how we might define this term moving forward, and how this may impact equity goals.

Theoretical Framework: Approaching Equity from Credential vs. Learning Orientations

There is a growing recognition that developmental math and institutional structures around it are a consequence of and often reproduce structural inequalities in K-12 education (e.g., Larnell, 2016; Ngo & Velasquez, 2020). That is, the developmental population is *created* through often unexamined institutional norms and values. We aim to make the values and associated equity implications that are implied by various definitions of developmental math explicit, with the goal of proposing a way to move forward with how we understand and define developmental math.

Historically, developmental math was created to provide access to college math classes by providing instruction on content that has traditionally been considered prerequisite to advanced study, such as algebra, that students may not previously have had the opportunity to master, or that they have forgotten after a gap in enrollment between high school and college (e.g., Dotzler, 2003). Providing access to advanced study in math is motivated by two distinct, but related, equity goals: providing access to (a) college credentials (e.g., degree progression, retention), which we refer to as a *credential orientation*, and (b) math learning (e.g., procedural/conceptual knowledge), which we refer to as a *learning orientation*. Both orientations center equity, but have different outcomes of interest, even as they are interdependent (Figure 1). Considering only one at a time may have negative equity consequences. Problematically, research demonstrates that inequities exist in both developmental students' access to college credentials (e.g., Boatman & Long, 2018; Crisp & Delagado, 2014; Sanabria et al., 2020; Xu & Dadgar, 2018) and their access to rich and meaningful math learning or instruction (e.g., Givvin et al., 2011; Goldrick-Rab, 2007; Hammerman & Goldberg, 2003; Stigler et al., 2010; Webel & Krupa, 2015).

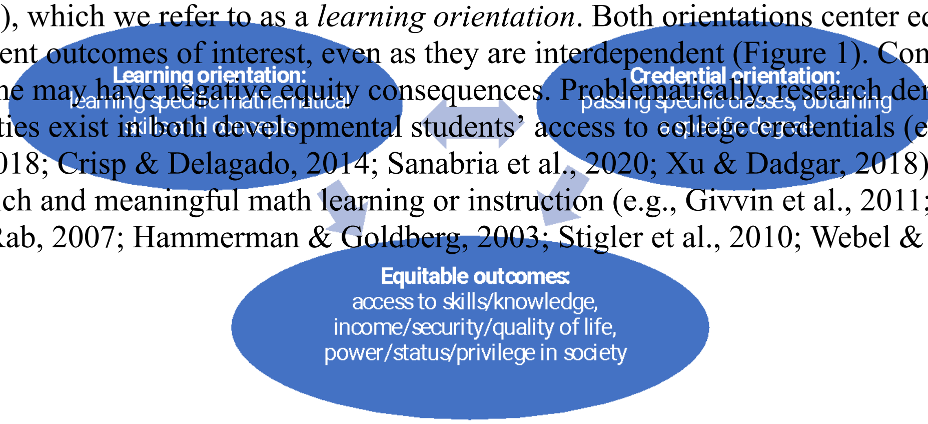

Figure 1. *Framework Relating Learning and Credential Orientations to Equity Approaches in Developmental Math*

Method

We conducted a comprehensive literature search for original reports related to developmental math. This work is part of a larger project. Here we focus only on how developmental math was defined or characterized in highly cited empirical reports or peer-reviewed journal articles.

Sample

To identify articles related to developmental math, we searched EBSCOhost for journal articles or reports published between 2000 and 2020 (inclusive) with abstracts that included the word "developmental" or "remedial", a word with the stem "math", and one of the following: college(s), universit(y/ies), post-secondary, postsecondary, or undergraduate(s). We removed duplicates, brief reports of full reports that were also included in the sample, and any articles that were not about developmental math instruction, classrooms, curricula, instructors, or students enrolled in U.S. colleges or universities. This resulted in 446 reports: 281 (62%) peer-reviewed journal articles and 168 (38%) non-journal reports. Of the 281 peer-reviewed articles, 66 (23%) were published in journals usually consumed by a math education audience. The remaining articles were published in journals with a more general education audience or that target an educational research subdomain, with the higher education audience the most prominent (47%).

Because we were interested in analyzing the most "influential" definitions in the literature, we used citation frequency as a rough proxy for a report's "influence" in order to determine which reports to code. Towards this end, in June 2022 we used Google Scholar to find the number of times each report in our sample had been cited (26 reports did not show up on Google Scholar, in which case we entered 0). We calculated the Annual Citation Rate (ACR; total number of citations divided by the report's age, in years) for each report. We formed our final subsample of influential reports by including any report that had the top 10 highest ACR and/or the top 10 total number of citations in one of the following categories: peer-reviewed journal article aimed at a math education audience, peer-reviewed journal aimed at a general education audience, and non-journal reports. We sampled from different groups to be able to contrast the definitions used by different stakeholders. There was overlap between articles with top ACRs and top overall number of citations, so the final sample included 36 records (8% of the total sample). The list of the 36 coded reports is available at Open Science Framework. Here we focus on two groups of reports within this sample: those geared at a math education audience and those not published in math education journals, hereafter referred to as "non-math education reports".

Analysis

Development of Coding Scheme. Using the constant comparison method (Lincoln & Guba, 1985), we developed an emergent coding scheme to capture the most common characterizations observed across the literature (Table 1). These were *Level* (e.g., described as "not-college-level"), *Credit* (e.g., described as "not-for-credit"), and *Content* (e.g., described in terms of the content covered or the course names). The three characterizations are necessarily intertwined, but capture different implicit orientations about developmental math, discussed in the next section.

Table 1. Coding scheme for characterizations of developmental math

Code & Description	Example
Level: Developmental math courses cover content that is not "college-level", sometimes described as secondary school level.	"Broadly speaking, the term 'developmental education' connotes a set of policies and practices designed for students who are underprepared to do college-level work in a given area. The goal of this experience is to give students the knowledge, skills, and habits that will help them be successful in the college-level version of the course (Bailey et al., 2016). The growing use of developmental education reflects an increasingly normative transition from high school to college, which while predicated on completion of secondary schooling, does not necessarily imply adequate preparation for what is deemed 'postsecondary' work." (Valentine, et al., 2017)
Credit: Developmental math courses are non-credit courses.	"With their open-door admission policy, community colleges serve a population with diverse needs and a wide range of skills. In order to prepare this diverse population for college-level courses, community colleges offer non-credit developmental courses in math, reading, and writing." (Ashby, et al., 2011)
Content: Courses cover specific math topics, typically substantially similar to second year school algebra or below.	"Remedial math includes basic arithmetic, pre-algebra, beginning algebra, intermediate algebra, and geometry. College-level math includes all courses that address topics of a skill-level equal to, or greater than, college algebra." (Bahr, 2008).

During the code development process, we noticed that sometimes characterizations of developmental courses were mentioned, but that developmental math was never explicitly defined. A lack of an explicit definition suggests the assumption that the reader has a shared understanding of what is being discussed, which may be problematic given the complex nature of developmental math. To capture such instances, we coded whether the characterizations were part of an explicit definition, an implicit definition (in which some characteristics of developmental math were described but no explicit definition was given), or whether there was no clear attempt to define developmental math (either explicitly or implicitly).

Coding Developmental Math Characterizations. Each report was coded by two coders. Initial agreement across all codes was between 81% and 92%. Further norming was undertaken to reach consensus for all codes. Codes for the characterization of developmental math were not mutually exclusive. Codes for the nature of the definition were mutually exclusive.

Results

Table 2 gives the coding distribution in the sample overall and for our subsamples of interest. "Not college-level" was the most common characterization of developmental math (92%), followed by mathematical content (67%) and then "not-for-credit" (53%). Characterization choice appears field related. Non-math education reports used "not-college-level" (100%) and "non-credit-bearing" (70%) characterizations more often than math education (77% and 23%, respectively). In contrast, math education research favored characterizing developmental math by content (85%) compared to non-math education research reports (57%). While "non-credit" and "not-college-level" characterizations might be presumed to be linked, these characterizations only co-occurred in 53% of reports. In addition, while the specific math content might be presumed to determine whether a course is "college-level", these characteristics did not always co-occur, especially in math education literature where 41% of papers that characterized developmental math in terms of content did not characterize the course as "not-college-level".

Table 2. Summary of characterizations of developmental math in research articles in the sample

	Overall		Math-education		Non-math education	
	n	%	*n*	%	*n*	%
College-level	33	91.7	10	76.9	23	100
Not for credit	19	52.8	3	23.1	16	69.6
Mathematical content	24	66.7	11	84.6	13	56.5
College-level & not for credit	19	52.8	3	23.1	16	69.6
College-level & mathematical content	21	58.3	8	61.5	13	56.5
All three	12	33.3	3	23.1	9	39.1
n	36		13		23	

In terms of implicit versus explicit definitions, 7 (19%) reports did not provide either an explicit or implicit definition; only 9 (25%) provided an explicit definition. The distribution of the nature of the definition was similar between non-math education and math education reports.

Problematizing Characterizations of Developmental Math

The characterizations of developmental math courses that we identified (level, credit, and content) align somewhat with the credential and learning goal orientations for developmental math discussed in the Theoretical Framework. However, the extent to which these characterizations measure the intended credential and learning goals is unclear. While there is much discussion in the literature about whether existing developmental math courses serve students, we could find no substantial discussion about whether or not existing *definitions* of developmental math serve these goals. Here we attempt to address that gap.

Level Characteristic

The most commonly used characteristic to describe developmental math was “not-college-level”, which often co-occurred with both “not-for-credit” and content characteristics (and by extension both credential and learning orientations). But what constitutes “college-level” math content was often left undefined and unexamined. Doing so invites a deficit framing of students in developmental classes by implicitly suggesting that developmental students lack necessary skills for engaging in college-level math work (e.g., Larnell, 2016). Indeed, characterizing developmental math courses as “not-college-level” suggests an assumption that students can only access college-level math by first repeating high-school course content; however, this assumption is problematic (e.g., Stigler et al., 2010) and unsupported by evidence.

Credit Characteristic

Characterizing developmental math courses as “not-for-credit” was particularly common in non-math education reports (and by extension, higher education research literature), which is consistent with a credential orientation that stresses degree progress. However, credits may not be a good measure of degree progress, and measuring credits in isolation de-couples equity from any direct relationship to learning outcomes. For example, there are many credit-bearing courses (e.g., precalculus) that carry credits but do not always “count” towards STEM degrees.

Previous scholarship has critiqued the non-credit characteristic of developmental courses for introducing stigma (e.g., Larnell, 2016) and not directly furthering degree progress (e.g., Logue et al., 2016). However, an oft-neglected issue with “not-for-credit” characterizations is that non-credit developmental courses have *inequitable time costs* for students. Students must still invest time in the material, regardless of whether credit is awarded. Simply attaching credits to all courses does not necessarily address this inequity. For example, co-requisite models often merge non-credit and credit-bearing math courses to produce a single for-credit course with additional non-credit hours attached (Meiselman & Schudde, 2021; Ran & Lin, 2022). While this may reduce the number of terms needed to access “college-level” math, it does not reduce the *time capital* students invest in the non-credit portions of the course. This exacerbates existing time inequities, as Black, Hispanic, female, and “non-traditional” students are more likely to both take developmental math (Chen, 2016) and to have disproportionately less time capital to invest in college (Wladis et al., 2018, 2021a, 2021b, 2022; Conway et al., 2021).

Critical structures, such as financial aid, do not give developmental students, or others with low time capital or high academic time demands, more time for college. Instead, higher time costs, which are the consequence of structural inequities, are borne by individual students (e.g., Wladis et al., 2018). Real systemic change requires an attempt to equalize time inequities, rather than focusing solely on credits, which requires shifting our definition of developmental math.

Content Characteristic

Characterizing developmental math courses as those that cover particular mathematical content was typically linked to whether that content was considered “college-level” or not. However, which courses signal the transition to “college-level” varies, ranging from Intermediate Algebra (e.g., Logue et al., 2016) to Calculus I (e.g., Hsu & Gehring, 2016). Sometimes “college-level” appears to be defined as “not-secondary-level”, but this is also contradictory, as many classes often considered “college-level” are regularly taught in high school: for example, courses above Algebra II (typically called Intermediate Algebra in college) almost universally carry college credit, yet 70% of students who enrolled directly from high school into college had taken a course above Algebra II in high school (IES, HSLS:09).

The content characteristic appears to be motivated by a learning orientation, yet learning objectives for these courses were systematically underspecified. Typically reports characterized content by the specific objects of study (e.g., linear equations) or specific course titles. But these characterizations tell us little about how students might be expected to engage with those mathematical objects. This is inconsistent with how courses are designated as "college-level" in other disciplines: for example, students might study Shakespeare in the secondary or postsecondary context, yet college Shakespeare courses are not typically classified as "developmental"[1]. This is presumably because it is not the specific *object* of study that determines the "level", but rather *how students engage with that object*. Mathematicians also do not classify "level" based on the objects of study, but by how one reasons about them: both first grade arithmetic and number theory focus on the integers, but at radically different levels.

Developmental algebra courses have typically taken the same teaching/learning approaches as 8th/9th grade Algebra I (Givvin et al., 2011; Grubb et al., 1999; Mesa et al., 2014; Stigler et al., 2010). However, college students are developmentally different from 14-year-olds: they have typically already passed an Algebra I class (e.g., Ngo & Velasquez, 2020); they have more sophisticated reasoning skills, independence, and life experience (e.g., Mesa et al., 2014); and they often excel in academic areas in which computational math skills are not a prerequisite. Yet, existing developmental algebra courses rarely leverage these strengths. Research suggests that developmental algebra students are capable of engaging in more rigorous reasoning, justification, generalization, and abstraction about core algebraic objects, without requiring extensive prerequisite courses in computation (e.g., Givvin et al., 2011). Thus, it is possible to offer no-prerequisite algebra courses at the college-level, if we re-define "college-level" as being measured by the *way in which students engage with those algebraic objects*. In fact, offering such courses is critical if we are to provide students access to college-level math: students need opportunities to develop the higher-order-math skills that will be necessary for upper-level math courses, rather than spending time repeating procedural processes that they already practiced in high school. This, along with other features of our problematization and interrogation of other definitional characteristics of "developmental math" in the literature, leads us to propose one potential new definition of developmental math.

New Definition of Developmental Math

In this section we present one potential new definition of developmental math, where developmental is no longer the complement to college-level, but rather a *subtype* of college-level. In particular, we propose to define developmental math as follows:

Definition: Developmental math courses in college are courses that (1) require **no extensive prerequisite knowledge of algebra** (or other computational skills beyond arithmetic), (2) provide students with **immediate access to college-level math** (defined based on the kinds of reasoning/justification, abstraction/generalization, and particular conceptions expected of students), and (3) provide students with **necessary time resources** for learning college-level math, based on their individual math time demands and access to time capital more generally.

This reconceptualization addresses several issues associated with current characterizations of developmental math. First, by positioning developmental courses around college-level skills that do not require algebra, this conceptualization is an asset-based approach that focuses on

[1] Special thanks to Carolyn James for the specific use of Shakespeare as a metaphor.

leveraging college students' strengths (such as their developmental maturity). Doing so also provides better access for *every* student to develop higher-order mathematical skills from the start, which are necessary to succeed in advanced math courses. Second, positioning these courses as college-level also eliminates stigma and practical problems associated with offering courses not-for-credit. Lastly, this conceptualization explicitly recognizes and addresses systemic *time inequities* that have been ignored by existing structures.

Reconceptualizing what developmental math *is* also requires reconceptualizing how success in developmental math is assessed. As previously discussed, measures of success require both a credential and learning orientation. Towards these goals, measures of success in a reconceptualized developmental math framework could include: 1) whether the courses meet the criteria stipulated in the developmental math definition above; 2) what students are actually learning in these courses (e.g., using concept inventories or other validated assessments [e.g., Carlson et al., 2010; Peralta et al., 2020; Wladis et al., 2018]); and 3) whether students are given the time resources needed to succeed in these courses (e.g., validated measures of time capital/demands [e.g., Wladis et al., 2018; Conway et al., 2021]). We note that if these three measures are met, we should also naturally see other positive outcomes (e.g., grades, persistence, general and STEM-specific degree progress and attainment). However, more traditional measures alone do not necessarily ensure that the first three measures are being met, and thus that equity in terms of access, learning, and time capital is being attained.

We recognize that our proposed definition requires a dramatic shift in how developmental math is implemented and thought about. If adopted, it also requires a renegotiation of undergraduate mathematics at large. This is not an easy proposition and would likely be the work of a generation of researchers and practitioners working together. However, substantial evidence suggests that existing definitions and implementations of developmental math are both inequitable and ineffective. We contend that dramatic reconceptualizations are necessary.

Conclusion

In this paper we have proposed to re-frame the definition of developmental math around two critical areas: (1) the extent to which developmental courses provide students access to true "college-level" math content (defined by the types of reasoning, abstraction and conceptions in which students engage, rather than computational skill), and (2) the extent to which developmental math courses provide students access to the time resources needed to address inequities in other resources (e.g., financial, prior educational access). These two foci of our revised definition align with the traditional learning and credential orientations, but in new ways that we have not seen represented in the literature. Our hope is that other scholars will build on this perspective, to further improve on our implementations of developmental math, so that it can better serve the equity goals developmental math was designed to support.

This new definition alone is not enough to solve all of developmental math's equity challenges. Research and advocacy are needed in many other areas, including: classroom and college climate, implicit bias, math anxiety and trauma, and specific teaching methods (e.g., Larnell, 2016; Martin, 2009; Mesa et al., 2014). This new perspective is just one important shift that we see as critical to more equitably serving developmental math students.

What is College-Level Mathematics? A Proposed Framework for Generating Developmental Progressions in Mathematics up to and through College

In this theoretical paper, our aim is to start a conversation about how "levels" in mathematics are operationalized and defined, with a specific focus on "college level". We approach this from the lens of developmental stages, using this to propose an initial framework for describing how learners might progress along a developmental continuum delineated by the kinds of reasoning/justification, generalization/abstraction, and types of conceptions that they hold, rather than by the particular computations learners are able to do, or the kinds of mathematical objects with which learners are engaging.

Keywords: college level; mathematical maturity; reasoning and justification; generalization and abstraction; conceptions

It is often assumed to be obvious whether a particular mathematics course is "college-level" or not; however, in practice, the transition point operationalized as "college-level" begins as early as Intermediate Algebra (Logue et al, 2016) and as late as Calculus I (Hsu & Gehring, 2016). In addition, determinations about which courses "count" as college-level are often based on syllabi that focus primarily on a list of computational skills on specific mathematical objects (e.g., linear equations, trinomials), rather than on how students reason with, justify, generalize or conceptualize mathematical ideas. Yet a conception of "level" that is driven more by the mathematical objects that are the focus of study, rather than *how* learners engage with those objects, contradicts many of the values of both mathematicians and mathematics educators about what high quality mathematics learning looks like. In addition, it further disadvantages students who may have strong higher-level thinking skills but who, for a variety of reasons, may not perform well on computational placement exams; currently, such students are often placed into non-credit bearing developmental courses that focus heavily on procedures, and which contribute to disparate impacts on college and economic outcomes (e.g., Bailey & Cho, 2010).

Mathematical learning is about more than just "content" (conceptualized as the specific mathematical objects of study or the particular procedures that students are expected to use): there are other skills, knowledge and practices that are important; yet much of this is left unarticulated in learning outcomes, and rarely used in the determination of course level. In this paper, we describe an initial framework for how we might define "college-level" mathematics, or more specifically, a spectrum of different "levels" of learning across the K-16+ mathematics curriculum as characterized by the kinds of reasoning, generalization, and conceptions that might describe developmental shifts or progressions in learning. This then includes a more focused discussion of how we might use such a framework to better articulate where the shift from K-12 to "college level" might occur in various mathematical domains.

Adolescent and Young Adult Development in Psychology and Neuroscience

It is known that the brain changes physically throughout the lifespan and that the last significant period of remodeling begins in adolescence and culminates in the early to mid-twenties. The parts of the brain most impacted by this last remodeling are those that control functions such as working memory, planning, and impulse control (Konrad et al, 2013). Based on this science, it is *developmentally appropriate* that college students should be able to interact with mathematical objects (e.g., algebraic expressions) in more sophisticated ways than younger students. Early educational literature, such as that of Piaget (1964), posited developmental stages for school-aged children that influence our expectations for what "grade level" means in subjects like math, reading, and writing. Psychology and neuroscience research acknowledge how understudied adolescents and young adults are and posit that much still remains to be learned about how brain development might impact behavior and learning (Blakemore, 2012; Shanmugan & Satterthwaite, 2016). In her survey of the field of adolescent brain imaging, Blakemore (2012) speculated about how changes in brain structure could make signal processing more efficient, which we speculate could have a direct impact on mathematics learning. This work in neuroscience compliments frameworks like that proposed by Erik Erikson (1994) for ongoing psychosocial development into and continuing through adulthood. Yet while it is known from neuroscience and developmental psychology research that college students differ developmentally from younger students, mathematics education frameworks have tended to ignore this when describing domains such as algebra that may be learned by students of widely varying ages. This paper seeks to explore how we might begin to conceptualize developmental stages as impacting how the same mathematical "objects" might be studied at different levels, with particular focus on what it might mean to do mathematics at the college level.

Proposed Mathematical Maturity Framework

In this paper we aim to problematize and redefine the term *mathematical maturity*. This term has been used in both research and practice to describe a kind of developmental progression like the one we hope to focus on here. However, this term has also been used in ways that are often vague and ill-defined; that provide deficit framings of students (e.g., "students can't take linear algebra before calculus because they don't have the mathematical maturity for the course"); and that describe binary destinations (e.g., students either have "mathematical maturity" or they don't) of what we conceptualize as a continuous life-long process of growth.

Mathematical maturity is a term used widely and often without formal definition within undergraduate mathematics education research and practice (Braun, 2019; Lew, 2019). In some instances, the completion of a specific course is used as an operational definition for the sake of a study, but even in those cases it is generally clarified that it is not the course *content* but a set of skills and increasing sophistication in how one approaches mathematics that is being referenced (Faulkner, Earl, & Herman, 2019; Lew, 2019). Two recent studies sought to determine how those using the term "mathematical maturity" define it. Faulkner et al (2019) interviewed engineering faculty and Lew (2019) interviewed mathematics faculty about their use of the term. Common definitions provided between these studies included many types of reasoning, generalizing, and conceptualizing, including the ability to: make connections across mathematical topics; use symbolic representations; relate different representations to one another and recognize when they describe the same phenomenon or relationship; choose between different representations for the purpose of solving problems; and understand if a solution to a problem makes sense.

Definition of Mathematical Maturity

Here we offer a new conceptualization of mathematical maturity via a framework, which we see as a starting point for describing how learners might acquire higher-level mathematical thinking skills and practices as they develop over time. We anticipate that this definition will evolve over time, but we present this as a first step, to start a conversation about what it means to learn mathematics at different "levels". A framework of this sort could then be used to generate new courses which could allow learners with missing "content knowledge" to nonetheless take a college-level, credit-bearing mathematics course that respects their different developmental stage compared to the age at which such content is traditionally introduced. For example, a course might require no algebra prerequisite, but allow students to engage with algebraic reasoning and justification at a higher level than would be expected in a typical K-12 algebra course.

We define ***mathematical maturity*** as a spectrum with no upper bound that describes the extent to which learners may acquire over time the ability to 1) reason and justify; 2) generalize and abstract; and 3) internalize particular conceptions of specific mathematical objects that occur throughout the curriculum. We conceptualize the process of developing mathematical maturity as a combination of physiological development and the outcome of particular mathematical experiences acquired over time. We now briefly present a framework for describing mathematical maturity which we have synthesized from existing research literature (Figure 1).

Increasing ability to reason and justify mathematically

Reasoning/Justification: To what extent are students expected to be able to reason (i.e., explain to themselves why/how something works), justify (i.e., communicate to others how/why something works), or prove (i.e., justify using more formal mathematical conventions accepted within a particular context)?

When reasoning, justifying or proving, what level of formality of language and convention is expected? (imprecise language vs. well-defined but informal language vs. formal mathematical terminology and/or symbols)

Increasing ability to generalize mathematical concepts

Generalization/Abstraction: How generalized is a learner's understanding expected to be (e.g., is the goal to understand a single example vs. a limited class of examples vs. a generic example)?
How explicit are students expected to be about the boundaries of the problem space? What kinds of connections between domains or representations are they expected to make?

Increasing ability to internalize conceptions of objects

Specific Conceptions/Concept Images: In a particular domain, which particular conceptions or concept images are learners expected to acquire (e.g., if a process vs. object transition, what is the specific object that is supposed to result from reification/encapsulation)?

Figure 2. Mathematical Maturity Framework for Describing Developmental Progression through K-16+ Mathematical Curriculum, Three Possible Dimensions

We contrast this approach with traditional conceptualization of "level" which have tended to focus on computations on particular mathematical objects as the primary feature which determines the "level" of a course (Figure 2).

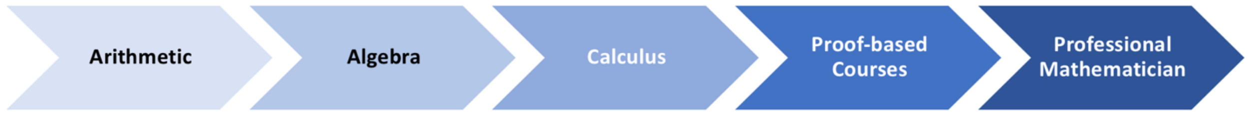

Figure 1: Informal model of progress through mathematics as currently conceived

In contrast, we consider which features are most relevant to determining the "level" at which the **same mathematical object might be learned at different points** in a students' K-16+ learning trajectory. We now describe each of the three dimensions of the framework in more detail.

Review of Literature from which the Proposed Framework was Drawn

Reasoning/Justification

One of the topics that is often discussed in the literature as a way of distinguishing whether students have "learned" mathematics, is the extent to which and ways in which students are able to reason or justify in mathematics. One of the major formal transitions in this area is when students are expected to generate mathematical proofs in college; substantial research has documented student difficulties with this. One explanation for this is that while students have experienced instruction focused on specific "content", students often do not come out of these courses with clear understanding of more general mathematical skills and practices, such as what constitutes mathematical proof (Selden & Selden, 2008). But formal proof simply describes one end of a much longer spectrum of skills, perspectives and practices. There have been extensive calls for students in K-12 to learn to reason and justify, long before the introduction of formal proof (e.g., National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010). And the processes of reasoning and justifying have been identified as critical mathematical skills that students may often not acquire during "standard" computational instruction (e.g., Mata-Pereira & da Ponte, 2017; Ball & Bass, 2003). Thus, reasoning and justification describes a core skill that is critical across mathematical domains.

Generalization/Abstraction

Another feature of mathematical "level" that often arises in the literature is the extent to which students are able to generalize about mathematical objects. To date, most of the research on generalization has been in the realms of early algebra (Carraher et al., 2008), pattern-forming (Amit & Neria, 2008), and linearity (Ellis, 2007) (see Ellis et al. 2022 for a more complete list). Notably, Ellis et al. (2022) is the first to consider students' generalizing activity across multiple domains and grade levels, ranging from middle school to undergraduates. Through their extensions of Ellis' (2007) taxonomy for categorizing types of generalization, they identified three main types: *relating*, *forming*, and *extending*. This framework enabled the researchers to identify what they considered to be generative (i.e., productive or useful) generalizing activity, and discuss how generalizing was both independent and dependent of the mathematical domain. We see this research area, and the RFE framework in particular, as having great potential for helping to illuminate our eventual taxonomy of delineating college-level mathematics.

Strongly related to generalization is the notion of abstraction. Abstraction may be defined as the processes that lead learners to grasp deeper understandings of mathematical structures, such as the underlying structure behind a vector space (Dreyfus, 2020, p. 13). Abstraction may also be thought of as a vertical reorganization of existing knowledge, or as a reconceptualization of information (as opposed to a de-construction). Many researchers have considered abstraction as part of a student's cognitive development, such as Piaget's ideas of empirical and reflective abstraction (Dubinsky, 2002), Thompson's processes and objects (1985), APOS theory (Asiala et al, 1997), Sfard's reification (1991), and Tall's structural abstraction (2013).

Conceptions/Concept Images

A third feature that often arises in studies of learners' progression through mathematical levels is the extent to which learners have particular conceptions about mathematical objects or concepts. One example that has been widely discussed is the transition documented by process-to-object theories (Sfard, 1991; Dubinsky, 1991; Gray & Tall, 1994), in which learners are theorized to conceptualize certain entities first as a process, and then later to reify/encapsulate that process into an object which can then subsequently be acted upon by even higher-order processes. For example, the expression $2x$ could be conceptualized as a process representing that 2 and x should be multiplied together. Later, a learner may conceptualize $2x$ as an object itself, representing the process of multiplying 2 by x or the result of multiplying 2 by x, without actually carrying out computation. Then $2x$ can be acted on by even higher-order processes, for example adding it to another object, $3x$, to obtain the result $5x$.

While students may switch back and forth between process and object conceptualizations, the ability to utilize an object conception is typically considered to be further along the developmental spectrum than using process conceptions alone (e.g., Sfard, 1991). Many higher-level mathematics courses also require object conceptions: for example, while arithmetic is rooted in a process conception of numerical computation, algebra requires that these same calculations be reified or encapsulated into objects (i.e., expressions/equations that can themselves be transformed using higher-order processes). Similarly, as algebra becomes more complex, students may be required to reify the process of the order of operations on algebraic expressions into subexpressions as objects (i.e., substrings of expression/equations that must be treated as unified objects); for example, this kind of higher-order structuring is necessary in order to perform function composition, u-substitution, or the chain rule in calculus. In fact, we can envision a larger progression in which one process is reified into an object, which is acted upon by higher-order processes which are themselves reified into an object, which is itself acted upon by even higher-order processes, etc. This progression has tended to be studied as individual shifts for one particular entity going from a process to an object, rather than discussed as a larger progression with many different shifts; however, original process-to-object theories precisely pointed out how reified objects became the focus of yet higher-order processes (Sfard, 1991), thus implying the existence of a larger progression containing many layers of more and more complex reified objects. Process to object views are likely not the only kinds of conceptual shifts that are expected of students as they progress through the mathematics curriculum; we present them here only as one example of how a key characteristic that determines the "level" of a mathematics course is the set of particular conceptions that learners are expected to internalize.

Brief Illustrative Example: The Distributive Property

In order to illustrate some of the affordances of the Mathematical Maturity Framework, we present one example of how this framework could be used to map out learning goals for the same object (the distributive property) at different stages of the K-16+ trajectory (Figure 3). The distributive property is first encountered in 3rd-5th grade, but is also the subject of study throughout the K-16+ curriculum. Currently, much focus is on which objects learners are expected to transform using the distributive property, yet research has documented extensive difficulties that students have in using the distributive property appropriately at many different levels (e.g., Malle, 1993; Schüler-Meyer, 2017). This may be because instruction often focuses on computation divorced from reasoning and justification. However, reconceptualizing the distributive property as a learning object by thinking about the types of reasoning, generalization, and conceptions students might use, could help us to shift our conceptions of how we determine the mathematical "level" of a particular course.

Algebra I (8-12th grade): Learners are expected to understand the symbolic representation $a(b + c) = ab + ac$ as a pattern in which a, b and c of the property represent objects (simple terms that are the product of a number and variable(s)). They are expected to conceptualize simple subexpressions such as px and qy as reified objects representing generic unknown numbers. The property is seen to hold because it represents two processes that produce the same numerical output for every possible numeric input from the domain into the expression which is being "transformed" by the property. They may or may not be expected to use an area model of multiplication to reason about or justify this idea, but they are not expected to prove the property, nor necessarily to generalize to algebraic objects with other forms.
Intro college-level algebra (lower-level undergraduate): Learners are expected to conceptualize the distributive property as a one-to-one mapping of specific reified subexpressions to a, b and c, respectively, in the property. Thus a, b, and c are seen as representing generic algebraic subexpressions and the specific reified subexpressions which are being mapped to variables in the property are seen as representing generic numerical values. The property is seen to hold because it is the process of replacing one expression with another equivalent one (substitution equivalence). The property is understood to be generalized to a generic number of terms, and students are able to describe this clearly but somewhat informally, and to justify why this is the case using an area model of multiplication. Reasoning and justification are expected, with well-defined language and some limited formal symbolism and terminology, but proof is not expected.
Abstract algebra (upper-level undergraduate or graduate): Multiplication and addition are conceptualized as abstract binary operations on an (often abstract) set, with a, b and c in the property representing generic set elements. Operations are defined axiomatically. The distributive law itself has been reified into an object: a property which a given set and pair of operations may or may not have. Learners are expected to prove, using formal mathematical terminology and symbolism, whether or not the left or right (or both) distributive properties hold for a given set with a given pair of operations (or for a larger class of sets with pairs of operations).

Figure 3. Examples of how levels of understanding of the distributive property might differ (as described by student learning goals) in high school versus lower/upper-level college, even when the objects which are the focus of the distributive property (algebraic expressions) are similar

The descriptions in Figure 3 are just one example of how we might describe learning outcomes which depict different levels of learning for a common mathematical "object". For students in the theoretical "intro college level" algebra class described in Figure 3, no extensive prerequisite proficiency in algebraic computation is required–however, once the learner starts working with the distributive property, higher-level reasoning/justification, generalization/abstraction, and reified objects are expected to be used and learned as a part of the curriculum. This is just one brief example of how using the Mathematical Maturity Framework as a tool for developing and describing learning in college-level mathematics may help us to shift our focus from computations on specific objects, to how students are learning to reason about, generalize and conceptualize specific key mathematical ideas as they progress along their mathematical learning trajectories up to and through college.

Conclusion

Our aim in presenting this framework is to shift our discussion of “college-level” mathematics (and levels in mathematics more generally) away from a focus on specific computations or particular mathematical objects, and towards a focus on reasoning, generalizing, and particular conceptual shifts. This reconceptualization can be particularly important from an equity perspective, since conflating computational skills with reasoning ability can be particularly detrimental to some of the most marginalized students. One example of this is developmental mathematics in college. The term “developmental” is often used to describe courses that are not “college-level”, but this definition is ill-defined in the research literature (Wladis et al, 2022) and may be circular (e.g., a course is developmental because it does not earn college credit and does not earn credit because it is not “college-level”). Most students in college are in fact re-taking mathematics which they already took in high school (e.g., 70% of those who attended college the year after graduating HS had already taken at least one math course above Algebra II [IES, HLS, 2009], and 52% of students who enroll in Calculus I in college have taken calculus previously (Sadler & Sonnert, 2016), yet what makes some of the courses that students repeat in college “college-level” and others not is unclear. We see this as a critical equity issue in mathematics: many college students (particularly those from more marginalized groups) are labeled “developmental” in college (with both stigma and practical barriers attached to these labels) because they are deemed “not ready for college-level work”, yet what it means to be ready for college-level work is not well-defined.

The transition from high school to college is also not the only transition point in mathematics learning in college that has been documented to be difficult for students. For example, many students struggle with the transition to proof in undergraduate mathematics (Selden & Selden, 2008). One reason the observed difficulty with many transition points into and through college mathematics may be that as a community we have not yet clearly enough articulated the specific goals of instruction, as defined in terms of particular types of higher-order thinking skills such as reasoning, generalization, and specific conceptions of mathematical concepts; nor have we adequately described on a larger-grained scale how we might expect students to progress through these developmental stages as they mature mathematically. This paper is an attempt to start a conversation about the potential of reframing “college-level” classifications based on specific high-level thinking skills, rather than organizing it around the specific mathematical objects to be studied or the particular calculations to be made. Our hope is that this will lead to more productive and equitable ways of teaching and assessing students in college, and across the K-16+ mathematics spectrum.

Syntactic Reasoning and Cognitive Load in Algebra

Claire Wladis

Kathleen Offenholley
CUNY

In the context of proofs, researchers have distinguished between syntactic reasoning and semantic reasoning; however, this distinction has not been well-explored in areas of mathematics education below formal proof, where student reasoning and justification are also important. In this paper we draw on theories of cognitive load and syntactic versus semantic proof-production to explicate a definition for syntactic reasoning outside the context of formal proof, using illustrative examples from algebra.

Keywords: Syntactic reasoning; Semantic reasoning; Cognitive load; Algebra

In this paper we outline a framework for analyzing student reasoning in mathematics, using the distinction between syntactic and semantic reasoning. This distinction has been a helpful framework for analyzing proof construction (Weber & Alcock, 2004) but has rarely been used as a framework for analyzing reasoning or justification in other mathematical domains where formal proof is not common. Even when syntactic reasoning is referred to directly in the context of proof, it is often conflated with manipulation of symbols without understanding. In this paper, we explicate a definition for syntactic reasoning outside the context of formal proof, presenting it as a form of reasoning that is distinct from rote "symbol pushing". We then use one example from school algebra to illustrate: 1) how syntactic and semantic reasoning play critical and complementary roles in this context; 2) how leveraging syntactic reasoning can reduce cognitive load; and 3) how preferences for syntactic or semantic reasoning approaches may relate to prior knowledge and schema. Our aim is to start a conversation about the potential affordances of more explicitly attending to syntactic reasoning in task and curriculum design and instruction.

Syntactic and Semantic Reasoning

In the literature on student proof construction, a number of studies have explored syntactic versus semantic reasoning during proof production. Weber and Alcock (2004) define syntactic proof production as drawing "inferences by manipulating symbolic formulae in a logically permissible way" and semantic proof production as using "instantiations of mathematical concepts to guide the formal inferences that [the prover] draws". In some work these categories are binary and assigned to a whole proof production, but in other work (e.g., Weber and Mejia-Ramos, 2009) syntactic and semantic reasoning are conceptualized as describing different steps in a students' reasoning process, where students may switch back and forth between different approaches; the latter is the approach we aim to take.

We also point out two key distinctions between our definitions of syntactic reasoning and those that have been used in proof literature. In particular, Weber and Alcock's (2004) definition of syntactic reasoning as drawing "inferences by manipulating symbolic formulae in a logically permissible way" is for us incomplete—we are not only interested in the result of a student's calculations, but also in their reasoning[1]. A second key distinction is that while Alcock & Inglis (2008) classify reasoning as syntactic if it takes place within the "representation system of

[1] We note that in other work, Weber (2005) distinguishes between *syntactic* and *procedural* proof production (the latter being based more on imitation of particular proof "templates" without necessarily understanding why they are valid)—this distinction is similar to, but different from our distinction between syntactic reasoning and symbolic manipulation that is not grounded in syntactic reasoning.

proof," we discuss a context in which syntactic reasoning can occur beyond proof production, which we call an "abstract symbolic system."

Abstract Symbolic Systems

We situate our definition of syntactic reasoning within *abstract symbolic systems*: self-contained systems in which the symbolic objects are what Tall et al. (1999) describe as *axiomatic objects*, or objects that arise "from specifying criteria (axioms or definitions) from which properties are deduced by formal proof" (p.239). This is also related to, but more narrowly defined than, what Goldin (1998) termed a **symbolic system**—a set of conventions and implicit or explicit axioms for the use of mathematical symbols which is:

1. **Abstract**, in the sense that it does not necessarily have any "real world" or alternative representations beyond what is specified by the axioms in the system.
2. **Self-contained**, in the sense that one has all the tools one needs already within the system to be able to identify or generate equivalent objects.

Our Definitions. *Syntactic reasoning* is reasoning which justifies mathematical work by referring back to conventions and axioms *within* the abstract symbolic system. *Semantic reasoning* involves justifying mathematical work by connecting it to representations or concept images *outside* the abstract symbolic system (e.g., the concept image of multiplication as area).

Distinguishing syntactic reasoning from "symbol pushing"

We have observed a tendency in the mathematics education community to frame syntactic reasoning as normatively undesirable, and semantic reasoning as normatively superior (see e.g., Easdown, 2009; Weber & Alcock, 2004). This is likely a reaction to approaches to teaching in which students are taught to manipulate symbols without connecting them to relevant underlying mathematical reasoning (e.g., Stacey, 2010). However, it is important to distinguish between syntactic reasoning versus symbolic manipulation that is disconnected from relevant logical reasoning.[2] We contend that the former is an essential component of mathematical reasoning, complementary to semantic reasoning, and necessary to manage the cognitive load of syntactically complex tasks. In our framework, syntactic and semantic reasoning are viewed as two essential and complementary components of mathematical reasoning.

For our definition of syntactic reasoning, it is not enough that a student manipulates symbols, even correctly—they must show evidence of reasoning within an abstract symbolic system. For example, a student may correctly transform with the distributive property in the following way: $2(3x + 5) = 2{\cdot}3x + 2{\cdot}5$. However, what reasoning this student has used is not clear from this work alone. Here are some examples of explanations that we would and would not consider to be syntactic reasoning (these examples are fictional, but have been written to mimic common forms of explanation that college students have provided in other empirical work):

1. ***Student 1 (neither syntactic reasoning nor semantic reasoning):*** *You take whatever is on the outside of the parentheses, and put it next to each thing inside the parentheses.*
2. ***Student 2 (syntactic reasoning):*** $2(3x + 5)$ *has the form* $a(b + c)$ *if we let* $a = 2$, $b = 3x$ *and* $c = 5$. *We know from the distributive property that* $a(b + c) = ab + ac$, *so we know that* $2(3x + 5) = 2{\cdot}3x + 2{\cdot}5$ *by substituting* 2, $3x$ *and 5 into the correct variables in the distributive property.*

[2] We use the modifier "relevant" because students who are "symbol pushing" often use complex or abstract forms of reasoning that are not connected to the relevant mathematical-logical justification.

3. ***Student 3 (semantic reasoning):*** *When you have two terms that are doubled, it doesn't matter if you add first and then double the result or double each term separately. Because either way you are still doubling each individual term.*

Student 1 describes a procedure but does not draw on any conventions or axioms of the abstract symbolic system in their justification, so this is not considered syntactic reasoning by itself. Student 2, in contrast, is drawing only on conventions and axioms given in the abstract symbolic system to justify their work. Unlike the others, Student 3 has drawn on meanings for multiplication and addition that go beyond what is given in the axiomatic system; this student is using other definitions of addition (e.g., as combining parts or terms) and multiplication (e.g., as doubling) to justify their work. Some readers may prefer the semantic explanation to the syntactic one or vice versa. We note only that both draw on distinct forms of reasoning, and that each approach directs cognitive resources towards something different. The syntactic approach directs resources in working memory towards parsing complex syntax so that a learner can view complex expressions as "having the form" $a(b + c)$. On the other hand, the semantic approach directs cognitive resources towards understanding *why* the distributive property can be derived from specific conceptions of addition and multiplication. However, the working memory resources necessary to process this semantic explanation may increase significantly as the subexpressions which represent a, b and c become progressively more syntactically complex. We likely do not expect students to justify the distributive property every single time that they use it, just as we do not expect students to semantically justify every sum or product every time that they calculate. Ideally, students would be able to employ *both* forms of reasoning when solving problems, switching *back and forth* between them strategically, in ways that both maximize their understanding of the underlying mathematics, and keep the cognitive load of a particular problem to manageable levels.

Cognitive Load and Strategic Selective Attention

There are several key features of cognitive load theory. Firstly, it characterizes learning as the process of encountering novel information, processing it in working memory, and then (to the extent that it is perceived as useful) encoding it in some way into long term memory (see e.g., Kalyuga, 2010). During this process of learning novel material, elements which are encountered during learning are encoded into mental schema[3], which vary in size and complexity based on the learner's expertise in a specific knowledge domain (de Groot, 2014; Ericsson & Kintsch, 1995; Sweller et al., 2019). The number of elements that can be held in working memory does not vary for "novices" vs. "experts" in a given domain; rather, it is the complexity of the mental schema that make up the individual elements which varies based on a learner's level of expertise in a particular area (de Groot, 2014; Ericsson & Kintsch, 1995; Sweller et al., 2019).

Thus, during the process of problem solving, how much cognitive load a particular task requires will vary based on the existing mental schema of the learner. A task that is perceived to have a dozen elements by a "novice" might be perceived as all fitting into a single mental schema for an "expert" in that domain (and thus from a cognitive load perspective, would take up only one element of working memory for the "expert"). In addition, the information encoded in mental schema may be automated, so that it is no longer processed consciously. This reduces the cognitive load for the learner, but also removes much of the work of solving problems from their conscious mental awareness (Cooper & Sweller, 1987; Sweller, 2011). This may have

[3] We note that the term "schema" is used differently in cognitive load literature and should not be conflated with more specific usage in mathematics education research (e.g., APOS theory [Dubinsky, 1991]).

consequences for both learners and instructors: for instructors who have automated particular complex schema, attempting to explain these processes which they no longer execute consciously can significantly increase their cognitive load during instruction (Lee & Kalyuga, 2014), and also make it difficult for instructors to accurately gauge the cognitive load that a “novice” (who does not have these automated schema) might experience from the same problem.

Strategic selective attention

Because syntactic and semantic approaches can have different implications for cognitive load, switching back and forth between these two approaches may be one way of strategically managing cognitive load within a single task. This could be described by theories of selective attention. *Selective attention* is a measure of the extent to which someone is able to filter out irrelevant information during the problem-solving process and focus only on the aspects of the problem that are salient to the task at hand (Broadbent, 1958; Treisman, 1964). Research has established that selective attention may be a key skill in mathematical problem-solving and is related to students’ working memory (see e.g., Arán Filippetti & Richaud, 2016; Campos et al., 2013). Most use of selective attention in the mathematics education literature focuses on it as a learner’s ability to filter out completely irrelevant information (e.g., on a one-step problem about red apples, ignoring information about green apples), but we focus on a related but slightly different aspect of selective attention, which we term ***strategic selective attention***: a student’s ability to *temporarily* ignore information that is not relevant to the *current* step in solving a problem (but which may be relevant at another step, or to interpreting the answer, etc.). For example, a student may temporarily ignore concept images that are helpful for reasoning semantically during a problem-solving step that is focused on syntactic reasoning (or vice versa), in order to lower their cognitive load.

Because strategic selective attention allows a student to temporarily ignore information that is not relevant to the current step, it narrows the amount of information that must be held and processed in working memory and can therefore be critical once mathematical problems become more complex. Thus, learning to work in valid ways with abstract symbolic systems by focusing on syntactic reasoning could be key to helping students reduce the cognitive load of many standard mathematics problems. To illustrate how strategic use of syntactic reasoning could help to reduce the cognitive load of mathematical problems, we present a few examples of how a standard algebra problem might be justified. We do not contend that any particular choice of when to reason syntactically versus semantically is right or wrong—this may vary for different people in different contexts.

Illustrative Example

As a starting point for discussion, we consider the following problem, which is a standard question in school algebra, typically introduced in 8th or 9th grade in the U.S.:

Example 1. Simplify $\frac{6x^2+2x}{2x}$ completely (assume $x\neq 0$).

We have chosen this example because it is fairly accessible, but student errors are nonetheless quite common, often involving invalid “cancelling” procedures, for example (Malle, 1993):

$$\frac{6x^2+\cancel{2x}}{\cancel{2x}} = 6x^2$$

Researchers have explained this invalid form of ‘cancelling’ in a variety of ways: generalizing from a limited set of examples where this heuristic holds to contexts where it no longer holds (Matz, 1982, p.26), and attending to visual similarities and patterns on the page (Erlwanger, 1973; Kirshner & Awtry, 2004). We note that if a student is performing this cancelling approach, they are *not drawing on important syntactic meanings within this abstract symbolic system*. For example, one critical syntactic meaning is that the numerator $6x^2 + 2x$ is a single unified object, and cannot be partially canceled, as is done in the work above. Another critical syntactic meaning is that canceling represents the replacement of a single fraction of the form $\frac{a}{a}$ with the equivalent expression 1 (assuming $a \neq 0$); it does not represent a "disappearance" of the objects being "cancelled".

A "semantic" reasoning approach

We now present a semantic reasoning approach, shown in Figure 1. However, we first note that no approach to this problem in its current form can be 100% semantic, because at a minimum, syntactic reasoning is necessary to read the symbolic expression. (For example, we need to know that when a number is written next to a letter, it means multiplication.) Therefore, because no approach justifying mathematics written using symbolic representations is 100% semantic, we write the word semantic in quotes for this overall example.

Step 1	$\frac{6x^2+2x}{2x}$ $= \frac{6x^2}{2x} + \frac{2x}{2x}$	**Semantic reasoning:** Fractions can be thought of as parts of a whole, where the top number represents the number of pieces and the bottom number represents the size of the pieces. So, if we want to split these two subexpressions into two separate fractions, it will have the same meaning as long as we use the same denominator for both fractions, using the denominator that was in the original fraction.
Step 2	$= \frac{(2x)(3x)}{2x} + \frac{2x}{2x}$	**Syntactic reasoning:** Because of the generalized associative/commutative property of multiplication, we can perform multiplication using any order or grouping (as long as only multiplication is involved). So $6x^2 = 6 \cdot (x \cdot x) = (2x) \cdot (3x)$.
Step 3	$= \frac{2x}{2x} \cdot (3x) + \frac{2x}{2x}$	**Semantic reasoning:** Dividing by a number is the same as multiplying by the reciprocal of that number because both dividing by c and multiplying by $\frac{1}{c}$ can be thought of as breaking the original number up into c-many equally-sized groups, and then taking the size of just one of those groups. **Syntactic reasoning:** Combining this semantic reasoning with the generalized commutative/associative property of multiplication, we can replace $\frac{(2x)(3x)}{2x}$ with $\frac{2x}{2x}(3x)$.
Step 4	$= 1 \cdot (3x) + 1$	**Semantic reasoning:** Dividing anything by itself will always be 1, because everything goes into itself only once, so $\frac{2x}{2x} = 1$ as long as x is not zero.
Step 5	$= 3x + 1$	**Semantic reasoning:** Multiplying anything by 1 is just like taking it one time, so it does not change it.

Figure 1: Using "Semantic" Reasoning

In Figure 1, the reader will notice the label "syntactic reasoning" for the two areas where the generalized commutative/associative property of multiplication is used. Students may be asked to justify this property semantically in specific cases, but are not expected to justify the general case semantically (i.e., that when multiplying any number of factors, neither the order nor the grouping matters). The generalized case is typically justified formally using proof by induction, which is by definition a syntactic justification that is not appropriate for most K-12 (or even college) students. Thus, most students who use the generalized commutative/associative property of multiplication are using it syntactically, as a stated axiom within the abstract symbolic system within which they are working.

Hidden forms of syntactic reasoning in our "semantic" example

Embedded within each step labeled 'semantic reasoning' is hidden syntactic reasoning which is necessary in order for the semantic reasoning to be connected to the symbolic representations. In Figure 2, we now fill in some of that reasoning, making the implicit more explicit for Step 1.

Step 1	$\frac{6x^2+2x}{2x}$ $= \frac{6x^2}{2x} + \frac{2x}{2x}$	**Syntactic reasoning:** In this expression, we can treat $6x^2$ and $2x$ at the top of the fraction and $2x$ at the bottom of the fraction each as a unified subexpression, because of the convention that the top and bottoms of fractions should be treated as unified subexpressions, and because according to the order of operations, exponents and multiplication come before addition. So, we can think of this as $\frac{a+b}{c}$ where a represents $6x^2$, b represents $2x$, and c represents $2x$. **Semantic reasoning:** Fractions can be thought of as parts of a whole, where the top number represents the number of pieces and the bottom number represents the size of the pieces. So, addition involving two subexpressions at the top of a fraction $(a + b$ $)$ represents addition of one number of pieces of the same size from another. So, if we want to split these two subexpressions into two separate fractions, it will have the same meaning as long as we use the same denominator for both, using the denominator in the original fraction.

Figure 2: First Step of Expanded "Semantic" Reasoning Example, with "Hidden" Semantic Reasoning Added

There are several interesting things to note about the expanded example in Figure 2. Firstly, in each step, the semantic reasoning is dependent upon some underlying syntactic reasoning. Although this reasoning is hidden, it is still needed to complete the problem. Thus, many semantic explanations provided to students during instruction and in curriculum may actually be more syntactic than they seem and may hide key parts of justifications from students.

Secondly, this explanation reads as quite long, because it combines the necessary syntactic reasoning with added semantic explanations which are, in a sense, justifications of the properties that need to be used when justifying syntactically (in a purely syntactic example these properties might be treated as axioms that do not require justification). Thus, there is increased cognitive load needed to provide both semantic and syntactic justification simultaneously. This increased load may be desirable in some cases and undesirable in others, depending on factors which will vary from one problem-solver to another, and from one instructional context to another.

The role of cognitive load in choices to implement syntactic vs. semantic reasoning

Many readers who are "experts" in algebra (e.g., algebra instructors, mathematicians) may prefer the short "semantic" justification in Figure 2 and feel that the expanded "semantic" justification in Figure 3 carries a higher cognitive load, because it contains significant amounts of "extraneous" information. For these experts, the syntactic reasoning that has been explicitly given and broken down in detail in the expanded explanation represents prior knowledge that they have already reified into unified schema and automated. Thus, unpacking this prior knowledge by breaking it down and making it conscious requires more cognitive effort.

On the other hand, for a problem-solver who lacks some of these schema, or who has not automated them (or has automated non-normative syntactic meanings), the additional information given in the expanded explanation may be helpful, or even essential, to understanding the “semantic” example. Including these additional details may make the “semantic” justification accessible in a way that it was not before. This contrast between how an “expert” and a “novice” might experience worked examples with additional explanatory information is similar to patterns that have been found in the research literature, in which additional explanatory information improved the performance of “novices” but slowed down “experts” who did not need it (the “expertise reversal effect”; see e.g., Kalyuga, 2007; Kalyuga et al., 1998). We note, however, that the cognitive load in the expanded “semantic” justification is still quite high. We see this expanded “semantic” justification as a useful tool for unpacking many of the different kinds of knowledge that are necessary for understanding the justification of the short “semantic” example; it is *not* intended to be presented as a useful example of how this might be taught to students.

We are left with the challenge of how to teach justification without overloading students’ working memory, even in cases where they have not yet acquired the necessary schema and automated syntactic knowledge to parse a short “semantic” justification. One option is to break down the complex network of interacting information into isolated elements which can be learned separately, each with a lower cognitive load individually. Studies that have employed this kind of approach in other contexts have shown that it can help students to learn complex interdependent types of knowledge which would have a too high cognitive load if learned all at once (see e.g., Pollock et al., 2002). Further research is necessary to determine the best methods.

Conclusion

In this paper we have described how syntactic reasoning could be defined for mathematical contexts that do not use formal proof. Our definition of syntactic reasoning is distinct from mere “symbol pushing.” It requires not just manipulation of symbols, but reasoning behind symbolic manipulation that draws on specific syntactic meanings of the abstract symbolic system in which the manipulations are being conducted. Thus, in our framework, semantic reasoning does not have to be present for productive and authentic mathematical reasoning to occur.

We have illustrated how syntactic and semantic approaches to problems may impact the cognitive load of particular tasks differently, particularly with respect to the existing schema of the problem-solver. We deconstructed one particular algebra task in order to illustrate many of the hidden ways in which semantic reasoning depends on syntactic reasoning as soon as algebra is written symbolically. This “hidden” syntactic reasoning may relate to the difference in cognitive load that “experts” and “novices” experience. “Experts” may have already automated much of the syntactic reasoning that they use, whereas “novices” may have no awareness of the role that syntactic reasoning plays. “Experts” may also be unaware of their own unconscious automated processes, which may perpetuate implicit, rather than explicit, handling of syntactic reasoning in curriculum and instruction. This suggests that to maximize rich understanding and minimize cognitive load for all learners, more research is needed to understand how syntactic reasoning can best be taught to learners with varied levels of prior knowledge, and to tease out how students and instructors can leverage strategic selective attention to switch between syntactic and semantic modes of reasoning.

Reconceptualizing Algebraic Transformation as a Process of Substitution Equivalence

Claire Wladis
CUNY

Benjamin Sencindiver
CUNY

Kathleen Offenholley
CUNY

In this theoretical paper, we describe how algebraic transformation could be reconceptualized as a process of substitution equivalence, and we discuss how this conceptualization affords mathematical justification of transformation processes. In particular, we describe a model which deconstructs the process of substitution equivalence into core subdomains which could be learned serially and then re-integrated, in order to make them accessible to students with lower prior knowledge in syntactic reasoning. Our aim in presenting this model is to start a conversation about what the core components of knowledge might be in order for students to reason about and justify algebraic transformation using symbolic representations.

Keywords: algebraic transformation; substitution equivalence; reasoning and justification; syntactic reasoning; cognitive load

Algebraic transformation has been identified as a core task of algebra (e.g., Kieran, 2004), yet students often struggle to transform algebraic expressions and equations correctly (e.g., Agoestanto et al., 2019; Dustin & Coleman, 2012). One reason may be that algebraic transformation is often taught procedurally. Without the connection to syntactic reasoning, students may not understand why certain transformations can be justified mathematically as preserving equivalence. For example, in the case of equations, students often do not realize that valid transformation produces an equation that has the same solution set as the original (e.g., Pilet, 2012, 2013). In this paper, we develop a theoretical model for how algebraic transformation could be reconceptualized as a process of substitution equivalence. Our model describes separate but related concepts necessary to use substitution equivalence to replace one expression or equation with an equivalent one during the problem-solving process. This model is the result of a decades-long design research experiment that we do not report on here; analysis of those data is the focus of other ongoing research (e.g., Wladis et al, 2022a, 2022b, 2022c, 2022d, 2022e). Instead, in this paper, our goal is to describe the theoretical model and its relationship to existing theory, including a discussion of its affordances in helping us to understand how learners might reason about and justify algebraic transformation.

Theoretical Framework: Generalizing Computational Versus Relational Views of the Equals Sign to Equivalence Relationships Preserved by Algebraic Transformation

Research on the equals sign distinguishes between whether students have a computational (the equals sign is a cue to compute what is on the left and put the answer on the right, which can lead to errors such as $2 + 4 = 6 + 2 = 8$) or relational (the equals sign represents a relationship between two equal quantities) conception of the equals sign (e.g., Stephens et al., 2013). We could similarly generalize this beyond the equals sign to any type of equivalence such as equivalent algebraic expressions or equations. For example, a ***computational view of equivalent algebraic expressions (equations)*** would describe a learner who sees transformation as a command to perform some sort of procedure on the expression (equation) to produce a resulting expression (equation), without realizing that there is an equivalence relationship between the original and resulting expressions (equations) (e.g., contributing to such errors as "cancelling" the $2x$ in the top and bottom of the expression $\frac{6x^2-2x}{2x}$ (e.g., Cunningham & Yacone,

2013) or to believing that $6x^2 - 2x$ could be interpreted to sometimes mean $6(x^2) - 2x$ and sometimes mean $(6x)^2 - 2x$, even though the two expressions do not produce equal outputs for most inputs of x). A ***relational view of equivalence of expression (equations)*** would view transformation as a way of replacing one expression (equation) with an equivalent one: thus, transformations are only permitted if they preserve equivalence (i.e., produce an equivalent expression [equation]). Further, reasoning about or justifying which transformations are allowed requires determining which preserve equivalence. The relational conception allows for justification of computation, whereas a purely computational conception does not. In particular, because the relational conception requires the notion of *replacing* one expression (equation) with an equivalent one, this is an example of substitution equivalence. Thus, algebraic transformation could be reconceptualized as a process of substitution equivalence, which could be viewed as a ***relational conception of algebraic transformation***. This conceptualization then also links the action of transformation directly to its justification: namely, whether it is equivalence-preserving.

A Motivating Example

In order to provide a concrete example of how algebraic transformation can be conceptualized as a process of substitution equivalence, we choose one common algebraic task:

Example 1. Simplify $\frac{6x^2-2x}{2x}$ completely.

We have chosen this particular task because student errors from employing a computational rather than relational view of transformation are common (e.g., invalid "cancelling" of $2x$); thus it is an illustration of some affordances of taking a relational approach. Here is one possible way that substitution equivalence could be used to begin to simplify this expression:

Step 1	$\frac{6x^2-2x}{2x} = \frac{6x^2}{2x} -$	$\frac{6x^2-2x}{2x}$ has the form $\frac{a-b}{c}$ (where $c\neq 0$), so we can use the property $\frac{a-b}{c} = \frac{a}{c} - \frac{b}{c}$ (where $c\neq 0$) by substituting $a = 6x^2$, $b = 2x$ and $c = 2x$ into the property, which gives us $\frac{6x^2-2x}{2x} = \frac{6x^2}{2x} - \frac{2x}{2x}$.
Step 2	$= \frac{(2x)(3x)}{2x} - \frac{2x}{2x}$	Because of the generalized associative/commutative property of multiplication, we can perform multiplication using any order or grouping (as long as only multiplication is involved). So $6x^2 = 6\cdot(x\cdot x) = (2x)\cdot(3x)$.

Figure 1. Example substitution equivalence justification for solution to Example 1

Components of a Relational View of Transformation

If a learner has no experience with reasoning syntactically, the details in steps 1 and 2 above would produce a cognitive load that is too high for a learner to understand or reproduce this solution. However, the explanations in steps 1 and 2 can be broken down in to more discrete knowledge elements (which we call subdomains) that could each potentially be learned separately, and then reintegrated later. By identifying these elements separately, we serve two goals: 1) this may allow us to better diagnose which specific conceptions are the cause of observed difficulties; and 2) this may allow us to teach substitution equivalence in smaller "chunks", limiting the cognitive load placed on learners. In Figure 2 we illustrate the model; we begin by describing each subdomain individually.

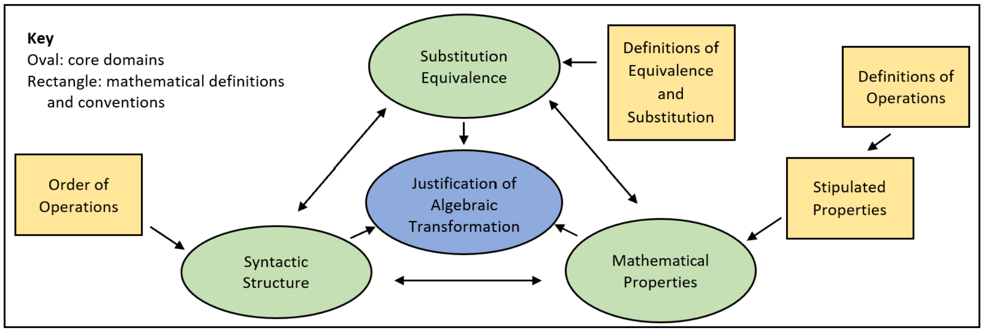

Figure 2. Model of Algebraic Transformation as Substitution Equivalence

Substitution Equivalence

To understand why $\frac{6x^2}{2x} - \frac{2x}{2x}$ can replace $\frac{6x^2-2x}{2x}$ in Step 1 above, a student must understand that any expression can be replaced with an equivalent one during the problem-solving process. Similarly, they must understand that if $a = 6x^2$, $b = 2x$ and $c = 2x$, then a, b and c can be replaced with $6x^2$, $2x$ and $2x$, respectively, in the property $\frac{a-b}{c} = \frac{a}{c} - \frac{b}{c}$, and the property will still be true because this is substitution of one subexpression for an equivalent one. During Step 2, they must also understand that $6x^2 = 6\cdot(x\cdot x) = (2x)\cdot(3x)$ means that the subexpression $6x^2$ can be replaced by the equivalent subexpression $(2x)\cdot(3x)$, and the resulting expression will be equivalent to the original one. All three of these processes are facets of the concept of ***substitution equivalence***: that one mathematical object can be replaced with another during the problem-solving process if and only if those two objects are equivalent (Wladis et al, 2022a).

Equivalence: Having a conception of substitution equivalence requires some underlying definition of equivalence, which in this case could simply be a stipulated insertion equivalence definition of expressions (Zwetzschler & Prediger, 2014, e.g., two arithmetic expressions are equivalent if they produce the same result for every possible combination of variable values). Or it could be a different definition of equivalence (e.g., a generalized equivalence relation definition). Regardless of the definition, in order to use substitution equivalence, a student has to recognize some key characteristics of the concept of equivalence more generally: that equivalence is a *stable relationship between two specific objects, based on some well-defined criteria* (Wladis et al, 2022a, 2022b). In other words, equivalence is a relationship (not a computation) between two objects (it requires two things to be compared) that is well-defined (it requires an unambiguous set of criteria for determining whether those two things are equivalent), and finally: two things are either equivalent or not, and they stay that way (two objects are not equivalent sometimes and not others; they don't "become" equivalent with transformation—rather, transformation reveals a pre-existing equivalence relationship).

Substitution: Using substitution equivalence also requires a more general definition of substitution, in which it is conceptualized as the replacement of one unified subexpression with an equivalent unified subexpression. For example, if a student only conceptualizes "plugging a number in" for a letter as substitution, it becomes difficult to talk about replacing $6x^2$ with $(2x)\cdot(3x)$ in the expression $\frac{6x^2}{2x}$ to generate $\frac{(2x)\cdot(3x)}{2x}$ as a process of substitution equivalence.

Thus, the domain of substitution equivalence describes the extent a learner can conceptualize equivalence as a stable relationship between two objects that meet well-defined criteria, and the extent to which the learner understands that one object can be replaced with another during the problem-solving process if and only if the two are equivalent, based on a stipulated equivalence relationship. This is more than being able to execute more complex substitutions correctly; it includes the ability to justify transformations because they preserve equivalence, by describing the particular equivalence relationship that is preserved by that transformation.

Syntactic Structure

Understanding the concept of substitution equivalence alone is not enough to have a relational view of transformations: for example, in Steps 1 and 2 in Figure 2, in order to perform substitution correctly, it is necessary to identify the correct unified subexpressions that can be substituted out or in. Another skill that is necessary to tackle the task above is the ability to parse the intended meaning of the syntax $\frac{6x^2-2x}{2x}$ by recognizing which substrings of the expression can be treated as ***subexpressions***, or which substrings of the expression could have brackets placed around them without changing the syntactic meaning of the expression (i.e., the expression would still represent the same operations on the same objects in the same order). In this example, this would mean being able to recognize that this expression has the following syntactic meaning as it is currently written: $\frac{(6(x)^2)-(2x)}{(2x)}$, and that $6x^2$ and x^2 are both subexpressions, but $6x$ is not.

Just as substitution equivalence can be seen as a more structural than computational approach (i.e., as a relational versus a computational view), understanding syntactic structure can also be seen as a shift from thinking computationally to thinking structurally. This is related to what has been observed by Sfard (1991) and others (Asiala et al., 1997 Dienes, 1969, Dubinsky, 1991, Gray & Tall, 1994), when they observe that an expression like $\frac{6x^2-2x}{2x}$ can be viewed as a process of squaring x, then multiplying 6 by that result, then separately multiplying 2 by x, then taking that result away from the first result, then dividing that result by the result obtained after multiplying 2 by x again. Or, it can also be seen as an object that is a reification/encapsulation of a process: the anticipated final result of the process described above (whether or not one has actually carried that process out). We focus on this slightly differently by focusing on how and whether a learner is able to identify *subexpressions as objects*. This requires more than simply a reification of the process of computation, but rather, a reification of the process of the order of operations: in the computational view, a learner would conceptualize the process of the order of operations as telling us that x must first be squared, and then 6 must be multiplied afterwards by the result; in contrast, in the structural view, a learner would conceptualize the order of operations as being reified into a fixed structure where x^2 is conceptualized as a unified subobject (i.e., a subexpression) which is a part of the larger expression $6x^2$.

We call the domain that includes knowledge of how to parse algebraic symbolic representations and to identify subexpressions ***syntactic structure***. This includes not just the ability to normatively interpret the symbols, but also the ability to link that interpretation to a normative justification (i.e., by explaining how the order of operations and other stipulated conventions dictate which substrings are subexpressions). Our definition of syntactic structure is closely related to the notion of *surface structure* as defined by Kieran (1989) and others in linguistics (e.g., Chomsky, 1966)[1], and is also related to Malle's *Termstrukturen*, or "expression structuring" (1993). We discuss this in detail elsewhere (Wladis et al, 2022c).

Using Mathematical Properties, or "Form Mapping"

Substitution equivalence and syntactic structure alone are not enough to justify the transformation work in Figure 1. To use the property $\frac{a-b}{c} = \frac{a}{c} - \frac{b}{c}$ (when $c \neq 0$) to determine that $\frac{6x^2}{2x} - \frac{2x}{2x}$ is equal to $\frac{6x^2-2x}{2x}$ in Step 1, a learner must do several things. First, they must map one-to-one each subexpression in $\frac{6x^2-2x}{2x}$ to each variable in the "form" $\frac{a-b}{c}$ so every symbol in $\frac{6x^2-2x}{2x}$ gets mapped to a symbol with the same syntactic meaning in $\frac{a-b}{c}$, and the mapping preserves the relative order of all the subexpressions and symbols in the expression. Second, learners must use the form $\frac{a}{c} - \frac{b}{c}$ to map the same subexpression to the same variable in $\frac{a}{c} - \frac{b}{c}$ as they did in $\frac{a-b}{c}$. Thus, the ***using properties (or form mapping)*** domain describes the extent to which a learner can construct one-to-one mappings from a symbolic representation to a mathematical property so that every symbol is mapped to a symbol (or syntactic convention) with the same meaning in the property, and each variable in the property is mapped to a subexpression (with the same variables mapped to the same or equivalent subexpressions).

As with the other two subdomains, this also involves a shift from a process to object view: the student must shift from conceptualizing the use of properties as plugging in one particular set of values (or variables) into the property, to thinking of the property itself as a canonical representation of a particular existing structure in the expression which they are attempting to transform. The form mapping required to use the property on more complex expressions requires that the student be able to think structurally about subexpressions as objects in the expression that they are trying to transform, as well as the relationship between these various sub-objects, and whether this is the same relationship as the relationship between various variables in the property. They must also have a relational view of equivalence, as the property must be conceptualized as a statement about the relationship between the original expression and the transformed result. A student might also reify the process of substitution into the particular form mapping object itself. There are many different objects which the student could conceptualize (the form mapping itself; the property as a canonical representation of structural relationships, etc.); the key difference is that the student is doing more than simply "moving around" symbols in the expression in an attempt to produce a pattern that "looks like" the property.

This domain includes not just the ability to use properties to correctly transform one expression or equation into an equivalent one, but the ability to reason or justify how a particular structural mapping of subexpressions and symbols in the expression/equation to various variables and symbols in the property allows us to make an argument about the equivalence of the original expression/equation and the resulting expression equation.

Learning subdomains serially

The subdomains of substitution equivalence, syntactic structure, and using properties are all deeply interconnected, and are all necessary in order to conceptualize algebraic transformation as substitution equivalence. But they need not be learned all at once; the cognitive load of such a

[1] Our use of the term *syntactic structure* should not be confused with Chomsky's use, which is different.

task is likely to be too demanding for learners with limited prior experience with syntactic reasoning. Thus, as a brief illustration, we demonstrate some ways in which aspects of these domains might initially be learned separately, or serially (and then later re-combined). In other contexts, this approach has been successful at improving student learning of complex ideas by reducing cognitive load (e.g., Pollock et al., 2002).

Syntactic structure and subexpressions

There are many ways that we could ask students questions that only draw on their knowledge of syntactic structure, and not require other types of complex and interrelated syntactic reasoning skills. For example, consider the following question, which limits the task not only to just identifying syntactic meanings, but also to identifying only *one* syntactic meaning at a time, significantly reducing the number of elements which must be held in working memory: "In the expression $\frac{6x^2-2x}{2x}$, what is being squared? Use the order of operations to justify your choice." In other research, we have found that many college students identify $6x$ as the base of the exponent instead of x (Wladis et al, 2022c), often because they have extracted their notions of which subexpressions "look right" based on experience, rather than reifying them from the process of the order of operations (even when they can recite the order of operations correctly, or use it to calculate correctly with numbers). This suggests that it may be essential to tackle syntactic structure individually, before proceeding to other syntactic reasoning skills which may be more complex and interrelated, and all of which depend upon a student first being able to identify the "right" subexpressions in an expression to be transformed.

It may also be necessary to ask students whether there is more than one right answer to this question. In our research, we have encountered students at many levels who have explained that an expression can have multiple correct meanings, where different meanings provided by the student are not equivalent (Wladis et al, 2022c). Thus, another component of this subdomain is discussing with students that all expressions must be well-defined, with one unambiguous meaning. Students may not realize that this is a core tenet of mathematics.

We note that determining whether a student has an object or a pseudo-object conception of the order of operations may be difficult to determine when looking only at "standard" problem contexts. Students have created pseudo-object mental schema precisely because they appear to mimic the subexpression structurings of expressions and equations that "work" during situations seen during instruction (e.g., Aly, 2022; Erlwanger, 1973). Often it only becomes obvious that students' justifications for choosing certain subexpressions are not mathematically valid when students are given more "non-standard" problems, or when students are asked directly how their choice of sub-expression relates to the order of operations (in our research, a common response, even from students in higher-level courses such as calculus was "it doesn't relate to the order of operations" [Wladis et al, 2022c]). Giving students explicit instruction in syntactic structure may act to mitigate this issue that has been observed elsewhere in the literature.

Substitution Equivalence

As with the syntactic structure subdomain, the substitution equivalence domain (and by extension equivalence subdomain) can be thought of as an element which could be learned separately, to reduce the cognitive load of learning syntactic reasoning all at once. For example, in this particular problem, it might be important to find out if a learner understands that replacing $\frac{6x^2-2x}{2x}$ with $\frac{6x^2}{2x} - \frac{2x}{2x}$ during step 1 is a process of replacing an expression with another equivalent expression. Some students may have a computational rather than relational view of equivalence of expressions or equations, where they see $\frac{6x^2}{2x} - \frac{2x}{2x}$ as the result of "doing something" directly to $\frac{6x^2-2x}{2x}$ and do not see an equivalence relationship between the two expressions (or may not even conceptualize equivalence as a relationship between two things, but rather as a process of computation) (Wladis et al, 2022a, 2022b). This can be seen particularly clearly when we look at the substitution equivalence that the student needs to recognize in order to perform step 2. We could, for example, limit the cognitive load of that step almost exclusively to the process of substitution equivalence if we asked: "Suppose that $6x^2 = (2x)\cdot(3x)$. Use this fact to replace the expression $\frac{6x^2}{2x} - \frac{2x}{2x}$ with an equivalent expression, and to explain why the new expression is equivalent to $\frac{6x^2}{2x} - \frac{2x}{2x}$." As long as a student has enough understanding of syntactic structure to know that the numerator of a fraction is always a subexpression, and they understand the notion of substitution equivalence, this information should be sufficient for them to be able to replace $\frac{6x^2}{2x} - \frac{2x}{2x}$ with $\frac{(2x)(3x)}{2x} - \frac{2x}{2x}$ and to explain why the two expressions are equivalent. This can later be combined with more robust knowledge of identifying subexpressions to combine the two domains of substitution equivalence and syntactic structure, after students have had opportunities to master key conceptions in each subdomain separately.

Using Properties/Form Mapping

As with the syntactic structure and substitution equivalence domains, the using properties/form mapping domain can also be thought of as an element that could be learned separately, in order to reduce the cognitive load of learning syntactic reasoning all at once. For example, in this particular problem a student could be asked: "Let $a = 6x^2$, $b = 2x$ and $c = 2x$. Then use the property $\frac{a-b}{c} = \frac{a}{c} - \frac{b}{c}$ (where $c\neq 0$) to explain why $\frac{6x^2-2x}{2x} = \frac{6x^2}{2x} - \frac{2x}{2x}$." In this example, students need to have a basic idea of substitution equivalence, but they do *not* need to be able to identify the subexpressions of $\frac{6x^2-2x}{2x}$, as this has already been done for them. Thus, a task like this could be used to allow students to practice their knowledge in the domain of using properties, without yet requiring substantial knowledge of syntactic structure, and thus reducing the learner's cognitive load by allowing them to focus on fewer domains at a time.

After a leaner has had the opportunity to master substitution equivalence and syntactic structure, these separate conceptions that have been learned serially could be reintegrated with the using properties domain to complete questions like Example 1 without being given the specific values for *a*, *b* and *c*. Then, once the conceptions necessary to engage with these types of problems have been mastered, students could be given questions where they need to choose the particular property that could be fitted to the structure of a given expression (or equation); after that, they could be asked to select the property which serves a particular goal (e.g., producing an equivalent expression without parentheses, or with a particular form, etc.); and finally, after mastering each of these serialized tasks, they could progress to being asked to plan out the usage of a sequence of properties necessary to accomplish some larger goal.

Conclusion

In this theoretical paper we have aimed to identify and explore some necessary (but not necessarily sufficient) types of knowledge that are essential for students to be able to transform algebraic expressions and equations with understanding (by which we mean, to be able to reason about and justify these transformations in mathematically valid ways). We have framed this around the lens of substitution equivalence, with the aim of deconstructing complex knowledge structures into simpler component subdomains which could be learned serially before being reintegrated, to allow students with low prior knowledge in syntactic reasoning to build up this knowledge in ways that do not overload working memory. Our hope in presenting this model is to start a conversation about how we could more explicitly address reasoning and justification when teaching, and assessing learners' knowledge in, algebraic transformation.

Professional Obligations in Mathematics Courses for Teachers

Patricio Herbst[1] Daniel Chazan
University of Michigan University of Maryland

Amanda Brown Vilma Mesa
University of Michigan University of Michigan

This theoretical contribution draws on earlier work by Herbst and Chazan (2012; also Chazan et al., 2016) in which they describe the position of a mathematics teacher in an educational institution as accountable to stakeholders who issue four types of professional obligations. We propose an application and adaptation of that framework intended to address the case of instructors who teach undergraduate mathematics courses to future teachers. Considerations of not only the academic but also the professional ends of these courses are key in our application of the theory of obligations.

Keywords: instruction, professional obligations, professional preparation, undergraduate mathematics courses, mathematics courses for teachers

Understanding the work of teaching undergraduate mathematics courses for prospective elementary and secondary teachers is of interest to the RUME community (e.g., Hauk et al., 2017; Lai et al., 2019; Martin, et al., 2020; Yan et al., 2020). Separately, the professional obligations framework (Herbst & Chazan, 2012) has been found useful for RUME researchers to examine the decisions undergraduate mathematics instructors make (e.g., Bennett, 2022; Shultz, 2022; Shultz et al., 2022). In this theoretical contribution we offer an application and adaptation of the professional obligation framework to account for specific demands on the position of instructors of mathematics courses for teachers.

Improvement of Mathematics Courses for Teachers

Recommendations for improvement in the mathematical preparation of teachers, have posited that mathematics courses for teachers should include what researchers have called mathematical knowledge for teaching (e.g., AMTE, 2017; CBMS, 2012) for two reasons. First, research in mathematics education has documented how the mathematics needed for teaching includes types of knowledge that have not been commonly covered in university mathematics courses, even in those dedicated to teachers (Ball et al., 2001). Second, research in mathematics education has also documented that mathematical knowledge for teaching (MKT) can make a difference in the mathematical quality of instruction and in students' achievement (Hill et al., 2005; 2008). Given the prevalence of university-based teacher preparation in the number of entrants to the profession (Ronfeldt et al., 2014), it seems that if university mathematics courses for teachers could increase the MKT of new teachers (see Laursen et al., 2016), the improvement of mathematics courses for teachers could serve to improve the systemic capacity for mathematics teaching in K-12.

But because mathematics courses for teachers have been taught for decades (Ferrini-Mundy & Findell, 2010; Kilpatrick, 2019; Murray & Star, 2013), improvements in these courses need to

[1] The writing of this paper has been supported in part by National Science Foundation grant DUE- 1725837. All opinions are those of the authors and do not necessarily represent the views of the Foundation.

consider and contend with extant curriculum, instruction, and assessment practices of those courses, all of which are anchored in institutional practices. Accounts of how individual instructors relate to such recommendations and how much they know about pedagogical content knowledge and the knowledge needed to teach teachers are valuable (Lai, 2019; Superfine & Li, 2014), but to make sense of how improvement could go, we also need accounts of the system in need of improvement (Bryk et al., 2015).

Some accounts of the system take the perspective of observers – for example noting the flow of people into K-12 teaching coming from university teacher education programs versus alternative certification (e.g., Ronfeldt et al., 2014) or charting the changes in MKT observed in courses of mathematics for teachers (Laursen et al. 2016; Pape et al., 2015). These observer accounts may help reformers understand what effects changes in university instruction may have in K12 instructional capacity. But that information by itself is unlikely to address some of the tensions instructors in these courses have to manage, which relate not only to their own knowledge and experiences (Lai, 2019) but also to the environments in which they work and the demands those environments place on them (Herbst et al., 2018). It is therefore important to understand the position and the roles of instructors of those courses. This involves not only understanding individuals in terms of what they are disposed to do but also the sets of systemic relationships and intact practices in which they are involved and that likely enable them to be so disposed (Bourdieu, 1990). To advance in this direction, the theoretical claim we make is that the professional obligations framework (Herbst & Chazan, 2012) can be used to describe how instructors of mathematics courses for teachers orient to their work.

The Professional Obligations of Mathematics Teaching

Chazan et al. (2016) describe the work of a teacher in terms of an institutional position–defined in relation to institutional stakeholders–and the various roles the teacher plays in the activities the institution expects them to engage. Mathematics instruction (narrowly defined as helping students learn a course of study) is a particularly important activity in which the teacher plays a role, but not the only such activity (e.g., mentoring youth is another such activity). The stakeholders Chazan et al. (2016) identify include (a) the Client–individual students and their advocates are stakeholders inasmuch as they are expected to benefit from schooling; (b) Knowledge–the accumulated knowledge and knowledge-producing practices of humankind, personified in scientific communities of knowledge producers, are stakeholders inasmuch as knowledge is to be disseminated and preserved through schooling; (c) Society–represented by community leaders, sponsors, and authority figures–is a stakeholder, putting at stake shared values, customs, needs, and goals of a society, community, or nation inasmuch as those stakes are to be interpreted, disseminated, and preserved for a new generation through schooling; and (d) Organization–the administrative, economic, and legal aspects of an organization are stakeholders inasmuch as school institutions need to abide by them. While these stakeholders are stakeholders of schooling and thus make room for instruction as well as other activities, they serve to specify the position of a teacher inside an educational institution, providing sources of justification for decisions that an individual teacher might make in the activities they engage in–particularly, in instruction. Chazan et al. (2016) identify these sources of justification as professional obligations, and they name them (a) the individual obligation (to students as individuals); (b) the disciplinary obligation (to the knowledge disciplines that are sources of the content of instruction); (c) the interpersonal obligation (to the society in which the class of students are to integrate themselves); and (d) the institutional obligation (to the various institutions that serve as environments for the activities in which the teacher plays a role). Those stakeholders structure the institutional space in which (mathematics) instruction takes place and individuals hired into teaching positions are socialized into roles in various activities in which it becomes natural for them to feel obliged in the ways that the four obligations describe. The obligations neither erase individual responsibility nor prevent individual agency; rather, they identify resources and constraints available to individuals to publicly warrant actions and decisions.

Those warrants for actions and decisions may be especially useful in the activity of mathematics instruction, especially as our field concerns itself with instructional improvement. Because instructors' agency needs to be co-opted in order to make some such improvements, it is important for improvement efforts not only to acknowledge the expectations teachers work under but also to identify resources that may support their participation in institutional argumentation around changes in practices. If instructional improvement requires instructors to act in ways that deviate from the expectations they or their students have coming into class, justifications may be needed. The professional obligations can help provide such justifications. Further, if recommendations for instructional improvement may seem to push teachers beyond what feels viable to them, the professional obligations may help practitioners negotiate those recommendations.

Because practical rationality and the obligations framework describe the position in which instructors are and the role they are expected to play in instruction (and because they are not a theory of action for improvement along a particular direction), they can identify sources of justification that instructors might use to argue both for and against change in any direction. As such, this framework can help researchers understand reactions against reform and it can help frame institutional discussions about improvement that acknowledge where different parties are coming from. However, practical rationality was originally developed to examine the position and the instructional role of mathematics teachers in academic contexts (that is, in the study of mathematics, be that in K-12 schooling or in mathematics courses for mathematics majors). The application of the framework to the mathematics instruction of professionals, who will use mathematics to do professional work requires some adaptation.

Expanding the Theory of Practical Rationality to Account for the Experiences of Instructors of Mathematics Courses for Teachers

We contend that in order to understand the position and the instructional role of those who teach mathematics courses for teachers, it is worth describing the instructional practice in which they are involved as contested by a tension between two different instances of the instructional triangle (Cohen et al., 2003): Each instructor of undergraduate mathematics courses for teachers is in a position from which they can be disposed to see the course they teach as both an undergraduate mathematics course and as a mathematics teacher preparation course.

Much work in mathematics education that attends to the work of teaching implements this attention by looking at the individual who does the teaching–for example, in terms of their beliefs and knowledge. In the case of mathematics courses for teachers, an important distinction among instructors runs along issues of academic preparation and professional identity: Individual instructors may have doctoral degrees in mathematics or in mathematics education, and, in some cases, they may not have doctorates; their professional identity may include having been teachers or not, doing mathematical research, doing mathematics education research, doing both kinds of research, or doing no research. Those contingencies may impact the way in which they take up their position (e.g., hired to teach mathematics courses for teachers vs. hired for other reasons and assigned to teach such courses). While we do not deny the importance of attending to those sources of individual differences, understanding how they matter in the way individuals play their role in instruction and how they recognize the various obligations is beyond the scope of this paper. In proposing an adaptation of the obligations framework from the theory of practical rationality, we are deliberately bracketing out those sources of individual differences to describe the set of resources and constraints that support the position in which all instructors of mathematics courses for teachers are hypothesized to be and arguing that it is more complex than that of instructors of mathematics courses for academic and scholarly preparation (e.g., mathematics courses for mathematics majors). We sketch this adaptation below and indicate what further research could be done to gather evidence of how these obligations operate.

The Institutional Obligation on Instructors of Mathematics Courses for Teachers

The institutional environments in which one finds mathematics courses for teachers include not only the mathematics departments that offer these courses and the colleges which employ the instructors but also the teacher education programs that admit the students and require them to take these courses. At least in the United States, these tend to be separate organizations within universities. All those organizations hold the instructor accountable in some way. Some of those mechanisms of accountability may be common across organizations, unspecific to the courses, and inscribed in rules and policies (e.g., work contracts, class schedules). Mathematics departments also hold instructors accountable (e.g., expectations for office hours and syllabi). Teacher preparation programs are likely to exercise this accountability through expectations that become visible when they are violated (e.g., education advisors letting teacher education students fulfill alternative requirements when they fail mathematics courses for teachers, or students themselves feeling empowered to confront mathematics instructors on matters of content choice when they don't see its relevance for future teachers). We contend that the location of mathematics courses for teachers in institutional environments that include these various organizations makes for instructors' institutional obligation to be more complex than that of instructors of mathematics courses for mathematics majors. We suggest that research could endeavor to elicit from instructors narratives of episodes in which their instructional decisions were shaped by explicit interactions with teacher education personnel or expectations they have internalized from prior interactions with teacher education faculty or students. Research could elicit from mathematics department chairs and from teacher education coordinators the expectations their respective institutions have for these courses. What experiences do teacher education programs expect these courses to provide their students and how do they convey these expectations to mathematics instructors? Are those expectations different among mathematics courses for elementary and secondary teacher preparation? How do those expectations play out in recruiting and evaluating instructors of those courses?

One strategy that mathematics departments have employed to ensure attention to the needs of teacher education programs is to employ individuals with degrees in mathematics education or who participate in mathematics education professional communities to teach mathematics courses for teachers. Research could document the diversity of episodes in which instructors with different professional profiles are called to attend to the institutional obligation as well as how the departmental discussions on curriculum, pedagogy, and assessment in mathematics courses for teachers incorporate attention to the expectations from teacher education programs. Research might also document how teacher education program discussions incorporate and process information from instructors and students of mathematics courses for teachers (e.g., about the quality of students' mathematical work or the difficulty of courses). While it seems auspicious that mathematics departments might employ faculty interested in and prepared for mathematics teacher education in teaching these courses, we cannot assume that a change of instructor will eliminate any need for institutional accountability on the part of these instructors. Instead, it seems important to describe how this institutional accountability is experienced by instructors with different preparation and to gather case knowledge on how instructors handle institutional influences on their instruction.

The Individual Obligation on Instructors of Mathematics Courses for Teachers

The obligations framework proposes that students, as the clients of education institutions, hold teachers accountable to serve them as individuals. The case of students in mathematics courses for teachers is similar insofar as they are undergraduate college students: Instructors are obligated to attend to them as whole persons, with cognitive, emotional, and physical needs and goals. As young adults, students are likely to be able to advocate for many of these needs themselves rather than through their parents. But for instructors of mathematics courses for teachers, the individual obligation seems more complicated. We suggest that the instructor may also need to be accountable to their students as future professionals, attending to other aspects of their individuality that the students themselves may not be as ready to advocate for. These include aspects of the professional identity of a teacher that will be important for the individual presentation of self of these novice teachers when they commence their professional life. Instructors' accountability to students as clients may compel them to see their students not only as individuals with present needs and desires but also as future professionals with future needs.

Research could elicit instructors' narratives to find out what aspects of students' future professional identity emerge in the course of instruction as compelling opportunities for instructors to make individual accommodations. Personal characteristics often part of moral character (e.g., self-control or intellectual honesty), individual beliefs (e.g., about mathematical ability), and skills (e.g., voice projection) might be included and that instructors may recognize opportunities to build students' sense of professional identity when characteristics like those emerge in the context of classroom work. Research should especially attend to how instructors negotiate with prospective teachers the need for them to learn material that might seem difficult or uninteresting to them at the moment (during college years) and whether and how instructors' recognition of an obligation to students as future professionals serves them in such negotiation.

The Interpersonal Obligation on Instructors of Mathematics Courses for Teachers

The obligations framework proposes also that society is another stakeholder of the work of teaching and the source of a professional obligation for instructors to conduct their classes in ways that steward social values and goals. Insofar as an undergraduate class includes young adults that have to interact with each other in socially productive ways and that will incorporate themselves into the social world after college, it is likely that instructors will feel compelled to steward some social values and expectations that apply to everybody (e.g., taking turns in conversation, respecting the personal space and property of others). But insofar as the undergraduates will be teachers, some of those values and expectations may concern the role that teachers play in society. A salient one is a sense that society needs teachers for its children (Beckmann, 2011) and that these teacher cadres need to represent the diversity of society (e.g., Bristol & Martin-Fernandez, 2019; Frank, 2019). This has implications for instructors with regards to the ways that their courses and the grades they assign in those courses tend to serve as a gateway not only for individual students to get their degrees but also, and especially, for society to receive its teachers. Students' interactions with instructors and their course material can also affect students' continued interest in the profession of teaching. The interpersonal obligation suggests societal needs that should compel instructors not to alienate students from mathematics or discourage their desire to teach mathematics in K-12 contexts.

We suggest that research could better unpack how instructors encounter and respond to opportunities to attend to the interpersonal obligation. What are some ways in which instructors' obligation to recruit and form teachers that can serve society is and can be displayed? How has it been ignored?

The Disciplinary Obligation on Instructors of Mathematics Courses for Teachers

The disciplinary obligation as proposed by Herbst and Chazan (2012) alludes to mathematics instructors' obligation to represent the discipline of mathematics when they teach in classrooms. One could expect this disciplinary obligation to be present also for instructors of university mathematics classes, including mathematics courses for teachers. For example, because textbooks and lecture notes are presentations of course content rather than disciplinary communications (as journal articles are), it is expected that this didactical transposition of knowledge (Chevallard, 1991) may depart from the norm in mathematical communication (e.g., sometimes stating a proposition without providing proof or providing a definition that goes beyond necessary and sufficient conditions). Instructors might show recognition of their obligation to the discipline of mathematics if in the context of such pedagogical practices they pointed out to students that the statement could be proved even if the proof is beyond the scope of the course or that some of the stipulations of a definition are implied by others.

But in addition to an obligation to the discipline of mathematics, Knowledge as a stakeholder can be expected to hold instructors of mathematics courses for teachers accountable in other ways. The progress made by mathematics education research in the last few decades added to the fact that this scholarship has become more widely known among and practiced by college mathematics instructors (such as RUME participants), suggest that instructors might recognize a disciplinary obligation toward the knowledge generated in mathematics education research. This scholarship includes at least two types of knowledge worth noting, both contained within the notion of mathematical knowledge for teaching and illustrating the interdisciplinary nature of mathematics education research. The first is specialized knowledge of mathematics or mathematically specific knowledge needed for teachers to engage in tasks of teaching mathematics. As Ball et al. (2008) have argued and illustrated, this is purely mathematical knowledge that reveals itself as needed in the context of tasks like creating problems for students or analyzing the mathematical errors students make in problems. The second is empirical knowledge about students' understanding of mathematics and the ways in which students might respond to instructional strategies; that is, elements of pedagogical content knowledge. We distinguish these two types of knowledge because their truth status results from different types of inquiry, one more deductive, founded on mathematical reasoning, and the other inductive, founded on scientific reasoning. We suggest that research could elicit from instructors narratives of episodes in which their awareness of research on mathematics teacher knowledge has compelled them to deviate from, qualify, or add to the content they teach.

Furthermore, the professional practical knowledge of mathematics teachers, which is not warranted solely by mathematical or scientific reasoning but also informed by policy and educational politics, may contribute yet a third source of accountability to knowledge for instructors of mathematics courses for future teachers. Documents such as the Common Core Standards (National Governors Association, 2010), exercise a transdisciplinary accountability similar to that of the disciplinary mathematical knowledge or the interdisciplinary knowledge from research in mathematics education. For example, while a mathematical concept (e.g., geometric transformations) might be well defined in different ways, a Standards document may implement a particular choice of definition to be used in K-12 settings and that choice may serve as a justification for the instructor of a geometry course for teachers to make instructional decisions (e.g., not to adopt the definition provided in the textbook, but to change it to match that of the Standards). Similarly, professional organizations such as NCTM have at times advocated for including the history of mathematics with its teaching as means to show students that mathematics is a human activity; such recommendations add transdisciplinary resources and constraints to instructors. The investigation of the instructors' position needs to account for the various knowledge sources of the disciplinary obligation. Because these disciplinary sources come from different origins and epistemologies, it seems important to inventory not only the ways they present themselves as opportunities or as constraints to instructors, but also to document how instructors handle them when they might not align with each other.

Conclusion

In their approach to improvement science, Bryk et al. (2015) argue that a needed step toward improvement is to secure an understanding of the system in need of improvement–how the system works–from the multiple perspectives that are called upon to work toward improvement. Instructors are important in improvement not only because their agency can (and needs to) be co-opted to realize improvement but also because their perspective on how the system works can help anticipate what may happen with those improvement efforts (including their own). Instructional improvement thus requires not only relying on instructors as agents of change but also incorporating the rationality (in the sense of sensibility or sense-making) of instructors as a vital component of improvement efforts. We contend that incorporating this rationality means seeking ways to reconcile (a) what instructors are disposed to accept as part of their roles in instruction and how they perceive their position in the higher education system and (b) how their position in a system of power relations and institutional regulations conditions them to be so disposed (Bourdieu, 1990). We argue that at the college level, where traditionally instructors of record have had much authority to decide what to do, it is important to understand not only who the instructors are and what they know or believe, but also how they see the system in which their effort is inscribed and that avowedly needs to be improved. In our discussion of the obligations as they apply to instructors of mathematics courses for teachers, we elaborate on how each of these obligations might split into different branches. Better understanding empirically how these various branches of professional obligations actually show up for instructors of mathematics courses for teachers can help in the quest of improving the mathematical preparation of teachers. Eventually, measures can be constructed to assess the extent to which individual instructors recognize the different aspects of each obligation as hypothesized above. Further, similar kind of layout for empirical inquiry could guide the study of instruction in mathematics classes for other professionals (e.g., engineers, nurses).

The role of derivatives across multivariable and vector calculus instruction using multivariational reasoning and students' interpretations of matrix equations

Zachary S. Bettersworth
Arizona State University

Multivariable and vector calculus (MVC) encompasses a wide array of different types of functions and the extension of numerous ideas from univariable calculus to MVC contexts. In this paper, I reflect on some of the more recent work on student thinking and learning of derivatives in MVC settings by leveraging some of the recent work on students' multivariational reasoning and student thinking and learning of linear algebra topics. I conclude with examples of ways to conceptualize derivatives as linear transformations to support students in progressing towards a unified notion of the derivative concept throughout MVC instruction.

Keywords: student thinking, multivariable calculus, derivatives, partial derivatives

Students in the United States are first introduced to the notions of multivariable and vector-valued functions in a multivariable and vector calculus (MVC) course. As a lead up to studying vector-valued functions the course introduces vectors, vector operations, graphing in three-dimensional coordinate systems, partial and directional derivatives, multiple integration, line and surface integrals, vector fields, the gradient operator, and the fundamental theorems of vector calculus (Stewart, 2011). Each of these concepts is important, but I am concerned that students perceive MVC as a collection of disconnected ideas and shortcuts (Harel, 2021), as opposed to an interconnected web of meanings. I am curious about ways students' understandings of MVC ideas are interconnected and how they extend their understanding of rate of change and accumulation functions (P. W. Thompson et al., 2019) to MVC contexts. In this paper, I want to reflect on ways to use current research in mathematics education to draw attention to how nuanced students' ways of thinking about MVC topics can be. To demonstrate my intention, I isolate my focus to the various uses of partial derivatives detailed across recent math education literature and reflect on how to make connections between students' reasoning about partial derivatives and their meanings for their symbolizations of linear approximations for different functions. I draw on co-variational and multivariational reasoning (Thompson & Carlson, 2017; Jones, 2022), in relation to an altered version of a theoretical framework from linear algebra (Andrews-Larson & Zandieh, 2013; Zandieh & Andrews-Larson, 2019).

A Review of the Literature on the Teaching and Learning of Partial Derivatives

Over the last five years, there has been an increase in mathematics education research investigating students' understandings and ways of thinking about multivariable calculus topics. These topics include: multiple integration (Jones & Dorko, 2015), ways of thinking about scalar and vector line integrals (Jones, 2020), students' treatments and conversions of graphical registers for gradient vectors (Moreno-Arotzena et al., 2021), manipulatives for supporting students in graphing surfaces (Kang et al., 2020; Wangberg, 2020; Wangberg et al., 2022), students' covariational reasoning about partial derivatives (Mhkatshwa, 2021), and students' multivariational reasoning (Jones, 2018, 2022). The various ways that partial derivatives are seemingly used by students and researchers are described in Fig. 1. Each use of partial derivative described in Fig. 1 is nuanced, but heavily emphasizes contexts of functions of two variables.

Interpretation	Description of interpretation	Related articles
Partial derivatives as slopes of tangent lines to traces	Intersect the graph of the function $z = f(x, y)$ with a plane $x = a$. Find the coordinate triple $(a, b, f(a, b))$ and draw the tangent line in the y direction contained in the plane $x = a$ at the given point. The slope of that tangent line is the value of the partial derivative of f with respect to y $f_y(a, b)$.	(Martínez-Planell et al., 2017)
Directional derivatives as slopes of a tangent plane in a particular direction	Intersect the graph of the function $z = f(x, y)$ with the plane $z = f_x(a, b)(x - a) + f_y(a, b)(y - b) + f(a, b)$ at the coordinate triple $(a, b, f(a, b))$. The change in depth (variation in z) measured with respect to the horizontal displacement (the length of the direction vector $\vec{u} = \langle \Delta x, \Delta y \rangle$ which is parallel to the xy plane) is the value of the directional derivative $D_{\hat{u}} f(a, b)$.	(Wangberg et al., 2022) (Martínez-Planell et al., 2017; McGee & Moore-Russo, 2015)
Partial derivatives as rate of change functions	Given an amount function $z = f(x, y)$ the rate of change of z with respect to y as y varies through a small-enough interval containing $y = b$, mentally holding the value of x fixed at $x = a$, is the value of the partial derivative $f_y(a, b)$.	(Mhkatshwa, 2021)
Partial derivatives as components of the gradient vector	Given a multivariable function $z = f(x, y)$, the gradient is a vector pointing in the direction of the greatest directional derivative $\|\|\vec{\nabla} f(a, b)\|\| = D_{\hat{u}} f(a, b)$ whose tail is located on the contour plot of f at (a, b). The x component of the gradient is the partial derivative of z with respect to x and the y component of the gradient is the partial derivative of z with respect to y so that $\vec{\nabla} f(a, b) = \langle f_x(a, b), f_y(a, b) \rangle$.	(Moreno-Arotzena et al., 2021)
Partial derivatives as entries in the Jacobian matrix	Given a function $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$, the linear transformation, represented by the Jacobian matrix J, produces the best, local, linear approximation for f when $x_1 = a$ and $x_2 = b$. The components of matrix J are all of the first-order partial derivatives of the components of a given function, where each row is the transpose of the gradient of each component function.	(Harel, 2021)

Fig. 1: Interpretations of partial derivatives across recent math education research literature

Some of the earlier mathematics education research on MVC instructional design investigated students' responses to tasks within cycles of a Genetic Decomposition from APOS (action, process, object, scheme) theory which also leveraged Duval's theory of semiotic registers (Trigueros Gaisman & Martínez-Planell, 2013). The Genetic Decomposition for teaching partial derivatives of two-variable functions emerged from characterizing in-class activities for teaching two variable functions (Martínez-Planell & Trigueros Gaisman, 2019) and partial derivatives and directional derivatives through explicit lecture on 3D slopes (Martínez-Planell et al., 2017). McGee's tactile graphing manipulatives reinforced the notion that explicit attention to 3D slopes may provide students with a way to measure amounts of vertical change in terms of an amount of horizontal change, corresponding to the value of the directional derivative of a given two-variable function (McGee et al., 2012, 2015; McGee & Martínez-Planell, 2014; McGee & Moore-Russo, 2015). Students reasoning about 3D slopes (in the x and y direction respectively) and geometric conceptions of constant rate of change (as slopes) provided them with ways to reason about the values of partial derivatives graphically in 3D space. The research detailing the instructional implementations of the 3D acrylic surfaces of Wangberg and colleagues' also supported the notion that students reasoning about multivariable rates of change in graphical contexts require ways to envision measuring amounts of vertical in terms of the corresponding horizontal change to conceive of the values of directional derivatives as the slope of the surface in a given direction (Wangberg, 2020; Wangberg et al., 2022). Reasoning about surfaces as something to be traveled upon is extremely useful, however care should also be taken to ensure students make connections between tactile approaches to graphing surfaces and also reasoning about how the shape of the graph is a record of how the values of three quantities change together (Moore & Thompson, 2015; Weber & Thompson, 2014).

There are fewer research articles investigating how students conceive of vector-valued amount and rate functions. Jones investigated how students think about scalar and vector line integrals (Jones, 2020). Researchers have also investigated the ways students think about vectors and vector operations in the context of linear algebra (Lee, 2022), or physics (Dray & Manogue, 2006; Roche, 1997). However, there is a need for research experiments investigating how students think about and learn calculus ideas related to the derivatives of vector-valued functions, (i.e., divergence, curl, Green and Stokes' theorem, etc.). The research literature in physics education has also addressed ways to support students in using partial derivatives, and the relevant notation, to reconstruct Maxwell's equations of thermodynamics (Cannon, 2004; J. R. Thompson, 2006; J. R. Thompson et al., 2012). Some physics education researchers have leveraged Zandieh's derivative framework to determine the efficacy of tasks and instructional interventions in thermodynamics courses (Bajracharya et al., 2019). Further, Roundy and colleagues discussed how instructional issues may emerge when different disciplinary practices impact students' conceptions of the use of partial derivatives (Roundy et al., 2015). For instance, mathematicians and physicists appear to leverage partial derivatives in different ways in their disciplines. It would be prudent to continue the dialogue between math and physics instructors at each institution to determine ways to support students in shifting or extending their understanding of partial derivatives flexibly across the STEM disciplines.

Theoretical perspective

Before elaborating on various interpretations and uses of partial derivatives for different function types, I am going to discuss students' conceptions of different types of functions. MVC courses encompass many different types of functions sorted into at least two groups: (1) functions with multiple independent quantities and (2) functions with multiple dependent quantities (including vector-valued outputs). When discussing functions with more than one independent quantity, I will say *multivariable* functions (i.e., $z = f(x, y)$ or $w = g(x, y, z)$ as opposed to *univariable* functions (i.e., $y = f(x)$). To distinguish between functions with multiple dependent quantities and a single dependent quantity I will say *vector-valued* and *scalar-valued* respectively. It is highly unlikely that most students have encountered multivariable functions, or the corresponding notation, by the time they enroll in MVC. Some students may have encountered vectors and vector operations in the context of physics or linear algebra (LA). In Calculus I and II, most students have encountered univariable function notation, input/output tables, and memorized information about the graphs of various function families, along with a thorough introduction to derivative and integral techniques. However, it appears less likely that most student have been supported in reflecting on the idea of univariable functions (across various representational contexts) as sets of invariant relationships relating the values of two quantities whose values vary in tandem with the realization that, at any moment, the value of the independent quantity determines exactly one value of the dependent quantity (P. W. Thompson et al., 2017; P. W. Thompson & Carlson, 2017).

The literature reporting on researchers' investigations and theories about student thinking related to the function concept encompasses several decades of experimental results and theory (Breidenbach et al., 1992; M. P. Carlson, 1998; Monk, 1994; Oehrtman et al., 2008; Sfard, 1992; Zandieh et al., 2017). While there have been some studies investigating student thinking about functions of two variables (Kabael, 2011; Martínez-Planell & Trigueros Gaisman, 2019; Yerushalmy, 1997), the math education theory of student thinking about multivariable and vector-valued functions is comparatively less developed (Rasmussen & Wawro, 2017). I am genuinely curious about how students make sense of the sheer number of different *types* of functions covered in a single semester of MVC instruction (i.e., multivariable functions, parametric equations, vector-valued functions, vector fields, linear and non-linear transformations), in relation to their understanding of calculus ideas related to each function type (e.g., the divergence and curl of multivariable vector-valued functions graphed as vector fields).

Mathematics education researchers might ask research questions related to the various ways students conceive of different types of functions (e.g., action vs. process views of functions of two variables, a structural vs. operational views of linear transformations, covariational or multivariational views of parametric functions). Students' conceptions of univariable functions likely impact their understanding of multivariable functions, and eventually more general mappings such as linear transformations (Trigueros Gaisman & Martínez-Planell, 2013; Yerushalmy, 1997; Zandieh et al., 2017). Addressing the ways students think about and generalize their understanding of the function concept across their undergraduate mathematics course sequence is an important consideration for research and instructional design. Zandieh, Ellis, and Rasmussen (2017) analyzed students' conceptions the function concept cutting across the students experiences from high school algebra to linear transformations in linear algebra. I am curious about how students' notion of function, unified or otherwise, interacts with their conception of derivatives across various MVC contexts. Investigating students' *stable ways of thinking* about functions (P. W. Thompson et al., 2014) seems like a necessary first step to investigating how students conceptualize multivariable rate functions and partial derivatives more generally. Leveraging theories to investigate how students think, generalize, and symbolize their conceptions of functions, and their derivatives, is also worthwhile and relevant to the current trajectory of mathematics education research.

To that end, Jones recently expanded his multivariational framework (Jones, 2018, 2022) based on some of the work emerging from Carlson et al.'s (2002) covariational reasoning framework and Thompson and Carlson's (2017) variation and extended covariation frameworks. Jones described three types of multivariation as well as a framework describing students' multivariational reasoning (MR) mental actions. Jones defined three types of multivariation: (1) independent multivariation (i.e., functions of the form $z = f(x, y)$), (2) dependent multivariation (i.e., situations like the ideal gas law $PV = kT$), and (3) nested multivariation (i.e., composite, or parametric functions $y = f(x)$ where $x = g(t)$). Jones' multivariation and MR framework seem viable for building models of student thinking to determine how students engage in quantitative reasoning (P. W. Thompson, 1993, 2022) about multivariable and vector-valued functions. Further, modeling student thinking to determine how they coordinate the values of multiple quantities changing together is a viable lens for investigating how students conceptualize multivariable rates of change and, eventually, multivariable rate functions.

For example, suppose a student possesses a process view of the function $f(x, y) = xy^2 - xy$ where $z = f(x, y)$ (independent multivariation). The student mentally fixes the value of $x = a$, through decomposing the situation into *isolated covariations*. By considering how the value of z

co-varies with y as the value of y varies from -2 to 2 (holding the value of x fixed), the student can rely on previous ways of thinking about graphs of univariable functions. The student coordinates their mental image of the 2D graphs of $z = ay^2 - ay = ay(y-1)$ for particular values of a with images of the various traces situated in the planes $x = a$ pictured in $\mathbb{R}^3$. The student may reconceive of the situation and anticipate the shape of the surface as an emergent process through mentally coordinating the changing shape of the traces as x varies from -2 to 2. This is exactly the hypothetical learning trajectory (HLT) proposed by Thompson and Weber via the *sweeping out* metaphor (Weber & Thompson, 2014).

Mentally fixing the value of $x = a$ corresponds to the *reducing into isolated covariations* MR mental action and sequentially reconceiving of x as a varying quantity corresponds to the *coordination of multiple simultaneous changes* MR mental action, and perhaps, eventually, *smooth continuous multivariation*. This series of Jones' set of MR mental actions highlights one of the ways a student may come to graphically quantify the partial derivative of the function $f(x, y) = xy^2 - xy$ with respect to y, holding the value of x fixed at $x = a$, by associating their images of each trace of the surface which emerged through their initial conception of how the values of y and z *co*-varied together. The linear approximation for this particular trace (corresponding to the intersection of the graph of $z = f(x, y)$ and the plane $x = a$) emerges by assuming a constant rate of change (specifically $f_y(a, b)$) relating amounts of variation in the value of y away from $y = b$, and the corresponding amount of variation in the value of z emerges from pretending there is a constant rate of change relating amounts of variation in the values of y and z, i.e., $\Delta z \cong f_y(a, y)\Delta y$ or $z - f(a, b) \cong f_y(a, b)(y - b)$. Providing students with the opportunity to conceptualize partial derivatives as imagined constant rates of change due to variation in the value of y, holding the value of x fixed, may undergird why explicit discussions 3D slopes have proven helpful to students when reasoning about the values of partial derivatives as the slopes of tangent lines to the trace of f (Martínez-Planell et al., 2017).

Zandieh's (1997; 2000) derivative framework demonstrated how nuanced students' conceptions of derivatives can be. Each of the three process-object layers (ratio, limit, and function) encapsulates the *reification* of a particular process into a more static, *structural* conception of that layer (Sfard, 1992). The columns of Zandieh's framework encompass various contexts in which the framework can be used to depict the various aspects of a student's conception of derivatives. As Zandieh (1997; 2000) noted in the articulation of her derivative framework, each of the process-object pairs (the rows of the framework) correspond to a particular component of the derivative concept. The ratio, limit, and function layer may have their uses in particular contexts, but each aspect of the derivative concept is important to the overall conceptual structure. Students may have conceived of aspects of the derivative concept as contextual, or comprising the entire concept (Zandieh & Knapp, 2006). For example, in graphical settings, students may claim derivatives are slopes of tangent lines, but in a related rates task, a student may claim derivatives are just rate of change functions, without recognizing an implicit graphical connection to their previous statements about slopes of tangent lines. Investigating the ways students extend their understanding of derivatives to multivariable contexts is non-trivial. However, Zandieh's derivative framework is viable for articulating some of the nuanced aspects of the derivative concept in MVC. One such aspect of derivatives in MVC contexts, that is rarely discussed, is the conception of *derivatives as linear transformations*, as represented by the Jacobian matrix (Gravesen et al., 2017; Harel, 2021).

Zandieh, Ellis, and Rasmussen addressed the ways that students interpret linear transformations in relation to their high-school conceptions of function (Zandieh et al., 2017).

Zandieh et al. (2017) noted that students' concept images of function (from $\mathbb{R} \to \mathbb{R}$) may be separate from their conception of linear transformations as matrix equations. However, as students progress through the semester, their concept images become more interwoven to shift towards a unified notion of the function concept. I hypothesize that direct discussions of linear transformations are necessary to support students in extending their understanding of derivatives, more generally, towards a unified notion of the derivative concept. Zandieh and Andrews-Larsen discussed the various ways students interpret matrix equations (Larson & Zandieh, 2013), and extended their framework to include more nuanced interpretations of systems of linear equations and matrix equations (Zandieh & Andrews-Larson, 2019). I have outlined theoretical students' interpretations of the various roles that partial derivatives play in producing linear approximations for two types of functions in Fig. 2. Again, the various types of derivatives present in MVC may perpetuate students' apparent conception that MVC topics are seemingly disjoint and highly contextual. I hypothesize that centering the idea of derivative as a linear function, or transformation, which produces the best local, linear approximation of *any* type of function will help support students in conceiving of a more unified notion of derivative and thus leading towards coherence of MVC instruction in the minds of students.

Interpretation of $J_f \Delta\vec{x}$	**LT example:** $f: \mathbb{R}^2 \to \mathbb{R}^2$, $y_1 = P(x_1, x_2)$, $y_2 = Q(x_1, x_2)$	**MVC example:** $f: \mathbb{R}^2 \to \mathbb{R}$, $z = f(x, y)$	**Verbal description of each interpretation**
Linear Combination Interpretation **(LC)**	***Linear combination of amounts of change:*** $\begin{bmatrix}\Delta y_1\\ \Delta y_2\end{bmatrix} \cong \begin{bmatrix}\frac{\partial y_1}{\partial x_1}\\ \frac{\partial y_2}{\partial x_1}\end{bmatrix}\Delta x_1 + \begin{bmatrix}\frac{\partial y_1}{\partial x_2}\\ \frac{\partial y_2}{\partial x_2}\end{bmatrix}\Delta x_2$ $\Delta\vec{y} \cong \frac{\partial\vec{y}}{\partial x_1}\Delta x_1 + \frac{\partial\vec{y}}{\partial x_2}\Delta x_2$	***Coordination of amounts of change:*** $\Delta z_x \cong f_x(a,b)\Delta x$ $\Delta z_y \cong f_y(a,b)\Delta y$ $\Delta z \cong \Delta z_x + \Delta z_y$	Approximation emerging from coordinating the amount of variation in the value of the vector or scalar-valued dependent quantity due to variations in the value of each independent quantity separately.
System of Equations Interpretation **(SE)**	***System of linear approximations:*** $\Delta y_1 \cong \frac{\partial y_1}{\partial x_1}\Delta x_1 + \frac{\partial y_1}{\partial x_2}\Delta x_2$ $\Delta y_2 \cong \frac{\partial y_2}{\partial x_1}\Delta x_1 + \frac{\partial y_2}{\partial x_2}\Delta x_2$	***Linear approximation:*** $\Delta z \cong \frac{\partial f(a,b)}{\partial x}\Delta x + \frac{\partial f(a,b)}{\partial y}\Delta y$ $z \cong \frac{\partial z}{\partial x}(x-a) + \frac{\partial z}{\partial y}(y-b) + f(a,b)$	Approximation for each dependent quantity (as a component of a vector-valued output) due to simultaneous variation in the value of each independent quantity.
Dot product interpretation **(DotP)**	***System of dot products:*** $\Delta y_1 \cong \vec{\nabla}P(a,b)\cdot\begin{bmatrix}\Delta x_1\\ \Delta x_2\end{bmatrix}$ $\Delta y_2 \cong \vec{\nabla}Q(a,b)\cdot\begin{bmatrix}\Delta x_1\\ \Delta x_2\end{bmatrix}$	***Dot product:*** $\Delta z \cong \vec{\nabla}f(a,b)\cdot\begin{bmatrix}\Delta x\\ \Delta y\end{bmatrix}$	Approximation for each dependent quantity as emergent from a geometric relationship as projection or based on the angle between the gradient vector and a direction vector.
Transformation interpretation **(LT)**	***Approximating a non-linear transformation:*** $\Delta\vec{y} \cong J_f\Delta\vec{x}$ $\begin{bmatrix}\Delta y_1\\ \Delta y_2\end{bmatrix} \cong \begin{bmatrix}\frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2}\\ \frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x_2}\end{bmatrix}\begin{bmatrix}\Delta x_1\\ \Delta x_2\end{bmatrix}$	***Inner product:*** $\Delta z \cong \vec{\nabla}^T f(a,b)\begin{bmatrix}\Delta x\\ \Delta y\end{bmatrix}$ $\Delta z \cong \begin{bmatrix}\frac{\partial z}{\partial x} & \frac{\partial z}{\partial y}\end{bmatrix}\begin{bmatrix}dx\\ dy\end{bmatrix}$	Approximation of the output space via the linear transformation represented by the Jacobian matrix.

Fig. 2: Theoretical student interpretations of linear approximations altered from Zandieh & Andrews-Larson (2019). The geometric context column has been omitted due to space limitations.

Based on some of the uses of partial derivatives pictured in Fig. 1 and the relevant math education literature on student thinking about partial derivatives, I altered Zandieh and Andrews-

Larson's framework for students' interpretations of matrix equations to anticipate various ways students could interpret and symbolize derivatives in the context of constructing linear approximations for different types of functions. The table in Fig. 2 could be used to anticipate students' conceptions and symbolization for scalar and vector-valued functions with more than two independent or dependent quantities (e.g., multivariable, scalar-valued functions with three or four independent quantities). While the table in Fig. 2 only elaborates on linear approximations for functions involving independent multivariation, the interpretations can be applied to situations involving nested multivariation through the chain rule and conceptualizing products of matrices as compositions of linear transformations (Harel, 2021).

The MR mental action of *reducing to isolated covariations* seems necessary to conceive of linear approximations while coordinating the amount of variation in the value of the output vector or scalar-valued dependent quantity (z) due to separate variations in the value of each pair of independent quantities (x_1 and y_1 and x and y respectively). Coordinating the amount of total variation, or at least an approximation of this amount of variation, emerges from the *coordination of multiple simultaneous changes* MR mental action. The LC and SE interpretations more readily highlight the *reducing to isolated covariations* and *coordination of simultaneous changes mental actions* due to the emphasis on coordinating net changes in the values of the dependent quantities due to separate amounts of variation in the values of each independent quantity.

Conclusion

One way to continue to build on the current state of the mathematics education research literature on the teaching and learning of MVC topics is through coordinating research on student thinking about linear algebra concepts in conjunction with burgeoning theories about student thinking within the context of MVC instruction (Cobb, 2007). One approach is to leverage an altered version of Zandieh and Andrews-Larsen's (2019) framework elaborating students' interpretations of matrix equations in the context of constructing linear approximations for multivariable and vector-valued functions with Jones' (2022) elaboration of MR to anticipate ways students can interpret and symbolize derivatives in MVC. The ways in which students conceive of multivariable and vector-valued rate of change functions necessarily depends on their conceptions of amount functions. Future research studies should seek to coordinate students' symbolization activity with their associated meaning in graphical and non-graphical contexts (Tyburski et al., 2021). Triangulating students' meanings and stable understandings of vector calculus ideas will help to extend the research field's understanding of how students learn and interpret vector calculus ideas and notation.

In this manuscript, I have summarized the recent work on the ways students use partial derivatives in MVC. It should be restated that there are different *types of functions* present in a MVC course, but there are also numerous ways students could conceptualize them; as one example is the diverse approaches to coordinating variation in the values of numerous quantities. As Zandieh, Rasmussen, and Ellis noted, students' conceptions of the function concept may vary widely depending on the context. My hope is to gain insights into the nuanced ways students interpret, use, and symbolize partial derivatives when creating linear approximations.

Future studies could extend the theory I have presented here by applying it to students' written work in MVC contexts. This report is largely theoretical and based almost entirely on my experiences working with students enrolled in a conceptually oriented MVC course for two academic years in conjunction with my research with the IOLA research group.

Theoretical Considerations for Designing and Implementing Intellectual Need-Provoking Tasks

Aaron Weinberg

Steven R. Jones
Brigham Young University

The idea of intellectual need (IN) has received much interest from instructors in trying to design tasks that engage students in impasse-driven learning. However, we argue that the literature on IN is currently insufficient for supporting the careful design and implementation of tasks meant to provoke IN. In this paper, we examine two shortcomings: (1) What exactly IN can be created for, and (2) How an instructor might support students in navigating the experience of resolving the confusion and constructing the targeted meanings. For the first of these, we describe the category error of thinking of producing IN for a "topic," and use the idea of conceptual analysis to suggest a way to address this shortcoming. For the second, we bring in control-value theory to explain what an instructor might attend to in order to ensure that the disequilibrium stays productive and does not lead to frustration and disengagement.

Keywords: Intellectual Need, Task Design, Constructivist Pedagogy, Epistemic Emotions

Introduction and Literature Review

Educators and researchers have long described the positive impact of "desirable difficulties" and "failure-driven scaffolding" on student learning (e.g., Dewey, 1938; Kapur, 2015; Sinha et al., 2020). Studies have shown that experiencing cognitive incongruities (e.g., Graesser et al., 2005), working on problems prior to instruction (e.g., Kapur & Rummel, 2012), and experiencing impasses (e.g., VanLehn, 1988; Kapur, 2014) are associated with improved learning and constructive reasoning. Graesser and D'Mello (2012) proposed that these results align with Piaget's (1971, 1985) work on cognitive development—specifically, the idea of disequilibrium, in which the impasses students encounter prompt them to revise their cognitive schemes or construct new ones to accommodate for novel stimuli and experiences.

In the context of learning mathematics, Harel (e.g., 2013), described the role played by cognitive disequilibrium in the learning process in terms of the construct of the *intellectual need*, which is the perceived need to resolve "a perturbational state resulting from an individual's encounter with a situation that is incompatible with, or presents a problem that is unsolvable by, his or her current knowledge" (p. 122). Since its introduction, intellectual need has been a widely-cited principle of instructional and curriculum design (e.g., Burger & Markin 2016; Caglayan, 2015; Foster & de Villers 2015; Koichu, 2012; Leatham et al., 2015; Rabin et al., 2013; Zazkis & Kontorovich, 2016). The idea of intellectual need has been enthusiastically endorsed by some instructors. In their planning, these instructors begin with a target mathematical concept ("[x]") and then begin their lesson planning by asking something like: "If [x] is aspirin, then how do I create the headache [i.e., the intellectual need]?" (Meyer, 2015).

Despite its widespread use in the research literature, there is little guidance about how to design and implement effective intellectual need-provoking (IN-P) tasks. Weinberg and Jones (2020, 2022) proposed a theoretically-grounded framework for IN-P task design, but identified issues in need of further clarification, elaboration, or theoretical justification in both their own framework and the research literature on intellectual need generally. First, Weinberg and Jones (2020) noted that the research literature has not clarified what a student can experience intellectual need *for*, an issue that we believe is at the origin of subtle but significant epistemological contradictions in IN scholarship. Second, Weinberg and Jones (2022) highlighted the importance of attending to the role played by students' affective states as they engaged in mathematical activity, but their framework did not clarify how to account for these states in IN task design or implementation.

On its face, it is possible for one to interpret the idea of IN as suggesting that an instructor need only design a task in which their students are required to confront a problem they do not yet possess the intellectual tools to solve. However, we believe this view orients instructors to develop tasks that might stimulate interest and motivation, but fall short of promoting students' constructive mathematical reasoning. In this theoretical paper, we address these gaps in the research literature by presenting an example of a task designed to provoke intellectual need, highlighting some aspects that, upon further inspection, potentially fall short of engendering this cognitive state, and synthesizing additional theoretical perspectives to ameliorate these gaps.

An Example

We begin by presenting an example of a typical task, some variation of which is commonly included in curricula and instruction to motivate the concept of a derivative. For our example we chose to follow the presentations in some widely-used textbooks[1], viewing textbook presentations as potentially reflecting the authors' instructional intentions. This is supported by the authors' descriptions of their texts as "a teaching tool for instructors and … a learning tool for students" (Stewart et al., 2021, p. xi). Suppose a calculus instructor expects their students to learn about the concept of a derivative and considers how to create an intellectual need for the topic. If they follow the exposition of some of the textbooks we examined (e.g., Larson & Edwards, 2018; Hughes-Hallet et al., 2017; Stewart et al., 2021), they will likely begin by posing either "the tangent problem" (i.e., how can we compute the slope of a tangent line?) or "the velocity problem" (i.e., how can we compute instantaneous velocity?). If an instructor adopted the later approach, they might facilitate an informal discussion of velocity and, typically, define "average velocity" as an *arithmetic*—as opposed to *quantitative—operation* (i.e., division of the change in position by corresponding elapsed time) (Thompson, 1990). Then, the instructor might pose a problem or example in which they demonstrate an inability to perform this computation, either due to insufficient information or an indeterminate form (i.e., "0/0"). The instructor using this approach might highlight the conundrum that "we are dealing with a single instant of time, so no time interval is involved" (Stewart et al., 2021, p. 81) and suggest computing the average velocity over successively smaller time intervals. Then, the instructor might represent the situation using a graph with a point representing the time of interest , and add a second point on the graph with arbitrary coordinates. The instructor then might propose that students imagine that the second point approaches the first point (e.g., Stewart et al., 2021; Hass et al., 2019). Alternatively, the instructor might follow slightly different presentations, such as suggesting that students choose points closer together (e.g., Larson & Edwards, 2018; Herman & Strang, 2020), or that they imagine "zooming in" (e.g., Boelkins et al., 2018; Hughes Hallett et al., 2017).

When the instructor first proposes the problem with finding an instantaneous velocity, the students ostensibly do not possess the intellectual tools to solve this problem. Consequently, an instructor might be tempted to view this initial task as having provoked intellectual need (in their students) for the concept of instantaneous rate of change, and view the definition of the derivative at a point as having resolved this intellectual need. However, as we will argue below, there are additional considerations that are essential for understanding if IN was actually

[1] We examined Stewart et al. (2021), Larson & Edwards (2018), Hughes Hallet et al. (2017), Hass et al. (2018), Herman and Strang (2020), and Boelkins et al. (2018).

produced and what, exactly, it was produced for. Furthermore, the instructor might have only made their students experience confusion, without necessarily helping them navigate the experience of resolving this confusion, and constructing a justification for the necessity of derivative at a point.

DNR-Based Instruction in Mathematics

The concept of intellectual need is one of many theoretical constructs organized within an elaborate framework called DNR-based instruction in mathematics (Harel, 2008). The DNR theoretical framework is grounded in several constructs, the most germane of which (for the present paper) we report here. The triad of mental act, way of understanding, and way of thinking is central to the concepts domain of the DNR framework. Mental acts are the basic applications of cognition to our experiential world; they encompass behaviors such as interpreting, proving, conjecturing, inferring, justifying, explaining, generalizing, and predicting. Harel (2008) defined the cognitive constructs way of understanding and way of thinking and described their respective relations to mental acts:

> A person's statements and actions may signify cognitive products of a mental act carried out by the person. Such a product is the person's way of understanding associated with that mental act. Repeated observations of one's ways of understanding may reveal that they share a common cognitive characteristic. Such a characteristic is referred to as a way of thinking associated with that mental act (p. 490).

We regard an individual's way of understanding a mathematical idea as synonymous with their meaning for the idea (Thompson et al., 2014). We interpret meanings in terms of Piaget's notion of a scheme as an internalized organization of actions, images, and operations constructed and refined through distinct forms of abstraction (Tallman, 2021).

Harel's mathematics premise frames mathematical knowledge as a union of historically institutionalized ways of understanding and ways of thinking. Additionally, Harel (2008) expressed the the reciprocity between these distinct forms of mathematical knowledge in the duality principle, which states, "Students develop ways of thinking through the production of ways of understanding, and, conversely, the ways of understanding they produce are impacted by the ways of thinking they possess" (p. 899). The *knowing premise* asserts,"Knowing is a developmental process that proceeds through a continual tension between assimilation and accommodation, directed toward a (temporary) equilibrium" (Harel, 2008, p. 894). Relatedly, the *knowing-knowledge linkage premise* states, "Any piece of knowledge humans know is an outcome of their resolution of a problematic situation" (Harel, 2008, p. 894).

Commensurate with these theoretical premises, *intellectual need* (IN) is a psychological state–with cognitive and affective entailments–resulting from an individual's interpretation of a problematic situation, the resolution of which requires the individual to extend, modify, or create knowledge structures. Unlike confusion, intellectual need results from an individual's conception of a problematic situation in a way that orients them to engage in the constructive activity required to resolve the situation. IN is thus energetic in that it stimulates, rather than impedes, generative mathematical reasoning.

Harel distinguished different categories of IN. A need for *certainty* motivates deductive reasoning; it is a need to prove, or remove doubts. A need for *causality* is a need to identify the cause of some phenomenon. A need for *computation* involves a desire for efficient quantification. A need for *communication* refers to an obligation to persuade others that an assertion is true. Finally, a need for *connection and structure* entails a commitment to identify similarities and analogies and to abstract unifying principles.

Issue #1: Intellectual Need for What?

There is a subtle category error lurking behind a statement like, "I want students to experience an intellectual need for derivative." Replace "derivative" in this sentence with "constant rate of change," "radian measure," "polynomial rings," "Lyapunov functions," and the category error remains. The issue is this: students cannot experience an intellectual need for a mathematical *topic*. A student can, however, experience an intellectual need to engage in the actions that form the experiential basis of a particular *meaning*, or way of understanding, that they expect might enable them to resolve a problem *they* have conceptualized.

We previously described the experience of intellectual need as a stimulant for generative mathematical activity, *not* a state of confusion that paralyzes reasoning and induces an affective state of interest, analogous to the curiosity provoked by having witnessed a compelling magic trick. These affective states result in the student being receptive to *absorbing* (to use a term consistent with Meyer's aspirin-headache metaphor) the mathematical concepts communicated to them, or the skills demonstrated for them, by a knowledgeable expert. This type of affective experience is nearer to how Harel described affective *need*, indisputably useful but certainly not identical in its affordances for supporting students' learning as IN. So where exactly is the category error in aspiring to support students' experience of IN for derivative (or any other mathematical "topic")? Intellectual need cannot, on the one hand, be conceptualized in a manner consistent with Piaget's idea of *equilibration* of cognitive structures–and radical constructivist epistemology generally–while on the other hand promote an exclusively affective state where learning is a product of a *fundamentally empiricist process* (i.e., perception). Theoretical coherence requires that both the inducement of IN and the learning afforded by its experience be a product of the actions, operations, abstractions, and generalizations *of the learner*.

Intellectual need is thus a need to engage in the precise actions that must be internalized and organized to form targeted ways of understanding (i.e., cognitive schemes) through *pseudo-empirical* and *reflecting abstractions* (Piaget, 2001). A meaning, or understanding, exists only in the mind of an individual, and thus consists of an elaborate organization of idiosyncratic images, actions, and operations (diSessa, 1988; Tall & Vinner, 1981; von Glasersfeld, 1995). Successfully engendering IN therefore requires an instructor to be cognizant of the mental actions and conceptual operations entailed in the meanings they want to support or necessitate (Tallman, 2021; Tallman & Frank, 2020). Without such awareness, an instructor cannot design problematic situations that require students to engage in, and abstract from, these actions.

Solution to Issue #1: Conceptual Analysis. Thompson (2008) described conceptual analysis as the process by which an instructor or curriculum designer clarifies the ways of understanding they intend to support, and elucidates how these understandings depend on and contribute to developing particular ways of thinking. In other words, a conceptual analysis is an articulation of "what students might understand when they know a particular idea in various ways" (Thompson, 2008, p. 43). Conducting a conceptual analysis involves (1) unpacking what it means to conceptualize a mathematical idea in a specific way, and (2) explicating the cognitive activity necessary to construct the targeted understanding. Conducting conceptual analyses is therefore essential to an instructor's development of tasks that effectively necessitate the actions that form the basis of the ways of understanding (i.e., schemes) an instructor or curriculum designer expects students to construct.

Applied to the archetypal tasks described above for motivating students' learning of derivative at a point, a conceptual analysis would specify what it means to understand instantaneous rate of change and clarify how this understanding depends on particular conceptions of constant and average rate of change. Moreover, the role of quantitative and covariational reasoning in the structure and development of the targeted understanding would be made explicit. A conceptual analysis would highlight the distinction between two of the meanings that are implied in the example above. One such meaning—a quantitative meaning—involves conceptualizing average rate of change as a proportional relationship between changes in the measures of distance and time and the successive approximation process as involving thinking of these quantities as continuously covarying and measuring this covariation. In contrast, a second meaning—a geometric meaning—involves thinking of the distance-time pairs as represented as points on a graph of the function, thinking of average speeds as the "slantiness" of lines connecting the two points, and then thinking of the "approaching" process as suggesting a pattern in the "slantiness." These two meanings can be coordinated, but this coordination is automatic. Though it is far beyond the scope of this paper to provide an example of such a conceptual analysis we encourage the reader to reflect on the experiences that might be required to support these distinct students' understanding of each of these meanings of instantaneous rate of change.

Issue #2: Managing and Leveraging Students' Experiences

Suppose that the instructor was successful in provoking intellectual need for a particular meaning of the derivative at a point—for example, the quantitative meaning described above (i.e., the limiting value of successive approximations of instantaneous velocity by average velocities over successively smaller amounts of change in time). The research literature on intellectual need is largely silent on what the instructor needs to attend to and how they should act to guide students through the process of constructing the relevant schemes that will enable them to resolve the disequilibrium. In particular, the students are in a state of cognitive disequilibrium and might react negatively to the confusion that is associated with being in such a state. In this section, we adapt theoretical perspectives from the research literature on student affect to highlight these issues and propose aspects of the class' activity that can guide instructors' attention and action.

Control-Value Theory and Epistemic Emotions. Numerous researchers (e.g., Mandler, 1975; 1999; Morton, 2010; Stein & Levine, 1991; Tallman & Uscanga, 2020) have highlighted the critical relationship between the emotions students experience, their engagement with a task, and their subsequent cognitive activity. Pekrun (2000; 2006) proposed a theory of the emotions that students experience in academic settings: the students' emotions are influenced by their perception of the extent of their *control* over their activity and its outcomes, and their emotions are also influenced by their *values*—their perception of the importance of the activity and outcomes. Muis et al. (2015) found that students' experiences of emotions in mathematical settings were closely related to the extent to which they valued mathematics and the degree to which they felt a sense of agency over their engagement with the class' pedagogical practices and of the mathematics they were learning.

Pekrun and Stephens (2012) classified academic emotions into achievement emotions (such as anxiety and contentment); topic emotions (e.g., how the individual feels about the mathematical topics); social emotions (such as pride and shame); and epistemic emotions, which arise when "the object of their focus is on knowledge and learning" (Muis et al., 2015, p. 173). Epistemic emotions arise from "knowledge states involving discrepancy, incongruity, or conflict between cognitive schemas" (Nerantzaki, 2021, p. 2). These emotions include surprise, curiosity, enjoyment, confusion, anxiety, frustration, and boredom (Pekrun et al., 2016) and have been explored by numerous researchers (e.g., Efklides, 2017; Loewenstein, 1994; Mandler, 1975, 1984; Metcalfe et al., 2017; Touroutoglou & Efklides, 2010; Vogl et al., 2020).

We anticipate that curiosity and confusion are the epistemic emotions most closely linked to experiences of intellectual need, though IN is not reduced to students' experience of these emotions, as previously argued. Curiosity is "the complex feeling and cognition accompanying the desire to learn what is unknown" (Kang et al., 2009, p. 963) and it arises when a student experiences a gap in their knowledge (Loewenstein, 1994; Metcalfe et al., 2017); Litman (2008) proposed that epistemic curiosity motivates students to learn new ideas, and, thus, appears to be closely related to the role of intellectual need in the DNR framework. Similarly, confusion occurs when students are unable to assimilate new information into their cognitive schemas and must engage in accommodation (D'Mello et al., 2014); thus, confusion appears to play an important role in students' experiences of intellectual need. However, while curiosity tends to uniformly support students' participation and learning (e.g., Arguel et al., 2019), confusion can either support or hinder student engagement (e.g., Lodge et al., 2018), and D'Mello et al. (2014) distinguished between what they called "productive" and "unproductive" confusion.

Solution to Issue #2: Monitoring and Leveraging Epistemic Emotions. To think about how an instructor can attend to students' epistemic emotions, we can organize the students' engagement with an activity through a model of affective dynamics, such as the one proposed by D'Mello and Graesser (2012) in Figure 1:

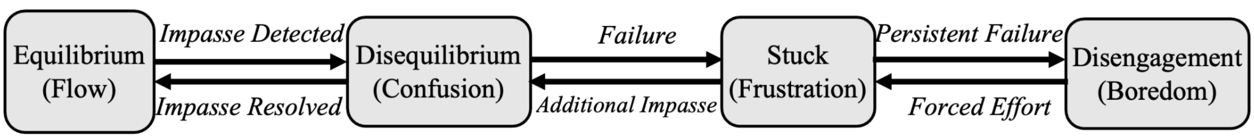

Figure 1. D'Mello and Graesser's (2012) model of affective dynamics

When students begin working on the instantaneous velocity task, the teacher needs to understand the students' perceptions of their roles in mathematics classrooms—a component of their values about mathematical ways of thinking—to help students experience an impasse. When the students recognize their inability to compute the instantaneous speed *and* can articulate the reason for this inability, they shift to a state of disequilibrium; as suggested by D'Mello and Graesser's (2012) model, this shift corresponds with epistemic emotions of either curiosity or confusion (or both).

At this point, as the instructor begins to help students begin the process of articulating and constructing meanings for the targeted schemas, they need to carefully monitor the students' perception of control over their cognitive activity and the targeted outcomes, and also need to remain cognizant of the students' values to help align the activity with those values. In particular, to prevent students from experiencing persistent failure that leads to boredom, the instructor needs the students to experience confusion productively by monitoring their experiences of failure and providing support to move students back into a productively confused state (unfortunately, D'Mello and Graesser (2012) were not able to identify the specific actions that stimulated this transition in affective states).

After working within a state of disequilibrium, the instructor needs to help their students resolve their disequilibrium in a way that leads them to, by Harel's (2008) knowing-knowledge linkage principle, generate the target mathematical meanings for instantaneous velocity. This requires that the teacher helps the students articulate the meanings they need to construct, thereby enabling them to believe that it is possible to resolve the impasses they are experiencing. In the case of instantaneous speed, this could entail helping students articulate the quantities of distance and time involved in the situation, focus on the amounts of change of these quantities, imagine these quantities as varying and co-varying, and then focus on the relationship between the quantities. During this process, the teacher needs to, first, continue to align the class activity with the students' perception of their control over the outcomes of the activity and, second, to help align the act of constructing meaning for instantaneous velocity with the students' values.

Discussion

In this paper, we set out to provide theoretical clarifications on key ideas in designing IN-provoking tasks. In particular, we focused on what IN can be experienced for, what experiencing IN should lead to in terms of student actions, and how to guide students through the disequilibrium toward the resolution of the problem

If the concept of intellectual need is to be consistent with its theoretical premises and epistemological foundations, students' experience of it must induce the precise actions that are abstracted and internalized to form the substrate of cognitive schemes (i.e., *ways of understanding*). Intellectual need is a need for *action*–it sets in motion a constructive process by provoking the experiential basis of knowledge structures, in a manner consistent with Piaget's notion of equilibration and, crucially, the cognitive mechanisms by which equilibrium is established. While affective needs are of value in mathematics education, experiencing them alone does not necessarily place students on a trajectory to constructing targeted ways of understanding. In this paper we distinguished intellectual need from other types of experiences that stimulate interest, provoke curiosity, or foster motivation. We clarified the relation between intellectual need and to constructivist epistemology so that mathematics educators might be better positioned to engender this productive experience through thoughtful task design and implementation. We proposed Thompson's (2008) notion of conceptual analysis as the essential process that positions instructors and curriculum designers to effectively create intellectual need-provoking tasks.

Although the research literature includes numerous examples of tasks that are designed to provoke intellectual need, there has been little guidance or theoretical framing about how an instructor should engage their students after the task has been presented. The disequilibrium that results from the stimulation of intellectual need is associated with particular affective states, and there is a critical relationship between these states and the students' activity. The perspective of control-value theory allows us to frame this activity to identify and help students manage these affective states by focusing on the students' perceptions of control of their activity and coordinating this with the value students place on their activity and its outcomes. In particular, by focusing on epistemic emotions can help instructors identify particular affective states and their likely antecedents so that the instructor can help students articulate the meanings they need to construct, successfully resolve their disequilibrium, and leverage intellectual need to support student learning.

Decentering and Interconnecting as Professional Skills in the Preparation of New College Mathematics Instructors

Shandy Hauk
San Francisco State University

Natasha Speer
University of Maine

Making progress in justice, equity, and diversity in post-secondary teaching and learning requires systemic change. The development of novice instructor professional knowledge is a critical subsystem of the undergraduate mathematics education system. Novices play key roles in instruction and have the potential to play key roles in change efforts later in their careers. Yet, there is little in the way of theory to support research and development in this area. In other fields, professional development that engages novices in building skill at self-sustaining, generative change as professionals is the ground in which agency for change is seeded and nurtured. We describe two dimensions of professional skills for interacting with ideas and people: decentering and interconnecting. In this report, we explore and illustrate the role of these dimensions in professional development for novice college mathematics instructors.

Keywords: professional development, novice instructors, TAs, decentering

Research in the undergraduate mathematics education (RUME) community has generated findings, materials, and programs that have shaped today's post-secondary mathematics instruction. Changes that leverage this research often occur as a result of efforts by "change agents"– people who notice and seize upon opportunities for improvement who work with others to enact change. Some things are known about the work and characteristics of change agents in undergraduate education (e.g., Froyd et al., 2008; Henderson et al., 2011). However, despite their key roles in undergraduate education, much remains to be learned about how someone becomes a change agent. The work of the RUME community has advanced the teaching and learning of undergraduate mathematics through curricula informed by research, innovations in assessment, programs to support instructors and many other things. For such efforts to reach more students, we need to ensure that future faculty have the knowledge, skills, and dispositions to be change agents and to successfully leverage the RUME work as they initiate and sustain change.

Twenty-first century approaches in professional learning about college teaching have included opportunities for novices to imagine and build purposefully towards future-self goals – addressing questions like "How will I define my professional success as an instructor? How will I measure that and be accountable for it?" If we also want instructors to consider and answer the question, "How will I contribute to innovative change in my professional community?" this needs to be a focus of professional learning opportunities we offer. Thus, we need to consider how professional learning can support novices to become effective instructors now while also positioning them as the next generation of those who act as agents of positive change.

Take any example where a department seeks to implement a program innovation and questions arise: What needs to be happening for new instructors so they can teach in the targeted ways? And, later, when a person graduates from Innovative U. and lands a job at Status Quo College, how does that person – who is a relative novice in college mathematics instruction and departmental politics – initiate and maintain productive exchanges with others to improve teaching and learning? The answers to both questions include building social and management skills for interacting with structures and power constraints in various ways (Elizondo et al., 2020). For change that disrupts the academic mathematics status quo, skills must be grounded in an understanding of the norms and values of the status quo, how those are different from and similar to new norms and values (e.g., those anchored in justice and anti-racism), how to enact change from the former to the latter, and how to determine the nature of the success of the change (and start a new cycle of change based on it).

Change requires non-linear, multi-dimensional, and context-sensitive efforts. To succeed as a change agent, one needs awareness and knowledge about subsystems, understanding and anticipation about how those subsystems connect, interact, and influence one another, and skill at seizing opportunities to generate new learning from each professional encounter. Creating equitable, inclusive mathematics learning opportunities for students requires an analogous set of skills and knowledge. As part of a larger effort (Hauk & Speer, forthcoming), this report presents two theory-driven dimensions of professional learning and illustrates how they apply to the design of professional development about teaching for novice instructors. We argue that these dimensions (decentering and interconnecting) serve today's novice instructors both to be better equipped as instructors and to navigate future demands and function as change agents in tomorrow's departments and universities[1].

Decentering as a Professional Skill

Around the world, mathematics courses and programs in most post-secondary institutions are built on an instructor-centered model (PCAST, 2012). This approach has been effectively self-sustaining for many decades. The practice of lecturing has been passed on from generation to generation of college teachers through personal classroom experiences and through graduate school training with curricula that preserve lecturing as the status quo. Now, however, it is clear that an instructor-centered approach is not universally effective or appropriate (see, e.g., Abell et al., 2018; Bressoud et al., 2015; Freeman et al., 2014; Laursen et al., 2014). That is, instructor-DEcentered methods are needed.

Research on instructor-decentered approaches has paralleled research about equity in post-secondary teaching. Both point to the value of student-centered methods. It is worth noting that explicitly, at this moment in the educational research and practice communities (and more broadly) there is not a well-defined, crisp, and shared definition of equity (Aguirre, et al. 2017; Gutiérrez 2012). Beyond "fairness," equity is evidenced by the absence of disparities: membership in a group that has been historically disadvantaged or oppressed is not correlated to access to opportunities, attainment of educational outcomes, or achievement of life goals. Our use of equity is in the spirit of this definition.

The apprenticeship of observation is powerful. People tend to teach the way they were taught (Lortie, 1975). It is important for novice instructors to experience teaching that models and provides touchpoints in their efforts to teach differently (e.g., more equitably). For example, professional learning opportunities can be offered in ways that model instructor decentering. Thus, novices can refer to how they have recently been taught, in professional development, to contrast with the power-culture-driven, instructor-centered experiences that likely make up the bulk of their histories as learners.

What is Decentering?

Successful implementations of the kinds of instructional practices described as equitable call for teaching that elicits and utilizes student contributions and student choice (Jacobsen et al.

[1] Note: This report is not a primer on how to design professional learning about teaching for novice instructors (for that, see, e.g., Bragdon et al., 2017; College Mathematics Instructor Development Source [CoMInDS], 2021; Council of Graduate Schools, 2021; Deshler et al., 2015; Saichai & Theisen, 2020 and references therein).

2012). The expectation emerging from research and practice is that instructors facilitate discussions to which students contribute their thinking and voices. This kind of instructional decentering is, at its most basic, the act of seeing from someone else's point of view and has historical roots in the work of Piaget (1955). It entails the instructor engaging with students as a participant in interaction, rather than as the center of interaction.

In decentering, instructional attention is on uncovering, understanding, and expanding on what students know and do to include novel, non-standard, and standard mathematical ideas and methods (Carlson et al., 2007; Rahman, 2018; Teuscher et al., 2016). Being self-aware and facilitating self-aware learning by students are the focus (instead of attention and authority vested largely in the instructor). Decentering requires attention to other people as (potentially) different from oneself, noticing nuances in similarity and difference between one's own views or experiences and those of others. In its most developed forms, decentered instructors bridge across similarities and differences in formulating in-the-moment responses to situations.

An important step in building skill at noticing how the thinking of students is similar to or different from an instructor's own is creating the opportunity in one's classroom to hear and see student thinking. Decentering depends on a variety of individual instructor factors (e.g., self-knowledge, goals, orientations, beliefs, psycho-social challenges).

Novice instructors need to learn how to create, maintain, and manage classroom environments where undergraduates are participants in student-centered ways. This includes instructors learning about many things from a student-centered perspective, such as content, curriculum, and assessment (Bok, 2009), communication and interaction (e.g., related to classroom authority or socio-political factors, Gutiérrez, 2009, 2013; Winter & Yackel, 2000), as well as how to learn in and from instruction itself (Speer & Hald, 2008). Learning to elicit student thinking and learning how to shape instruction based on that thinking is the foundation on which generative change is built (Franke et al., 1998).

Development of Decentering Skills

Professional development can provide opportunities for instructors to build skill in decentering, along with other facets of cross- or intercultural competence. There is a developmental continuum for decentering: from an ethno-centric view that everyone is like me to an ethno-relative view, that any person (including me) is like and unlike every other person in identifiable and valuable ways (Bennett, 2004).

Some common components in professional development create opportunities for instructors to experience and learn about decentering (e.g., have novice instructors attempt the mathematics tasks from the course and come together to discuss them). Current research and development in RUME continues to provide ideas for the professional preparation of novices that include opportunities to model decentered instruction, from the CoMInDS collection (2021) to specific professional guidance on particular practices (e.g., cooperative learning using group-worthy tasks; Reinholz, 2018). We contend that if novices develop and use skills in decentering (and interconnecting, discussed next) in their work as instructors of mathematics they will be better prepared to leverage those skills in their future work as change agents.

Interconnecting as a Professional Skill

While decentering is awareness from within the perspectives of others, interconnecting uses meta-awareness to make connections across perspectives and contexts. This can occur at many levels and grain sizes. Such linking is essential in developing and nurturing coalitions, an essential component of local and systemic change (Kotter, 2012). A mathematics class is a foundational opportunity for coalition. Many other structures and groups rely on and influence it. Figure 1 offers one way of seeing the relationships among people and instructional structures.

RUME reports describe many instructional practices, what happens inside the disk labeled INSTRUCTION in Figure 1. Some reports describe content aspects (Figure 1, MATH), others cognition by students (individually or jointly, as represented by the arrows in Figure 1). A few reports address what happens from the perspective of another layer in Figure 1, the region labeled PROFESSIONAL DEVELOPMENT. For those involved in *providing* professional development to new instructors, this report itself is a contribution to the outermost region in Figure 1, LEADERSHIP DEVELOPMENT.

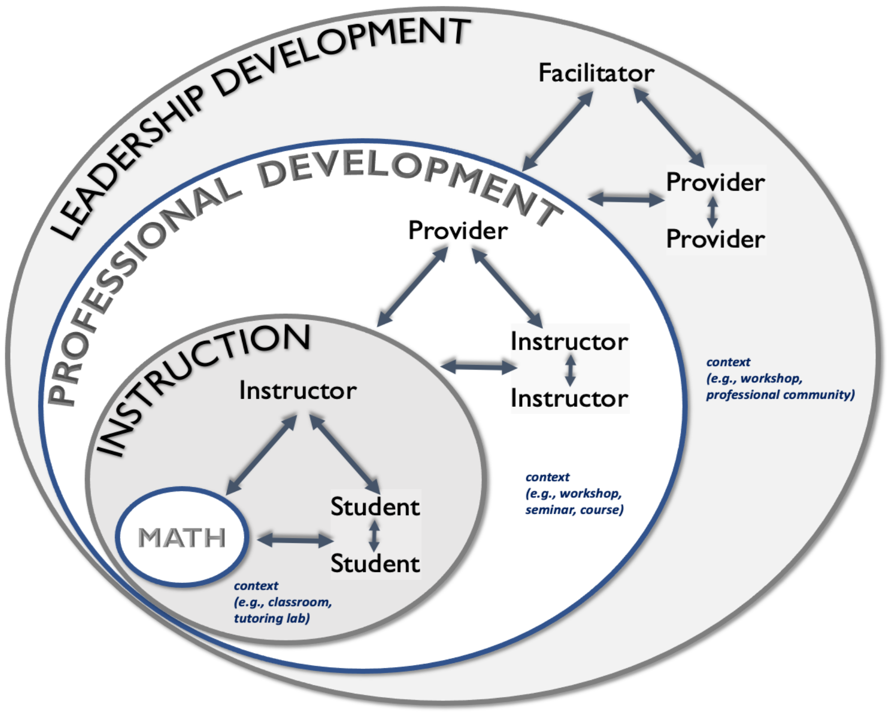

Figure 1. Model of the nested, self-similar systems of learning in mathematics (based on Carroll & Mumme, 2007).

Interconnecting: Examples

As an example, consider interconnecting rooted in the concept of derivative (MATH in Figure 1). If an instructor is aiming to help students learn about the idea of a derivative, instructional goals are influenced by what the instructor understands about students' knowledge of slope, ratio, and change. Interconnecting by the instructor involves noticing how students' conceptions may support or constrain the way learning progresses. That is, the instructor considers what is happening at the Students ←→ Students node in Figure 1, where the kind of thinking brought to mind for students might include m in $y = mx + b$, previous experience with unit rate, experiences that discretize change (e.g., compare slope at point A to slope at point B), or treating change as covariational. Instructors develop skill at interconnecting by knowing these student conceptions as well as the dynamics of communicating about them in a multi-contributor, student-centered, context (the arrows in INSTRUCTION). Instructors also consider and link to students' thinking in selecting formats (e.g., group work on some problems, viewing a pre-class video for a topic). Instructors connect across and prioritize the mathematical and contextual factors, to decide what is instructionally useful. Novices learn about these interacting connections in and from their teaching and through professional development.

When someone embarks on providing professional development to support instructors to learn to teach, they are taking on the challenge of thinking at another layer out: a meta-meta-awareness of connections is required. Providers of professional development need to think about how to have novice instructors interact with ideas of mathematics teaching (and each other) in ways that will help those instructors think about how to support students to interact productively with mathematical ideas (and each other). Continuing the derivative example in the PROFESSIONAL DEVELOPMENT region of Figure 1, for the Provider there are additional considerations about what instructors will need to know and do if they are to create the desired learning opportunities for students. For example, identifying learning goals might occur in various professional activities (e.g., as a step in lesson design, or as a provided component in a set of curricular materials). Novice instructors also may need opportunities to learn about, have practice with, and connect across the mathematics of limit, limit quotient, and derivative along with instructional approaches that may be particularly effective (e.g., students working on a group-worthy task in which limits, rates, and limits of ratios are compared and contrasted). This, too, may occur through various professional learning tasks that are designed for use with novice college instructors (e.g., in an interactive activity, or in a teaching guide).

Also needed by novice instructors– as they notice and structure their understanding of a web of interconnections – is guidance about how to orchestrate mathematical and instructional ideas while decentering. This includes building knowledge about working in racially, ethnically, and linguistically diverse classrooms (e.g., a reading about student funds of knowledge and how to leverage those in teaching; González, et al., 2011) as well as creating and maintaining socio-mathematical and social norms in the classroom (e.g., a professional learning activity about what to do the first day of class to begin setting norms). These all make up the "content" of the professional development (in Figure 1, this includes the MATH, information about students and instructors as well as context knowledge from research and practice about the interaction arrows in INSTRUCTION back and forth among MATH, instructor, and students). Also part of the information that novice instructors interconnect is the learning about teaching they encounter in hallway conversations with colleagues and other informal interactions (Latulippe, 2009).

In particular, interconnecting includes instructors thinking about students' thinking about mathematics. In an analogous fashion, those who provide professional learning opportunities must concern themselves with an additional level of interconnecting: Providers think about how instructors are thinking about how students are thinking about mathematics.

Development of Interconnecting Skills

Like decentering, skill at interconnecting develops from an ethno-centric to ethno-relative orientation (Hauk et al., 2015). It may begin in a self-focused denial of differences (e.g., no connections are needed since it is only MATH that matters). Further development of skills for interconnecting will go through a phase characterized by a tendency to polarize, to focus on mathematics as disconnected from human interaction (e.g., there is one best or right way to solve every problem). From there, development moves to a search for universals, connections that are compressed into a single process, but not multiple interconnected processes (e.g., there are "objective" or "mastery based" ways that are universally applicable to assess *all* students, and grades become the essential element of interaction for instructor and student, disconnected from students' mathematical funds of knowledge). With time and intentional development, one can learn more about mathematical ideas, contexts, and human interactions and reflect on teaching with greater attention to relational details (e.g., learning about implicit bias and suddenly noticing it in every word problem in the text), but how to use this knowledge to improve opportunities to learn, classroom climate, and interactions with others remains elusive. At its most developed, interconnecting is adaptive— networks of people and their interactions can be anticipated (enough) that teaching serves the needs of the people, and networks of people, in and outside the room (Hauk et al., 2014).

Interconnecting is important for change agents because they need to know how people, policies, and perspectives function in and across interacting systems (e.g., in and beyond those shown in Figure 1). The knowledge from that is extremely valuable when advocating for a change in one part of a (sub)system: one can anticipate how change in one place will cause or necessitate change in another.

Data-Driven Interconnecting and Decentering

It is clear from the variety in approach and the nature of successes in the research and practice literature that collecting and examining data for decision-making is valuable (Laursen, 2019). One method for planning for and examining the success of change that has been used effectively in RUME is the four frames or "lenses" model (Bolman & Deal, 1991; Reinholz & Apkarian, 2018). This model is one way of describing what is interconnected in change efforts. It involves considering the evidence of change in terms of **Structures:** rules, policies, procedures, management; **Power:** resource allocation, formal and informal seats/sources/sinks of power; **People:** demographics, experiences, needs; **Symbols:** meaning and culture, rituals and habits, stories, sensemaking.

End-of-term grades are only one form of readily accessible local data (like hearing from only one student in the classroom). In taking a systems approach to change, useful data for determining need and success are generated in intentional and inclusive ways, from across diverse stakeholder groups. Identifying stakeholder groups happens when change agents decenter, look outside themselves and the voices of the status quo.

More can be learned from collecting and analyzing types of data that are largely absent in existing reports: instructor and implementation data. Now is the time to interconnect across contexts. Examples of how to do that as part of the professional development of novice instructors include activities in which novices and/or providers:

- Gather observational data about the nature of classroom questions and answers (American Association for the Advancement of Science, 2013).
- Data-mine learning management systems for evidence of equitable and inclusive instruction (e.g., an audit of time/contributions to discussion fora broken down by student demographics, or a review with feedback to instructors of course sites in learning management systems using a rubric; Baldwin et al., 2018).
- Conduct surveys of instructors about practices and instructor interactional experiences of teaching – including experiences of racialized or sexualized or gendered interactions (Sue et al., 2011), repeat these types of data gathering, analysis, and reporting in and through the professional development experiences, where instructors are the learners.

Some tools for such data collection exist already (e.g., Laursen, 2019). However, next steps include moving into data gathering at the broader levels in Figure 1 and a group-level decentering that includes identifying and inviting outside experts to support connected knowledge growth about each other as thinkers and doers of instruction (Henderson et al., 2011; Reinholz, Stone-Johnson, et al., 2020). Such expertise will help programs create professional learning opportunities that are informed by research on equitable and just teaching development (including ideas learned in other disciplines, e.g., in biology, Gormally et al., 2016).

Generating the Future

As in any field, organizational change requires a multi-threaded effort across personal reflections, development, cycles of professional preparation, implementation, evaluation, administrative-level accountability, within and across-institution continuous improvement work, and broad policy efforts to support large scale change within and across subsystems (Deszca et al., 2019). Although individual humans play key roles in change, some have found it productive to view organizational change focused on interaction, foregrounding relationships among people as they communicate with each other and interact with organizational structures, symbols, and power (Elizondo et al., 2020; Kotter, 2012; Reinholz, Rasmussen, et al., 2020; Slemp et al., 2021). Students can only benefit from the efforts of the RUME community if people residing in mathematics departments can initiate and help sustain organizational change.

Many members of the undergraduate mathematics community have taken on roles as change agents, responding to needs and shaping efforts to improve teaching and learning. There may be additional benefits to the community if, in parallel with these efforts, we aim to develop and refine theory. The history of mathematics education includes many examples of the productive interplay between empirical research and theory development (e.g., studies of problem-solving and theory about meta-cognition, studies of teachers and theory about mathematical knowledge for teaching). Having additional theory-development around the characteristics, roles, knowledge, and skills of effective change agents would certainly be welcomed. That can further inform the theory-building efforts we have begun to lay out in this report.

We have asserted that decentering and interconnecting are key to success as a change agent. We based this assertion on examination of what organizational change entails. The research and practice communities will likely benefit if these claims are investigated in conjunction with organizational change efforts. Parallel efforts to create theory and enact change can lead to the accumulation of knowledge which can, in turn, inform the next cycle of efforts.

It is worth noting that change efforts can fail because people do not know about, or do not know to, pay attention to interconnected-ness and the complexity that comes from decentering. For example, it can be fatal to a change effort to focus attention on one thing (e.g., "all that is needed to reform how this course is taught is changing the textbook" or "student-centered instruction will fix the problem" see, e.g., Henderson, 2011). If we design and test ways of helping novices develop skill at decentering and interconnecting in their mathematics classrooms, that creates a foundation for further design and theory development for analogous skills used more broadly to contribute to change efforts in their departments.

As is true in the broader literature, collaboration by a group of change agents, not all of whom are mathematicians, is valuable (Laursen & Austin, 2020; McShannon & Hynes, 2005; Saichai & Theisen, 2020; Theobald et al., 2020). A corollary of acquiring skill at decentering is that it prepares one to be a participant in a collective effort (e.g., with a classroom full of students, with a department full of colleagues, with a cross-professions team). With attention to decentering and interconnecting, the next generation of change agents will be equipped to participate in the collective action required for future change.

Balancing the Unbalanceable: A Theoretical Perspective for Teaching and Learning in Undergraduate Mathematics Classrooms

Candice M. Quinn
University of North Alabama

I propose a theoretical model for teaching, learning, and assessing mathematics learning in the undergraduate mathematics classroom combining participatory and acquisition views of learning. The model, Balanced Learning Needs Framework, was created from an organization of the 10 learning needs proposed by Sfard in 2003. I align the model with different forms of classroom instructional techniques used in an undergraduate Calculus I classroom. Included with the organization of the learning needs, this conceptualization has the potential to impact both teaching and assessment methods in undergraduate mathematics classrooms.

Keywords: participatory learning, acquisition learning, Calculus I, assessment

Many theories and frameworks exist to help researchers try to understand the phenomena of teaching, learning, and assessment within mathematics education (Radmehr & Drake, 2019). Dubinsky and McDonald (2001) stated how: "models and theories in mathematics education can support prediction, have explanatory power, be applicable to a broad range of phenomena, help organize one's thinking about complex, interrelated phenomena, serve as a tool for analyzing data…" (p.275). In this paper I provide a framework designed for a larger study that was used to investigate learning in an undergraduate Calculus I course. This proposed framework helped to organize the researcher's thinking about learning (Dubinsky & McDonald, 2001) in both social and individual classroom. Two main learning theories guided the construction of the proposed framework: situated and constructivist. Together, the theories and framework guided each aspect of construction of the Calculus course: setup, course design, classroom instruction, and assessment of learning.

Theoretical Background

Sfard (1998) metaphorically described students' development of knowledge under situated learning theory as participatory and under constructivist learning theory as acquisition. I consider a combination of the two learning theories (using their metaphors) along a continuum (Figure 1). This combination of situated theory as participatory learning and constructivist theory as acquisition learning is the theoretical foundation for proposed framework. Vygotsky's sociocultural view of learning is placed in the middle of the continuum. Although this view of learning does place importance on the social process of learning, Vygotsky still considered the internalization of knowledge in the learner's mind (Sfard, 2003).

While creating the framework, I reflected on both metaphors for learning, and considered knowledge as something that is both acquired in the individual learner's mind and co-created from participation within a community of practice. The largest difference between the two perspectives is regarding the emphasis and need of social interaction and where knowledge is constructed (i.e., in the mind of the individual learner or in the community). The framework is created with the notion of holistic learning where an individual both acquires knowledge (cognitive-acquisition perspective; Cobb & Bowers, 1999; Sfard, 1998) and constructs knowledge through participation within a community of practice (situated-participatory perspective; Cobb & Bowers, 1999; Sfard, 1998; Lave & Wenger, 1991).

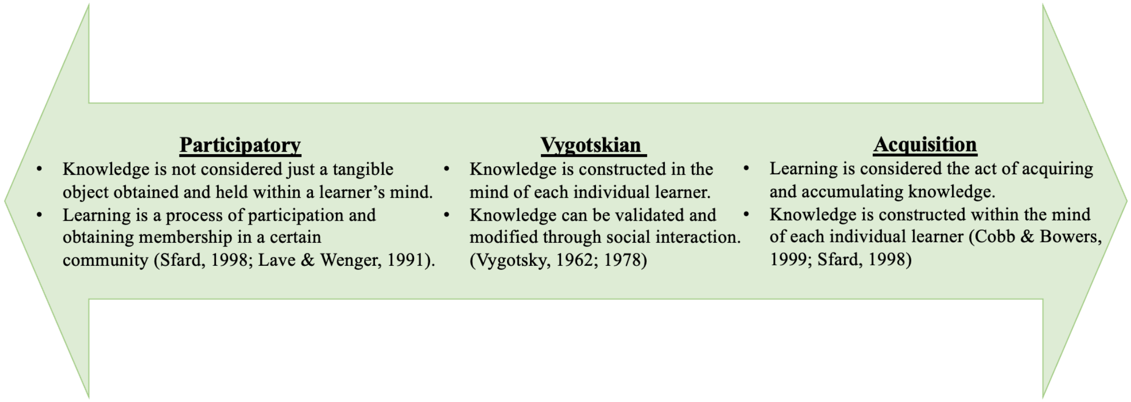

Figure 1. Participatory-acquisition Learning Continuum.

Alignment of Learning Needs

Expanding upon Sfard's (2003) presentation of the 10 needs of mathematics learners, I constructed an organized model to represent these learning needs (LN) within the situated (participatory) and constructivist (acquisition) learning theories. This organization is a representation of how the LN can be systematized to enhance teaching and learning for undergraduate mathematics, as well as focusing on equitable assessments of learning. Each of the 10 LN corresponds to knowledge creation either within the mind of the learner or within the community of learners.

We can align the respective LN with the ideas of learning and knowledge to either an individual unit (i.e., acquisition) or a group unit (i.e., participatory). That is, each need may be internally driven (i.e., for internal knowledge construction) or socially driven (i.e., for participation within a community), or a combination of both. The majority of the needs as defined by Sfard (2003) are primarily driven either only by one or the other. I classify the LN into three main categories: internal needs, social needs, combination needs.

Internal Needs

There are four internal LN that each student has in order to construct mathematical knowledge: a need for *meaning*, *structure*, *repetitive action*, and *difficulty*. Constructivist views of learning attend to the internal needs of the learner and consider knowledge creation within the mind of the individual learner. Either Piagetian or Vygotskian, or both, perspectives of constructivism influence each of these needs.

All learners have this need to make *meaning* of the world around them and communicate their *meaning* of the world to others (Bruner, 1997; Sfard, 2003; Vygotsky, 1962). The creation of *meaning* is an internal process used by all learners to understand and make sense of the world around them (Piaget, 1953; Sfard, 2003). This view of *meaning* as internally constructing knowledge about the world around them and assessing one's internally constructed knowledge aligns with the acquisition view of learning.

The need for *structure* incorporates both the Piagetian notion of reorganizing mental schemes when acquiring new information and Vygotsky's hierarchical organization of new concepts (Bruner, 1997; Sfard, 2003). The need for *structure* incorporates what students already know (i.e., previous or prerequisite mathematical knowledge) and connects this knowledge with new ideas and concepts (Sfard, 2003). This view of *structure* is an extension of the need for meaning and builds on one's internally constructed knowledge, and therefore also aligns with the acquisition view of learning.

Through the process of *repetitive action* with mathematical ideas learners can reorganize their internalized knowledge (i.e., structure) to add the new mathematical object into their current knowledge schema (Piaget, 1953). This view of *repetitive action* is an extension of the need for structure, as a way of organizing new meaning, and rectifying one's understanding (Sfard, 2003) which considers knowledge to be something that is internally constructed. Therefore, *repetitive action* aligns with the acquisition view of learning.

The final internal need is the need for *difficulty*. Sfard (2003) stated that "true learning implies difficulties" (p. 366), what these difficulties are, however, is not the same for all learners. Therefore, learning requires a level of *difficulty* unique to each learner depending on previous constructed mental schema (Piaget, 1953). This corresponds to Vygotsky's Zone of Proximal Development (ZPD) in which each student has already built a certain level of ability and learning occurs inside of their ZPD with assistance (Vygotsky, 1978). This view of *difficulty* incorporates one's internally constructed knowledge and cognitive abilities, which aligns with the acquisition view of learning.

Social Needs

There are four social LN that each student has in order to construct mathematical knowledge: a need for *social interaction*, *verbal-symbolic interaction*, *well-defined discourse*, and *sense of belonging*. As with the internal LN, the social needs may be met with different means for each learner, and each are further described below.

Social interaction can be broadly defined as an exchange of ideas between an individual and another person via written or verbal communication (Sfard, 2003). Vygotsky (1962) suggested that *social interaction* is an essential part of learning especially for one to obtain a conceptual understanding of objects or ideas. *Social interactions* provide the space for students to challenge their preexisting notions about mathematical ideas. Lave and Wenger (1991) suggested that *social interaction* is essential for one to show knowing by doing within a community (i.e., situated learning theory). Therefore, the need for social interaction aligns with the participatory view of learning.

Social interaction and being able to communicate one's ideas and knowledge require learners to use both *verbal* (i.e., talking and listening) and *symbolic* (i.e., reading and writing) representations of knowledge and thoughts (Sfard, 2003). This idea that knowing comes from having a word or symbol is grounded in discursive psychology (e.g., Harre & Gillet, 1995). Sfard (2003) described the importance of either a *verbal* or *symbolic* use to give meaning as "one just cannot construct the meaning of a concept before introducing a word or a symbol with which one can think about that concept. The sense of *understanding* [emphasis added] then develops through the use of the word or symbol" (p. 374). Therefore, *verbal* and *symbolic representations* are a need of learning mathematics because these representations provide the tools for social interactions to occur, and aligns with the participatory view of learning.

The need for *well-defined discourse* follows from the needs for social, verbal, and symbolic interactionism. *Discourse* in mathematics becomes well defined when sociomathematical norms centered around what is considered mathematical argumentation are established in the classroom (Yackel & Cobb, 1996). Engagement in mathematical argumentation requires students to have intellectual autonomy (Yackel & Cobb, 1996). Specifically, students would need to understand their own "mathematical capabilities" (Yackel &

Cobb, 1996, p. 473) as they judge and decide what constitutes a mathematical argument of another student. This notion of *discourse* in the classroom among students includes both social interaction and the use of verbal or symbolic representations of knowledge, and aligns with the participatory view of learning.

A *sense of belonging* is a human need to feel valued as a member of a community. A student's *sense of belonging* can be defined as their "sense of being accepted, valued, included, and encouraged by others (teachers and peers) in the academic classroom setting and of feeling oneself to be an important part of the life and activity of the class" (Goodenow, 1993, p. 25). Ultimately, if students do not feel they belong in a field of study, classroom, or group they are less likely to continue or engage with that group (Cheryan et al., 2009; Strayhorn, 2019), and thus makes this is an important need that must be addressed for all mathematics learners (Sfard, 2003). This need to belong aligns with the participatory view of learning because it includes a community or members outside of oneself.

Combination (Internal and/or Social) Needs

The last two LN either fall in the middle of the proposed continuum between (i.e., significance and relevance) or span (i.e., balance) both the participatory and acquisition metaphors for learning. First, *significance and relevance* as one LN is placed in the middle of the continuum. This need is what can drive the motivation for the learner (Sfard, 2003). If we consider the ideas from Piaget where new knowledge can only grow out of existing knowledge, then learners must internalize the *significance* of what they are learning as they reorganize their mental schemes (Sfard, 2003). If we consider instead the importance of social interaction in learning, the *significance and relevance* of new knowledge can come through social interactions and participation within a community (Lave & Wenger, 1991). Because the *significance and relevance* can be formed/made either internally by one's own drives and thoughts, or influenced by one's peers in their learning community, this LN is placed in the between the internal and social needs.

The last LN may seem obvious now and yet may be the hardest one to meet: the need for *balance*. This essential LN both corresponds to the requirement for the learning environment to maintain a balance between the participatory and acquisition metaphors for learning; as well as attempting to balance the other nine LN for each student. A further description of how the balance need is deciphered and represented is provided in the following section.

Balanced Learning Needs Framework

The framework presented (Figure 2) arranges the 10 LN along a continuum of two main metaphors for learning (i.e., participation and acquisition). This continuum is represented as a balance scale, where the *balance need* is represented as the lever, holding the remaining nine needs, placed upon a fulcrum that can pivot between the two learning metaphors. I chose this representation to demonstrate the importance of both social and individual LN. The idea is that if only one side of the balance is met in the learning environment, then learning is hindered for the students. The arrangement of the needs toward the participatory or acquisition side was done meaningfully; the vertical placement, however, is not meant to imply any order among those needs placed on each side. The placement on the left (or right) only implies these constructs *lean toward* the participatory metaphor (or acquisition metaphor) for learning.

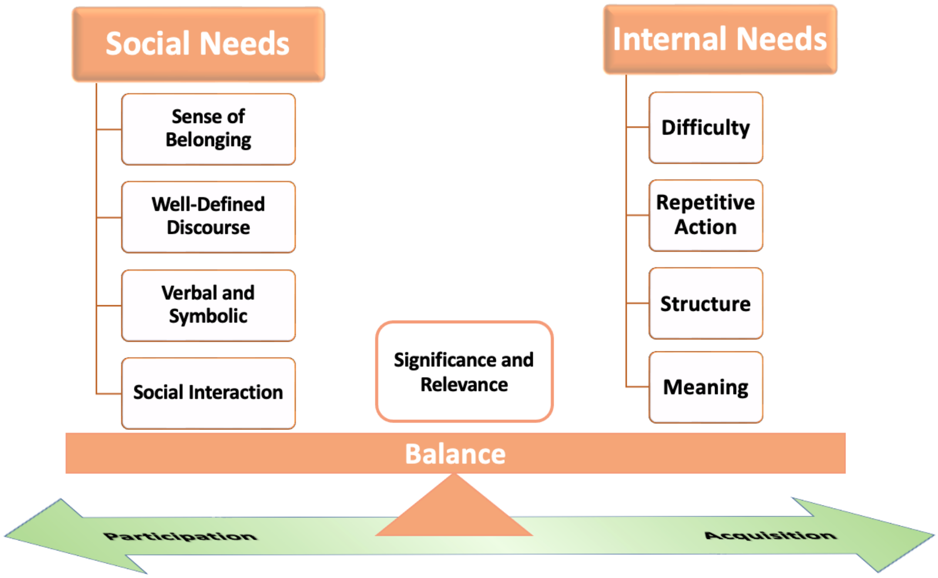

Figure 2. Balanced Learning Needs Framework

The author posits that the Balanced Learning Needs (BLN) framework presented here is a multidimensional construct with interrelated elements that impact student learning in either social or lecture settings. The framework can be utilized by academics to reflect upon the learning environment within their undergraduate mathematics courses and the implications for instructional and assessment practice. In the next section, I provide an example of how different classroom instructional methods from a Calculus I course that align with each learning need.

BLN Framework with Classroom Instruction

Sfard (2003) suggested "to meet learners' multifarious needs, the pedagogy itself must be variegated and rich in possibilities. The learning individual is a complex creature with many needs that must all be satisfied if the learning is to be successful" (p. 384). Educators must help create learning environments that allow students the opportunity to meet each need through equitable instruction (Sfard, 2003). Therefore, equitable instruction refers to the instructional techniques used to support the development of the 10 needs for *all* students and promote a balance between the needs, the metaphors of learning, and the students. For instance, collaborative group work is an equitable instructional practice that, if implemented with fidelity, students are given opportunities to explain their thinking and justify their mathematics using both verbal and written methods (Perry, 2018).

Often, it is difficult to connect theories of teaching and learning with the actual implementation of classroom activities and assessments. In Table 1, I provide an outline of how classroom activities and instructional practices meet each of the LN in the BLN framework. The course components described in Table 1 were implemented in a Calculus I classroom that also included individual and group testing methods. I provide a rationale for the assessment methods in the next section. Note, in the table below, *lecture* refers to instructor-centered classroom moves (i.e., instructor reviewing prerequisite material or concepts), without student-to-student engagement. Additionally, lecture may include whole class discussions and clarifications of mathematical language and symbols.

Table 1. Learning Needs Matched to Course Instructional Techniques.

Learning Need	Course Component	Description of how the component of the course was designed in an attempt to meet each learning need
Meaning (Internal)	Lecture and web-based homework	Allows students to work through problems and build their own internal meaning.
Structure (Internal)	Lecture and web-based homework	During lectures, instructor attempts to build structure in lecture by identifying connecting concepts from student's previous knowledge. Homework allows students to extend and organize new information to their previous knowledge.
Repetitive Action (Internal)	Lecture and web-based homework	Individual practice time in lecture and the homework time on the computer allow the students multiple problems to practice.
Difficulty (Internal)	Lecture and web-based homework	Instructor designs lecture and homework problems with a certain level of difficulty to allow the students to productively struggle when building their knowledge.
Social Interaction (Social)	Group Setting and web-based homework	Student-centered activities during group work require students to talk through problems and social interact to complete the learning activity. Students could choose to either work alone or with a peer on the homework allowing for more possible time for social interaction.
Verbal and Symbolic (Social)	Lecture and Group Setting	During lecture, after students initially explored a concept during group work, instructor provides the students with the formal terminology and symbolic representations of the concepts. During group work, students needed to communicate with one another using both verbal and symbolic representations for the mathematics.
Well-defined Discourse (Social)	Lecture and Group Setting	During lecture, the instructor sets the sociomathematical norms and models mathematical discourse that is needed for the students to engage in mathematical argumentation. During group work, the students establish the group's norms and engage in discourse.
Sense of Belonging (Social)	Lecture and Group Setting	During the lectures, instructor attempts to encourage all students to participate in whole class discussions and feel that they could share any idea, thought, or question. During group work, instructor monitors each group to ensure each student felt comfortable: (1) with their group members, (2) to voice their ideas, and (3) encouraged to share their ideas with their group.
Significance and Relevance (Combination)	Lecture, Group Setting, and web-based homework	Because this need is driven by the learner and can be met either while working alone or in a group setting, this need can be met for any learner within any one or all of the course components.
Balance (Combination)	The course as a whole	The instructor attempts to maintain balance by providing equal opportunity for each need to be met in their designed course component.

An instructors view of where knowledge is constructed largely impacts the environment of the classroom and how information is presented to students. Although student-centered instruction has been shown to increase student learning outcomes (e.g., Bressoud, 2011; Freeman et. al, 2014), traditional lecture is still a prominent form of instruction in undergraduate calculus courses (Bressoud et al., 2015). Note in the table above, both lecture and student-centered activities were used in the classroom as instructional techniques. As both aspects of classroom instruction can help students construct their mathematical knowledge. Additionally, web-based homework was included as an instructional technique, as there has been a large increase in the use of web-based homework systems in undergraduate mathematics education (Serhan, 2019).

Discussion

The creation of the BLN framework came from both anecdotal and empirical evidence from students' formative and summative assessments in Calculus I classrooms. Many tests in a mathematics classroom assess what is "easy" to measure and not what is "worth" measuring (National Research Council, 1993), especially at the undergraduate level. Consider the following four main purposes of assessments: an individual student's proficiency of the subject matter in knowledge and skills; an individual student's performance after working within a group; group effectiveness and productivity; and students' interpersonal skills (Webb, 1995). In mathematics classrooms, however, students are usually formally tested only on individual expertise of the subject matter knowledge. The testing of individual knowledge and skills helps perpetuate the competitive nature of learning mathematics. Although competition can also be a motivation for learning, many women in mathematically intensive areas of study can feel isolated in competitively focused environments. Therefore, if a learning environment is created with an attempt to balance the LN of each student using the BLN framework, then a shift in assessment also needs to be considered. For instance, increased use of student-centered teaching strategies creates a mismatch between the learning and assessing contexts: students are asked to work in groups to learn together cooperatively, but are tested individually and potentially competitively. If we consider assessing knowledge in the space it is constructed (i.e., assessing the constructed knowledge on the lever at both sides of the fulcrum) then group testing may be a necessary addition to undergraduate mathematics courses.

Limitations and Future Research

I recognize that the proposed BLN framework being enacted in a classroom might differ depending on the pedagogical beliefs of the instructor. The framework was created from the perspective of one researcher, and still requires further empirical testing and validation. I have begun to explore this framework on the social side using group testing environments. Preliminary results did indicate how a lowered sense of belonging for female students impacted group performance on a group exam (Quinn, 2021). That is, their sense of belonging decreased and they underperformed in the group setting. Additionally, measuring the needs in a collaborative learning environment verses traditional lecture environments may help to show the *balance* needed between the pedagogy and learning environments in the classroom to help all students learn. Future testing of the framework will include individual and group testing methods to measure the internally constructed knowledge (i.e., individual exams) and socially constructed knowledge (i.e., group performance).

Building Instructional Capacity Across Difference: Analyzing Transdisciplinary Discourse in a Faculty Learning Community focused on Geometry for Teachers Courses

University of Michigan

Amanda Milewski
University of Michigan

In response to enduring methodological tensions in analyzing collaborative discourse, we detail an assemblage of argumentation analytic methods that can support research about faculty learning communities interacting across substantive differences. Drawing on our research with a cross-institutional faculty online learning community, we use data to show how theories from discourse analysis, systemic functional linguistics, and argumentation modeling can be operationalized to support researchers in brooking methodological tensions, including framing argumentation as the topic of or a resource for investigation and considerations of collaborative discourse as both process and content. Our methodological findings illustrate an example of this operationalization, highlighting analysis of transdisciplinary, collaborative discourse in a community composed of instructors of college geometry courses required for pre-service teachers. We share possible uses for this methodological approach vis-a-vis research about the professional work of undergraduate mathematics education and pre-service teacher preparation.

Keywords: Geometry, Argumentation, Professional Development

In explaining the exigencies of continued research about discourse in mathematics education, Sfard (2015) argued that researchers ought to investigate communication not merely as a means for learning, but as “the centerpiece of the story—the very object of learning” (p. 249). Such is our interest in faculty members’ collaboration around instructional improvement, in their discourse is a product of their collaboration. However, as Sfard (2014) and others have detailed extensively, research about discourse in mathematics education is theoretically and methodologically diverse, and so does not rely on a common set of assumptions, conceptual models, or analytical tools (Niss, 2007; Ryve, 2011). In our own research with a faculty online learning community (FOLC) of college mathematics instructors, we encountered the need for methodological resources to support analysis of instructors’ discourse—specifically, methods that would align with our goal of understanding the nature of the arguments among a diverse community of practitioners. This need is not unique to our research team. In an extensive review of research about instructors’ collaborative discourse, Lefstein et al. (2020) found that “the field would benefit from greater coherence between theoretical perspectives and research designs” (p. 11). In mathematics education research, we see evidence of such coherence from scholars using argumentation theories and models to analyze classroom discourse (see, e.g., Conner et al., 2022) and teachers’ knowledge and beliefs (see, e.g., Nardi et al., 2012). In turn, our methodological approach contributes careful consideration and practical examples of analyzing argumentation in undergraduate mathematics instructors’ collegial discourse.

In this paper, we detail a qualitative methodological approach that supports the investigation of undergraduate mathematics instructors’ cross-disciplinary knowledge resources—including synthetic geometry knowledge and mathematical knowledge for teaching geometry. We demonstrate this approach in the context of analyzing faculty members’ collaborative discourse geared toward the development of a curricular resource for instructors of college geometry courses required for pre-service secondary mathematics teachers. With attention to relevant methodological disputes, we illustrate how an assemblage of social semiotic methods—guided by Toulmin's (2003) and Gilbert's (1997) argumentation models—can support analysis of instructors' collaborative discourse across disciplinary and institutional differences.

Relation to the Literature: Argumentation Analysis in Mathematics Education

Discourse analytic research in mathematics education commonly adopts a fundamentally social constructivist stance towards human thought and knowledge (Sfard et al., 2001). That is, researchers assume that knowledge is socially and culturally, rather than individually, constructed; is dynamic rather than static; and is inherently contextual (Palincsar, 1998, p. 354). Unlike formal logic-based argumentation models, informal and quasi-logical argumentation models and theories involve inductive or diffuse disputes in which participants can "explore positions flexibly" (Nussbaum, 2008, p. 349) and in which different "ways of representing the world" can become "premises" supporting (a potential plurality of) conclusions (Fairclough & Fairclough, 2012, p. 86-87). In the data we share from our study with a FOLC, mathematics instructors' interactions are discursive activities situated in their development of a curricular resource. In many ways, the group's discourse represents their efforts to build a plane while they fly it (so to speak)—with the destination being instructional improvement. A review of research shows methodological challenges when conceptual fidelity requires researchers to consider this kind of collaborative discourse in which argumentation is more exploratory in nature.

Taylor (2001) named key tensions that researchers face in discourse analysis work: (1) investigating discourse as the topic of study versus analyzing discourse as a means of (or resource for) investigating something else and (2) fore-fronting the process or content of discourse. Conceptualizing discourse as process means focusing on the interactivity of discourse, including questioning the functions or effects of talk. In contrast, conceptualizing discourse as content typically focuses on the recurrence of themes, ideas, or other elements in the corpus of text. While these tensions exist across discourse analytic approaches, we identified how they are instantiated in argumentation analyses related to mathematics education research and research about educators' collaborative discourse.

Mathematics education research that analyzes argumentation often focuses on deliberate classroom interactions, such as patterns of teacher and student participation in formal (logical) argumentation. Such scholarship often frames argumentation as the topic of study. For instance, Forman et al. (1998) described their aims in analyzing transcriptions from a mathematics lesson as "understanding …the socialization of argumentation in her mathematics classroom…[and] to provide teachers and teacher educators with a detailed picture of argumentation in this classroom (p. 529). We also found several examples of researchers studying students' argumentation in the context of proof activities, illustrating further scholarly focus on argument as the main topic of investigation (see Harel & Sowder, 1998; Knipping, 2003; Rodd, 2000; Weber & Alcock, 2005). Still, many of these same researchers (and others) have related their findings to other phenomena, suggesting argumentation is a resource for engaging concepts relevant to social constructionist notions of learning. For instance, Krummheuer (2007) analyzed students' argumentation and theorized that their contributions reflected their learning autonomy.

Research about teachers' professional knowledge and learning communities has used argumentation as a resource to investigate other educational phenomena—most notably, teachers' beliefs, values, and knowledge (e.g., Conner & Singletary, 2021). Scholarship like this has demonstrated the need for researchers to analyze argumentation as both topic and resource. For instance, Nardi et al. (2012) showed that teachers' arguments could be understood in terms of mathematical accuracy and other professional concerns (including pedagogical, curricular, and personal considerations).

Mathematics education research in our review often elided distinctions between argumentation as content and process. We posit that the mathematical nature of logical argumentation and the cultural diffusion of mathematical thought into more popular and informal modes of argumentation (Keitel, 2006) mean that, in mathematics education research, the process and content of argumentation can both be objects of study vis-a-vis the same phenomenon (e.g., students' proving work in Hollebrands et al., 2010). Similarly, social constructionist frameworks can complicate distinctions between the content and process of argumentation. Researchers who have investigated the quality of collaborative discourse as a matter of process as much as content have faced this challenge (Lefstein et al., 2020). For instance, scholars noted that facilitators can help provide the *content* of expertise (Horn & Kane, 2015) and facilitate social *processes* (Kintz et al., 2015). We conclude that field-specific conceptions of mathematics and learning must inform these kinds of methodological distinctions.

Conceptual Framework & Operating Theories

Theoretical underpinnings of our research guide our attention to how and why undergraduate mathematics instructors draw on diverse knowledge resources to engage in collaborative argumentation. We discuss our study, including the community, its members, and its formation, in this report's research methodology section. We focus on the theories and models of argumentation we have operationalized to facilitate analysis premised on treating discourse as both topic and resource and content and process. In particular, we discuss Toulmin's (2003) six-part model of argumentation and Gilbert's (1997) theory of coalescent argumentation.

Toulmin (2001) averred that analyzing argumentation should balance attention to the social situation of the argument and attention to its artifacts (i.e., texts). Gilbert (1997) wrote that "we need to shift the focus…from the *artifacts* that happen to be chosen for communicative purposes to the *situation* in which those artifacts function as a component" (p. 46). In both views, analyzing argumentation involves the particularities of the situation, including participants' motivations, goals, and positioned relationships. In bringing these two theories together, we do not want to reduce Toulmin's and Gilbert's robust bodies of work to narrow facets or conflate shared theoretical implications with common theoretical assumptions. Instead, we consider how their theories complement each other—allowing for dual-attention to argumentation as both (a) topic and resource and (b) content and process.

Toulmin's model includes six parts: claim (conclusion), data (evidence or grounds for the claim), warrants (justifications explaining the relationship between the data and the claims), backings (beliefs or evidence underlying warrants' logic), qualifier (claim's degree of certainty), and rebuttals (conditions that would make the claim untenable). Not all arguments fit this framework, as others have noted (Ellis, 2015; Schwarz, 2009). Still, as Inglis et al. (2007) wrote, Toulmin's framework is "less concerned with the logical validity of an argument, and more worried about the semantic content and structure in which it fits" (p. 4). That is, the Toulmin framework is useful for decomposing everyday reasoning, even if partially. On the other hand, coalescent argumentation captures how participants may join their justifications to achieve collaborative aims. Of note, Gilbert's theory directs attention to multi-modal, goal-oriented, and position-based argumentation (Gilbert, 1994; 1997; Godden, 2011)—a conceptualization compatible with Toulmin's larger theory of argumentation. Extending Toulmin-esque theories of informal argumentation, Gilbert suggested that models of argumentation could include warrants of varying sources. Warrants from other sources (what Gilbert calls "multi-modal" participation), include the emotional, the visceral (e.g., "That's a sensitive subject for me"), and the kisceral[1] (e.g., "It strikes me as the right thing to do"). Attention to multiple modes increases possibilities for coalescence (e.g., two participants may not agree on the logical validity of a claim, but they might find coalescence around a claim for which one finds logical warrant and the other finds emotional warrant). Gilbert (1997) also theorized that people engage in argumentation with multiple goals, including task goals and face goals (see Gilbert, p. 67-68). Thus, we understand resolution may be oriented toward a shared aim (e.g., the development of a curricular resource) *and* that participants have various other goals and priorities (e.g., maintaining relationships).

Engaging in participants' complex positions is a key to using the tools of coalescent argumentation (Gilbert, 1997). So, beyond modeling individual micro-arguments, coalescent argumentation can help us understand how participants relate micro-arguments to their diverse knowledge resources, institutional contexts, and sustained community engagement. We draw on Toulmin's model to support investigation of the topic and content of FOLC members' multiple arguments. When argumentation does not resolve in a single conclusion or involves more diffuse discursive engagement with elements of argumentation, we draw on Gilbert's (1997) theory of coalescent argumentation. Based primarily on these two theories, we developed an approach to support our analysis of participants' micro-arguments (argumentation as topic and content) and situating those micro-arguments in disciplinary, institutional, and community-specific contexts and relationships (argumentation as resource and process). This approach allows us to analyze participants' multiple, dynamic, and sometimes contradictory or unrelated positions and to understand a mode of argumentation in which members of the FOLC neither invalidate participants' starting positions nor disengagement from reasoning together. In our methods and results sections, we detail how we operationalized the theory of coalescent argumentation to interpret argumentation that initially included two oppositional positions—and out of which a third position emerged and coalesced them without invalidating their logic.

Research Methodology

Our research occurs in the context of an FOLC that focuses on "Geometry for Teachers" (GeT) courses (i.e., college geometry courses required for prospective secondary mathematics teachers). Within the FOLC, 15 GeT instructors formed a working group to discuss student knowledge outcomes. Working group members' exchanges have included argumentation concerned with the state of the American college geometry course, which Grover and Connor (2000) had identified as having a "wide diversity" of course elements and a lack of consistent curriculum or instruction across institutions (p. 47).

While GeT courses are typically taught out of mathematics departments, these courses are usually taught by mathematicians or mathematics educators. The 15 members of the FOLC working group are a balance of instructors who identify as either mathematicians or mathematics educators. Some GeT courses are exclusively taken by future teachers, while others are electives

[1] Gilbert (1994) defined the kisceral mode as a "the mode of communication that relies on the intuitive, the imaginative, the religious, the spiritual, and the mystical" (p. 10). People often draw upon kisceral reasons in their everyday argumentation, and Gilbert noted (2011) that kisceral experiences can often be recast as strictly rational. Elaborating on the kisceral mode of argumentation, Gilbert (2011) gave the example of Euclid's Fifth postulate as a subject of knowledge that has often elicited "a *feeling* about what was right, what made sense, and what fit" (2011, p. 164).

for mathematics majors. In some cases, the GeT course is the only one that covers geometry content. Unlike many other college mathematics courses (e.g., Calculus), there is no broad consensus about what should be included in a GeT course, as there are many different types of GeT courses (Grover & Connor, 2000; Venema et al., 2015). To improve secondary geometry instruction, the FOLC working group realized it would be useful to identify a set of essential student learning objectives (SLOs, hereafter) for inclusion in GeT courses. *Essential* means the identifying content knowledge that all prospective secondary geometry teachers should learn in the course. They created this list of SLOs to help other GeT course instructors, especially new ones. The working group met monthly for the first year and a half and biweekly for the past six months to develop, elaborate, and steward the SLOs. The instructors' work is framed by their shared commitment to developing consensus—and SLOs that reflect that consensus—while navigating significant differences in their preparations, institutional and departmental affiliations, and disciplinary orientations. Our study of this group's work aims to understand the professional reasoning that occurs across such a situational landscape.

Results: Operationalizing a Methodological Approach

In this section, we show how a methodological approach drawing on both Toulmin and Gilbert provides a basis for conducting argumentation analysis without a single conclusion and towards a common goal. The analytical process has two major parts: (1) modeling micro-arguments and (2) mapping and analyzing position interactions, including coalescence.

Modeling Components of Micro-Arguments

One of the primary goals of the FOLC's working group has been to write SLO narratives that are detailed enough for GeT instructors outside the FOLC to use. The process of drafting these narratives starts with a subgroup of two to three people writing an initial draft narrative for each SLO and bringing it to the whole group for discussion and revision; this process repeats with the second draft and so on. The data in this section comes from a one-hour whole group meeting in March 2021, where the group reviewed a revised draft of the narrative of an SLO devoted to the role of definitions in mathematical discourse. As context: In a previous meeting about the first draft of the narrative, there had been a lively discussion about what constitutes non-Euclidean geometry, and whether they needed to define Euclidean and non-Euclidean geometry for their readers—as they themselves had varying definitions of these two types of geometries. Our example highlights exchanges between three participants: Miriam[2], Royce, and Michael. Over the course of the discussion, Miriam, Royce, and Michael engage in argumentation around issues related to teaching the nature of definitions in GeT courses.

To analyze the interactions and relationships between the arguments in the meeting(s), we first applied Toulmin's (2003) extended model of argumentation to meeting transcripts. We coded participants' turns of talk to identify claims (i.e., any conclusions they offered). Then, we coded turns of talk for contributions to arguments in service of a claim (or counter-claim). Each claim and its related elements (e.g., data, backing) represented a micro-argument that was putatively connected to the arc of the group's inquiry. Because we coded transcripts of verbal conversations, this process also involved looking for linguistic indicators of argumentation (e.g., "because"), including the use of modal qualifiers (e.g., "probably"). One example micro-argument consisted of the following elements, made by a participant called Miriam: (*claim*) the SLO narrative text uses too many examples of non-Euclidean geometry; (*data*)

[2] Pseudonyms are used for the participants in the study.

examples from the SLO text; (*qualifier)* the issue is context-specific, given the group's aims in writing the SLOs; (*warrants*) explaining that too many non-Euclidean examples might seem to promote a non-Euclidean approach to the course; and, finally, (*backings*) citing twice that she feels worried (a *kisceral* justification) and that her GeT course would show the need for the text to be less weighted toward non-Euclidean examples (a *logical* justification).

While completing the Toulmin (2003) diagramming of the transcript data helped us map the (quasi-)logic of the micro-argumentation, we also wanted to understand connections to the group's larger processes and individual and shared contexts for their work. We understood the group as sharing the goal of developing the SLOs. Gilbert (1997) detailed coalescent argumentation beginning from identified opposing sides (e.g., pro, con) of an "avowed disagreement" (p. 104). Thus, we identified disagreements participants had in direct relation to the SLO narrative, allowing us to thematically group elements of micro-arguments according to their indicated positions vis-a-vis a common dispute. Through this analysis, we identified three positions (i.e., thematic clusters of arguments): (1) the SLO should use examples of Euclidean geometry; (2) the SLO should use examples of non-Euclidean geometry; and (3) the SLO should explain the relevance of teaching the nature of definitions to pre-service teachers.

Mapping & Analyzing Position Interactions, Including Coalescence

In Gilbert's (1997) theory of coalescent argumentation, argumentation is not necessarily dialectical, because dialectical exchanges resolve in affirming the validity of some arguments and the invalidity of others. Toulmin's (2003) model of argumentation is well-suited for representing more dialectical exchanges, including collective participation (Krummheuer, 2007; Nardi et al., 2012). Diagramming micro-arguments illuminates participants' practical reasoning. Analyzing coalescence across the arguments illuminates the multi-modal rationales disparately maintained by various participants and that ultimately facilitate consensus. Figure 1 illustrates three parts of the argumentation occurring between Miriam, Royce, and Michael.

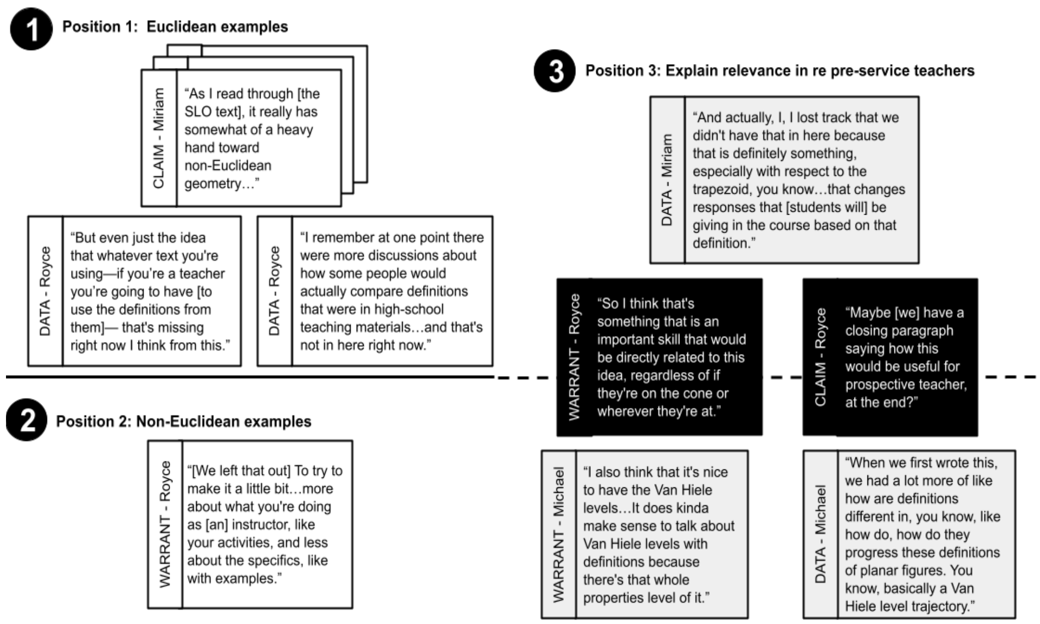

Figure 1. Modeling Phases of Argumentation Leading Toward Coalescence

Position 1 is constituted by micro-arguments advocating for using examples from Euclidean geometry. It includes Miriam's previously-described argumentation. It also includes two pieces of data that Royce offered in response to Miriam. Royce also offered a warrant that would support Position 2 (advocating for using non-Euclidean examples). However, he also gave a warrant that could support Position 1 *or* Position 2: "…that's something that is an important skill that would be directly related to this idea, regardless of if they're on the…." Here, Royce amplified Miriam's point that an example about defining a circle on the surface of a cone does not necessarily communicate the same set of skills she is saying a Euclidean geometry example might *and* offered justification for why non-Euclidean examples would still suffice. This warrant serves as the first indication of potential coalescence. Miriam responds to Royce's warrant by using it to agree with Royce's suggestion that they add additional text detailing the relevance of teaching the nature of definitions for pre-service teachers. This suggestion—a claim that represents Position 3—thus gains Miriam's support and allows her to maintain the rationale she employed in arguing Positions 1. It also allows Michael to accommodate his own rationale. Specifically, Michael identifies that Royce's data—a reference to structuring the narrative of examples in a way that would align with Van Hiele levels—is reason to support Royce's suggestion. Notably, Miriam and Michael's continued participation *could* align with the previous arguments made vis-a-vis Position 1 and 2, but they built coalescence around a third position that allowed them to maintain elements of the rationales underlying Positions 1 and 2.

Applications to/Implications for Teaching Practice or Further Research

Thus, we claim that Gilbert's (1997) theory of coalescent argumentation is complementary to Toulmin's (2003) modelling of arguments. We identify coalescent argumentation's suitability for theoretical and empirical investigations of mathematics instructors' professional discourse in situations that support developing consensus without invalidating participants' individual rationales. We operationalize tenets of coalescent argumentation, including using the Toulmin framework to model multi-modal argumentation, bounding arguments by identifying positions (i.e., thematic clusters of micro-arguments), and analyzing interactions across positions to identify possible coalescence. We suggest that the theoretical implications of the three principles of coalescent argumentation—that argumentation is multi-modal, position-based, and goal-oriented—may have wide-reaching applications in mathematics education research.

Scholars in the RUME community have advocated for qualitative researchers to align their research questions and methods (Melhuish & Czocher, 2022), and for more research about cross-disciplinary knowledge resources in undergraduate STEM instruction (Speer et al., 2020). Lefcourt (2020) noted that, while there has been "increasing attention…on making undergraduate courses for mathematics teachers relevant to the work of teaching," it is uncertain how such efforts can occur with larger degrees of "scope, scale and impact" (p. 830). Even though we are explicit about our methodological approach's conceptual boundaries and limits, we share it to support conceptually-aligned research in undergraduate mathematics education that examines questions about cross- and trans-disciplinary knowledge resources and instructors' practical applications of these knowledge resources in their mathematics teaching.

Investigating Student Perceptions towards Mastery-Based Grading in Precalculus

Melissa Newell
Iona University

Michelle Rabideau
University of Hartford

In this study, mastery-based grading was implemented in three sections of precalculus taught at two institutions. We investigated student perceptions towards this grading system by analyzing math autobiographies written by the students at the beginning of the semester as well as responses to surveys that were distributed at three points in the semester. In this paper, we present our results and discuss the implications to help support students during mastery-based courses.

Keywords: mastery-based grading, precalculus, standards-based grading

Mastery-based grading is not new, but it has begun to receive more attention from undergraduate mathematics educators who are looking for a different way to assign grades that will both accurately reflect their students' progress in the course and temper some of the anxiety and negative attitudes towards mathematics that their students may possess. In this study, we investigated students' (N=21) perceptions of a mastery-based grading scheme being used in a semester-long precalculus course. The use of mastery-based grading is new for many students, so they may need more support to adapt to it. Our results give indications of where this support is needed and in what forms.

Background

Since there are many forms that mastery-based grading can take, we will begin by defining our method of mastery-based grading. We adapted the ideas of Nilson (2015), first developing a set of learning objectives for a precalculus course, then creating a direct link between the objectives in the course and a student's overall grade. In general, students are graded based on how many of the course learning objectives they have mastered. Mastery of the learning objectives can be assessed in a variety of ways, for us this was done using tests, but a key feature of the system is that students do not receive partial credit for partial understanding, rather they must show the grader that they have full proficiency with the objective (Collins, et al., 2019). While students do not earn partial credit, a key element in mastery-based grading is that students are given multiple attempts to demonstrate proficiency on the learning objectives. In addition to the learning objectives, we also developed additional requirements including homework completion and projects to include in the criteria for each grade.

The increase in implementation of mastery-based grading in undergraduate mathematics courses has brought with it an interest in studying the grading scheme and reporting on its effects and outcomes specifically in those contexts. Benefits have been noted in these settings, such as improving students' attitudes towards mathematics, increasing students' confidence in their mathematical abilities (Stange, 2018), and giving the students more control over their final grade (Williams, 2018). Additional benefits were seen by Harsy and Hoofnagle (2020), who found that students felt that their final grade more accurately reflected their knowledge as opposed to grades in a traditional grading environment. Since students know the requirements for each grade from the first day of class, they are able to set goals and make choices to study objectives they feel will allow them to achieve those goals.

There is also evidence that the emphasis that mastery-based grading often puts on reattempting mastery can alleviate stress associated with tests (Stange, 2018) since the reattempts give flexibility for students to continue working on an objective over time. However, there may also be drawbacks to this in terms of student motivation; for example, students may be tempted to put off learning objectives or not take first attempts as seriously as they would in a traditional environment (Weir, 2020). One traditional purpose of mastery-based grading and learning is to allow each student enough time to master the content for the course (Bloom,1968). However, a course typically has a set ending date, limiting the time available. Instructors will need to think deeply about how they can support their students to set appropriate goals and strategies for success. To do so, it would be useful to understand more about the students' perspectives, which is the goal of this study.

Research Question

The results discussed in this paper are part of a larger study investigating mastery-based grading within college-level precalculus classes conducted by the authors. For the purposes of this paper, we will be discussing our findings related to the following research question: How do students' opinions of mastery-based grading change throughout the semester?

Methodology

This study collected data from three sections of precalculus taught at two different institutions in the same semester. One section was offered as a 3-credit course at a small, private, liberal arts college in the northeast United States (Institution 1) while the other two sections were offered as 4-credit courses at a medium, private university in New England (Institution 2).

Course Structure

The grades for students in the three sections were based on their proficiency on 27 learning objectives as well as their homework completion and their completion of up to two projects. Proficiency on the learning objectives could be shown on five test days, four during a regular class period and one in place of a final exam. Within the 27 objectives were 7 core objectives, which needed to be mastered to pass the class. The questions used for the tests were common across the three sections, as were the homework questions and projects. The base letter grade depended solely on proficiency on objectives and project completion. Students needed to complete one or two projects to earn a B or A in the class, respectively. After the base letter grade was decided, homework scores impacted whether the letter grade would have a plus, minus, or neither attached to it.

Data Collection

The data for the larger study consists of both quantitative and qualitative data, collected through student responses to three surveys, math autobiographies written by the students at the beginning of the semester, homework scores, and test responses and scores. To address the research question above, we use the qualitative data from the surveys and math autobiographies.

Each survey contained various closed- and open-response questions. In this paper, we focus on the analysis of responses to those questions relating to the students' views on the grading used in the class. The first survey was completed in the first two weeks of the semester and students responded to the open-ended question, "What are your first impressions of the grading system in this class?" In the second survey, sent to students after they had taken two tests, the students responded to the open-ended question, "At this point in the semester, what are your impressions of the grading system in this class?" A third and final survey was sent at the close of the semester, and students responded to four open-ended questions in which they discussed their ideas about the grading structure in the class, those questions being:

1. In preparation for your tests, how did you choose which learning objectives to attempt?
2. Do you believe the grade you will receive in this class accurately represents how much you have learned? Why or why not?
3. Do you think your overall grade would have been better, worse, or the same in this class if you had been graded traditionally? Why?
4. What are your impressions about the grading system used in this class?

Math autobiographies were written by students at the beginning of the semester describing their past experiences with mathematics and their expectations for the current course.

Participants

Students in the three sections of Precalculus were emailed an invitation to participate in each survey. Participating in at least one survey indicated the student's consent to being a participant in the study, as indicated by filling out a consent form on the survey. A total of 21 students agreed to participate in the study, twelve on Survey 1, thirteen on Survey 2, and ten on Survey 3. Out of the 21 participants, seventeen submitted math autobiographies but only eight of those referred to the grading used in the class. There were 8 participants from Institution 1 and 13 from Institution 2. To protect our participants' identities, throughout this paper you will see participants referred to by code. Participants at Institution 1 are labeled using the letter N followed by two digits (ex. N20), whereas those at Institution 2 are labeled using the letter R followed by two digits (ex. R01).

Data Analysis

The math autobiographies and survey responses to open ended questions were analyzed using an inductive thematic analysis (Patton, 2002). To investigate the students' opinions about mastery-based grading at different points in the semester we focused on the students' initial perceptions, perceptions after taking two tests (midsemester), and their perceptions at the end of the semester.

To analyze the initial impressions about the grading scheme we considered the responses from math autobiographies and from the first survey. To analyze the midsemester impressions that students had about the grading scheme, we analyzed their responses to the question from Survey 2 that was discussed above. Finally, to analyze the students' opinions about the grading system at the end of the semester we considered the responses to the four open response questions on Survey 3.

Discussion of Results

This section will briefly describe the categories discovered through the analysis of initial impressions, midsemester impressions, and final impressions that students had about the grading scheme.

Initial Impressions

There were four categories that emerged during our analysis of the responses to Survey 1 and the math autobiographies.

Confusing. Responses showed that several students saw the grading system as confusing or strange to them. For example, N20 wrote the grading scheme was "confusing but might be beneficial". These responses were not surprising since for many students this was the first class in which they had experienced mastery-based grading.

Straight-forward. There were a few students who thought the grading was clear. N50 said, "I love how straight forward, and easy the grading is". Similarly, R09 emphasized the clarity of the learning objectives, saying, "I think they are really helpful in keeping me focused. Nothing feels jumbled together, I can clearly see what path I need to take."

Retries. We also saw that students were excited about the ability to retry objectives that they had not shown proficiency on with their first attempt. R12 mentions, "I feel like it is way less stressful for us new incoming students who are use to just having to fail if we do bad on a test … with the way you grade our tests I get to redeem myself with questions I may get wrong which is very comforting." This was an aspect of the grading that students seemed to grab on to as a positive aspect of the method, although there was some hesitancy from R06 who said, "I think it's cool that I can retry topics at my leisure but I hope I don't mess up on a lot so it snowballs into a disaster."

Pacing. Students also mention that the grading scheme will give them more freedom and/or independence to complete objectives at their own pace and that there is less stress due to the pacing of the class. N50 says, "I see myself doing well in this class because I'll be able to go at the pace I want … I'll be able to complete [objectives] on my time."

Midsemester Impressions

Through our analysis of the responses to Survey 2, three categories emerged. Two of the categories were similar to two found in the initial impressions, so we chose to use the same name and definition for them.

Confusing. Even at the midsemester mark, after the students had taken two tests, there were still students who found the grading scheme confusing or strange. However, it seemed that there was some improvement in understanding. R10 said, "I'm very confused by it still, but looking at each individual grade I've received helps me calculate what my overall grade is."

Retries. Students continue to mention the benefit of being able to retry objectives. R10 says, "I love the fact that you can attempt each core objective until you receive the grade you want."

Stress. A new category that emerged spoke to the students' perceived stress and anxiety levels in the course, with some students feeling that the level of stress was heightened by the grading scheme and some feeling that it was lessened. From R09, "It makes the class feel more intense, like we have less room for error, and over all, just a really stressful and weird experience." With an opposing view, R11 says, "I really enjoy it. I think that because of how the tests work and how we're able to retry problems, my anxiety is much lower for this class."

End of Semester Impressions

Four categories emerged through our analysis of the four open-response questions from Survey 3. One of the categories, Stress, uses the same name and definition as was found in the midsemester analysis since the ideas were similar.

Stress. A couple students mentioned opposing views on their perceived stress and anxiety levels due to the grading scheme. R01 said, "Objective based learning didn't help me change how I study, but rather gave me huge amounts of anxiety as my failings kept weighing on me" whereas R02 said, "I think it showed that it is up to us to work hard but also it is okay if not every day is our best day because we get another shot. It took a lot of the anxiety down."

Strict. Students spoke more specifically about the requirements in the grading system, most likely due to the additional questions included in the final survey. Some students felt that the grading structure was too strict and that they were marked wrong for too small of errors along with not having enough opportunities or ways to show their understanding. R09 felt that "there were small mistakes [they] made from calculation or missing one step of a five part problem where in any other class [they] would have gotten some type of credit for it because [they] clearly understood how to do the problem." Others mentioned they wanted the projects to count differently, such as R06 saying, "Through doing the projects and homework I have done so much more and the projects will not even be factored into my grade unless I have everything done [that is necessary for an A or B]."

Effort. As we see in some of the examples for Strict, students also discussed that their effort in the class has affected their feelings toward the grading system. Several students felt that the effort they put in for the course was not reflected in their grade, as we saw from R06 above. However, there was also a student, N04, who mentioned that because they always felt they had more chances to complete objectives, they did not put in enough effort: "If it was graded traditionally I think my grade would've been higher, because more pressure levied upon me every week meant that I wouldn't have procrastinated until the last minute to do everything."

Core. Several students mentioned the core objectives in their responses. This was often relating to how they chose which objectives to study for, stating that they focused on the core objectives first, but we also had students say that they believe the expectation of and focus on mastering the seven core objectives caused them to miss out on other objectives. R09 said, "Most of the class still needs core objectives on the final and are at a high risk of failing." It is worth noting that of the 18 participants that did not withdraw from the course, only 7 had completed the core objectives prior to the final, so the concern about core has some merit for our sample.

Implications

We believe that investigating students' perceptions of mastery-based grading is important to understanding how we can support them in our courses. By considering three different points in the semester, we were hoping to gain insight into how support can adapt to the changing concerns of students. Our results indicate that there are some concerns that remain present throughout the semester, while others may emerge later after the students have been able to experience more of the consequences of the grading. Understanding these concerns is useful in planning for a course, especially for instructors who are new to this grading style.

For example, while emphasizing the opportunities for students to retry objectives can alleviate some of their concerns early in the semester, it may be beneficial to have specific recommendations about how to take advantage of these opportunities so that the pressure is not just pushed to the end of the course or due date. This agrees with findings by Matz, Derry, Bennett, LaRose, and Hayward (2022), who found that the use of behavioral nudges can lead to better outcomes for students. In their study, personalized email reminders were sent prior to assessment due dates. Other ideas could be to have class discussions about study strategies, hold individual meetings to plan for future assessments, or to structure the course with some intermediate deadlines.

These results represent a portion of the data we collected. In addition to the math autobiographies and survey responses, we also collected tests, homework scores, projects, and grades. We hope the RUME community can provide insights on how to further explore these results and make connections to the other data sources.

Ongoing Efforts to Develop an Assessment Tool for Students' Participation in Defining

Tenchita Alzaga Elizondo
Portland State University

Kristen Vroom
Michigan State University

Adam Eide
Oregon State University

There has been a push to develop curricula that engages students in various mathematical practices (e.g., defining). As more curriculums of this type arise, there is a greater need for assessment tools for students participating in these practices. We see Modeling Eliciting Activities (MEAs) as one answer to this need. In this study we discuss how the six design principles of MEAs can be used to (re)design an assessment tool for students' defining activity.

Keywords: Modeling Eliciting Activities, Assessment, Defining, Classroom Practices

One common goal of many curriculum designers is to engage students in mathematical practices such as defining, conjecturing, and proving. This engagement can be a means to support students in learning about mathematical concepts (Larsen, 2013; Lockwood & Purdy, 2019; Oehrtman et al., 2014; Swinyard, 2011) and/or as a means to increase students' participation in these practices themselves (Larsen et al., 2022; Rasmussen et al., 2005; Zandieh & Rasmussen, 2010). We have engaged students in mathematical practices for both reasons in our ongoing efforts to design inquiry-oriented curriculum for Introduction to Proof courses.

We have faced a practical problem in our efforts: the lack of an appropriate assessment tool to reveal students' participating in mathematical practices. While there are relevant concept inventories (e.g., Melhuish, 2019; Mejía-Ramos et al., 2017), these take an acquisition lens on learning (Sfard, 1998) to measure students' understandings of important concepts or skills rather than a participation lens. We also found relevant observational tools (Melhuish et al., 2021; Melhuish & Thanhesier, 2017); yet, using these would require one to analyze classroom data to get a sense of whether students' participation changed overtime.

An assessment tool that measures students' participation in mathematical practices would be useful for us as researchers to measure the efficacy of our materials on student participatory learning. Additionally, the need for an assessment tool has been echoed by the instructors who use our curriculum materials; they want their tests and quizzes to reflect what they do/teach in class. This study aims to make progress on this goal for the case of assessing students' participation in defining - a practice that our curriculum materials are specifically engineered to promote. In doing so, we hope to open the discussion about how such an assessment could be adapted to assess students' participation in other classroom mathematical practices (Cobb & Yackel, 1996; Rasmussen et al., 2015). In what follows, we introduce Model Eliciting Activities (MEAs), which informed our design and revisions of the assessment.

Conceptual Framework

Lesh and his colleagues (2000) describe MEAs as tasks designed so that students' work "reveal explicitly the development of constructs (conceptual models) that are significant from a mathematical point of view" (p. 362). These tasks emphasize communication and reflection by asking students to explain their reasoning, thinking, and strategies including revisions and refinements. Teachers and researchers have used these artifacts to assess students' conceptual understanding (e.g., Carlson et al., 2003), problem-solving strategies (e.g., Chamberlin & Moon, 2005), and metacognition (e.g., Kim et al., 2013). In our study, we aim to add to this literature by using MEAs as a tool to assess students' participation in classroom practices, and specifically, we are designing an assessment tool that elicits a model of students' defining activity.

The six principles to guide the creation of productive MEAs with guiding questions (adapted from Carlson et al., 2003, pp. 472-473 to fit our defining context) are: (1) *Model Construction* (Does the task immerse students in a situation in which they are likely to confront the need to develop their defining activity?), (2) *Construct Documentation* (Will the task require students to reveal their defining activity?, (3) *Reality* (Will students make sense of the situation by extending their own knowledge and experiences?), (4) *Model Shareability and Reusability* (Does the model provide a general model for analyzing this type of defining activity?) (5) *Effective Prototype* (Is the situation simple?), (6) *Self-Assessment* (Does the task promote self-evaluation on the part of the students?). This study aims to answer: How can the MEA principles guide the design of an assessment tool for students' participation in defining?

Methods

Data for this study comes from an NSF-funded projected (ASPIRE in Math IUSE #1916490) that aims to create modular inquiry-oriented introduction to proof curricular and instructor support materials. One goal of the curriculum is to support students in participating in defining. A typical defining task sequence first engages students in a situation in which an informal idea of a concept emerges. Then students create and negotiate (non-)examples of the concept and then the teacher and students work together to refine their informal idea into a formal definition (see Vroom, 2020). We expected that our course would support students to strategically use (non-)examples when creating and testing their definitions, and to use those (non-)examples to strengthen their understanding of the concept to support them in formalizing their informal ideas.

Our primary goal with the assessment was to measure how students' participated in the sort of defining that our curriculum materials supported. The assessment had two main parts. First, the students were asked to define two concepts in a similar manner as our curriculum materials. To do so, students were asked to read an informal description of a concept, come up with (non-)examples, and write a formal definition. The two made-up concepts on the assessment were called Mirror-point Functions (described as "functions defined on a domain D that have at least one input-value that is the same as the corresponding output-value") and Repeat Functions (described as "functions where no matter what input you consider, that input maps to the same output value as the input that is one unit to the left of it"). We had no expectations for a "correct" definition as our focus was on the students' defining activity. The second part of the assessment was a "strategy guide" task that asked students to reflect on and articulate how they engaged in the previous defining tasks. We anticipated that the students' responses would provide us insights into how/if the students engaged in defining in such a way that was supported by the curriculum.

Creating and refining the assessment was a cyclic process in which we designed (or redesigned) the assessment, tested it with students, and analyzed the students' assessment responses and conducted follow-up interviews. We administered our assessment in three community college courses over the course of a year. For each course we administered the assessment during the first week of the course and then again during the last week. After each administration, we invited students to a follow-up semi-structured interview to discuss their responses. This resulted in a total of 18 pre-assessments with 6 follow-up interviews and 16 post-assessments with 7 follow-up interviews. Our data analysis focused on how, if at all, the assessment satisfied the six MEA principles based on what the students expressed on the assessment and follow-up interviews. We used this analysis to redesign the assessment before the next administration. In this report, we primarily focus on the second part of the assessment (the strategy guide task) since it provided us the most insight into how students participated in defining activity. The most updated version of the task is given in Figure 1. We will refer to this figure (and it's labeled parts) in the next section.

> **Strategy guide.** Notice that in the previous two sections you were given a name for a concept along with an informal description of the concept. Then in part B you were asked to write a definition. Now your job is to write a strategy guide that would help other students do what you just did on their homework! This strategy guide should explain exactly what the students should do (and how) to create a definition. Imagine they are given some NEW concept and an informal description and then they are asked to write a definition. Fill in the bulleted list below (add more bullets if needed) to write this general strategy guide. b. c.
>
> *After creating examples and non-examples of a given concept, you will be asked to write a formal definition of the new concept on part B. In order to write this definition, you should…* a.

Figure 1. Latest version of "how to write definitions" strategy guide prompt

Results

In this section we discuss how our assessment meets each of the six MEA principles and describe refinements that were made to address issues we found during our implementations.

Model Construction Principle

Given that we wanted to assess students' defining practice, designing a task in which they would create a model of that practice was critical. We addressed that need (and this principle) with the strategy guide task, where students were asked to create a guide for writing a formal definition for any concept. To do so, the students had to generalize their defining activity and thus, construct a model of their practice. In our first version of this task, students were informed that the strategy guide would be used to prepare students to write definitions on their exam and that "*They will not know what they will be asked to define [...] in advance.*" We found that this prompt was confusing for students, especially about what we meant by a "strategy guide". Some students opted to skip the task altogether while one student attempted the task but adding the note "I'm still a little unclear about this portion". To be more explicit about the desired model, we refined the task by adding a sentence starter (see Figure 1a).

Construct Documentation Principle

Presenting students with the opportunity to create a model of their activity (by creating a strategy guide to address the previous principle) was only part of the battle. We also needed to design the strategy guide task in such a way that the students explicitly revealed their defining activity. We wrote the strategy guide prompt in such a way that would encourage students to reflect back on their activity on the previous tasks to not only generalize it (as part of the Model Construction Principle) but also to document that generalization (as part of the Construct Documentation Principle). For instance, the first version of our prompt stated "*This strategy guide should explain what exactly the students should do (and how) to create the definition requested in part B of the example exam items.*" In the previous tasks, "Part B" was where students were asked to create a formal definition of the concept. By directly pointing to that part of their tasks, we hoped students would reflect on and document that aspect of their activity.

As part of the response to the students' initial confusion described in the previous subsection, we edited the prompt to make it clearer that we wanted students to create a guide that reflected their activity in the previous tasks by expliciting stating to reflect on what they did as they defined the two given concepts on the assignment, see Figure 1b. Not only did we see the refined prompt as supporting students in creating a general model of defining activity (addressing the

Model Construction Principle) but it also made it clearer that the model should reflect their activity when completing the previous tasks. This edit appeared successful. For instance, one student wrote for their first two steps in their guide “1) Look at the differences between examples and non-examples, and 2) Look at the similarities between examples.” During the student’s follow-up interview, they confirmed that this was reflected in what they did to create definitions, saying “it did yeah, that's what I use here.”

Reality Principle

In our original design of the assessment, we framed the strategy guide as a guide for a friend who would be taking an exam in which they would define some new concept. Students at this stage of their mathematics career have substantial experience studying for and taking mathematics exams. Thus, we felt that students could “make sense of the situation based on extensions of their own personal knowledge and experience” (Lesh et al., 2000, p. 367). While the revisions of the assessment described above showed promise, we kept running into a problem that could often be tied back to the context of the task: students provided general test taking strategies rather than strategies that reflected their defining activity. For instance, one students’ guide listed “1. remember the difference between for all there exists and there exists for all. 2. practice defining familiar terms such as linear function. 3. become comfortable with making mistakes, you probably won’t come up with your formal definition on your first try.” The fact that this guide was written about preparing for an exam rather than defining was confirmed in a follow-up interview where this student said in reference to his second point “That isn't so much a thing I used here. It's a thing that I’d use if I was getting ready for a test….”

After encountering several responses similar to the one above, we reflect on how the exam context failed to meet the reality principle and how we could refine it. We determined that students might struggle to see the exam context as realistic for their defining activity since they most likely have never been put in a position during an exam where they are asked to engage in such an exploratory task. Instead, we realized that the task would be better suited in a “homework” context as it aligns more closely with the situation in which students would be doing this kind of activity. We reflected this context in Figure 1b as it suggests students will be in a similar situation as them.

Model Shareability and Reusability Principle

In order to meet this principle, the model students are asked to develop needs to be general enough that it can be used by someone other than the writer itself (i.e., shareable) for other scenarios than the one that motivated its creation (i.e., reusable). Our assessment works to meet these requirements by having students write a strategy guide *for another student* and by asking that the strategy guide be written so that it can be used for *any* concept. We found that framing the task as writing a guide for a peer seemed natural for students. This was perhaps unsurprising since other scholars have successfully written Model Elicit Activities with a similar framing (e.g., Carlson et al., 2003; Vroom, 2020). Additionally, we found that our previously discussed edits to the prompt also were effective in supporting students to create a general model that can be reused when defining other concepts (see Figure 1b and 1c).

Effective Prototype Principle

As mentioned, the assessments first engaged students in formally defining two concepts: mirror-point functions and repeat functions. We saw these two tasks as “effective prototypes” of defining activity since students would have knowledge of various function properties at this point and thus should be able to make sense of a new property. Additionally, there is no one "right answer"; we acknowledge students would likely have different interpretations of the given informal descriptions. At the same time, we aimed to write the descriptions so that the different interpretations would be rich enough that students would be able to come up with various (non-)examples to support their defining activity. We encountered a problem when it came to our initial description of mirror-point functions. Initially, we had not clarified the "at least one" property in the description, this led to various students interpreting the statement to mean *all* input-values needed to equal the corresponding output value. With this interpretation only one type of function fits the description (i.e., $f(x) = x$ for all x in the domain) making the task trivial. As such, we added the "at least one" note to enrich the context and encourage a wider variety of (non-)examples.

Self-Assessment Principle

To create a rich model that reflects the descriptiveness and transparency that we are searching for in an assessment, students need to be able to assess themselves whether their model was adequate. One way we addressed this need was by asking students to create a strategy guide for *any* concept. This provided criteria for which students could assess their model: can this guide be used to any concept a student might encounter? More explicitly, we addressed this principle in the follow-up interviews by asking students "How does your strategy guide reflect what you did when you wrote your claims about mirror point functions and repeat functions?" With this question, the students were encouraged to assess how/if their strategy guide reflected their defining activity (another criteria of their guide). We found this question to be particularly revealing as it often identified when there were discrepancies between the students actual defining activity and what they had written in the guide. Given its revealing nature, we hope to incorporate a similar question in future versions of the guide in hopes that it supports students to refine their guide to more accurately reflect their activity.

Discussion

Through working with students we have found that MEAs seem to be a productive first step for developing an assessment tool that documents the extent to which students participate in the sort of mathematical practices that our curriculum materials aim to support. We found that the MEA principles supported some effective refinements, including more explicitly articulating what kind of model we expected the students to create and document in the strategy guide (i.e., with the use of sentence starters, emphasizing the need for generality, and being explicit about reflecting on their activity) and by changing the context of the task from an exam to homework so that the activity was more realistic to the students.

Our experience also generated a number of questions that we will pose to the audience for discussion. Specifically, we encountered that one limitation of using MEAs is that rather than assessing students' activity directly, we are assessing their ability to reflect on and articulate their activity, which is a higher-order task (Wheatley, 1992). With that, we wonder: 1) What kind of insights might we gain from a "high bar" assessment of this type? What are ways we can mitigate this challenging aspect of the assessment?

Investigating Norms in a Professional Learning Community

Corinne Mitchell
Virginia Tech

Research has shown that support from collaborative professional development communities benefits faculty introducing student-centered instruction to their classrooms (Henderson, Beach, & Finkelstein, 2011; Speer & Wagner, 2009). While the RUME community has some understanding of how professional development groups can be effectively formed to support teachers (e.g., Kelley & Johnson, 2022)*, further research is needed. In this study, I investigate the norms established within one such professional development community: an online working group designed to support teachers' implementation of an inquiry oriented abstract algebra curriculum. Preliminary results indicate that participants established norms related to working on tasks, contributing ideas and responding to each other's contributions, and sharing authority.*

Keywords: Instructional change, professional learning communities, sociopedagogical norms

In response to calls for reform in undergraduate mathematics education in the United States, various modes of student-centered instruction have been developed. To support faculty in implementing student-centered curricula, professional development resources like curricular support materials (e.g., Larsen et al. 2013) and summer workshops (e.g., Andrews-Larson et al. 2016) have been developed. This study focuses on online working groups (OWG) that supported mathematics faculty learning to teach inquiry-oriented abstract algebra (Larsen et al. 2016). Prior research has suggested the importance of community building in professional development groups (e.g., Clark et al. 2008, van Es, 2009, Kelley & Johnson, 2022), but the mechanisms by which such communities develop need more exploration. Thus, this case study aims to answer the research question: what community norms develop in online professional development groups?

Literature Review and Theoretical Framework

Inquiry-oriented instruction (IOI) is a type of student-centered instruction aimed at supporting students as they work individually and collaboratively on carefully designed mathematical tasks (Rasmussen & Kwon, 2007). As students inquire into new mathematical ideas, instructors inquire into students' mathematical reasoning, seeking to reveal and leverage students' informal conceptions toward more formal mathematics. Because IOI emphasizes classroom social interactions as grounds for the reinvention of mathematical concepts, it is crucial for teachers and students to negotiate social and sociomathematical norms that foster meaningful learning opportunities within the classroom community (Gravemeijer, 2020). While there has been some research regarding norms in inquiry-oriented (IO) classrooms (e.g. Rasmussen et al. 2005, 2009, 2010; Serbin et al. 2020), recent developments in instructional support for IOI necessitate further investigation into normative behaviors in professional development groups. Primarily, I am interested in understanding the social norms established by Teaching Inquiry-Oriented Mathematics: Establishing Supports (TIMES; NSF Awards: #1431595, #1431641, #1431393) online working group participants as they developed a professional learning community in their online meetings.

A professional learning community (PLC), as defined by Kruse, Louis, and Bryk (1995), is focused on cultivating peer interactions between teachers to improve teaching and learning. A

PLC has five central characteristics: reflective dialogue, focus on student learning, interaction among teacher colleagues, collaboration, and shared values and norms. Similar to Clark et al. (2008), the emergence of OWG social norms was investigated, viewing the OWG as a PLC. Social norms are defined by Cobb & Yackel (1996) as a person's "beliefs about [their] own role, others' roles, and the general nature" of classroom activity (Cobb & Yackel, 1996, p. 178). These beliefs are developed collaboratively between the instructor and students as they interact in the classroom and "characterize regularities in communal or collective classroom activity" (Cobb & Yackel, 1996, p.178). Serbin et al. (2020) documented norms related to working on mathematical tasks, students sharing contributions, and students responding to others' contributions in inquiry-oriented abstract algebra (IOAA). Norms surrounding students contributing to group discussions included sharing contributions, explaining their reasoning, and explaining difficulties they experienced. Finally, norms about responding to others' contributions in group discussions involved asking clarifying questions, being nonjudgmental, and providing productive feedback.

Because professional development literature suggests that modeling the type of instruction expected from participants is an effective strategy (Elmore, 2002), the focus here was on whether norms documented in IO classrooms were present in the OWG. OWG participants often worked through mathematical tasks, discussed their pedagogical reasoning, and provided feedback on each other's instructional practices, a clear parallel to the IO classroom activities documented by Serbin et al. (2020). According to Clark et al. (2008), just as student behavioral norms can be negotiated in a classroom, participant behavioral norms can be negotiated in a PLC. Dick et al. (2018) termed established expectations for participation when teachers talk with their colleagues about instruction *sociopedagogical* norms, taking direction from Cobb and Yackel's (1996) conceptualization of behavioral norms which are specific to the community's content area. Hence, such a conceptualization can be broadened to describe the rules and expectations for the facilitator and participants' behaviors within the OWG as they develop a community of practice, drawing parallels between the social norms previously documented in IO classrooms and those observed in this study.

Sharing authority has also become a central theme of discussion in research on student-centered instruction (e.g. Ball, 1993; Cobb et al. 1992). Given that some classroom activities parallel OWG activities, it is reasonable to suspect that norms surrounding sharing authority may also arise. Because one of the primary goals of IO approaches to teaching and learning is creating a community of mathematical discourse, instructors often avoid resting the validity of claims on "teacherly authority", rather aiming to use their authority in the classroom community to encourage norms surrounding discussion, reasoning, and mathematical argument (Ball, 1993). That is, teachers may take advantage of their ability to direct the future actions of the class with the goal of encouraging students' epistemic authority, which concerns how participants treat themselves and others as more or less knowledgeable rather than concerning the actual depth of individuals' knowledge (Byun et al. 2020). Because the OWG was composed of teachers with varying levels of expertise with implementation and had clear parallels to IO classroom activities, the notion of sharing epistemic authority as a normative social behavior was adopted.

Context and Methods

This investigation takes place within the context of a broader project, Teaching Inquiry-Oriented Mathematics: Establishing Supports (TIMES; NSF Awards: #1431595, #1431641, #1431393), a research and development project focused on supporting large-scale implementation of several inquiry-oriented mathematics curricula at the undergraduate level. To investigate best practices in bringing IOI to scale, TIMES utilized three forms of instructional supports: curricular support materials, summer workshops, and online working groups. The curricular support materials provided additional online resources to teachers. The summer workshops provided a three-day intensive session where participants became acquainted with the instructional tasks and curricular resources. Finally, the online working groups met for one hour each week during the semester following the summer workshop to work on instructional practices and discuss implementation issues with the goal of providing ongoing, content-specific support.

My primary focus is an online working group (OWG) that met for 14 weeks in the fall semester of 2016. The members of the OWG were engaged in implementing the IOAA curriculum designed by Larsen et al. (2016), a research-based, student-centered curriculum designed to engage undergraduate students in reinventing fundamental concepts of group theory. The group consisted of two instructors currently implementing the curriculum, one instructor preparing to teach in the following academic quarter, and one facilitator with previous experience teaching IOAA. The teachers were introduced to the curriculum materials in the summer workshop and met synchronously online via Google Hangouts once per week to reflect on the curriculum and implementation with a facilitator. Members of the OWG were regularly asked to share reflections on their instruction and investigate the curriculum tasks from a mathematical perspective. These online meetings were recorded and sections were transcribed for retrospective analysis. Social norms were analyzed as they developed throughout these meetings, using a priori codes developed by Serbin et al (2020) and emergent codes from the analysis related to sharing authority. Taking direction from Clark et al.'s (2008) conditions for documenting the development of norms, it was inferred that a behavior was normative to the OWG if it was commonly enacted without prompting, participants did not challenge someone enacting that behavior, and/or participants challenged someone when they did not comply with that behavior.

The OWG consisted of three instructors, Elena, Laura, and Roger, and one facilitator, Mickey. Mickey facilitated the OWG as a former TIMES fellow, having participated in the previous year as a new IOAA instructor. Elena, Laura, and Roger had experience teaching abstract algebra, but had not used IOAA. Because Roger's institution operated on a quarterly schedule, he was unable to teach the course synchronously with Elena and Laura. It is worth noting, however, that Roger was an active contributor in most discussions, and that the OWG continued to meet with Roger after their fall semester classes concluded to support his instruction during the winter quarter.

Results

Throughout the semester, Mickey indicates implicitly and explicitly that he is trying to model IOI within the online working group, making comments like "I hope I'm modeling what I would like to do in the classroom," and even describing the function of the OWG using language commonly applied in IO curricula design: "We're generating teacher thinking, building on teacher thinking, and developing a shared understanding, and then bringing it into the formal world." This supports my investigation of documented classroom social norms developing within the OWG. I found that participants enacted social norms related to working on tasks, sharing and responding to others' contributions, and sharing authority. Illustrative examples are presented below.

Working individually first.

Mickey explicitly stated the expectation for participants to work on tasks individually first with phrases like, “Everybody, take a minute or two to think about it,” and “I want you to take a few minutes before you answer this [question].” After this, participants thought to themselves and worked quietly until prompted to share their thoughts. In one instance, after Mickey had posed a question to the group, Elena began to respond immediately and Roger interjected, “I thought we were thinking to ourselves.” Roger challenging Elena when she did not give others time to think independently serves as evidence that this was an established social norm in the OWG.

Explaining reasoning.

Mickey also encouraged the group to share their ideas, beginning most meetings by inquiring into the teachers’ perspectives and continually asking for their contributions. He also positively reinforced this expectation by emphasizing key ideas, repeating them to the group or saying phrases like, “Can you say that again? We’re going to write it up here on the board.” Encouraging each other’s contributions was commonly enacted by the rest of the group throughout the semester. For instance, after Laura shared some thoughts on a clip of her teaching, Elena responded, “Tell me a little bit more about your thought process.” This is also evidence for the development of norms around participants explaining their thinking. Mickey explicitly stated the expectation for participants to explain their reasoning, saying “I’m going to press my teachers to give reasons for their teaching actions.” This behavior seemed normative, since it was encouraged by the facilitator and enacted without prompting by the rest of the group.

Sharing difficulties.

A similar type of contribution involved participants sharing the difficulties they experienced with curriculum tasks. Mickey would often open a meeting by saying, “So, tell us about your week – what went well, what didn’t?” to encourage participants to share their struggles. For the last 11 meetings, teachers regularly shared about their difficulties without being prompted. In many instances, this contributed to rich conversations surrounding pedagogical moves and inquiring into students’ thinking. After working on a curriculum task about group isomorphism concepts, Roger shared that he “struggled with the additive notation,” explaining that he switched to multiplicative notation with the goal of preventing students from being confused. Elena and Laura then both shared their experiences with developing shared notation in the classroom, which suggests that the norm of sharing difficulties often supported group discussion.

Showing support.

The fact that Elena and Laura responded to Roger by explaining their experiences is also evidence of norms about providing productive feedback. In particular, the norm that participants should be supportive and share their strategies was often enacted throughout the semester. Responding to others’ struggles by sharing strategies was first encouraged by Mickey after Laura described her difficulty with graded work, asking Elena and Roger to discuss their approach to assessment in IOI. Later, it was evident that providing productive feedback was a norm when Elena explained some difficulty she was having with a student during discussion, prompting the group to respond by asking explicitly for their suggestions. It also became normative for participants to encourage each other – when Roger explained that he was overwhelmed by the pacing of the course, Laura responded, “You can do it, you can, you’ll get there!” and proceeded to suggest different strategies to help Roger stay on track.

Sharing epistemic authority.

Mickey also promoted participation by using his deontic authority to encourage participants' epistemic authority. Often, when a participant asked Mickey a direct question, he would redirect it to the entire group, saying phrases like, "So that [question] is for everybody, I can answer later," and "I think this [topic] merits at least a three-to-five-minute discussion. I'll add a disclaimer that I have no idea how to handle that situation." Sharing epistemic authority became a social norm throughout group discussions. On occasion, Mickey would get excited about a topic and monologue for a few minutes. The group nearly always became quiet and tended to not respond to Mickey's monologues, which I view as evidence of participants challenging Mickey for breaking the norm of sharing authority. Because Mickey was challenged for not enacting this behavior, it can be thought of as a social norm within the OWG.

Table 1. A description of online working group norms.

Category	Norm Name	Description	Prototypical Quote
working on tasks	working individually first	participants engage with content independently before discussing with the group	"Take a few minutes before you answer this [question]."
	explaining reasoning	participants explain their thinking	"Tell me a little bit more about your thought process."
sharing and responding to contributions	sharing difficulties	participants discuss their teaching challenges	"I struggled with the additive notation."
	showing support	participants provide encouraging feedback	"You can do it; you'll get there!"
sharing authority	sharing epistemic authority	facilitator redirects discussions away from his expertise toward group discussion	"So that [question] is for everybody, I can answer later."

Discussion and Questions

The fact that the OWG possesses the characteristics of a professional learning community occurred mostly by design; teacher colleagues were expected to engage in reflective dialogue focused on pedagogical strategies and student learning. The shared norms they established around working on tasks, sharing and responding to each other's ideas, and sharing authority are relatively unsurprising in terms of professional development. However, the fact that these norms parallel the norms documented in IO classroom communities is notable. One norm not previously established in the literature that could be explored further was that of sharing conversational space, since participants regularly noted that they wanted to avoid dominating a discussion and prompting others to respond. In addition to further exploration of norms, this research could provide a basis for designing facilitator training in how to support and intentionally develop productive norms in PLCs.

Questions for the audience:

1. Are there other norms from professional development literature relevant to the OWG?
2. Other aspects of this community were not captured in these norms (e.g., comradery) – how can these aspects be documented and analyzed?

The Influence of an Experiential Learning Social Justice Class on Undergraduate Students' Beliefs About Mathematics and Mathematics Teaching

Linda C. Burks
Santa Clara University

Kathy Liu Sun
Santa Clara University

In this study, we explore the influence of an experiential learning social justice math class on undergraduate students' beliefs about mathematics and mathematics teaching. Twenty-three undergraduate students participated in this ten-week long class. Students reflected on their learning by responding to weekly journal prompts and designed a learning product for the high schools. Students' journal entries and project design will be analyzed to answer three research questions. How does the class influence students' beliefs about mathematics? How does the class influence students' perceptions about who does mathematics? How does the class influence students' understandings of how to teach math equitably? Preliminary results suggest the following: Students' views of mathematics expanded from a focus on application and problem solving to include intrinsic values of mathematics such as beauty and exploration. Students' perception of mathematicians became more inclusive. Students' understanding of equitable teaching varied.

Keywords: Experiential Learning, Social Justice, Reflection, Beliefs

Introduction

For over two decades, there has been a call for undergraduate mathematics to become a "gateway not a gatekeeper" (Douglas, 2017; Bryk & Treisman, 2010; Cooper, 1996). Mathematics educators have been identifying equitable teaching methods (Ching & Roberts, 2022; Martin, 2019; Hand, 2012) and focusing on the teaching of mathematics for social justice (Branson & George, 2022; Su, 2020; Gutiérrez, R. 2018; Leonard et al., 2010). As equitable teaching practices are gradually being established, promoted, and practiced in undergraduate mathematics (Leyva et al., 2022), there is an opportunity for mathematics departments to go deeper. In particular, the authors designed an experiential learning class to delve directly into issues of mathematics education and social justice.

In this study, we consider three research questions about the impact of this class on the undergraduate students who participated.

1. How does the experiential learning social justice class influence undergraduate students' beliefs about mathematics?
2. How does the experiential learning social justice class influence undergraduate students' perceptions about who does mathematics?
3. How does the experiential learning social justice class influence undergraduate students' understandings of how to teach math equitably?

Literature Review

In this review, we first present literature related to beliefs about mathematics, beliefs about who does mathematics, and equitable math teaching. These correspond to three themes common to research on equitable mathematics teaching: positioning of mathematical power, psychological approaches to teaching, as well as specific pedagogical approaches (Yolcu, 2019).

We then highlight literature related to the role of experiential learning courses in deepening undergraduates' understanding of social justice issues.

Beliefs about mathematics

Ernest (1989) and Muhtarom (2019) highlight three philosophies of mathematics which are prevalent in the teaching of mathematics: beliefs: instrumentalist, Platonist, and problem solving or constructivist. At the lowest level, instrumentalist belief is that mathematics is a "useful, but unrelated collection of facts, rules, and skills" (Ernest, 1989, p.8). The Platonist view is that mathematics is an unchanging product of interconnected structures and truth which is invented, but not created. The problem solving or constructivist view is that mathematics is a dynamic field open to revision and connected to other disciplines.

The shift of mathematics away from being a "gatekeeper" to a "gateway" into STEM fields represents a shift from a deficit orientation to asset orientation (DiGregorio & Hagman, 2021; McGee et al., 2021). This language shift also represents a change in thinking about mathematical power. Rather than demonstrating power in achievement to reduce the education gap, there is a movement to "rehumanize" mathematics in ways that empower all students to benefit from and contribute to mathematics (Gutiérrez, 2018; Ching & Roberts, 2022). A narrow view of mathematics limits the diversity of people who do mathematics. In *Mathematics for Human Flourishing*, Francis Su (2020) argues that mathematics meets the intrinsic human desire to build virtues: virtues such as exploration, play, truth, beauty, justice, struggle, and power.

Beliefs about who can do mathematics

Representation is important for students to identify as someone who can do mathematics (Oyserman & Lewis, 2017; Boaler & Greeno, 2000). Productive learning mindsets are also key to helping students identify as someone who can do math (Casad et al., 2018). Having a mindset of relevance is related to the idea that mathematics is relevant to the individual learning it (Romero, 2019). A mindset of belonging is about learning mathematics within a welcoming community (Romero, 2015). Growth mindset is the idea that intelligence can be developed through effort rather than being an innate ability; in a classroom this means mistakes are opportunities to grow and asking questions deepens understanding (Latterell & Wilson, 2022; Sun, 2018; Dweck, 2014; Boaler, 2013).

Equitable Math Teaching

Equitable math teaching is student centered. Equitable teaching methods includes active learning (Burke et al., 2020), flexible structures (Levya et al., 2022) and grading systems (Fernandez, 2021), and a focus on high expectations (Jamar & Pitts, 2005) cultural relevance (Bartell et al., 2017), and student engagement in which problem solving is key (Samson, 2015; Hake et al, 2003; Suh & Fulginiti, 2011). Along with teaching in ways that promote social justice, equitable practice also involves math that teaches social justice (Gutstein & Peterson, 2005). As we search for ways to teach math in ways that promote social justice, we consider five basic questions: *Who*, *What*, *Where*, *Why* and *How* we teach (Branson & George, 2022).

Experiential Learning and Social Justice

Experiential learning and reflection are critical components of deepening understanding of social justice. Experiential learning provides a tangible way for students to grapple with the abstract concepts of social justice (Pugh, 2014). Online service experiences have also been shown to contribute to students' understanding of social justice (Ahmad & Gul, 2021). Group discussions and individual reflections help students synthesize and analyze the issues within the context of their teaching experience (Jacob, 2006). It is also thought that reflection is a key piece of developing effective tutoring strategies (Johns & Burks, 2022).

Context

The authors designed an upper division undergraduate math class, *Mathematics Education and Social Justice* which examines issues of social justice surrounding mathematics education in U.S. public schools. Topics included problem solving, pedagogy, power, meaning, struggle, and freedom. Class time was split between student-led discussions of the readings and small group problem solving tasks. The immersive experience involved tutoring precalculus onsite at local high schools whose student body was an underrepresented population; due to the pandemic, seven of the twenty-three undergraduates tutored online through Zoom. The experiential learning social justice component cultivated social justice, civic life, civic perspective, and civic engagement. The tutoring component helped the undergraduate students grow in their ability to understand student thinking and developed ways to strengthen high school students' understanding of precalculus content. Three overarching themes were presented.

- What is math?
- Who does math?
- How can we teach math more equitably?

Mathematics Education and Social Justice was first taught in the ten-week long spring quarter of 2022 at a mid-sized private university on the west coast. The twenty-three students enrolled in the class included math, computer science, engineering, finance and economics majors. Weekly readings included chapters from Mathematics for Human Flourishing (Su, 2020) supplemented by readings about pedagogy and equity in mathematics. Students responded to weekly journal prompts to reflect on their tutoring experiences within the context of the readings and discussion. For their final project, the undergraduate students designed a learning product which could be used by teachers in the local high schools where they tutored.

Methods

We will use the constant comparative process to analyze the journal entries (Yin, 2009). First, the authors will identify incidents, or idea threads, which demonstrate any of the three main ideas: "What is math?", "Who does math?" and "How can we teach math more equitably?" To reach an agreement on the incident, we will identify incidents together for two randomly selected transcripts and then do so independently for the remaining entries. We will then meet to assess agreement on the incidents. Note that a single incident may contain two main ideas. For example, the idea thread from Student 4, Journal 1 in Table 1 addresses both the ideas: "What is math" and "Who does math." This thread illustrates the belief that math is useful for the student's major; it also indicates the belief that some people have a natural talent for math and that effort can help a student succeed in school mathematics.

Once the idea threads for the week one journal entries are identified, we will develop a code book using inductive and deductive processes. In the idea thread from Student 4, Journal 1, the a priori code applied to "What is math" will be instrumentalist, because this student sees math as being useful to their major. We will also develop emergent codes if the "What is math" idea threads when one of the three a priori codes do not apply. For example, the idea thread from Student 3, Journal 1 in Table 1 indicates that the student thought of math as memorization.

Table 1. Sample codes

Parent Code	Sub Code	Example
What is math	Instrumental	Once I got to high school, I started putting a little more effort into math, mostly because I knew my grades were going to matter for applying to colleges. The real switch, however, came about halfway through high school when I started looking at what major I wanted to pursue. From that point on, I realized the importance of math for my life and aspirations. (Student 4, Journal 1)
Who does math	Innate gift Effort for grades	
What is math	Memorization	I felt like multiplication tables were too hard. I had a difficult time focusing in order to memorize them and it took a lot of effort from my parents and myself in order to work through that difficulty. (Student 3, Journal 1)

We will follow a similar process to address the second research question. A priori codes will be based on the beliefs that mathematics intelligence is an innate gift or achieved through effort. In the incident above from Student 4, Journal 1, the a priori code applied will be an innate gift because they are "naturally good" at math. Emergent codes will be developed as different views of mathematicians arise in the idea threads. That same incident will have an emergent code describing "effort for grades" as that is different from effort for growing math intelligence.

We will follow a similar protocol for the third research question. A priori codes for teaching math will be developed around Su's (2020) ideas to teach math for human flourishing through exploration, problem solving, and play. After coding journal entries, we will develop a rubric to analyze the final project in terms of those same equitable math teaching practices.

Upon completion of the codebook, we will divide remaining journal entries between the authors to identify and re-code the idea threads. We will then engage in a two-step process to assess reliability. First 100% of each author's journals will be given to the other author to ensure all idea threads in the journals were captured and identified accurately. We will then calculate the percent agreement between the authors. The second process of reliability assessment will be seeking agreement on codes that were applied to each idea thread. Again, 100% of each coder's journals will be exchanged and the percent agreement calculated.

To address the first research question, we will examine general trends across the beliefs about mathematics. To address the second research question, we will examine patterns across beliefs about who does math. To address the third research question, we will connect student's understanding of equitable teaching with different student characteristics, such as college major.

Preliminary Results

While the full data analysis has yet to be completed, these are some preliminary findings related to each of the three research questions.

How does the experiential learning social justice (ELSJ) class influence undergraduate students' beliefs about mathematics? Rather than change students' beliefs about mathematics, the ELSJ learning experiences expanded students' beliefs about mathematics. At the beginning of the quarter, most of the undergraduate students described mathematics as memorized facts, procedures, or a tool; in contrast, the four mathematics majors tended to see math as problem solving and logical thinking. By the end of the quarter, most students moved from seeing mathematics as a set of rules to a set of ideas and a way of thinking. In addition to seeing math as a toolkit, students became aware of the intrinsic value of mathematics and see mathematics as a way of "understanding the world." Most students moved forward along the continuum from an instrumentalist to a problem-solving view of mathematics.

How does the experiential learning social justice class influence undergraduate students' perceptions about who does mathematics? Students' experiences throughout the quarter also expanded their perception about who does mathematics. Undergraduate students, who saw themselves as innately good at math, grew to recognize that through persistence and effort, anyone can develop math skills. Students saw that invisible labels through 'grouping' could encourage or discourage that persistence and effort. Students began to see that all students have the potential to be mathematicians. In their last journal entry, one business major enthusiastically noted that anyone could be a mathematician, "even me!"

How does the experiential learning social justice class influence undergraduate students' understandings of how to teach math equitably? Students' journal entries gave evidence to their thoughts about teaching math equitably, such as high expectation, relationships, motivation and engagement, and such; the final projects revealed the depth of their understanding. Some groups were able to identify ways to provide higher order thinking and problem solving; this aligned with equitable teaching. Some other groups focused more on basic concepts and rote learning, which tend to perpetuate inequities.

Implications and Future Research

The reflections in this course influenced students' thinking about what is math, who does math, and how to teach math equitably. In person tutoring gave undergraduate students a chance to get to know underrepresented high school students, to build a joint learning community with them, and to experiment with what types of teaching strategies helped the students learn.

These undergraduate students scratched the surface of learning what equitable math education looks like. We need to continue to study equitable teaching practices at all levels: elementary through graduate school. At the undergraduate level, we can cultivate an open mindset about mathematics, an awareness of the disparities that exist, and highlight equitable practices such as building learning communities among students from different backgrounds.

The mathematics learning center is a natural place to cultivate that awareness (Reinholz et al., 2020). Tutors have a unique opportunity to develop a relationship with their students, to understand their students' thinking, to encourage a growth mindset, to engage students and build on their individual mathematical strengths. Raising tutor awareness of social justice issues and having tutors try out different teaching methods is one way to build a diverse learning community. Creating a sense of belonging in the math learning center is a critical first step. From there we can explore other teaching methods to promote equitable math teaching and make a difference in the mathematical future of the students who come.

Questions for Audience

1. Two key components of the class are the immersion experience and the reflection piece. What questions do you have about either of these?
2. What questions do you have about the specific reflection prompts?
3. How do these preliminary results impact what you will do in your own classes?

A Literature Review Across Discipline-Based Education Research: What is a Theoretical Framework and How is it Used in Education Research?

Jon-Marc G. Rodriguez
University of Wisconsin - Milwaukee

Jocelyn Elizabeth Nardo
Stanford University

Extant literature has emphasized the importance of education research being theory-based. To this end, many studies have an explicit "theoretical framework" section that describes the theoretical assumptions that inform the research. Nevertheless, there is large variation in the extent to which studies incorporate theory in the research process. This work describes a literature review conducted across discipline-based education research, focusing on the role of theory in research. We focus on a snapshot of theory use by analyzing studies published in 2021 (n=589) across biology, chemistry, engineering, mathematics, and physics education research journals. Preliminary analysis focuses on trends related to the presence of a theoretical framework and reflecting on how the theory is used in the research process. Our goal is not to evaluate the quality of research, but rather describe how theory is used to inform future work and open a cross-disciplinary dialogue about theory.

Keywords: theory; cross-disciplinary; research questions; methodologies

Research on teaching and learning within science, technology, engineering, and mathematics (STEM) has increased considerably as a collection of fields called discipline-based education research (Henderson et al., 2017; Singer et al., 2012; Talanquer, 2014; Trujillo & Long, 2018). Discipline-based education research (DBER) fields each reflect an interdisciplinary agenda, drawing from educational psychology, learning sciences, and STEM disciplinary fields to seek evidence-based knowledge and practices that improve our understanding of teaching and learning (Henderson et al., 2017; Slater, 2011). To this end, DBER consistently draws research methodologies from educational psychology and the learning sciences, such as case study, phenomenology, grounded approach (Charmaz, 2006; Denzin & Lincoln, 2008), and quantitative analyses (Petscher et al., 2013). Nevertheless, each DBER field has their own discipline-based perspectives with shared goals, norms, behaviors, and identity. The shared goals, norms, behaviors, and identity of the DBER fields are what make them individual communities of practice (Lave & Wenger, 2004; Rynearson, 2015; Wenger, 1998).

CoPs have boundary objects, understood as artifacts, documents, terms, and concepts that serve as an interface between boundaries of domain knowledge (Lave & Wenger, 2004; Pawlowski & Raven, 2000; Star & Griesemer, 1989). CoPs can communicate with one another through brokering, which includes activities by individuals that facilitate transactions and flow of domain knowledge (Lave & Wenger, 2004; Pawlowski & Raven, 2000; Star & Griesemer, 1989). When brokers use boundary objects (i.e., boundary object brokering), different CoPs can achieve convergence by creating shared information systems among different CoPs (Pawlowski & Raven, 2000). As a CoP, the field of mathematics education has a shared mission of encouraging quality research in undergraduate mathematics and its application to teaching practice (*RUME Charter*, 2010). Practices that bound the community together include contributing and attending conferences, publications in journals (e.g., *Journal for Research in Mathematics Education* and *Educational Studies in Mathematics*), and creating evidence-based practices used for instruction in K-12, undergraduate, and graduate spaces (Yığ, 2022).

Researchers interested in finding unifying concepts across mathematics education have explored how different epistemological perspectives have shaped emergent research (Hannula et al., 2004; Lester, 2005). Here, epistemological perspectives are summarized as theoretical frameworks, which use models for learning to define the constructs under investigation (Hannula et al., 2004). Theoretical frameworks in practice shape how research is designed, collected, analyzed, and shared (Lester, 2005). For example, recent literature reviews in mathematics education reveal that theoretical frameworks that underpin emotion- and motivation-based constructs are foundational for learning, but are currently undertheorized (Schukajlow et al., 2017) and theories in general are heavily fragmented across mathematics education research (Bikner-Ahsbahs & Prediger, 2014). Future themes for mathematics education research call for an emphasis on understanding the role of theoretical frameworks that maintain the validity and replicability of the field (Bakker et al., 2021).

In other DBER fields, theoretical frameworks are also inconsistently used and are often undertheorized within studies (Bussey et al., 2020; Lohmann & Froyd, 2010; Reinholz & Andrews, 2019). Thinking about how theoretical frameworks are organized across DBER fields can act as a transformative force in STEM higher education (Reinholz & Andrews, 2019). Importantly, theoretical frameworks can be used to connect multiple domains of knowledge that enable needed connection amongst the currently siloed STEM higher education landscape (Reinholz & Andrews, 2019). As DBER researchers, our role is to connect CoPs by using theoretical frameworks to facilitate the flow of knowledge across STEM disciplinary domains. Thus, we endeavor to understand how theoretical frameworks are used across DBER fields to support researchers framing mathematics education research and STEM education research broadly. The following project is a literature review study that draws on n=589 research articles published in 2021 across DBER journals with the highest impact factors in math, physics, chemistry, engineering, and biology. The project seeks to open a dialogue across DBER fields, focusing on the general question: *How do DBER research articles use theoretical frameworks in their work?*

Methods

Data Collection and Analysis

For the purposes of our literature review, we defined theoretical frameworks epistemically as, "a system of ideas, aims, goals, theories and assumptions about knowledge; about how research should be carried out; and about how research should be reported that influences what kind of experiments can be varied out and the type of data that result from these experiments" (Bodner & Orgill, 2007). We strategically chose this definition because (1) it was meant to cover the breadth of DBER fields; (2) it allows for flexibility while maintaining shared understanding; and (3) it emphasizes the role in overall research design.

The initial challenge with this literature review was to narrow the scope sufficiently to make this project feasible. This work is part of a larger project intended to contextualize the use of theory within the broader DBER landscape. For the purposes of this conference report, we focus on a narrow timeframe to draw connections across discipline-based education research fields. In particular, we report on education research studies published in 2021, with an emphasis on discipline-specific research journals (biology, chemistry, engineering, mathematics, physics), as opposed to journals that focus broadly on STEM education research. In the case where there were multiple discipline-specific education research journals, the journals for our sample were selected based on journal impact factors, as well as input from the relevant community regarding journal quality (Williams & Leatham, 2017). It is important to note there are limitations in using journal impact factors to measure research quality (Cameron, 2005), but their prevalence in academia provides a useful metric for gauging the likelihood that a community would be familiar with the journal. Our sample focused on research studies, that is, papers that describe the collection and analysis of data, contextualized within prior research; this excluded non-research papers such as editorials and commentaries. The final sample was n=589 research studies, collected from two journals for each community (except for physics). The journals sampled are in summarized in Table 1.

Preliminary analysis involved characterizing whether each study in the final sample had an explicit framework section (*Framework* vs. *No Framework)*. Here, the unit of analysis was the publication itself. In most cases, this was located toward the beginning of the manuscript with a title heading involving some variation of phrases such as "theoretical framework", "theoretical perspectives", "theoretical framing", etc. Characterization first involved the two authors coding all the chemistry papers in-tandem, requiring 100% agreement (Campbell et al., 2013). An independent coding team of two researchers applied this analysis to the chemistry sample, resulting in 93% agreement and a Cohen's Kappa of 0.85. Following this, one researcher coded the biology and engineering papers, and the other researcher coded the mathematics and physics papers. Further analysis focused on analyzing the studies within the *Framework* category to note how the theoretical framework was used throughout the different sections of the paper (i.e., research question; methods; findings; conclusions and implications); at the time of submission, this process has been applied to the chemistry studies only, with the intention of scaling to the remaining sample, with particular attention given to chemistry, physics, and mathematics trends for the RUME community.

Preliminary Results

For this report, we focus on providing a general overview of how many studies across the sample had an explicit theoretical framework, followed by providing an example of how a framework was used across a single study. Summarized in Table 1, there was large variation in whether studies had an explicit theoretical framework section, even within a specific discipline (e.g., engineering – 57% of studies had a framework in *Journal of Engineering Education*, but only 12% of studies had a framework in *International Journal of Engineering Education*). Claims regarding the generalizability of these values are limited and it remains to be determined how these values relate to the consensus of specific communities and the journal context. Notably, the lack of journal guidelines related to the inclusion of a theoretical framework help explain the low values for *Biochemistry and Molecular Biology Education* (3%) and *International Journal of Engineering Education* (12%); however, *Physical Review Physics Education Research* (37%) and *Educational Studies in Mathematics* (63%) have higher values despite also not having journal guidelines related to the inclusion of a theoretical framework.

Table 1. How many discipline-based education research studies published in 2021 had an explicit theoretical framework section?

DBER Field	Journal	Impact Factor	Framework
Biology	*CBE-Life Sciences Education*	3.365	25%

N=128	**N=68**		
	*Biochemistry and Molecular Biology Education** **N=60**	1.160	3%
Chemistry **N=110**	*Journal of Chemical Education* **N=45**	1.385	62%
	Chemistry Education Research and Practice **N=65**	1.902	55%
Engineering **N=173**	*Journal of Engineering Education* **N=42**	1.569	57%
	*International Journal of Engineering Education** **N=131**	1.280	12%
Mathematics **N=76**	*Journal for Research in Mathematics Education* **N=17**	3.676	53%
	*Educational Studies in Mathematics** **N=59**	2.402	63%
Physics **N=102**	*Physical Review Physics Education Research** **N=102**	2.412	37%
*Indicates journal submission guidelines do not mention theoretical frameworks/theory.			

In addition to characterizing whether or not a study had a framework, we are interested in how studies use frameworks as part of the research process. Focusing on the chemistry papers, we noted that 83% of the studies integrated the theoretical constructs throughout the different sections of the manuscript, which is consistent with our framing of how theory should influence study design (Bodner & Orgill, 2007). To illustrate, we provide an example research study published in *Chemistry Education Research and Practice* (Parobek et al., 2021). The study focused on students' reasoning related to a representation used in chemistry, a reaction coordinate diagram. Part of the challenge with this representation is that it looks like a *graph* (y-axis is *potential energy* and x-axis is *reaction coordinate*), but it is only used as a quantitative graph (i.e., a function) in upper-level physical chemistry courses. In most cases a reaction coordinate diagram is used as a qualitative tool where the x-axis does not have a physical meaning; see Parobek et al. (2021) for an in-depth discussion of reaction coordinate diagrams.

Relevant to our literature review, Parobek et al. (2021) integrated multiple frameworks, discussed in the "theoretical considerations" section of the manuscript: resources framework (Hammer et al., 2005); actor-oriented model of transfer (Lobato, 2003); graphical forms (Rodriguez et al., 2019); value-thinking and location-thinking (David et al., 2019); these frameworks draw across learning sciences, chemical education, and math education. Moreover, the theoretical constructs were well-integrated throughout each section of the paper, illustrating the guiding nature of the frameworks. For example, the research question adopts the language of the frameworks: "What mathematical *resources* do students *transfer* to make inferences about the points and trends on a reaction coordinate diagram?" (p.699, emphasis added). As part of this, the authors make it clear that the specific mathematical resources of interest are *graphical forms* and *location/value-thinking,* which influenced prompt development and data analysis:

> "These diagrams [representations used in interview prompts] were constructed with an awareness of existing graphical reasoning frameworks that highlight the various ways that students may interpret points and regions along a graphical trend … Iterative cycles of inductive and deductive coding … Each graphical reasoning code … is first designated according to the graphical reasoning frameworks that served as a lens for crafting these categories in the unique context of RCDs." p.701-702

Lastly, in the Findings and the Conclusions/Implications sections the authors contextualized the data within the previously discussed theoretical frameworks and reflected on what the theory suggests regarding how instructors can support students. In addition to exemplifying theory use, we assert this paper is important because of how it illustrates the ways in which communities of practice are connected through the theoretical framework, not only because of cross-cutting concepts and skills (e.g., energy and graphical reasoning), but through the epistemological assumptions reflected in theoretical frameworks used by different fields.

Conclusion

We assert theoretical frameworks currently act as boundary objects within mathematics education research field as well as DBER fields broadly, which contribute to the existing fragmentation and under-theorization characterized by scholars (Bikner-Ahsbahs & Prediger, 2014; Schukajlow et al., 2017). DBER researchers can participate in boundary object brokering by acting as brokers to support the flow of interdisciplinary knowledge through their valid and reliable use of frameworks. We are currently analyzing the data to elicit themes related to the larger dataset, with the intention situating chemistry, physics, and mathematics within the broader DBER context because of their relevance to the RUME community. Our goal is to use these data and findings to initiate a broader conversation about theory and its use in education research. For example, it is worth considering whether *every* study needs a framework and what a framework might (or might not) contribute to a specific study. Moreover, we need to reflect on the nature of different theoretical frameworks; in particular, the analytic power of frameworks – it may be difficult to design a study and operationalize some frameworks. Lastly, it would be helpful to discuss the process of developing a theoretical framework, especially in relation to established approaches such as grounded theory (Charmaz, 2006).

A Precalculus Student's Use of Slope in Finding Linear Equations and Linear Approximations

Kyunghee Moon
University of West Georgia

This article reports mathematical understanding of one of the precalculus students who participated in a teaching experiment. The experiment was designed to help students strengthen the understanding of the concept of rate of change and linear equations to prepare them for the calculus concepts: tangent line equation and linear approximation. Before the experiment, the student understood slope mostly as an algebraic ratio and could not use the slope to determine the y-intercept of the line. With the intervention, she strengthened her knowledge of slope as both algebraic and geometric ratios and used her knowledge to construct linear equations. In addition, she was able to use slope to determine linear approximations of function values in various functions. The results suggest that when provided with appropriate tasks and prompts, precalculus students can be better prepared for their upcoming calculus concepts.

Keywords: Slope, Linear equation, Tangent line, Linear approximation

Do precalculus students adequately understand linear equations for their upcoming calculus courses? In my teaching experience, I found that most calculus students struggled to find the equations of tangent lines or linear approximations. I initially thought that their struggles stemmed from their insufficient skills or understandings related to derivatives. However, after realizing that many students with correct derivatives could not construct tangent line equations, I speculated that their struggles were also due to their lack of understanding of linear equations. So I conducted a survey with precalculus students on two conversion problems from graph to equation and confirmed that students indeed had difficulty constructing a line equation unless the *y*-intercept could be easily observed from graph. Thus, in order to help them develop understanding of slope and linear equations, I designed and researched a teaching experiment (Steffe & Thompson, 2000) with a research question: How do precalculus students understand linear equations and in what ways understanding linear equations helps them construct equations of tangent lines or approximate function values? In this report, I share my preliminary findings and seek for suggestions and inputs for the future direction of research.

Theoretical and Concept Background

Slope as Algebraic and Geometric Representations

Representations, especially algebraic and geometric, play a central role in mathematics curriculum and instruction. Yet many students do not understand mathematical concepts by connecting representations or have difficulty connecting representations in mathematical problem solving (Dufour-Janvier, 1987; Even, 1998). Among the concepts requiring the connections of representations, rate of change has attracted a lot of research (such as Carlson et al., 2002; Nagel et al., 2019; and Thompson & Carlson, 2017). I here describe the rate of change in linear equations—slope—, using the framework by Nagle, Martínez-Planell, and Moore-Russo (2019).

Nagel et al. (2019) categorizes the concept of slope within the APOS framework (Arnon et al., 2014). Slope as an algebraic ratio is the formula, $\frac{y_2-y_1}{x_2-x_1}$. At an action stage of slope as an algebraic ratio, an individual knows the formula as a memorized fact and can compute the value with the ordered pairs provided. At the transition level (from action to process) of slope as an algebraic ratio, she understands that slope is independent of any two points and may also imagine obtaining the equation y-y_1 = m(x-x_1) or $y = mx+b$ without explicitly doing it. Yet she may understand slope only in algebraic aspect and has no geometric referents to justify the formula, $\frac{y_2-y_1}{x_2-x_1}$.

In comparison, slope as a geometric ratio is the rise over the run in a geometric figure. At an action stage of slope as a geometric ratio, an individual may see slope as a static image and do a simple counting to find slope. At this stage, she has no understanding that the numerator changes as the denominator changes; as such, she may struggle with the sign of slope. At the transition level (from action to process) of slope as a geometric ratio, the individual knows that slope is independent of the size of the triangle being used. As such, she may use slope to determine relationships of properties or to describe the behaviors of a line, such as increasing or decreasing.

When an individual reaches the transition level of slope as both algebraic and geometric ratio as well as understands slope as a parameter in $y = mx+b$ by freely moving between algebraic and geometric ratios, she reaches a process stage of understanding of slope. With a process conception, she could imagine conversions of slope among arithmetic, algebraic, and geometric representations, without explicitly doing the conversions (Nagle et al., 2019).

Tangent Line and Linear Approximation

When a function f is differentiable at a point, $x = x_1$, one can determine its tangent line to the curve with the formula, $y - f(x_1) = f'(x_1)(x - x_1)$. Unfortunately, neither the derivative nor the tangent line equation itself involved in the formula is easy for students. Many students do not conceptually understand that $f'(x)$ is the limit of the average rate of change (Asiala et al., 1997; Orton, 1983; Thompson, 1994). Neither do they understand the structure or meaning of the tangent line, making errors such as claiming the slope of the tangent line as $f(x_1)$ (Orton, 1983) or the tangent line as the derivative of $y = f(x)$ (Amit & Vinner, 1990). Further, many individuals may not be much familiar with point slope form in which the formula is presented. According to Nagel and Moore-Russo (2013), preservice secondary teachers rarely hold the point slope form in their concept map of slope. While 11 of 19 teachers included the slope intercept form, only 3 included the point slope form in their concept map.

There are two common ways to find a linear approximation. The first is to find the tangent line equation using the formula $y - f(x_1) = f'(x_1)(x - x_1)$ and to determine $y = f(x_2)$ by substituting $x = x_2$ into the equation. The second is to find the slope of the tangent line at $x = x_1$, $f'(x_1)$, find dy as $f'(x_1)dx$, and add dy to $f(x_1)$, yielding $f(x_1) + dy$ (see Figure 1). The cognitive processes involved in the two ways are quite different, although they may be intrinsically the same—as $y - f(x_1) = f'(x_1)(x - x_1)$ can be converted to $y = f(x_1)+f'(x_1)(x - x_1) = f(x_1) + dy$.

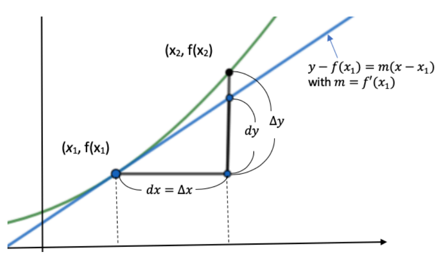

Figure 1. Linear approximation.

Methodology

The participants of this study were three precalculus students at a small state university in the southeast region of the US. I asked precalculus instructors to recommend their students who are active in classroom. I sent an invitation email to all 15 students recommended by their instructors. Three students responded to my email and participated in this study. Student 1 was a local high school student and had an Algebra 2 course at her high school prior to precalculus. Student 2 was a sophomore in biology and had a college algebra course at our university prior to precalculus. Student 3 was a freshman in computer science and had an advanced mathematics course at a high school in southeast Asia where English was the primary language of instruction.

Each of the three students were interviewed for a total of 5-7 sessions, with each session lasting about one and a half hours. The interviews were conducted in two stages. At the first stage—for the first one or two sessions—I used a form of semi-structured clinical interview (Ginsburg, 1997) to assess their level of understanding. The interview questions were designed to investigate their understanding of various forms of linear functions and quadratic functions as well as their ability to use rate of change in constructing function equations.

At the second stage—for the remaining sessions—I used a form of teaching experiment (Steffe & Thompson, 2000) to intervene their understanding, in particular, to strengthen their understanding of rate of change as well as to have them use slope in constructing equations and finding linear approximations. I began interviews with pre-designed tasks. As the interviews progressed, the tasks were modified and more tasks were created based on their responses.

The analysis of data began at the onset of the interviews. After each interview, I viewed the video recordings and prepared a time-coded written record of the content, including rough transcriptions of interesting episodes. At the same time, I developed codes based on the research questions, the framework of the study, and students' understandings observed in the data. During this initial stage of analysis, I came up with hypotheses on students' understanding and difficulties described in this report. In the next stage, I plan to review data by constantly comparing and revising codes in the spirit of constant comparative method by Glaser and Strauss (1967), which will help me confirm, rebut, or revise the hypotheses I made at the first stage of analysis.

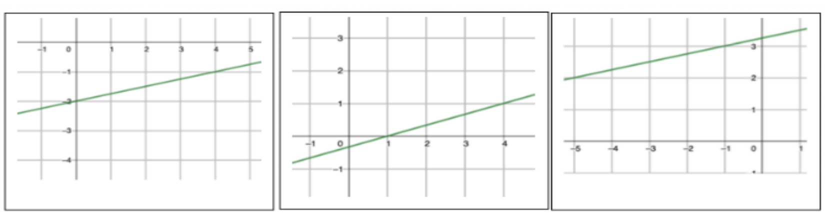

Figure 2. Linear equation task in pre-intervention.

Preliminary Findings

The results presented here are for Student 1 mostly from the interview and written data on the problems in Figures 2 and 3. The first graph of Figure 2 shows an integer valued y-intercept, but the second and third graphs do not. Figure 3 is three linear approximation problems designed at the level of precalculus or algebra. The problem 2 was provided with graphs of the function and the tangent line. Problems 3 and 4 were not provided with any graphs. Before given these problems, students were explained that a tangent line is almost identical to a curve at a given point and that the tangent line can be used to approximate function values.

Line Equations

Slope as an algebraic ratio and the Cartesian Connection. When constructing an equation for line graphs in Figure 2 during the assessment (at the first stage of the interviews), Student 1 chose two lattice points through which the line passes and found the slope of each line by calculating $\frac{y_2-y_1}{x_2-x_1}$ (action as an algebraic ratio). For the first graph, she read the *y*-intercept (0, -2) from the graph and successfully used the slope intercept form to determine the equation, $y = \frac{1}{4}x - 2$. For the second and third graphs, she wrote $y = \frac{1}{3}x + b$ and $y = \frac{1}{4}x + b$, respectively, but incorrectly determined the value of *b* as -0.3 and 3.3, respectively. When asked how she determined *b*, she said she guessed the values based on the locations of the *y*-intercepts.

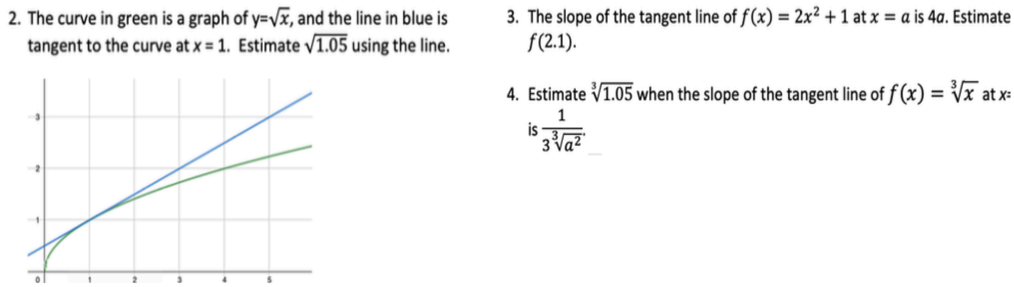

Figure 3. An example of linearization problem in teaching experiment.

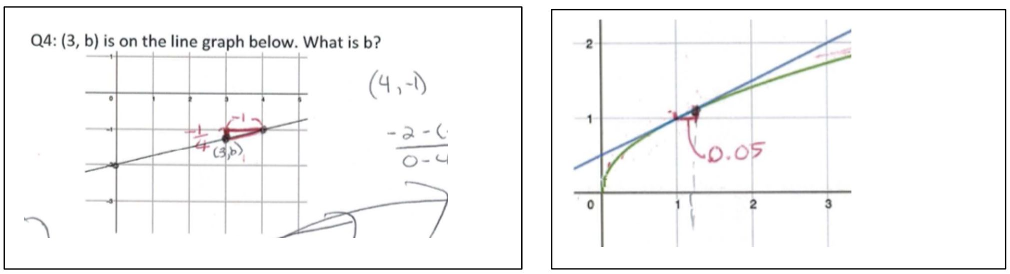
During the intervention, I asked her if the *y* = 3*x*+1 graph passes through the point (2, 7). She answered yes because 3(2) + 1 = 7, showing her understanding of the Cartesian Connection—"a point is on the graph of the line L if and only if its coordinates satisfy the equation of L" (Moschkovich et al., 2013, p. 73). I also asked her what the value of *h* was when the point (4, 1) was on the $y = \frac{1}{3}x + h$ graph. She wrote $1 = \frac{1}{3}(4) + h$ and successfully solved for h, confirming her understanding of the Cartesian Connection in the problem context. I then asked her to determine *b* in the third graph of Figure 2, which she struggled prior to the intervention. She wrote $2 = \frac{1}{4}(-5) + b$ by using the point (-5, 2) from the line graph and claimed that *b* = 13/4. This suggests that students may have difficulty activating their understanding of the Cartesian Connection when the whole graph is presented without a reference of a specific point.

Transition level as algebraic and geometric ratios. When asked to find the value of *b,* with (3, *b*) on the graph in Figure 4a, she picked two points, (4, -1) and (0, -2), found the algebraic ratio, $\frac{-2-(-1)}{0-4}$, and simplified it to ¼ (action as an algebraic ratio). She then wrote $\frac{b-(-1)}{3-4} = 1/4$ and solved for *b*, showing the understanding that slope between any two points on the line is constant (the transition level of slope as an algebraic ratio). When asked what the change in *y* is if 1 is the change in *x*, she said ¼ without any hesitancy or work, confirming her understanding of slope as an algebraic ratio in the transition level. When I asked her to use the idea on the graph to determine the value *b*, she drew a triangle using points, (4, -1) and (3, b), wrote -1 and -1/4 for the horizontal and vertical segments (Figure 4a), and found *b* as -5/4 after subtracting 1/4 from -1, showing a transition level of slope as a geometric ratio. I then asked her to use her geometric strategy to find the equations of the second and third graphs in Figure 2. She successfully found equations for both. For the third graph, for example, she came up with $y = \frac{1}{4}x + \frac{13}{4}$ by writing *b* as 3+1/4 with no drawing, by increasing Δy of ¼ to the y-coordinate of (-1, 3), hinting her understanding of slope as a process.

Linear Approximation

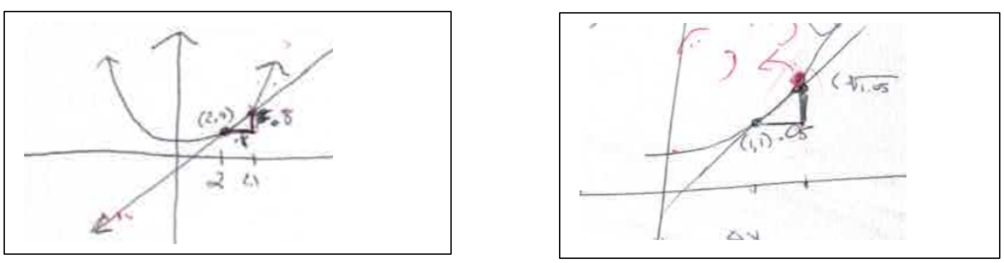
When asked to estimate $\sqrt{1.05}$ using the given tangent line (problem 2, Figure 3), she first determined the slope of 1/2 from the line graph and then the value of *b* based on the point (1, 1), by thinking $\Delta y = -\frac{1}{2}$ when $\Delta x = -1$, without drawing (the transition level of slope as an algebraic ratio). She then substituted x =1.05 into the tangent line equation, $y = \frac{1}{2}x - \frac{1}{2}$, and found the value of y for the approximation of $\sqrt{1.05}$ (the Cartesian Connections). When asked if there was any other way to find the estimate, she drew a triangle (see Figure 4b), found $\Delta y =$ .025 by setting up ½ = $\frac{\Delta y}{0.05}$, and added 0.025 to 1, showing the transition level of slope as a geometric ratio and possibly a process stage of slope.



(a) (b)

Figure 4. Slope in linear equation and its use in approximation.

For both problems 3 and 4 (in Figure 3), she first attempted to represent the functions in graphs. For $y = 2x^2+1$, she correctly drew a graph and its tangent line (Figure 5a) and found an estimate of $f(2.1)$ by performing a similar work to her work in the problem 2 in Figure 3. For problem 4, however, she asked for my help for the $y = \sqrt[3]{x}$ graph as she did not remember the graph. When asked if the shape of a curve mattered in the previous approximation problems, she said no and randomly drew a smooth curve along with its tangent line at $x = 1$ (Figure 5b). She then successfully estimated $\sqrt[3]{1.05}$ by doing a similar work to the previous problems.



(a) Estimate of $2(2.01)^2+1$ (b) Estimate of $\sqrt[3]{1.05}$

Figure 5. Use of slope in approximation.

Discussion and Future Research

As for the other two students, Student 2 showed at most an action conception of slope as both algebraic and geometric ratios throughout the intervention. Student 3 initially showed the transition level as an algebraic ratio, with little conception of slope as a geometric ratio. With the intervention, he developed a transition level as a geometric ratio. The results suggest that tasks such as those used in this study can strengthen student understanding of slope and linear equations that is necessary for the concepts of the tangent line and linear approximation. However, for students who profoundly lack the understanding of slope and linear equations, such as Student 2 who remained at the action stage despite intervention, more research is needed to investigate their underlying problems.

Learning Assistants: The Assets of Relationships in Mathematics Classrooms

Brinley Poulsen Stringer
San Diego State University

Near-peer mentor models to support students in mathematics are becoming increasingly used at institutions across the United States. One model, the Learning Assistant model, has been implemented at Crossroads State University. Using Yosso's Community Cultural Wealth framework, this paper discusses the qualitative impact this model has on students, learning assistants, and the instructor of a College Algebra class. Based on findings, additional qualitative research is suggested to further investigate the Learning Assistant model.

Keywords: Learning Assistants, Near-Peer Mentors, Departmental Change

The use of near-peer mentors has become more common among universities and colleges in the US in the past 15 years (Otero et al., 2010b; Sellami et al., 2017). Many different efforts are being used across the nation to combat STEM attrition at the college level, such as co-requisite models, active learning initiatives, and curricular reform (Battersby et al., 2015; Dawson et al., 2015; Estrada et al., 2016; Theobald et al., 2020). Near-peer mentors have been used as a way to help implement active learning and curricular reform, while also seeming to offer some unique benefits both socially and academically to support students. Near-peer mentors thus serve as a topic of interest when considering systemic change within mathematics departments (Barrasso & Spilios, 2021; Sellami et al., 2017). While near-peer is not a well-defined term, and different schools use various models to implement the use of near-peer mentors, typically these near-peer mentors are fellow undergraduate students who have demonstrated the skills to function as mentors in certain classes to support other undergraduate students.

Crossroad State University, a four-year Hispanic serving institution (HSI) in the southwestern United States, utilizes a variation of one such model, called the Learning Assistant (LA) model, to support students in introductory mathematics courses. In this model started by CU Boulder, students who have successfully passed a course can apply for a learning assistant position for that course to serve as an additional resource to students in the classroom (Otero et al., 2010a; Otero et al., 2010b; Top et al., 2018). These LAs receive pedagogical training and then work with instructors in classrooms to help facilitate discussions and promote student learning.

A body of research shows several improvements to student performance related to the implementation of the LA model. Studies have found that the LA model has helped increase the implementation of cognitively demanding tasks in the classroom, as well as improved student performance on higher order cognitive skills assessments (Sellami et al., 2017; Webb et al., 2014). Other studies have demonstrated increases in active learning and improved collaboration in the classroom, as well as improved student satisfaction in these STEM courses (Campbell et al., 2019; Sellami et al., 2017). Additionally, studies have found that the implementation of the LA model has helped to reduce DFW rates (i.e., the percentage of students who withdraw, or receive a D or F grade in the course) and close performance gaps for under-represented minority (URM) students (Alzen et al., 2018; Sellami et al., 2017). While many benefits have been measured quantitatively with the LA model, there is sparse literature to qualitatively describe the phenomena that are occurring from implementing this model.

Qualitative research is of interest to better understand *how* the LA model is making a difference. For instance, while it is valuable to know that studies have found LAs useful in supporting URM students, further study to know *why* this is the case can serve to further improve the model and support students. Where Crossroads State University's student population is composed of over ⅓ URM students, studying the qualitative impact of the LA model in Crossroad State's Mathematics and Statistics department is especially relevant. With this in mind, in this pilot study I set out to address this question: *What are the perceived assets of LAs as described by the students and instructor who work with learning assistants, and the LAs themselves?*

Analytical Framework

Yosso (2005) outlines the framework of *community cultural wealth*, which takes a more holistic look at the assets, or capital, that an individual brings with them into a given situation, assets which are often overlooked by societal norms. She articulates why these assets are overlooked through the lens of Critical Race Theory (CRT), explaining that Whiteness prescribes the norms of cultural capital, thus overlooking other types of capital that individuals, and especially those who are minoritized, carry. Yosso (2005) outlines six dimensions of community cultural wealth, or six types of capital, that minoritized individuals especially use to "to survive and resist macro and micro-forms of oppression" (p. 77). These six dimensions are 1) aspirational capital— the ability to maintain hopes and dreams despite facing real barriers, 2) linguistic capital—the communication skills gained through various uses of language and style, 3) familial capital— cultural knowledge nurtured from *familia*, 4) social capital— networks of people and community resources, 5) navigational capital— the knowledge and skills to maneuver various institutions, and 6) resistant capital— the skills fostered through opposition which help challenge the status quo. Where mathematics has long been a space of oppression (Kozol, 2005; Martin et al., 2010), Yosso's (2005) community cultural wealth framework serves as an appropriate lens to view some of the ways that students bring various assets with them into mathematics classrooms to help themselves and others persist through the gate-kept field. Especially from a qualitative research standpoint, this framework as the potential to bring to light data which would likely be overlooked in quantitative studies, providing rich insight into the LA model that so far has not really been explored.

Methods

Over the course of a semester, I conducted four class observations in two sections of a College Algebra course. All names used are pseudonyms. Elena, a Hispanic female senior studying mathematics, was the undergraduate learning assistant in one section, and Jesse, a white male junior studying engineering, was the undergraduate learning assistant in the other section. Both sections were taught by a graduate student with prior college mathematics teaching experience named Megan, a white female studying mathematics. Based on observations, both class sections were racially diverse, with a seemingly even distribution of male-presenting and female-presenting students.

At the end of the semester, I conducted a semi-structured focus group interview with three students (1 White female presenting student, 1 Asian male presenting student, and 1 Hispanic male presenting student) from the College Algebra sections I had observed. Additionally, I conducted a semi-structured interview with Elena (LA), Jesse (LA), and Megan (instructor). I had three different protocols—for students, LAs, and the instructor—each of which asked questions which allowed participants to elaborate their experiences working with (or being) an LA during the semester. The observations I had conducted earlier allowed me to ask more personalized follow up questions during each interview based on interactions between students, LAs, and the instructor I had seen during the semester. From these interviews, I generated memos of the salient ideas shared in response to each question, and then used a priori coding of Yosso's (2005) community cultural wealth framework to analyze the memos.

Findings

I will now discuss the findings across each of the six dimensions of cultural capital wealth, articulating how the experiences of working with (or being) LAs were perceived by students, LAs, and the instructor.

Aspirational Capital

Aspirational capital was described both by LAs and the instructor in the form of supporting the students and LAs, respectively, in their own trajectories as students. Jesse shared, "I might not do the most, but I want to show students that I want them to succeed," recognizing that while he might not be able to provide every support to help students, he wanted students to know that he was indeed there to support them and help see them through to succeed in the class. Elena described her love of helping students have "aha" moments in class, articulating her belief in their capabilities to succeed through the class.

Megan talked about enjoying the opportunity of working with LAs because she recognized it as a resource to help support these LAs in their own student careers. She expressed enjoying being able to help them grow and succeed by providing this mentoring opportunity to students. For both the LAs and the instructor, their recognition and belief in the students for whom they were supporting was a form of aspirational capital that benefited the class.

Linguistic Capital

There was one instance discussed of linguistic capital by students. They shared how LAs in the class could explain mathematical ideas in different language from the instructor, which was something they benefited from. Where mathematics is often described as a language, having various ways to discuss mathematical concepts is indeed a nod to linguistic capital. LAs are able to bring different perspectives into the classroom and articulate them in ways that students relate to, allowing for more opportunities for mathematical understanding.

Familial Capital

Familial capital was not discussed during the interviews, because the focus of the interviews was about an academic setting. Thus, questions did not focus on outside community where familial capital might have been mentioned.

Social Capital

Social capital was perhaps the most mentioned form of community cultural wealth during interviews, being discussed by students, LAs and the instructor. Students discussed how LAs would make small talk with them at the beginning of class, getting to know them on a more social level. Students expressed that this helped them to feel more comfortable with the LAs, giving them the courage to also approach them about mathematics questions during class. LAs also were aware of this phenomenon, and noticed students being more comfortable to approach them over the course of the semester.

LAs discussed specific examples of noticing how students at times seemed apprehensive to ask questions to the instructor, but were willing to call the LA over to ask questions they had about the math. As Jesse put it, he was aware that LAs "have a better influence on you as a student." Another form of social capital that LAs discussed had to do with the network that was formed with other LAs. Elena and Jesse both described the support they received from their LA peers in their LA roles, as well as the social support as students in general navigating their own courses.

The instructor was also aware of the connection that LAs had with students, being an easier authority for students to approach during class. Megan articulated this social capital by saying, "it's valuable to have a second person [in the class] that is potentially in a little bit more of a mediation kind of middle zone," describing the power dynamics that students might feel when approaching the instructor compared to a fellow undergraduate student. Megan also talked about the LAs being a great support to her, and someone to bounce ideas off. LAs were also a support and a network to the instructor, providing valuable insight about students and ideas for how to navigate class.

Navigational Capital

Both the instructor and the LAs discussed the ways that LAs supported both students and themselves in navigating the role of being a university student. The instructor discussed that because she had not experienced being a student at the university, she did not have the insight to provide her students related to questions regarding things like where to take an exam, where to get accommodations, or where to go for study help. Megan discussed the LAs as a major strength to the class because they were a few years ahead in their studies and were familiar with the various university systems that younger students often had questions in navigating.

The LAs also discussed on an emotional level understanding what it was like being a student at the university and being able to relate to students in this way while also giving them advice for how to navigate the systems of the university. LAs also discussed how being in LA positions had helped them to develop better skills to succeed in their own careers as students. Elena discussed improved time management skills from balancing being an LA and a student, and Jesse discussed developing more efficient study skills through helping model them to students he supported as an LA. Additionally, Elena discussed how taking this job had connected her to network of new faculty that were opening doors for her future career. Across these comments, it is very clear that these LAs both provided and developed navigational capital.

Resistant Capital

One student and both LAs discussed forms of resistant capital that LA positions brought to the classroom, and to the lives of the LAs, respectively. One student shared that this was his second time taking College Algebra because he had failed the previous semester and struggled a lot with the material. He happened to have Jesse as an LA both semesters. The student discussed that he felt that Jesse was aware his unique circumstance and would regularly check in on him. He described feeling grateful that Jesse wanted to help him persist and succeed this time around, despite his struggles. These small efforts on Jesse's part made a big impact on the student.

The LAs also talked about developing resistant capital in taking up these roles. Jesse talked about having imposters syndrome when first starting as an LA, but that this job had helped him learn how to make mistakes and learn from them—something he was not used to from his engineering courses working with other upperclass students. Elena said that she has "worked smarter" as a student from the skills she has gained being an LA. Both LAs discussed how taking up these positions had helped them to develop more confidence in themselves as students, and that they saw skills learned as an LA showing up in their own studies as students, helping them to persist through higher level STEM courses.

Discussion

These findings demonstrate a variety of assets that the LA model has afforded multiple groups of people associated with mathematics classes at Crossroads State University. When asked whether they would prefer to take a future math class with or without LAs, one student said, “I would obviously take the one with the [LA]”, and the other students shared similar sentiments. Megan said that given the choice, she would also choose to teach in the future with LAs rather than without them. Elena and Jesse both expressed how being an LA has afforded them both with meaningful personal growth and skills that continue to benefit them in their journeys as students. The LA model, from these interviews, seems to have a qualitatively positive impact on students, learning assistants, and instructors involved with the program.

Many of the assets described seem to relate to the *relationships* that are formed among LAs, students, and instructors. Where traditionally introductory mathematics courses are often taught as a lecture-style course (Webb et al., 2014) where an instructor relays information for students to passively absorb, with less opportunities to form relationships during class time, the LA model adds a more human element to the mathematics. While several studies have demonstrated improved quantitative gains, these findings perhaps point towards a major reason for these benefits—the opportunity for more personal relationships to be formed allows for additional capital to be utilized while teaching and learning mathematics. These findings matter because these are not the data that would necessarily be tracked to understand the value of implementing roles like learning assistants within a department. Yosso’s (2005) framework reveals several important assets that these LAs bring to the department that would not typically be measured.

Conclusion

This study demonstrates assets that LA roles can bring to a mathematics department, namely social and navigational capital among others. Further research should study the implementation of learning assistants within the department (i.e., professional learning and training models), and to investigate how this system can be improved. Additionally, it would be of value to understand the impact of learning assistants on STEM persistence by doing some type of ethnographic study over time by following students who have engaged with learning assistants during their careers, as well as following students who have taken up the role of LAs to see their trajectories. These are a few of many potential angles of qualitative work to better understand the benefits of near-peer learning models on the teaching and learning of mathematics.

Levels of Reflection in Strength-Based and Weakness-Based STEM Faculty Peer-Observation

The Teaching TRIOS project aims to promote strength-based faculty peer-observation of teaching for professional development. In this project, we present preliminary work from a comparative case study of two teaching TRIOS groups, one largely strength-based and the other primarily weakness-based. We seek to understand the levels of reflection facilitated by a strength-based and weakness-based approach to observation through the lens of the Onion Model for levels of change (Korthagen, 2004). Preliminary results indicate that a strength-based approach may promote more frequent reflection upon deeper aspects of oneself, such as beliefs, identity, and mission.

Keywords: Faculty Development, Peer Observation, Teaching TRIOS, Core Reflection

Many of our RUME colleagues are working to understand how to impact university instruction, at the level of the faculty (e.g., Yoshinobu et al., 2022), graduate teaching assistant (e.g., Ellis et al., 2019; Reinholz, 2017; Rogers et al., 2020), or through broad departmental change (Reinholz et al., 2020; Smith et al., 2021). In our work, we contribute to and extend this literature by providing an in-depth look into the discourse between university faculty when they are reflecting together upon one another's instruction, attending to the tone and content of their reflections. This research is in direct response to Esterhazy et al. (2021), who provided a call to action encouraging researchers to not only explore what works in collegial-level faculty development (CFD) but also how it works. In particular, they mentioned that the field is in need of greater understanding of "the actual interactions and the content of feedback provided during concrete [collegial faculty development] situations" (p. 255). Within this preliminary report, we explore the content of feedback provided during Teaching TRIOS debrief sessions, a Time-Sensitive (T), Reciprocal (R), Inclusive (I), Operative (O), and Strength-Based (S) instantiation of CFD that utilizes peer observation and has been used within the mathematics department, and more broadly across various STEM departments, at Middle TN State University (Bleiler-Baxter et al., 2021).

Within TRIOS teams, groups of three interdepartmental faculty observe one another's instruction and then meet to debrief. The goal is to unpack the strengths of the instructor observed during that class session. Unlike many traditional forms of peer evaluation, where the *observers* are positioned as coaches, the TRIOS model is intended to position the *instructor* as the coach and as an expert in their classroom setting. What we have noticed, though, is that some teams are more effective than others at debriefing in a truly strength-based way (i.e., attending to and unpacking the strengths of the instructor rather than identifying weaknesses or offering areas for improvement). In this research, we explore two such TRIOS teams, one team of mathematicians that tended toward weakness-based reflection, and one team of biologists that tended toward strength-based reflection. We ask the following research questions:

1. In what ways and upon what content do undergraduate-level faculty reflect within TRIOS debrief sessions that utilize a strength-based approach?
2. In what ways and upon what content do undergraduate-level faculty reflect within TRIOS debrief sessions that utilize a weakness-based approach?

Theoretical and Analytical Framing

Providing negative, yet honest, feedback on a teaching session can lead to uncomfortable moments and cause considerable anxiety (Esterhazy et al., 2021). Through this study, we offer a converse hypothesis rooted in *positive psychology* (Seligman & Csikszentmihalyi, 2000): focusing faculty feedback on the strengths of the instructor can facilitate a deeper, more vulnerable and positive level of reflection and promote professional development.

The Onion Model for levels of change (Figure 1; Korthagen, 2004) describes six levels at which teachers may be influenced to change their classroom practices, and therefore provides us with a lens to qualitatively view instructor reflection. Within this model, reflection can range from the outer, external layers such as *environment*, *behavior*, and *competencies* to the deeper, core layers of *beliefs, identity,* and *mission.* Reflection centered on the core levels can create room for deeper introspection and learning (Korthagen & Vasalos, 2005).

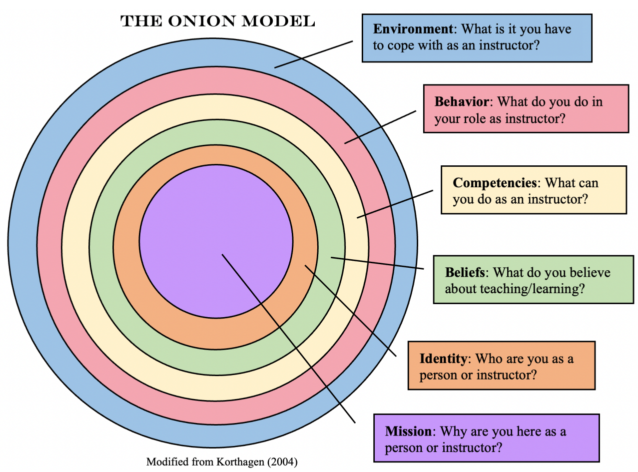

Figure 1. The Onion Model for levels of change, modified from Korthagen (2004).

Methods

Context and Data Collection

The study presented here is part of a state-level grant, awarded during the 2020-2021 academic year. The overarching objectives for the grant were to (1) support faculty in becoming more aware of and responsive to varied backgrounds, learning styles, and cultures of learners in STEM courses, (2) promote reflection among STEM faculty with respect to inclusive pedagogy, and (3) spark cultural change within STEM departments with respect to a focus on inclusion. We began the professional development (PD) program in Fall 2020 with nine faculty participants, three from Biology, three from Chemistry, and three from Mathematics. One of the faculty participants from the mathematics department was unable to participate in the program after the Fall semester due to a significantly increased teaching workload during Spring 2021, so the mathematics trio became a duo during the Spring 2021 semester.

One of the main levers of change in this program, especially with respect to goal 2, was a peer observation of classroom instruction initiative called Teaching TRIOS. In this manuscript we explore the Teaching TRIOS debrief sessions for the biology team (Betty, Bridget, and Brian) and the mathematics team (Margaret and Moby), which occurred during Spring 2021. We selected these two teams to highlight as cases in this manuscript because they illustrate clearly a strength-based approach (biology team) and a weakness-based approach (mathematics team) to debrief discussions, and hence provide us with insight into our research questions.

As this project was conducted during the COVID-19 pandemic, all TRIOS debrief sessions were conducted and recorded via Zoom. We did not collect recordings of the participants' class sessions, which were the topic of observation and discussion during the TRIOS debriefs. The six TRIOS debrief transcripts (three from biology, B1, B2, and B3, and three from mathematics, M1, M2, and M3) were edited, cleaned, and separated into talk turns. We define a talk turn to be the duration of one participant speaking until another participant speaks a complete word (i.e., interjections such as “hmm” did not separate a talk turn, but “yes” or “no” did). Transcript files were uploaded into Google Sheets to organize, classify, and analyze data.

Data Analysis

Our data analysis employed two layers of qualitative coding by talk turn. First, we coded each transcript to determine a quantitative description of the use of strength- or weakness-based approaches by each TRIOS team. Then, to compare the levels of reflection present within each TRIOS team, we coded the transcripts through the lens of the Onion model (Korthagen, 2004).

Strength-based and weakness-based reflections. Two members of the research team independently identified segments from the transcripts that demonstrated a strength or a weakness-based approach. After independently coding one transcript from each the biology and mathematics TRIOS teams, these researchers met to discuss their understanding of a strength-based and weakness-based reflection and developed the following definitions.

In a ***strength-based reflection****, an asset perspective on instruction is offered, often paired with a genuine interest in learning about instruction. These reflections are typically educative in nature.* For example, Brian (B2) commented on Betty’s risk-taking in the classroom,

> I applaud you for it, because what you did, I think, for some people would be considered risky. Where, it's like, it's easier just “tell them what they need to know, give them multiple choice exam don't take risks”, and it's like, but that is not the world of how we need to develop people, and so I really applaud you for what you're doing. Yeah, I mean, my notes are so much for myself of, like, “how can I adapt these?” Because this pushes me to go in ways I hadn't thought about so I'm, I really… overall just really well done.

In a ***weakness-based reflection***, *a deficit perspective on instruction is offered, often paired with interest in offering an alternative approach to instruction. These reflections are typically evaluative in nature.* For example, Moby (M1) commented on Margaret’s teaching, “Right there would have been another spot. Because you corrected [student] when maybe the class should have corrected [student].”

The same two researchers coded each transcript independently for strength- and weakness-based reflection and then met to discuss disagreements and reach consensus. Any talk turns where consensus could not be reached were reviewed by five team members and discussed to reach agreement. Each transcript finally received a sum total for the number of strength- and weakness-based reflections present in the transcript. In order to compare the transcripts, we then scaled the number of strength- and weakness-based codes each to the total number of strength- or weakness-based codes.

Levels of reflection: the Onion Model. We used the levels identified in the Onion model (Korthagen, 2004) to categorize faculty talk-turns as reflection upon environment, behavior, competencies, beliefs, identity, and/or mission. The entire research team coded two transcripts to refine our code descriptions for each of the six levels. The revised codebook was used by two researchers to evaluate the transcripts independently. Following the independent coding of each transcript, these two team members met to determine consensus. Any talk turns where consensus could not be reached were reviewed with five team members and discussed to reach agreement. Each transcript received a sum total for the number of codes from each category present. In order to compare the transcripts, we then scaled the number of codes per category to the total number of Onion Model codes.

Preliminary Results

Strength- and Weakness-Based Reflections

As stated above, we calculated the proportion of codes within a single transcript that demonstrated either a strength- or weakness-based reflection during the TRIOS debriefs for the biology trio and mathematics duo (Figure 2). Confirming our original impression, the biology trio largely embraced the strength-based reflection approach to the TRIOS debrief sessions, and although the mathematics duo illustrated more weakness-based reflections than strength-based reflections in their first two debriefs, their third debrief demonstrated growth in the use of a strength-based perspective.

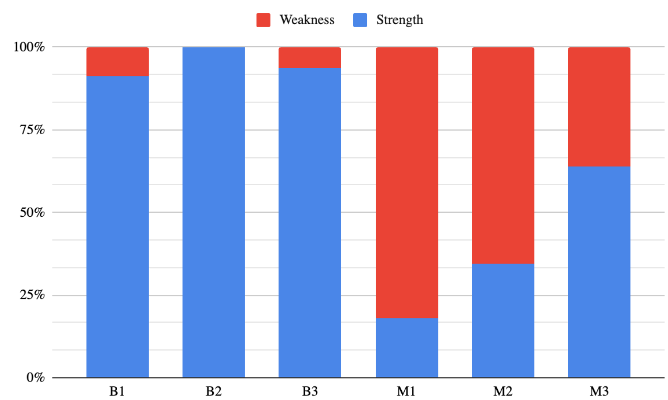

Figure 2. Proportion of codes demonstrating a strength- or weakness-based reflection by TRIOS debrief manuscripts for the biology trio (B1, B2, and B3) and mathematics duo (M1, M2, and M3).

This apparent change in approach is not surprising as all participants were reminded of the strength-based facet of the TRIOS program during whole-project faculty learning community sessions. It is also evident that the mathematics duo made fewer weakness-based reflections during each debrief. The third mathematics duo debrief (M3), in which 64% of coded talk turns included a strength-based reflection and 36% of coded talk turns included a weakness based reflection, was considerably shorter than other debriefs at 163 talk-turns compared to an average of 282 talk-turns across all six transcripts. Further, M3 still offered more weakness-based reflections than any of the biology team transcripts.

This observation regarding M3 along with the aggregate proportions of types of reflections for both the biology trio (95.3% strength and 4.7% weakness) and the mathematics duo (33.6% strength and 66.4% weakness) led us to consider the biology trio as an example of a group using a largely strength-based perspective and the mathematics duo as an example of a group using a largely weakness-based perspective to frame our analysis of the levels of reflection present throughout the debrief sessions.

Levels of Reflection in TRIOS Debriefs

The analysis of the TRIOS debrief transcript revealed a slightly different distribution of levels of reflection present in the biology trio's and mathematics duo's discussions (Figure 3). Although for both teams, the largest area of reflection was behavior and the smallest area of reflection was mission, the strength-based biology trio had a higher proportion of reflections regarding their beliefs (18.31%), identity (4.92%), and mission (1.37%) than the weakness-based mathematics duo (12.19%, 1%, and 0.5%, respectively). This indicates that it is possible a strength-based perspective may lead to deeper conversations and facilitate safe environment that facilitates reflection upon the most core features of oneself.

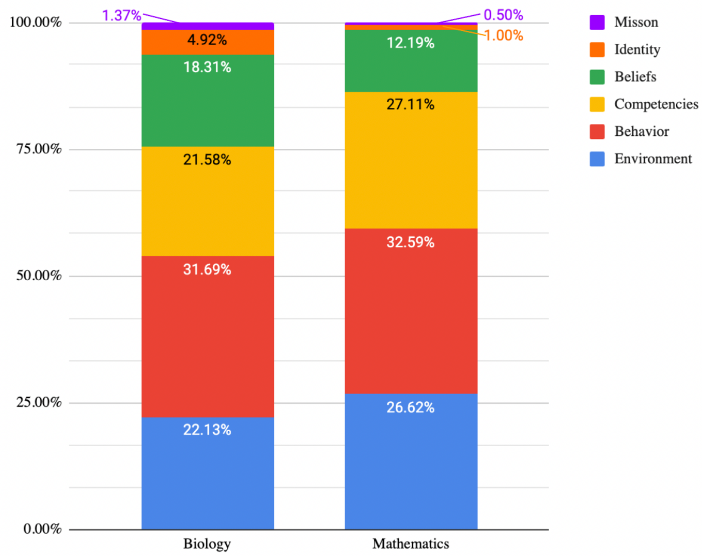

Figure 3. Proportion of levels of reflection across total Onion Model codes aggregated by biology (B1, B2, and B3) and mathematics (M1, M2, and M3) debrief transcripts.

Continued Research Plans

We have currently completed our coding and have explored the quantitative proportions of levels of reflection present in the two team debriefs, but we also plan to identify exemplary episodes for each level of reflection and consider the context of how a strength- or weakness-based reflection framed the subsequent conversation. This continued work will qualitatively respond to our hypothesis that focusing faculty feedback on the strengths of the instructor can facilitate a deeper, more vulnerable and positive level of reflection to promote professional development.

We also noted during our research team discussions a qualitative difference between certain strength-based and weakness-based reflections. Although we defined strength-based reflections to be *typically educative in nature* and weakness-based reflections to be *typically evaluative in nature*, we noted instances in which participants offered evaluative strength-based reflections. Future work distinguishing between evaluative and educative reflection may help us better respond to why a strength-based perspective alone may not promote deeper reflection.

Acknowledgments

This work was funded through the Tennessee Board of Regents Student Engagement, Retention, and Success Grant, 2020-2021 funding cycle.

Proof Without Claim: Problem Packaging

Alison Mirin

Andre Rouhani
Arizona State University

Dov Zazkis
Arizona State University

We present a case study of a student engaging in "proof without claim" tasks. In these tasks, students are presented with proofs in which the proposition being proven (its claim) is removed. Students are asked to ascertain what this missing claim is. This brief report serves (1) to illustrate how our novel proof without claim tasks can provide insight into how students engage with proofs and (2) as an existence proof that some students conceive of proofs as packaging for calculational math problems.

Keywords: Reasoning and proof, Undergraduate education, Preservice teacher education.

There is a significant body of research on the teaching and learning of proof-based mathematics (Stylianides et al., 2017). A lot of this literature has taken a deficit approach by highlighting various challenges that students face in proof-oriented content. This includes difficulties with constructing proofs (Iannone & Inglis, 2010; Weber, 2001), reading proofs (Dawkins & Zazkis, 2021, Inglis et al., 2012), translating novel arguments into proofs (Zazkis et al., 2015, Zazkis & Mills, 2017), and determining whether a given proof is valid (Selden & Selden, 2003, Alcock & Weber, 2005). Although it is useful to have a thorough list of challenges that students face, it is also important to understand the roots of these challenges.

In undergraduate mathematics, there is a transition between calculation-based courses and proof-based courses (Moore, 1994). A number of mathematics departments implement courses specifically to ease this transition (David & Zazkis, 2020). So, given the differences between proofs and calculations, the transition-to-proof courses also marks a transition in how students interact with mathematics, and by extension, what they might believe mathematics is. Since students have vastly more experience with calculation-based mathematics when they begin proof-based courses, it is reasonable to make sense of some nuances in students' approaches as an extension of their experience in calculation-based coursework (Dawkins & Zazkis, 2021). Importantly, such experiences might color students' engagement with proofs. Studying these conceptions has the potential to lead to meaningful improvements to proof education.

Through utilizing novel tasks, our work addresses the following question: How do students understand the relationship between a proof and what is being proven (its claim)? Addressing this question sheds light on how student thinking about proof might be influenced by past experiences with calculation-based mathematics. In the particular case study discussed here, we show evidence that at least some students view a proof as a container for a calculation problem. That is, students view proofs as essentially the same kind of task they encountered in their previous calculation-based classes, with its component sentences dressing up the calculation. This single case study is insufficient for making causal claims about the relationship between students' conception and their prior experiences with calculation-based course work. However, we do believe that conceptions transferred from those prior experiences are the most straightforward explanation for this phenomenon.

Task Design, Subjects, and Methods

We investigate this topic by creating and implementing the novel idea of *proof without claim* tasks. These tasks involve providing valid proofs while removing any explicit statements (claims) about what is being proven. Immediately prior to the proof is a statement "We will prove that" followed by a blank space, whereas after the proof is a statement "We have proven that" followed by another blank space. Students are prompted to fill in their interpretation of what should be in these blank spaces (Figure 1).

We developed six of these tasks in order to give insight into how students read and interpret proofs. This includes (1) how students determine what text goes in the blank spaces, and the related issue of (2) whether what they write in one blank space differs from what they write in the other. Our tasks included typical logical structures of claims, and they have employed basic proof strategies, such as proofs of universal claims via arbitrary instantiations, proof by counter-example, and constructive existence proofs.

The participant, Maria (pseudonym), was, at the time of the interview, an undergraduate preservice secondary mathematics teacher. She had successfully completed a transition-to-proof course. The interview lasted two and a half hours and can be categorized as an exploratory task-based clinical interview (Clement, 2000).

Results

Our data indicate that Maria views a proof as a package for three different components: the beginning (first blank), the middle (text provided between blanks), and the end (second blank). She brings a calculational orientation (Thompson et al., 1994) toward each individual part; the beginning describes what calculations or math problems are to be performed, the middle carries them out and serves as a holder for the constituent computations and equations, and the end presents the answer or result of these problems or computations. In other words, she appeared to conceptualize proofs as records of answer-getting problems. See Figure 1 for a typical example of Maria's work. Although there were six tasks involved, we use Figure 1 heavily as a typical example of Maria's work (due to space limitations).

The First Blank Box

In filling in the blank "claim" boxes, Maria indicated that she viewed the proofs as math problems where the "problem" is the first claim and the "solution" is the second claim. The reason we write quotations around "claims" is that, with the exception of a single task out of six, only once did Maria write in the first box what *we* would consider to be a claim. Her understanding of the first "claim" box as a repository for putting a math problem or prompt is evidenced by her writing of commands such as "find", "find out", and "prove". In other words, rather than writing propositions as her claims, she wrote instructions for what mathematical task to perform. For example, in the task disproving the statement "$2^{2^k} + 1$ is prime for all natural numbers k" (see Figure 1), Maria wrote "find f(k)" within the box for the first claim. In one task, she used the command "prove" in the first claim box. While "prove" is not the same as "find", we note that it shares the aspect of being a command; it is an instruction that might be given to a student to solve a math problem. Interestingly, in two different tasks, she listed "given" information in the first claim box. In one of these tasks, these "given" statements were listed in isolation. We note that, despite not including explicit commands, there is a sense in which writing the "given" information is similar to writing a command; both are pieces of information or symbolic prompts to be operated on or worked with towards a "solution". In other words, something is "given" in that it is information with which one will perform a task of finding an answer.

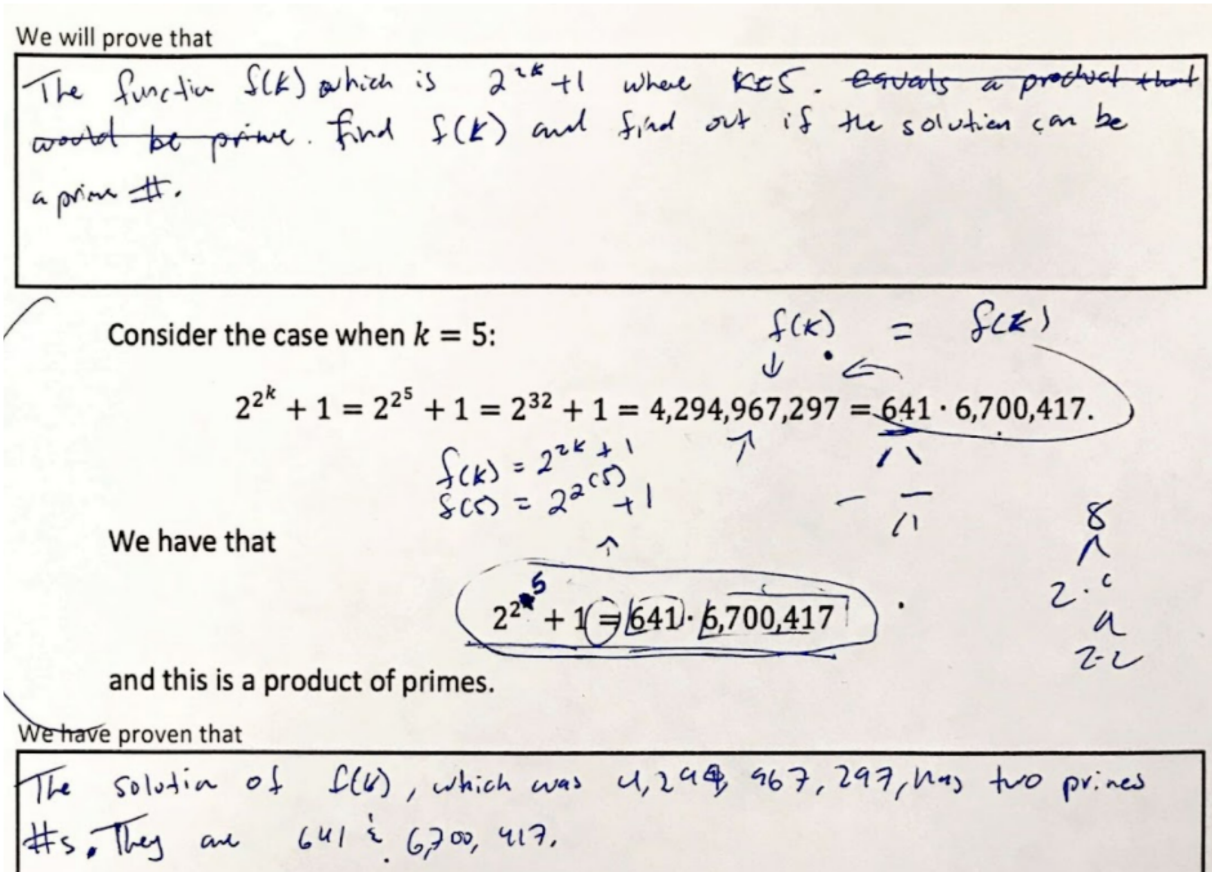

Figure 1. A typical example of Maria's work

The Second Blank Box

Interestingly, Maria did not write the same content in the second claim boxes as she did in the first claim boxes. Instead, in the second claim boxes, she wrote what we would call propositions. We can compare this with what she tended to do in the first claim box, which was to write an instruction or a calculation problem. Despite ostensibly being a proposition, when viewed in relation to the rest of the task (in particular the content of the first claim box), we understand Maria to be presenting the answer to the "question" or "problem" posed in the first box. Consider, for example, Maria's response to the task shown in Figure 1. While she wrote a command in the first claim box to "find $f(k)$" and to "find if the solution is a prime number", in the second claim box she wrote what her "solution" to $f(k)$ is and noted that it "has" two primes; in other words, the first claim box is for a question or prompt, and the second claim box is for a solution or answer. We see a similar structure in other tasks. For example, in a *proof without claim* task that proves the upper half of the unit circle has area $\frac{\pi}{2}$, Maria reports that the "derivative [sic] for the function $f(x) = \sqrt{1 - x^2}$ for $-1 \leq x \leq 1$ is $\frac{\pi}{2}$" in response to her first blank box command to "Given the function $f(x) = \sqrt{1 - x^2}$ for $-1 \leq x \leq 1$, find the derivative [sic] dx/dy". Another example of this structure is seen in a task that proves the quadratic formula (written with different symbols than the way it usually appears). In the first blank she inscribed the instruction “The equation $x^2 + px + q = 0$ has zeros, Please feel free to prove this how you think is best.” In reply, her second blank box read “The equation $x^2 + px + q = 0$ has two zeroes which are x = [...].” Maria correctly interpreted the last line of the proof, where x is isolated, as a statement of the zeroes of the function. Yet, taken together, the ways she inscribed the first and second blank boxes supports the idea that Maria was thinking of proofs as records of calculation problems.

The Middle

While Maria used the first claim box to write down the “problem” or command and the second claim box the “answer” or result, the middle served as a location for the computations leading to the answer. In the middle of the quadratic proof, Maria spent around five minutes attempting to verify the two algebraic steps—completing the square and rearranging terms. Throughout the study, Maria gave much attention to intermediary steps; her attention was on the particulars of the calculation rather than on the claim.

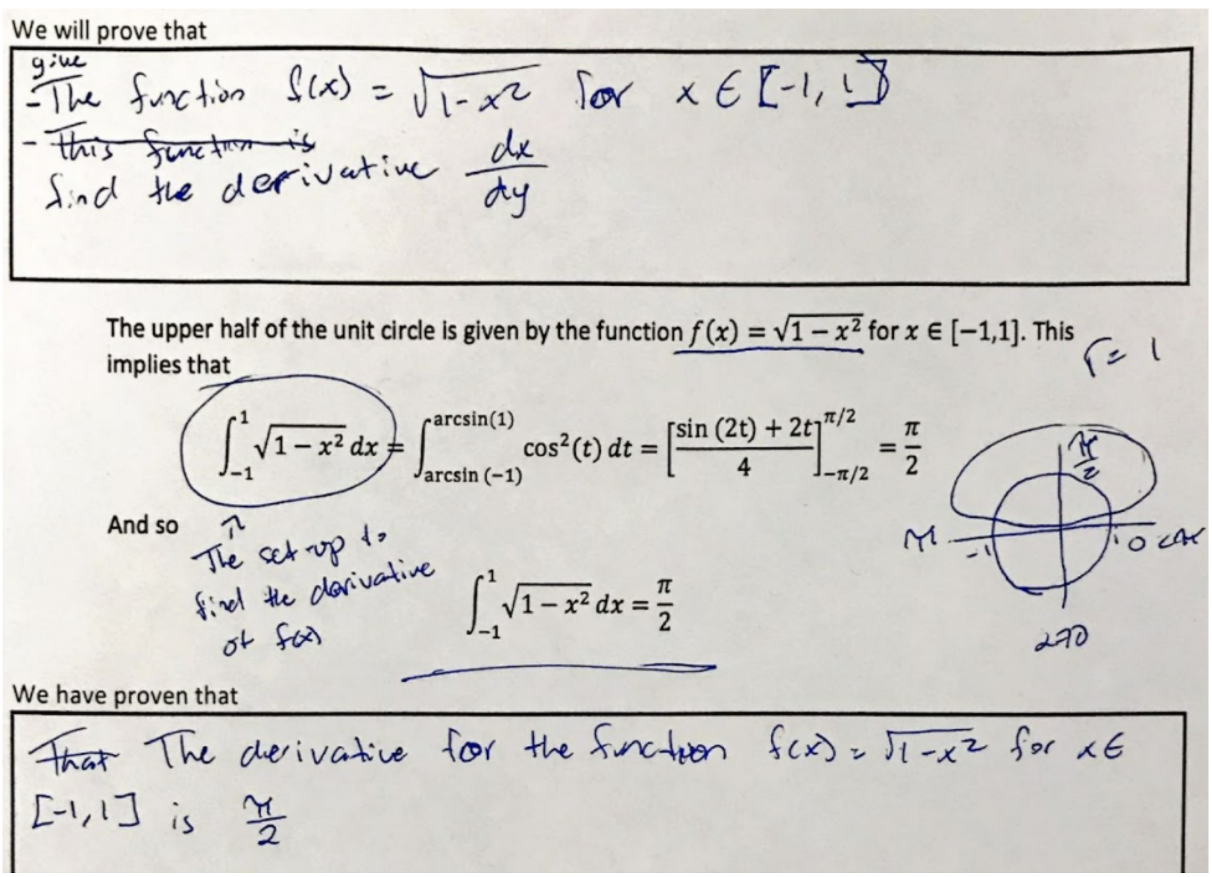

Figure 2. Another typical example of Maria’s work

Figure 2 (above) shows some inscriptions Maria made on the calculus task. This attention given to the intermediary steps is consistent with Maria’s overall view of a proof as packaging a calculation problem; the middle part is what she saw as the work to solve the “problem” being posed. Note that she circles the leftmost integral and inscribes below that it is “The set up to find the derivative [sic] of $f(x)$". In the first blank box she inscribed an instruction to find the derivative, and in the middle she indicates that she demonstrates that the way to start such a calculational-oriented problem is by writing the integral. In other words, her attention to intermediary steps can be understood as her focusing on the "problem" (the computation) instructed by the first box.

Figure 1 also supports our interpretation that the middle serves as a holder for the constituent computations. In drawing three arrows to 4,294,967,297 and labeling it "$f(k)$", Maria indicates that this is the $f(k)$ the proof is having her "find". Below that, she inscribes that "$f(k) = 2^{2^k} + 1$" and that "$f(5) = 2^{2^5} + 1$". Her other command from the first blank box, to "find out if the solution can be a prime number" is explored when she circles 641 and 6,700,417. From the middle of the task she extracts the numerical value of $f(k)$: "$f(k)$ is 4,294,967,297". This then allows her to present her finding as an "answer" in the second blank box and comment on it ("it has two primes"). Yet, Maria was not satisfied with her response and stated that it "has no meaning whatsoever" in relation to her transition-to-proof course. In reflecting on the task in Figure 1, Maria remarked that the mathematics presented in that task was not at all relevant to the mathematics she was learning in proof-based math—"I don't know what this has to do with proofs". For Maria, the task was at the pre-algebra level, because it only involved addition, multiplication, and a few exponents – she was attending only to the calculations when judging the proof's mathematical sophistication. Since this particular proof involved only pre-algebra calculations, she held this in conflict with the notion that proofs are part of higher-level mathematics. This supports our interpretation that what she saw as the mathematics of the proof was the calculational content in the middle, further supporting our interpretation that Maria saw the proofs as records of calculation problems.

Discussion and Future Directions

We reported exploratory findings on an undergraduate preservice teacher who recently completed a transition-to-proof course. This particular student made sense of these tasks by conceptualizing the first claim as a statement of a "problem" to be solved, the last claim as the "answer", and the middle as a location for calculations connecting top to bottom. Hence, ascertaining the claim amounted to determining to which "problem" these calculations correspond. This technique of *proof without claim* gave us insight into how this student conceptualized proofs. We believe prior calculation-based coursework to be a reasonable explanation for the phenomena highlighted in this preliminary work. Hence, future directions can expand the use of these tasks to a larger audience and more systematically explore the connections between such conceptions and students' prior course work.

Furthermore, it may be worth expanding interviews to include comparison tasks, where interviewees are presented with both a container for calculation-type response (e.g. Maria's work) and one for a normative response (e.g. a mathematician's) to a *proof without claim* task. Interviewees' responses to these comparison tasks have the potential to reveal additional nuances of students' conceptions of proof. In particular, since there is no blank claim box that needs filling, there is potential to confirm that some students truly believe the problem-calculation-answer format to be a legitimate proof format and perhaps more desirable than the normative response.

“When are we ever going to need abstract algebra?”

Kaitlyn Stephens Serbin
University of Texas Rio Grande Valley

Sthefania Espinosa
University of Texas Rio Grande Valley

Instructors who prepare prospective teachers should provide opportunities for them to make connections between Abstract Algebra and secondary mathematics. This study focuses on an instructor who guided prospective teachers to connect properties of algebraic structures with equation solving procedures by evoking their intellectual needs (Harel, 2013) for computation, structure, causality, and communication. The students resolved such intellectual needs by using ring properties as tools to justify their solutions to equations. We characterize the intellectual needs the instructor evoked, along with her pedagogical moves used to evoke them during class discussion. We discuss how we will extend this analysis and provide implications for teaching.

Keywords: Abstract Algebra, Equation Solving, Prospective Teachers, Intellectual Need

Understanding abstract algebra has the potential to support mathematics teachers in their various teaching practices (e.g., Baldinger, 2018; Murray & Baldinger, 2018; Murray et al., 2017; Serbin, 2021; Wasserman & Stockton, 2013; Zazkis & Marmur, 2018; Zbiek & Heid, 2018). However, this potential is often not realized (e.g., Cofer, 2015; Ticknor, 2012; Wasserman, 2017; Zazkis & Leikin, 2010). For teachers’ understanding of advanced mathematics to be useful in their teaching, they need to first make connections between the advanced and secondary mathematics that change their understandings of the content they teach (Wasserman, 2018). One content area in which prospective secondary mathematics teachers (PSMTs) can connect abstract and secondary algebra is equation solving (Wasserman, 2016). Understanding how the properties of algebraic structures are used while solving equations can help PSMTs develop a deeper structural understanding of the often-rote procedures used to solve equations (e.g., Murray & Baldinger, 2018; Serbin, 2020; 2021). This connection between algebraic structures and equations was the focus of a unit in a Mathematics for Secondary Teachers course, which is the unit of analysis for this study. The course instructor guided students to connect abstract and secondary algebra by evoking various types of intellectual need (Harel, 2013) that required students to find a new “tool” they could use to solve equations in $\mathbb{Z}_{12}$ and $\mathbb{Z}_5$. We investigate how the instructor evoked these intellectual needs, which led students to identify ring properties as “tools” to use to meet those needs. This study addresses these research questions: (a) What types of intellectual need did the instructor evoke as she implemented the equation solving task sequence during class? (b) Which pedagogical moves did the instructor use to make the need intrinsic to students?

Literature Review

Equation solving is a fruitful point of connection between abstract and secondary algebra (Wasserman, 2016). By the time PSMTs take an Abstract Algebra course, they are familiar with procedures used to solve equations, including canceling, simplifying, factoring, and using the zero-product property. Learning about the properties of algebraic structures can help PSMTs develop a deeper understanding of why those equation solving procedures work (e.g., Serbin, 2021; 2022). Wasserman (2014) demonstrated how attending to the assumptions underlying algebraic manipulation used in equation solving helped teachers understand the axioms and properties of algebraic structures. Murray and Baldinger (2018) similarly showed how teachers developed a deeper understanding of the properties used in equation solving and how they were connected to algebraic structures. Equation solving has also been used as a context for students to build formal reasoning about algebraic structures from their intuition. Cook (2015) showed how students could reinvent ring axioms by attending to properties that allow them to solve equations in $\mathbb{Z}_5$ and $\mathbb{Z}_{12}$. Cook (2014) also showed how students discerned properties of integral domains and fields by reasoning about zero-divisors and multiplicative inverses while solving linear equations. Overall, equation solving has been documented as a useful context in which students can connect abstract algebra and secondary algebra. Guiding PSMTs to make these connections is a fruitful approach for helping them better understand the content they teach.

Theoretical Background

This study leverages Harel's (2008) *necessity principle*, which suggests that students learn mathematics when they perceive an intellectual need for it. Harel (2020) defined an *intellectual need* as "A behavior that manifests itself internally with learners when they encounter an intrinsic problem—a problem they understand and appreciate" (p. 274). When students encounter a problem intrinsic to them, their intellectual need for something is evoked, which can be satisfied by finding a resolution. Harel gave teachers the responsibility of making intellectual needs intrinsic to the students. Harel (2013) found five categories of intellectual needs: (1) *need for certainty*, (2) *need for causality*, (3) *need for computation,* (4) *need for communication*, and (5) *need for structure*. The need for certainty refers to a person's desire to prove whether a conjecture is true or false occurs when students are asked to write proofs. The need for causality is the need to explain the cause that makes an assertion to be true. The students' need for computation can be evoked by the instructor when asking them to solve an equation, as it is described as an individual's need to quantify. A teacher can evoke students' need for communication by formulating spoken language into algebraic expressions and formalizing concepts. The need for structure is a need for organizing knowledge into a logical structure. Harel (2013) proposed the necessity principle can be used in instruction by teachers setting an intellectual need for a particular concept, translating this need into a set of questions, designing a task sequence that allows students to investigate these questions, and helping students identify the concept that is present in their solutions to these tasks. Our study focuses on an instructor's implementation of a task sequence in which she evoked students' various intellectual needs.

Methods

Study Context, Data Collection, and Data Analysis

Data were collected in a senior-level undergraduate Mathematics for Secondary Teachers course at a large research university in the US. This course covered topics from secondary algebra and precalculus that were connected to group and ring axioms and properties. Data were collected in the second unit of the course, which addressed the ring properties used while simplifying expressions and solving linear and quadratic equations in $\mathbb{Z}$, $\mathbb{Z}_5$, and $\mathbb{Z}_{12}$. The data include video and audio recordings of the first three class days of the instructional unit on equation solving. Each class was 75 minutes long. The course was taught by Dr. Grey (pseudonym), a mathematics professor and mathematics education researcher. For each clip of a task implementation, we summarized the task discussion and identified the tools students needed to do the task. We used deductive coding (Miles et al., 2013) to classify the type of intellectual need that was evoked by the instructor, using an a priori list of codes based on Harel's (2013) types of intellectual need: (a) need for structure, (b) need for computation, (c) need for causality, (d) need for communication, and (e) need for certainty. We also used inductive coding (Miles et

Figure 1. Summary of Intellectual Needs and Pedagogical Moves Used to Evoke These Needs on Tasks

al., 2013) to code the instructor's pedagogical moves used to make the intellectual need intrinsic to students in that video clip. We wrote analytic memos (Maxwell, 2013) that included justifications of our coding and explanations of how Dr. Grey's pedagogical moves evoked an intellectual need and made the need intrinsic to the students. We compared the coded video segments to identify patterns and relationships among the various intellectual needs evoked and the instructor's pedagogical moves used to evoke those intellectual needs.

The Instructional Task Sequence

Dr. Grey used an adaptation of Cook's (2012; 2015) task sequence for the guided reinvention (Freudenthal, 1991) of rings, which leveraged student reasoning about ring properties used to solve equations. Dr. Grey introduced the task sequence (see Figure 1) by comparing sets with one operation to sets that have two operations. Having previously learned about groups, the instructor began by evoking the students' awareness of sets with two operations by asking about the properties of these $\mathbb{Z}_5$ and $\mathbb{Z}_{12}$. She restricted the operations students could use to solve equations in $\mathbb{Z}_5$ and $\mathbb{Z}_{12}$ to only addition and multiplication (mod 12 or mod 5), so the tools students needed to use to satisfy their evoked intellectual needs were group/ring axioms or properties. Dr. Grey asked students to justify the algebraic manipulations in their equation solutions by identifying each of the properties used at each step. Students identified properties of additive inverse, multiplicative inverse, and identity. The instructor used these equation tasks to show students that not all properties hold for all sets. As the tasks progressed, students recognized that they needed additional tools to solve equations, such as the distributive property, cancellation rule, and zero-product property. Once they learned the properties in $\mathbb{Z}_5$ and $\mathbb{Z}_{12}$, the instructor presented equation solving tasks in $\mathbb{Z}$ and $2\mathbb{Z}$. Students then completed a table where they listed the properties of $\mathbb{Z}_5, \mathbb{Z}_{12}, \mathbb{Z}$ and $2\mathbb{Z}$ that they had found while solving equations. This led to the final task where they used the properties in the comparison table to define a ring.

Results

We identified four types of intellectual need evoked through the tasks: the need for structure, computation, causality, and communication. An overview of each task used during class, the tools needed for the task, the intellectual needs evoked by the instructor, and the instructor's pedagogical moves used to evoke those intellectual needs is presented in Figure 1.

How the Instructor Evoked Students' Need for Structure

Dr. Grey evoked students' need for structure at both the beginning and end of the task sequence. She made this need for structure intrinsic to the students by *juxtaposing different sets* together and having students identify similarities and differences in their structure. She posed task 1 (see Figure 1), in which she juxtaposed sets with one operation to sets with two operations to have students recognize a difference in the properties of those two kinds of sets. The students were aware of the structure of groups, so this task led them to see a need to understand the structure of sets with more than one operation. Dr. Grey further used this pedagogical move of juxtaposing sets in task 7, which prompted students to compare the rules used to solve equations in the different sets, $\mathbb{Z}_5, \mathbb{Z}_{12}, \mathbb{Z}$ and $2\mathbb{Z}$. This task allowed students to organize the properties they have learned thus far into a table to visualize which properties held for each of the sets. Dr. Grey's pedagogical move of juxtaposing sets evoked students' intellectual need for structure by organizing/listing the axioms they found for algebraic structures $\mathbb{Z}_5, \mathbb{Z}_{12}, \mathbb{Z}$ and $2\mathbb{Z}$ through equation solving. The students' intellectual need for structure prompted them to identify the axioms/properties these sets have in common that they later used to define a ring.

How the Instructor Evoked Students' Need for Computation

Dr. Grey's goal for the equation solving tasks was to evoke students' need for computation. She made this need intrinsic to them was by *asking students to justify their work by using ring axioms*. In Task 3, she asked students to find solutions to equations in $\mathbb{Z}_{12}$. She asked the students to write every property they had used to solve and why they used it. This pedagogical move allowed students to identify the properties needed to solve the equations. Once students had their solutions and explained their reasoning about them, the instructor evoked students' need for computation by *challenging a student's idea to prompt them to revise their work* by asking them follow-up questions. For example, in Task 3, the instructor prompted students' thinking by asking "What would happen if we could only use addition and multiplication?", when one of the students used division in their solution to an equation in $\mathbb{Z}_{12}$. Dr. Grey also evoked this need for computation by *revising students' written work to make it more precise/explicit*. In tasks 3d and 5d (see Figure 1), she provided a different approach to solving the equations that evoked students' thinking about how to approach these problems and how they could reduce their steps. Lastly, the instructor made this need for computation intrinsic to the students by *directing their attention to where properties can or cannot be used.* She made sure students were aware of how some properties do not hold for all sets. In task 4c (see Figure 1), Dr. Grey explained how the zero-product property holds in $\mathbb{Z}_5$ but not in $\mathbb{Z}_{12}$. Not being able to use this property evoked a need for students to find another way to perform the computation.

How the Instructor Evoked Students' Need for Causality

A need for causality was evoked by the instructor during several tasks. This intellectual need became intrinsic to the students by *asking them to justify their work by using ring axioms.* The task sequence consisted mostly of equation solving tasks, where students needed to show and justify their work in each step. These tasks evoked this intellectual need because students needed to explain why they could go from one line of the equation to the next. During Task 4c (see Fig. 1), students needed to explain why $-1(x+1)=0 \rightarrow x+1=0$ when solving equations in $\mathbb{Z}_5$. This need for causality was met by introducing the name of the property they had implicitly used: the zero-product property. Dr. Grey then evoked students' need for causality by *directing students' attention to where properties can or cannot be used* by asking them if the zero-product property would hold in $\mathbb{Z}_{12}$. This directed students to reason about why or why not this property would hold in another algebraic structure. Altogether, the instructor evoked students' intellectual need for causality, so students could explain why they could use certain ring axioms to solve an equation in a particular set and why some of the properties did not hold for other sets.

How the Instructor Evoked Students' Need for Communication

Dr. Grey evoked a need for communication in students and made this need intrinsic to them by *establishing a shared terminology of mathematical properties*. She asked students to name the properties used to solve equations in $\mathbb{Z}_5, \mathbb{Z}_{12}, \mathbb{Z}$ and $2\mathbb{Z}$, which evoked students' need to communicate the names of these properties. This need was satisfied by class's establishment of a shared terminology. For example, Dr. Grey changed a student's expression of "moving 8 to the other side" to use the language of "adding the additive inverse of 8 to each side of equation" in Task 5d (see Figure 1). This shared terminology helped students use precise mathematical language to communicate their justifications of their equation solutions and helped them create new definitions. The need for communication prompted students to give explicit names to the ring axioms they used to solve equations. Aggregating these named properties and comparing whether they held for $\mathbb{Z}_5, \mathbb{Z}_{12}, \mathbb{Z}$ and $2\mathbb{Z}$ allowed the class to define a ring on Task 7b.

Discussion and Conclusion

Engaging PSMTs in reasoning about the properties of rings used in equation solving can help them better understand connections between secondary and abstract algebra. A Mathematics for Secondary Teachers course instructor led students to make this connection by evoking students' intellectual needs (Harel, 2013) for structure, computation, communication, and causality on tasks involving equation solving in $\mathbb{Z}_5, \mathbb{Z}_{12}, \mathbb{Z}$ and $2\mathbb{Z}$. We identified the pedagogical moves that the instructor used to evoke students' various intellectual needs, which included: (a) asking students to justify their work by using ring axioms, (b) directing students' attention to what properties were involved in cancellation, (c) establishing shared terminology of mathematical properties, (d) juxtaposing different sets, and (e) revising students' written work to make it more precise/explicit. These findings provide a pedagogical implication for mathematics instructors who prepare PSMTs. Instructors can use Dr. Grey's pedagogical moves to make intellectual needs intrinsic to their students. Evoking students' intellectual needs that can be met by using ring axioms seemed to be a beneficial way to guide students to connect abstract and secondary algebra in this study. We plan to continue this analysis by identifying the intellectual needs and pedagogical moves used by this instructor in subsequent class days as the class transitioned from solving linear and quadratic equations to solving equations involving function composition. We pose the following discussion question to the audience: How can we further explore the relationships between the intellectual needs and pedagogical practices used to evoke the needs?

“What makes it eigen-esque-ish?”: Eigentheory Development in a Quantum Mechanics Course

Megan Wawro
Virginia Tech

Kaitlyn Stephens Serbin
University of Texas Rio Grande Valley

Eigentheory concepts are central in mathematics and physics; they serve multiple functions, such as symbolizing physical phenomena and facilitating mathematical computations. The words associated with eigentheory develop and vary over time (e.g., eigenvector, eigenstate), as do the associated symbols (e.g., Ax = λx, H|En> = En|En>). The focus of this study is how the concept of "eigen" develops over time for a quantum mechanics classroom community. We analyze the public displays of form-function relations used in the classroom community (Saxe, 1999). In this preliminary report, we summarize the forms and functions identified in the first 19 class sessions and share progress on our analysis of shifts in the uses of forms and functions over time.

Keywords: eigentheory, linear algebra, quantum mechanics, form-function, classroom analysis

Eigentheory concepts are central in mathematics and physics. They serve multiple functions, such as symbolizing associated physical phenomena and facilitating mathematical computations. Physics students reason about eigentheory concepts in Linear Algebra courses where eigen-equations often first look like $A\boldsymbol{x} = \lambda\boldsymbol{x}$, with $n \times n$ matrix A, $\boldsymbol{x}$ in $\mathbb{R}^n$ or $\mathbb{C}^n$, and λ is a scalar; they may also encounter $T(\boldsymbol{v}) = \lambda\boldsymbol{v}$, where T is a linear operator on vector space V. Students further reason about eigentheory in quantum mechanics, where eigenvalues of various Hermitian operators represent possible measured values of corresponding observables. Furthermore, physics students learn Dirac notation, in which eigenequations take on forms, such as $S_x|+\rangle_x = \frac{\hbar}{2}|+\rangle_x$ and $H|E_n\rangle = E_n|E_n\rangle$, and function to convey information related to spin and energy, respectively. In quantum mechanics, it is “eigen, eigen, eigen all the way” (Shankar, 2012, p. 30).

Several verbal, symbolic, and written forms can be associated with the same eigentheory concept, and many of these forms can serve different functions (Saxe, 1999) in both math and physics. These form-function relations can develop during class as the community’s common ground is negotiated through verbal or written communication. This development for eigentheory concepts in a Quantum Mechanics course is the focus of this study. We pursue the following research question: *How does the concept of "eigen" develop over time for a quantum mechanics classroom community?* To do so, we leverage a form-function analysis (Saxe, 1999), analyzing the public displays of form-function relations used in the classroom community. We identify each form that was used during whole-class discussion and infer the function of the form. So far, we have identified forms and functions from the first 19 class sessions. Our current analysis involves examining how shifts in the uses of these forms and functions occurred over time.

Literature Review

There is a growing body of literature on student understanding of eigentheory and teaching innovations that support student reasoning about eigentheory (e.g., Altieri & Schirmer, 2019; Beltrán-Meneu et al., 2016; Bouhjar et al., 2018; Gol Tabaghi & Sinclair, 2013; Karakok, 2019; Manogue et al., 2001; Plaxco et al., 2018; Pollock et al., n.d.; Salgado & Trigueros, 2015; Serbin et al., 2020; Wawro et al., 2019b). There are many conceptually complex aspects to a deep understanding of eigentheory. For example, interpreting the symbols $A\boldsymbol{x} = \lambda\boldsymbol{x}$ can involve recognizing the matrix-vector product $A\boldsymbol{x}$ as the same mathematical object as the scalar-vector product $\lambda\boldsymbol{x}$ (Thomas & Stewart, 2011). It can also involve conceptualizing eigenvectors as those $\boldsymbol{x}$ which are stretched by matrix A (e.g., Henderson et al., 2010; Sinclair & Gol Tabaghi, 2010). These correspond to a relational meaning of the equals sign (Knuth et al., 2006) and a functional interpretation of $A\boldsymbol{x} = \boldsymbol{b}$ (Larson & Zandieh, 2013), respectively, and have also been documented with quantum mechanics students (Wawro et al., 2019a; Wawro et al., 2020b).

Physical science students face additional complexities in reasoning about eigentheory, given that the mathematical objects and symbols relate to physical referents (Rodriguez et al. (2018). Researchers have suggested that interpreting mathematical symbolic expressions in terms of physical phenomena is a nontrivial endeavor for students (e.g., Caballero et al., 2015; Her & Loverude, 2020; Serbin & Wawro, 2022). Physics students face challenges in interpreting eigentheory symbols because those symbols and their word forms take on additional meanings in quantum mechanics contexts (Dreyfus et al., 2017; Gire & Manogue, 2011; Pina et al., 2022; Wawro et al., 2020a). For example, Wawro et al. (2020a) found that as physics students interpreted the meaning of the symbols in the eigenequations $A\boldsymbol{x} = \lambda\boldsymbol{x}$ and $S_x|+\rangle_x = \frac{\hbar}{2}|+\rangle_x$, a student was unsure how to resolve the disconnect between their geometric interpretation of the first equation and their quantum mechanical interpretation of the latter equation. Pina et al. (2022) also demonstrated different meanings students had for an eigenequation. They identified three different symbolic forms (Sherin, 2001) that physics students had for a position operator eigenequation that share a symbol template but have different conceptual schemata: a transformation which reproduces the original, an operation taking a measurement of state, and a statement about the potential results of measurement. These studies illustrate the complexity associated with interpreting eigentheory symbols and the varied meanings these symbols convey.

Theoretical Background

Through his anthropological work on the cultural development of mathematical ideas, Saxe (1999) created a framework for investigating the form-function relations created by individuals and a community over time. A *form* is a verbal, symbolic, graphical, or physical representation that takes on mathematical meaning. As individuals engage in activity or communication, they tailor forms to serve certain functions in activity, thereby establishing form-function relations. *Functions* are defined as the "purposes for which forms are used as individuals structure and accomplish practice-linked goals" (Saxe, 1999, p. 20). Forms can be adapted to serve several different functions, and functions can be served by different forms. For example, the form $y = 5x$ can function to conveying a constant rate of change or exhibit covariation of two variables, and the forms e and 1 can both serve the function of symbolizing a group identity (Plaxco, 2015).

Saxe and colleagues leverage this framework for analyzing the "reproduction and alteration of a common ground of talk and action over lessons in classroom communities" (Saxe et al., 2015, p. 71). Common ground refers to "shared knowledge of word meanings and norms for communication" that "enables successful communication and coordinated action" (Saxe & Farid, 2021, p. 8). Common ground is created as community members "produce and interpret displays of mathematical thinking, making use of representational forms (linguistic, graphical, gestural) to serve communicative and problem-solving functions" (Saxe et al., 2015, p. 4), is generated in interaction, and is at best taken-as-shared by community members. To identify how forms serve certain functions and how form-function relations shift over time, we perform microgenetic and ontogenetic analysis of the concept of "eigen" over a period of 19 class sessions.

Microgenesis is the process by which individuals construct representations by tailoring forms to serve functions that accomplish goal-directed activity (Saxe et al., 2015). This often occurs in public displays during class and contributes to the alteration of a common ground. Individuals are enabled and constrained by the common ground as they create new form-function relations. They can use familiar forms to serve new functions or recruit new forms to serve existing ones. Saxe et al. (2015) referred to the use of familiar forms or functions as continuity and the use of new forms or functions as discontinuity. *Ontogenesis* is characterized by shifts in microgenetic displays. An ontogenetic analysis involves an "analysis of continuities and discontinuities as individuals reproduce and alter form-function relations" (Saxe et al., 2015, p. 13).

Methods

The data analyzed in this paper come from an in-person, senior-level Quantum Mechanics course taught in a medium, public, research-active university in the northeast US. The semester-long, 3-credit course met three times a week for 50 minutes per class. The first nine weeks (23 days) of class sessions were video recorded, with a focus on capturing the professor and whole-class discussions. The professor was an experienced quantum mechanics instructor and physics education researcher. The course had 17 students and used McIntyre et al. (2012) as its textbook. The data sources were video recordings and associated transcriptions. Only exchanges that occurred with the entire class (as compared to small groups) were analyzed.

We imported transcripts into MaxQDA, which is a qualitative and mixed methods data analysis software (Kuckartz & Rädiker, 2019). We inductively coded (Miles et al., 2013) of both transcript and screen captures of slides and boardwork. We coded together while watching the videos, discussing our codes, and resolving inconsistencies as needed. We coded the instances in which "eigen" was explicitly used, as well as instances implicitly related to eigentheory. The implicit uses occurred when words such as state, value, or $\hbar/2$ were used in ways compatible with eigen-related interpretations. Our coding system had a nested organization according to form. At the primary level, main forms were separated according to what was characterized by "eigen" (e.g., eigenstate, eigenbasis). The second organization level separated main forms into the specific forms that existed in the data. For instance, the form "eigenvector - verbal" was assigned when "eigenvector" was said, the form "eigenvector - written" when "eigenvector" was written on the board or on a slide, and the form "$|+\rangle$ - symbolic" when the symbol $|+\rangle$ was used to convey eigenvector meaning. The final level of coding corresponds to the function that we interpreted the form to have when the form-function relation was detected. For example, any of the aforementioned eigenvector forms could have associated functions such as being an element of a basis that diagonalizes a spin operator or being part of the computation for determining the probability of measuring a certain spin value. If an instance involved more than one form – for instance, both saying and writing "eigenvector" – the same function was assigned twice; this resulted in two form-function pairs for that instance. We started preliminary ontogenetic analysis by examining how forms, functions, or form-function pairs were used throughout the data.

Preliminary Results

At the time of this preliminary proposal submission, we have coded the whole-class discussions of 19 consecutive class sessions for a total of 576 instances in which a form-function relationship for the concept of "eigen" was communicated. See Figure 1a for the distribution of those instances over the days. We have a small amount of remaining refinement to do (codes from Day 6 and some of Day 9 need to be added, Day 10 needs a final confirmation). We will complete this refinement prior to the conference and will integrate it into our presentation.

(a) 
(b)

Main Form	Number of unique form-function pairs in the secondary form category			Number of unique form-functions pairs in the main form category
	Written	Verbal	Symbolic	
Eigenvalue [188]	13	60	32	105
Eigenvector [73]	15	27	9	51
Eigenstate [229]	23	59	36	118
Eigenequation [65]	5	13	40	58
Eigenbasis [13]	0	8	1	9
Eigen(misc) [8]	0	8	0	8
	Total unique form-function pairs			349

Figure 1. Bar chart indicating the frequency per day of the instances in which a form-function pair for the concept of "eigen" was communicated (a), and summary of the various types of form-function pairs (b).

The form-function pairs are summarized in Figure 1b according to the six main forms of eigenvalue, eigenvector, eigenstate, eigenequation, eigenbasis, and miscellaneous uses (e.g., eigen-esque-ish, eigen math, eigen-ness). The numbers in the square brackets, which sum to 576, indicate the total number of times a form-function pair occurred in the data. The middle three columns organize unique form-function pairs with specificity regarding the form. For example, there were 32 different functions that were associated with a symbolic form accompanying "eigenvalue." For instance, the symbol a_n could be the form used to symbolize the eigenvalue in an eigenequation, the eigenvalues along the diagonal of a diagonalized matrix, or the expectation value of a measurement corresponding to an eigenstate; these are three of the 32 functions for the form "a_n - symbolic" within the Eigenvalue row / Symbolic column. On the other hand, the form "E_n - symbolic" could also pair with these functions in the energy context, such as symbolizing the nonzero entries of a diagonal energy Hamiltonian; that form-function pair is a fourth of the aforementioned 32 form-function pairs. In total, there were 349 unique form-function pairs.

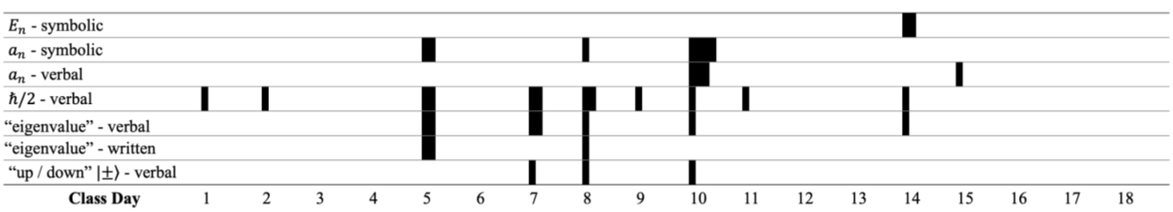

Figure 2. The dispersion of forms with the same function of *being the result of a measurement*.

Functions Associated with Several Different Forms

We performed a preliminary ontogenetic analysis by documenting the instances that different forms were used to serve the same function and determining the dispersion of those forms over time throughout the 19 class days. For example, conveying *the result of a measurement* (Fig. 2) and *a structure inherently tied to an operator* (Fig. 3) were two commonly-used functions, each associated with several forms in our dataset. The dispersion of the forms that served the function of *being the result of a measurement* is shown in Figure 2, and the dispersion of the forms that served the function of *being a structure inherently tied to an operator* is in Figure 3. The width of the black bar conveys the number of times the form occurred on that day (e.g., in Figure 2, the a_n symbolic form occurred twice on day 5, once on day 8, and four times on day 10).

We identified seven forms that were each associated with the function of *being the result of a measurement* (see Figure 2). This function was conveyed during ten of the class days, spread between days 1 and 15. Furthermore, in one class session (day 10), the class community used five of the seven different forms to serve this same function (see Figure 2). This illustrates how the class community associated the different eigenvalue forms of "a_n - symbolic," "a_n - verbal,"

"$\hbar/2$ - verbal," and "eigenvalue – verbal," and the eigenstate form of "up/down $|\pm\rangle$ - verbal" with the same function all in the span of one class session. Furthermore, we identified 15 forms that were each associated with the function of being *a structure inherently tied to an operator* (see Figure 3). By this function, we mean that the speaker was conveying some sort of structural quality imbedded in or inextricable from the operator. For example, a student claimed that certain given states "are eigenstates of the operator." This conveyed, in the "eigenstate – verbal" form, that eigenstates belong to or are a property operators, an inherent relationship between eigenstate and its operator. This function was conveyed in ten of the class days, spanning from day 5 to day 18, which illustrates a wide dispersion of the use of this function during class. On both day 7 and day 14, there were five different forms used that were all associated with this same function. Overall, these findings from the preliminary ontogenetic analysis illustrate how the class community used several different forms to convey the same function, even within the same class day. The recurrent use of the same functions over time demonstrates the continuity in the class community's use of those functions. The varied forms associated with the same function gives evidence to discontinuities present in the community's communicative displays over time. The class members altered existing form-function relations as they tailored different forms to serve the same function. Our remaining ontogenetic analysis will involve additional fine-grained examination of change over time; for instance, how the eigenequation itself changed form across contexts (e.g., abstract, spin, energy, position) but what threads of continuity exist and were leveraged throughout the semester as the classroom engaged with quantum mechanics.

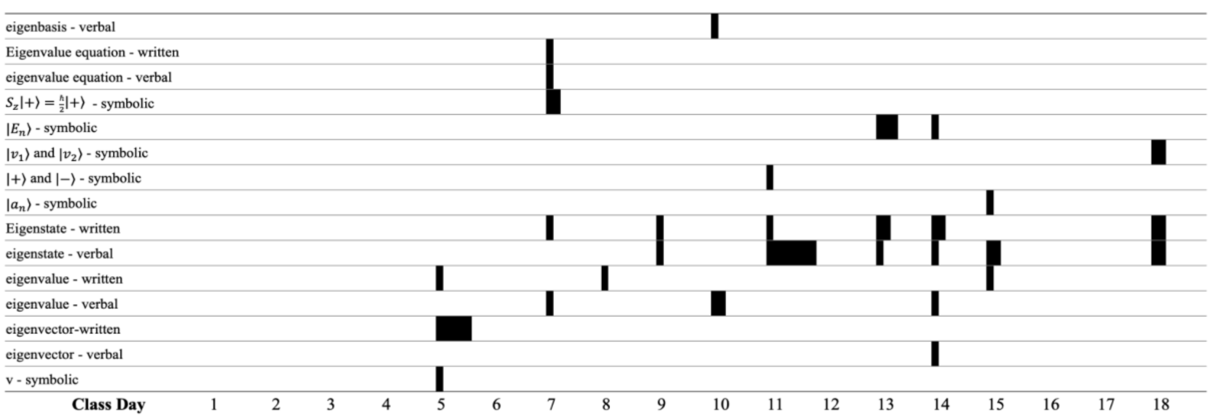

Figure 3. The dispersion of forms with the same function of *being a structure inherently tied to an operator*.

Conclusion

In this study, we are investigating a quantum mechanics class community's development of eigentheory over a span of 19 class days. We performed microgenetic and preliminary ontogenetic analyses (Saxe, 1999) of form-function pairs that the class used to communicate about eigentheory concepts. We plan to continue this analysis, as well as examine how these form-function relations are reproduced and altered over the remaining class days in our data set that address content related to wave functions. At the conference, we will engage the audience with discussion questions related to the pros and cons for various axial coding choices and the grain size of our codes, as well as solicit feedback specific to working with longitudinal classroom data and communicating about data related to both mathematics and physics.

We report on experiences of two Calculus 1 instructors who implemented teaching practices geared towards fostering students' mathematical creativity. While teaching a coordinated Calculus 1 course, these instructors participated in weekly professional development sessions on such teaching practices. Our preliminary analysis of participants' experiences describes how they navigated between the coordinated course structure and the added teaching practices discussed in the professional development. We utilize a zone theory lens to gain insight into participants' navigations in their professional environments, observing tensions between existing zone of proximal development and the zones of free movement and promoted action complex.

Keywords: Calculus, coordination, instructional practices, mathematical creativity.

The inclusion of mathematical creativity as a learning outcome in mathematics courses and programs has been discussed in numerous research studies and curriculum-standard documents (e.g., Askew, 2013; Levenson, 2013; Schumacher & Siegel, 2015; Silver, 1997; Sriraman, 2009). Despite these calls, the growth of explicit curricular work on creativity in mathematics courses, and professional development on teaching to include mathematical creativity at the tertiary level, has been slow. Recent work at the tertiary level has been limited to pre-service teachers (e.g., Bicer, 2021), mathematics majors in mathematics seminars (e.g., Mayes-Tang, 2020) or upper-division courses beyond Calculus (e.g., Omar et al., 2019). Thus, our overarching goal is to challenge dominant ways of teaching undergraduate mathematics by adding a focus on students' mathematical creativity and explicit teaching strategies to foster it.

In this preliminary report, we first describe our work with Calculus instructors. We discussed strategies to implement Calculus tasks geared towards fostering mathematical creativity in a semester-long online Professional Development (we refer to this professional development as C-PD here). Our project focused on Calculus 1 as this course plays a critical role in students' persistence in science, technology, engineering, and mathematics (STEM) programs (Rasmussen et al., 2019) and creativity is often overlooked in this course (Ryals & Keene, 2017). We also share results of preliminary analysis of data from the qualitative case study designed to explore the lived experiences of Calculus 1 instructors' implementation of creativity-based tasks (El Turkey et al., 2020) and teaching strategies to foster their students' mathematical creativity within a coordinated Calculus course. Our focus on coordinated Calculus 1 course was intentional - course coordination is considered a driver for instructional change (Rasmussen et al., 2019), and we believe it is timely to explore individual instructors' experiences within such structures. The research question of this study is: What are the experiences of Calculus 1 instructors in a coordinated Calculus course when utilizing teaching strategies to foster mathematical creativity?

Conceptual Framework

We situate our work on fostering students' mathematical creativity within the Developmental theoretical perspective (Kozbelt et al., 2010). The primary assertion of this theory is that creativity develops over time, and the main focus of investigation is a person's process and actions as opposed to the product created by them. Within this theoretical framing, we consider mathematical creativity as a process of offering new solutions or insights that are unexpected for the student with respect to their mathematics background or the problems they could have seen before (Savic et al., 2017). Fostering mathematical creativity with this conceptualization requires instructors to take intentional actions to engage students in the creative process of problem solving (Sriraman, 2005, Cilli-Turner et al., 2019).

In Tang et al. (2022), we examined teaching actions that students reported as contributing to their sense of creativity in their Calculus 1 course during which the instructors participated in C-PD. The student-reported teaching actions focused on designing and implementing creativity-based tasks using inquiry-oriented actions, in addition to holistic actions attending to students' affect. These teaching actions centered around students' lived experiences in these Calculus 1 courses, whereas in this paper, we shift our focus to the instructors' lived experiences implementing creativity-based tasks and teaching strategies in a coordinated setting.

We utilize a theoretical model proposed by Goos and colleagues (Goos, 2009, Goos et al., 2007; Goos & Bennison, 2019) to examine teacher learning and development, which applied and adapted concepts from Valsiner's (1997) zone theory. As this model centers its constructs in socio-cultural theory of teaching, it provides opportunities to examine our participants' experiences in their context (i.e., one institution's culture) and through their interactions with other C-PD participants while trying to utilize the C-PD materials.

Goos et al. (2007) describe three zones, each of which focuses on different aspects of teacher learning and development: the *Zone of Proximal Development*, the *Zone of Free Movement*, and the *Zone of Promoted Action*. Adapted from Vygotsky's (1978) work, the *Zone of Proximal Development* (ZPD) refers to the possibilities for developing new teacher knowledge and beliefs on content and pedagogy. The *Zone of Free Movement* (ZFM) focuses on "constraints and affordance within the professional context" (Goos et al., 2007, p. 26). It explores the environmental and contextual factors that allow or hinder certain actions. For example, teachers' views of curriculum design and assessment methods, and their connections to institutional culture and so forth are part of the ZFM. The third zone, the *Zone of Promoted Action* (ZPA), "represents the activities, objects, or areas of the environment in respect of which an individual's actions are promoted" (Goos & Bennison, 2019, p. 408). For example, in a department that focuses on active-learning strategies (i.e., institutional norm), an instructor may utilize teaching practices learned in a professional development on inquiry-based learning, which represents ZPA.

Overall, Goos et al. (2007) observed that these zones complement each other in the effort to describe teacher's learning and development. Goos et al. state, "For teacher learning to occur, professional development strategies [ZPA] must engage with teachers' knowledge and beliefs [ZPD] and promote teaching approaches that the individual believes to be feasible with their professional context [ZFM]" (p. 26). Also, the ZFM and ZPA are stated to be "dynamic and inter-related and form a ZFM/ZPA complex" (Goos & Bennison, 2019, p. 408) which plays an important role on learning and development of teaching strategies. For our study, this zone theory approach provides a structure to better understand the experiences of participants' teaching to foster mathematical creativity in a coordinated course environment.

Methods

We report on two instructor-participants at a university in the Northeastern United States. This works falls within a larger research project investigating students' mathematical creativity and the ways in which it can be fostered through teaching of Calculus I. Even though the larger research project consisted of 3 cohorts with 14 instructors total, we focused on only two participants, as they were in the same cohort and at the same institution in which the course was coordinated.

The two instructors chose their pseudonyms, and we also report their self-identified pronouns, genders and race: Farah Nurhalizah (They, Male, Asian) and On the 1s and 2s (She, Female, Black). These instructors formed the case for this study. At the time of the C-PD, Farah was a full-time instructor and On the 1s and 2s was an assistant professor, and both were in their first year teaching at this particular institution. Both participants had taught Calculus 1 more than 5 times previously with 6-10 years of teaching experiences.

Both instructor participants attended weekly online professional development with members of the research team to discuss the different components of the project: creativity-based task design and implementation; implementation of a reflection tool for formative assessment (Karakok et al., 2020); pedagogical actions; and attending to students' affect. All participants were asked to implement two common creativity-based tasks in their courses and design at least four additional tasks to implement. Participants could decide how to implement these tasks according to their setting. During the C-PD, they discussed implementation strategies with the research team and other instructor participants. We collected various data: Calculus teaching artifacts from prior semesters, video recordings of all C-PD sessions, participants' entrance tickets to weekly C-PD, video recordings of teaching of creativity-based tasks, and end-of-semester interview with participants. In this report, we share some of our initial analysis of video-recorded interview data from each participant. We started our data analysis with the interview data to gain insights into participants' experiences to identify critical moments or experiences before engaging with other data sources. For this initial coding (Saldaña, 2013) as the first cycle in our analysis, the first two authors read through the interview transcripts to get analytic leads to explore the lived experiences of teaching Calculus while attending to the C-PD. From this coding, we started our second cycle with a deductive approach to structure the observed experiences through a zone theory with ZPD, ZFM, and ZPA constructs. By the time of the conference, we aim to complete interview data analysis and analyze participants' entrance tickets and conversations during C-PD sessions with ZPD, ZFM, and ZPA constructs to describe their experiences.

Preliminary Results

We first note that both participants implemented only two creativity-based tasks, due to interruptions in teaching modality caused by the COVID-19 pandemic in the middle of the semester.

Farah Nurhalizah (They, Male, Asian)

Farah described their teaching Calculus 1 experience through its "highly coordinated" structure. They referred to this structure as a new experience for them in which "you have the same exams, the same homework, and the same worksheets even." Coordination was the most significant feature of their environment (ZFM) and Farah seemed to believe that it hindered their access to their already-established ways of teaching Calculus. In addition, Farah thought "[i]t took a while for me to get used to it… And I think students could feel that I wasn't like totally buying into the structure."

As we examined Farah's reported experience, we noticed that their negotiation between the recommended focus on conceptual understanding from the coordinator (ZFM) and the newly added focus on creativity from C-PD (ZPA) created a tension with their existing beliefs on teaching Calculus (ZPD). When asked how they could have adjusted pre-designed worksheets to incorporate fostering creativity tasks, Farah stated they would have "underemphasized the conceptual understanding as much…And…sort of do more creativity instead of conceptual." For Farah, conceptual understanding questions on worksheets required "theoretical foundation," definitions, and some proofs, which the course did not design to deliver them. For their section of the course, Farah "snuck in…the epsilon-delta definition," that they thought they were not supposed to do. The inclusion of definitions and some proofs for Farah was about being "intellectually honest," and relates to their existing beliefs of mathematics and teaching mathematics (ZPD).

As Farah tried to reconcile their existing teaching Calculus practices with these pre-designed worksheets and the coordination structure, they identified some aspects of the worksheets that could potentially foster mathematical creativity (ZPA). Incorporating their experience with C-PD on features of creativity-based tasks (El Turkey et al., 2020), they mentioned "some of the worksheet problems…had like some open-endedness" to them. Farah further noted that not all students got to these questions nor was there an emphasis to discuss or do these questions in class (ZFM). However, Farah thought that there was a possibility to foster creativity if they had a chance to discuss these questions. These observations highlight the dynamic and inter-related relationship of ZFM and ZPA in Farah's experience (ZFM/ZPA complex) (Goos, 2009). Furthermore, Farah's proposed method of using such worksheet problems through more flexible class discussion speaks to their developing ZPD on teaching Calculus 1 to foster mathematical creativity and navigation through the tension they experienced between their existing ZPD and the professional environment (ZFM).

On the 1s and 2s (She, Female, Black)

On the 1s and 2s's experience teaching Calculus 1 in a coordinated Calculus to foster creativity highlights explicit aspects of the ZFM/ZPA complex. Speaking about her experience teaching coordinated calculus (ZFM) and participating in C-PD (ZPA), she thought her teaching did not necessarily change in the current course, but this C-PD experience changed "how I think about calculus and encouraged me to include more…creativity tasks" in her future courses.

For On the 1s and 2s, one of the important differences between the coordinated worksheets (ZFM) and the creativity-based tasks (ZPA) was the goals of these tasks. She identified one of the goals of the creativity-based tasks as "what different ways can you think about this problem" or "what different ways can we as a group think about this problem" whereas the worksheet problems tended to have a goal of "can you get this answer?" With this noticing, and her interactions with Farah and other participants of the C-PD (ZPA), she was able to change some elements of the professional environment (ZFM). For example, they (all Calculus instructors, including Farah and the course coordinator) used one of the creativity-based tasks in their weekly check-in assessment. This task asked students to create a function where the limit exists at -1, but not continuous. Even though all instructors did this task in the same format on an assessment, On the 1s and 2s followed up with students, after the assessment, with a whole-class discussion on their solutions. As she believed her class "is a life that grows and changes and you have to adjust," explicit discussion in C-PD on how to design and implement creativity-based tasks provided her opportunities to envision how to navigate in her environment (ZFM).

Even though she and Farah were teaching their own sections of the same coordinated Calculus 1 course, her experience with the worksheets or the coordinated structure (environmental constraints) mostly interacted with the ZPA to form a ZFM/ZPA complex that informed her evolving ZPD. These ZFM/ZPA negotiations played a role in On the 1s and 2s's teaching experience for mathematical creativity.

Conclusion and Questions

Coordinated courses have opportunities to create coherent experience for students taking Calculus 1 and subsequent courses at the same institution. For instructors, coordinated structure could provide several opportunities: collaboration among faculty with shared objectives, professional development, and building of common tools and resources. Furthermore, Williams et al. (2022) claim that course coordination can be "a vehicle for shifting departmental culture" (p. 126). However, some instructors may feel loss of autonomy and flexibility in their teaching. This loss of autonomy relates to 'coordinated independence' construct, which is "intended to embrace how in-step elements of a calculus program work together with elements that allow for individual autonomy" (Rasmussen & Ellis, 2015 p. 114). As many institutions use or aim to use coordination for Calculus courses, it is important to explore the coordinated independence construct. This construct could allow us to understand the barriers and opportunities to create a coherent course design for students.

In this study, we examined instructor's experience of implementing teaching practices from a professional development in a coordinated structure. Our preliminary analysis results relate to how two instructors experienced "coordinated independence" in slightly different ways through a ZFM/ZPA complex. For Farah, this complex created a tension with their existing ZPD. Farah's existing ZPD was more aligned with the ideas promoted in C-PD (ZPA) than the coordinated calculus structure (ZFM). On the other hand, On the 1s and 2s identified certain aspects of the C-PD (ZPA) to make changes in her professional environment (ZFM) and had a vision to do more in her teaching practices (developing ZPD). These experiences, with their differing tensions and negotiations, may explain formally why it is difficult for teachers to incorporate creativity into their classrooms, particularly in a coordinated setting. We must acknowledge the unique nature of the setting in our analysis – COVID-19 forced many to use pedagogical tools that were not in their ZPD at all. In our future work, we will continue to explore these areas as they relate to the coordinated settings and instructors' developing ZPD.

We are interested to learn from audience:

1- What strategies do instructors use when they experience tensions between their zones of development?
2- What strategies do professional development facilitators need to adopt when instructor participants experience such tensions?

"Well, it's obvious": Students' Experiences with Mathematical Microaggressions

Anne Cawley
Cal Poly Pomona

Ryan Aniceto
Cal Poly Pomona

Seth Ricarte
Cal Poly Pomona

Robin Wilson
Loyola Marymount University

Mathematical microaggressions (MM) refer to the subtle ways in which mathematical authorities use language, behavior, and assumptions that communicate negative messages to students that they do not belong in mathematics (Su, 2015). This study analyzes the reflections of 173 undergraduate mathematics students who were asked to reflect on an article (Su, 2015) about MMs. Findings show that students experience different types of MMs, including microslights, microinsults, and environmental microaggressions. Our results indicate that female students were more likely to report experiences with MMs than male students. This research supports the need to investigate this phenomenon further and to develop initiatives at departmental and institutional levels to encourage more inclusive spaces in math classrooms.

Keywords: Mathematical Microaggressions, Microslights, Microinsults, Sense of Belonging

Microaggressions (MA) have been characterized as the intentional or unintentional indignities that communicate "hostile, derogatory, or negative" messages that target a person and/or their marginalized group (Sue, 2010). Within the realm of education, the prevalence and effects of MAs have been studied in relation to students' sense of belonging. Sense of belonging, in a university context, refers to the perceived social support and the experience of mattering or feeling cared about, accepted, respected, valued by, and important to the classroom and campus community (Strayhorn, 2018). Recent scholarship has revealed that MAs are prevalent in classrooms and inhibit students' sense of belonging, especially for students coming from marginalized groups (Solórzano et al. 2000; Yosso et al., 2009). As an example, Lewis et al. (2021) reported that a higher frequency of racial MAs significantly predicted lower overall sense of belonging for students of color, and similar connections between MAs and sense of belonging can be found in studies centered on women (McCabe, 2009).

Microaggressions have been well reported as widespread in academic spaces and detrimental to student outcomes. Within STEM departments, which already face issues in representation from marginalized communities, reports of MAs are distinctive. Students of color, especially Black students, report racial MAs from STEM instructors, advisors, and peers (Lee et al., 2020). Further work shows that the effects of MAs can be magnified in STEM spaces. Leyva and his colleagues (2021) report how discouraging classroom practices, many of which can be characterized as MAs, had discriminatory impacts on women and students of color. Marshall et al. (2021) noted that in the context of STEM, MAs hinder students' academic success and ability to participate in the academic pipeline, especially for students historically excluded from the sciences on the basis of race or ethnicity. MAs directly impact students' sense of belonging in STEM, and more needs to be done at an institutional level to better support student retention and sense of belonging within STEM fields (Lee et al., 2020; Rainey et al., 2018).

Our paper is framed through the subtle layers of microaggressions and how they can be received by mathematics students (Marshall et al., 2021; McKenna et al., 2021; Su, 2015). As an extension from discussions of racial microaggressions, Francis Su (2015) used the term *mathematical microaggression* (hereby labeled as MM), which refers to the subtle ways that mathematical authorities (such as instructors, classmates, or textbook authors) communicate that one does not belong in mathematics. Su offered examples such as “It is obvious/clear/trivial that…”, “The rest is just algebra,” and “There’s a trick for doing this” and elaborates that such comments can convey negative messages towards students (e.g., their knowledge is lacking, their questions are unwelcome, their potential in mathematics is limited). In order to highlight the undeliberate intentions in which MMs are often exchanged in math classrooms, he used the term *microslights*, which are defined as unintentional comments or language in which the aggressor is often unaware could be exclusionary. Accounting for more intentional and/or aggressive MMs from instructors toward students, McKenna et al. (2021) define *microinsults* as “intentional, subtle snubs” that can “demean one’s racial heritage or identity,” which we extend in the case of MMs to cover abrasive exchanges that targets students’ mathematical identity and perception of ability. Marshall and her colleagues (2021) define *environmental microaggressions* (EM) as relating to MAs that exist in the environment in which a person exists, not directly received by an individual. We adapt Marshall et al.’s (2021) definition of EMs to include any MM that exists in the experience of learning but is not inflicted by any one person to another person directly. For example, an EM could be witnessing peers understand a topic quickly or a professor moving quickly through a mathematical explanation. Because a student understanding a topic quickly is not done purposely to harm another person, we categorize this MM as subtly different than microslights or microinsults, which are more directed towards individuals.

Our study focuses on the MMs that mathematics students reflect on experiencing throughout their learning. This paper focuses on the following three research questions: 1) How do mathematics students describe experiencing MMs? 2) What types of MMs do students experience? 3) How do students’ experiences with MMs vary by gender?

Methods

This study took place at a large public university on the West Coast of the U.S., designated as a Hispanic-serving Institution. Data for this paper were collected between Fall 2019 and Spring 2022. The sample included 173 participants enrolled in calculus I (47 students in two sections) or abstract algebra (126 students in four sections), taught by the same instructor (Author 4). Course modalities included both in-person and virtual instruction. These classes incorporated inquiry-based learning and active learning and provided a significant amount of time for student collaboration and discussion during class instruction. Based on institutional data of the 173 students, 42.8% were female and 57.2% were male. 50.9% of the students were Latine[1], 3.5% were Black, 18.5% were AAPI, 13.3% were white, one student was Native American, 6.9% were undocumented[2], 3.2% two or more races, and 4% where race was unknown.

Throughout the course, students were asked to submit reflection assignments. In one of these assignments, students were asked to read Su’s (2015) article on MMs, to reflect on the paper, and to describe if they have ever been made to feel like they do not belong in mathematics. Students could reflect on any moments in their math experience. The instructor created this assignment as part of a series of assignments for the purpose of creating a more inclusive classroom space for collaborative learning. The 173 reflections form the data set for this study; each reflection was given an identifier that included the course and students’ gender, race/ethnicity, and major.

---

[1]*Latine* is a gender-neutral replacement of the term Latino. It has been used as a more linguistically natural alternative to Latinx or Latin@ for Spanish-speakers (Celis Carbajal, 2020).
[2] We note that “undocumented” is not a race or ethnicity, however, the university uses this category.

The data were analyzed using constant comparative methods (Corbin & Strauss, 2008). The first round of coding utilized deductive coding. All de-identified reflections were initially coded by all authors to identify microaggressions that students experienced in STEM, specifically mathematical, racialized, and gendered microaggressions. For purposes of this paper we focused on MMs and therefore analyzed these data in the second round of coding. First, we coded for *Who Received a MM* with four sub-codes emerging: i) student has directly received/experienced an MM, ii) student has never received/experienced an MM, iii) student has not directly received/experienced an MM but can imagine how it could affect others, and iv) student has inflicted an MM on another person (reflections could be coded for more than one sub-code). Next, for those students who indicated directly receiving an MM, we coded for *Type of MM discussed* and *Who/what inflicted the MM*. Finally, we coded for *Pushback to the concept of MM*. Pushback could include a student stating that MMs were not real or a student explaining away the MM by claiming that they themselves lacked discipline or knowledge or should be a better student. A third round of coding commenced where authors grouped types of MM directly received and labeled each as a microslight (Su, 2015), a microinsult (Mckenna et al., 2021), or an EM (Marshall et al., 2021). After each round of coding, the authors cross-coded a subset to verify validity of application of codes. Authors met to discuss any disagreements of codes.

Findings

From the 173 student reflections, 69.9% indicated having directly received a MM, 4% have never directly received a MM, 20.8% could imagine how MMs can negatively affect others, and 6.4% indicated that they have inflicted MMs on others. Students who directly received an MM (N=121) indicated 11 distinct types of MMs (see Table 1); 65.3% of students indicated a microslight, 16.5% indicated a microinsult, and 19.8% indicated an EM.

From the 121 students who received an MM, most indicated having received microslights, with 40.5% of students indicating the MM “It’s obvious/trivial/easy”. Representative of other entries, Edwin, a Black male student in abstract algebra said, “I heard…a professor say that a proof to a lemma was obvious. I didn’t ask about it, although I didn’t understand it, because I didn’t want to look dumb in front of my peers for not seeing an obvious proof”. Other students described similar experiences. Subsequently, 14% of students reported being told “You should have learned this before”, and 9.9% reported hearing “The rest is just algebra” or not being given enough wait time. Typical of “No wait time” examples, Lianne, a white female student in abstract algebra described experiencing professors say, “Does anyone have any questions?” with a very short pause before moving on. “Sometimes it takes a few seconds to build up the courage to ask a question, but when the teacher moves on too quickly it makes you wonder, ‘How does everyone else understand but me?’”. The remaining three microslights represented less than 10% of student responses and will not be discussed here. 16.5% of the students reported hearing the microslights that Su (2015) wrote in his paper, but did not specify the type.

Table 1: Frequencies by type of mathematical microaggression students reported directly receiving (N=121)

Type of Mathematical Microaggression	Frequency (%*)
Microslight	**79 (65.3%)**
It’s obvious, trivial, easy	49 (40.5%)
You should have learned this before	17 (14%)
“The rest is just algebra”	12 (9.9%)
No wait time	12 (9.9%)
Ignoring/dismissing questions, “see me after class”	8 (6.6%)

“The concept is not that bad”	6 (5%)
There is no such thing as a dumb question	6 (5%)
Microinsult	**20 (16.5%)**
Belittle/shame student	12 (9.9%)
Not believing in a student, “You’re not good enough”	8 (6.6%)
Environmental	**24 (19.8%)**
Seeing others get it quickly	18 (14.9%)
Professor moves too quickly/Skips Steps	7 (5.8%)
MM not specified	**20 (16.5%)**
Other	**11 (9.1%)**

*Note that totals are greater than 100% as some students reported more than one MM

Students reported experiencing microinsults less often than microslights; 70% of microinsults were reported by students in abstract algebra. Students discussed instructors belittling them or shaming them (9.9%) or not having an instructor believing in their ability to do mathematics (6.6%). For example, Reese, a Latino male student, felt belittled during class when he wrote a problem that he struggled with on the board and recounted the instructor’s response. “When she got to the problem she said, ‘I’m not even going to do this problem because it’s so easy, and if you need help on this problem you’re in the wrong class’”. This made Reese feel embarrassed and less intelligent than the other students in his class. Students described two ways of experiencing EMs; 14.9% of students indicated feeling like they did not belong when they saw other students understanding the material quickly while 5.8% of students described feeling excluded when instructors skipped steps or moved too quickly through the material.

Students who directly received a MM indicated receiving them from professors (63%), K-12 teachers (11.5%), peers (16.5%), and the textbook (6.6%). Alice, a female Asian American calculus student, explained how she experienced receiving MMs during class group work:

> There were times where I was in group work settings and I would ask a question and all the members would know how to do it. They would say, this is “obvious” and teach me briefly. It made me think that I am not qualified enough to be in this class because I was not able to learn my basics well enough.

Eleven students admitted to being a microaggressor toward a peer who was struggling with course material or students they were tutoring. All but two of these students were male. As an example, Douglas, a Latino male abstract algebra student mentioned, “I feel like [MMs are] very important as I’ve said some of these things to students I have tutored in the past. I didn’t personally consider the perspective of students who may be experiencing these same topics which I’ve been practicing for 3 to 4 years”. For most of these students, their reports of being microaggressors at a previous time were combined with reflections of their own teaching philosophy, newly informed by the potential negative effects of their previous comments.

Of the 173 reflections, 17 students (9.8%) demonstrated pushback against the discussion of MMs. Reasons behind pushback varied but largely arose from three perspectives toward MMs: i) MAs are unintentional and do not warrant emotional response, ii) MAs are an opportunity to call out a student’s shortcomings, and iii) discourse regarding MAs is a politicized diversion from addressing lack of effort. An example provided by Garrett, a white male calculus student, exemplified how MMs are an excuse for students to maintain poor effort:

> I feel that the use of microaggressions as an excuse to why a student feels like they are failing a math class is concerning. I feel that too many students do not put in the effort to

learn how to do math and refuse to ask questions which results in students blaming so called "microaggressions" on their failure.

All but one of the 17 students who demonstrated pushback to the idea of MMs were majors within the colleges of science and engineering. Five of the 17 students who displayed some pushback against MMs were female. We should note that these five students focused on the unintentional nature of MMs as a reason to push back and argued that they themselves may have been “too sensitive” when reacting to the MM.

There is evidence to show other findings when comparing gender. Female students more frequently experienced MMs than male students; 78.4% of female students (N=74) reported experiencing an MM compared to 63.6% of male students (N=99). Female students indicated higher experiences with microslights and EMs. A notable discrepancy occurs specifically with reports of microslights, where 52.7% of the female students reported having experienced microslights, compared to the 40.4% of male students. Male and female students indicated receiving microinsults at similar rates (12.1% compared to 10.8%). It should be noted that all students who indicated that they had never experienced a MM were male; none were female.

Discussion

Our study showed that a large proportion of students have directly experienced a MM. Most students experienced the “It’s obvious/trivial/easy” microslight. This microslight may have been discussed more than others as Su (2015) lists this in his paper as the first example of a MM. It is particularly notable that female students reported experiencing MMs more than male students. We believe that it is important for instructors to attend to the way these microaggressions acutely affect women. Findings indicate that the nature of MMs are carried on through students in their interactions with others. Microinsults are more severe forms of MAs, and even though they were less frequently referenced by students in their reflections, we need to consider how microinsults affect all groups of students. While students reported experiencing most MMs from instructors, students did indicate receiving them from peers, which is an important factor to consider when attempting to create a safe and welcoming classroom climate while utilizing active learning teaching techniques.

Types of MMs experienced align with previous findings, specifically that students do feel the impact of seemingly innocuous comments often found in mathematics classrooms (Leyva et al., 2021; Su, 2015). These MMs can directly impact a student’s sense of belonging in STEM, and is very impactful on marginalized students (Rainey et al., 2018), specifically women. This study points out that more research is needed to understand the ways both students and instructors experience and internalize MMs. It also suggests potential for including MMs in professional development for college math instructors, specifically examples of MMs and how they are received by math learners. We hope to learn from the RUME community ways that they acknowledge MMs with their students to form a more inclusive learning environment, as well as different ways to interpret our data.

While this study focused on understanding and categorizing the types of mathematical microaggressions students have experienced, we have begun preliminary analysis of the data in other ways. First, we continue to analyze the MM data for any differences by participant race and gender. While the Su (2015) paper focused on mathematical microaggressions, some student discussed racialized or gendered microaggressions within their reflections. Future analysis will explore the ways students talk about these important microaggressions and how they impact sense of belonging in math classrooms.

What Are Instructors Doing to Initiate Refinements of Students' Definitions?

Kristen Vroom
Michigan State University

Tenchita Alzaga Elizondo
Portland State University

A key feature of inquiry-based instruction is to develop formal mathematics by directly building on student thinking and contributions, which often requires engaging students in refining their work. In our experiences we have noticed that it is challenging for instructors to support this refining activity and so we see a need to better understand what instructors can do in-the-moment to initiate refinements. In this study, we investigated how three instructors across four courses guided their students through the refinement of one definition. We identified three different moves that these instructors used to support the definition refinements: (1) suggest an edit with implicit mathematical reasoning, (2) suggest an edit with explicit mathematical reasoning, and (3) ask a question to create a problematic situation. The first two moves focused on the refinement itself whereas the third move focused on a problem to motivate a need for a refinement. We discuss future research directions and implications of our work.

Keywords: Defining, intellectual need, teacher moves

A key feature of inquiry-based instruction is to develop formal mathematics by directly building on student contributions (Kuster et al., 2018; Laursen & Rasmussen, 2019; Rasmussen & Kwon, 2007). For instance, in many inquiry-based classrooms students are guided to reinvent formal definitions. To work with the students' contributions, the teacher supports students in refining their definition drafts so that their definition is equivalent to a standard definition given in textbooks. This is our intention with the curriculum materials that we are developing as part of a larger research project (ASPIRE in Math NSF IUSE #1916490). Our task sequences engage students in defining (Zandieh & Rasmussen, 2010) by first engaging them in a task that evokes a concept image (Tall & Vinner, 1981), then students and the instructor generate and negotiate examples and non-examples of the concept, and lastly they work together to refine an informal description of the concept towards a formal definition (see Vroom, 2020).

It is documented in the research literature that it is challenging for teachers to build on student thinking in general (Andrews-Larson et al., 2019; Johnson & Larsen, 2012; Speer & Wagner, 2009) and we have noticed this to be especially the case when refining students' definitions. In particular, students sometimes offer definition drafts that are inconsistent with mathematical norms and conventions since students are not only learning about the concept itself but also are in the midst of learning about formal mathematical language (Vroom, 2022). At the same time, formal mathematical language is highly technical and filled with nuances, but functions to articulate precise mathematical meanings (Halliday, 1978; Schleppegrell, 2007). Thus, we see that it is a non-trivial endeavor to support students to refine their definitions in such a way that they more effectively communicate the students' ideas to a broader mathematical audience.

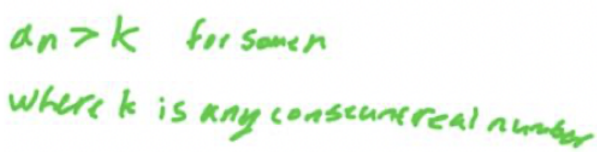
This study focuses on investigating what instructors do to support students in refining their definitions in such a way that supports them to abide by mathematical norms. Such an investigation will directly support our ongoing research project by informing instructor support materials for using our curriculum. This study will also add to the research literature on inquiry-based instruction by providing insights into how instructors can guide students to refine their drafts of definitions and potentially statements and proofs as well.

Theoretical Grounding

Instructors who teach with the ASPIRE curriculum materials are positioned as brokers (Rasmussen et al., 2009; Vroom, 2020; Zandieh et al., 2017) holding membership in the classroom community as well as having relevant knowledge about mathematical norms and concepts. In earlier work, Vroom (2020) described the role of a broker as they engage students in mathematical activity (e.g., defining) in which they aim to construct some product (e.g., a definition). In the case of defining, the broker engages in a cyclic process in which they iteratively aim to (a) make sense of a students' draft of a definition and its intended meaning in relation to how the mathematics community might interpret the draft and (b) support the students to edit the draft (in the case that it is not likely to be interpreted as the students intended). To support the edits, the broker can strategically share mathematical norms or build on the students' thinking, often creating an intellectual need (Harel, 2008; 2013) for refinement.

Harel claims that students should have an intellectual need to learn what we intend to teach them, where an intellectual need refers to a problematic situation that motivates the construction of the piece of knowledge (Harel, 2013). Thus, an instructor who aims to create intellectual needs for definition refinements would focus efforts on creating problematic situations for students. In the case of definition refinements, we see an intellectual need as referring to a problem with the draft that motivates both an edit and an understanding for why such an edit might resolve the problem. For example, the students in Vroom's (2020) study offered Figure 1A as their definition for a sequence that had "no upper bound". While explaining the meaning of the definition, the student described how it fit for the example in Figure 1B. To do so, he first sketched a horizontal line at k and then pointed out that he could find a sequence term that was greater than k (referring to the sixth term in Figure 1B). The teacher-researcher then attempted to create a problematic situation by pointing out that when the student described the definition with the example, he *first* introduced k but that his definition introduced n first and k last. Here, the teacher-researcher attempted to bring light to a problem: the structure of the definition did not match the structure of how he described his intended meaning with the picture. The teacher-research then explained that the student's meaning was clear when they explained it with the picture and suggested editing the definition so that it better fit his description. The student then altered the definition so that the variables were introduced in the same order as he introduced them with the picture, giving some evidence that the student experienced an intellectual need for refinement.

A.



$a_n > k$ for some n
where k is any constant real number

B.

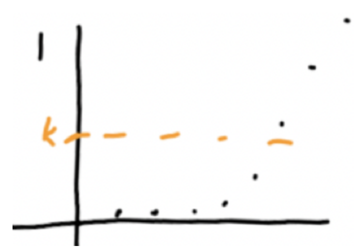


Figure 1. Students' draft of "no upper bound" definition.

Vroom's (2020) conceptualization of the broker emerged from a successful case study of a broker with a pair of students in a teaching experiment setting. This case was successful in the sense that the teacher-researcher worked with the students to refine the students' mathematical statements so that (1) the statements could be interpreted by the larger mathematical community as the students' intended and (2) the teacher-researcher seemed to create problematic situations that motivated definition refinements. Because the framework emerged in a laboratory setting, we were curious how (if at all) instructors in whole-class settings worked with students in a similar way. Specifically, in this study we aim to answer: what are instructors doing to initiate refinements of students' definitions?

Methods

For this study we investigated how three instructors across four courses guided their students through the refinement of one definition. The three instructors taught Introduction to Proof courses using curricular materials developed as part of the ASPIRE in Math project. One lesson of this curriculum focuses on mathematical language where students are guided to define several concepts and learn about the formal mathematical language that they used to do so. For this study, we focused on the instructors' moves during one of those defining tasks. In this task, students create a formal definition of a sequence they term "Eventually Constant". Students typically describe this sort of sequence as one that at some point gets "stuck" or "becomes constant". While this can be defined formally in several ways, one common formal definition is "A sequence x_n is eventually constant if there exists an $N \in \mathbb{N}$ such that for all $n > N$, $x_n = x_N$." After students develop a shared informal description of the concepts (e.g., a sequence that will get stuck at some point), students work in small groups to draft a definition. Then, students are guided to refine their draft(s) in a whole class setting. We use data from four courses, three of which were university courses and one a community college course. All four courses were conducted remotely with synchronous meetings over Zoom and with students using Google Docs during their group work. Data was collected using screen recordings of the class sessions, and small group work was captured by a researcher entering a breakout room to record the students' work. The focus task occurred over one day of the classes.

We began our analysis by watching the video of each of the defining sessions (four instructional days from the four classes). During this viewing we identified each moment that the instructor made some move to initiate a refinement of the definition. For each move we made note of the definition draft that was being refined and asked ourselves "What did the teacher do/say/ask during this time?" and "Do we see this as an attempt to create a problematic situation? Why or why not?", documenting our answers. We then documented what (if at all) refinement was made as a result of this move. As we documented each move, we constantly compared to previous moves to make note of any similarities or differences. In total we identified 15 teacher moves from the three instructors and through this constant comparison we categorized the 15 moves into three types: (1) Suggest an edit with implicit mathematical reasoning, (2) Suggest an edit with explicit mathematical reasoning, and (3) Ask a question to create a problematic situation.

Results

In what follows, we describe the three categories that we identified for what instructors were doing to motivate a refinement.

Suggest an edit with implicit mathematical reasoning

We identified instances from all three instructors where they suggested an edit with implicit mathematical reasoning (eight total instances). This type of move happened when the instructor highlighted a refinement that seemed (to us) to have mathematical value but the instructor did not explicitly state its value to the students. For instance, in one whole class discussion, an instructor highlighted a group's draft of their definition with the property: "there exists an a such that $x_a = x_{a+b}$ for all $b \in \mathbb{N}$". She read the property out loud and asked "what type of number does a have to be?" and added "we should probably indicate what type of value a is". After a student quickly responded "a natural number", the instructor agreed and edited the property by replacing "there exists an a" with "there exists an $a \in \mathbb{N}$". We see this instance of the instructor suggesting a particular edit that communicated that a is a natural number presumably because it is normative to not only quantify variables but also indicate what set the variable belongs to. This reasoning was left implicit since the instructor only emphasized the edit ("indicate what type of value a is") rather than also highlighting why this edit was advantageous.

Suggest an edit with explicit mathematical reasoning

We identified six instances (from two instructors) in which instructors suggested an edit with explicit mathematical reasoning. This type of move happened when the instructor highlighted a refinement and explained why the refinement had mathematical value. For example, one instructor was in a breakout room with two students who wrote the following draft definition in their Google Doc: "The sequence Xn is eventually constant if there exists X_m in X_n such that X_m=X_n for every n>m." The instructor said:

> "so the one thing I would say is usually when you declare a variable with 'there exists' or 'for alls' with sequences a lot of times you'll just do the subscript only. Like when you have X_m in X_n. [...] Here you say X_m in X_n, usually we don't do that, the reason why is that it sort of abuses the notation a little bit. On the one side you're thinking of a specific term sequence and on the other side you're treating it as a set. So that's a little bit of an icky way to do it."

We see this move as suggesting a particular edit ('there exists m in N' instead of 'there exists X_m in X_n') and the instructor explicitly shared the reasoning for that edit. In particular, the students' draft used sequence notation in two different ways: X_m represented a sequence term and X_n represented the sequence itself.

Ask a question to create a problematic situation

We identified only one instance in which an instructor asked a question to create a problematic situation with the students' drafts. In this instance, the students were in breakout rooms tasked with drafting a definition in a shared Google Doc. One group's first attempt read: "The sequence Xn is eventually constant if, eventually, there is a number in the sequence that repeats itself infinitely many times." The instructor added a comment to their definition that said: "Does this allow something like 1, 2, 1, 2, 1, 2, 1, 2… where 1 and 2 are repeated infinitely many times?" We see this as attempting to create a problematic situation because he highlighted a non-example of a sequence for which the property was true. Specifically, the sequence 1, 2, 1, 2, 1, 2, 1, 2… has two numbers (1 and 2) that repeat themselves infinitely many times but this sequence is not eventually constant since it never "gets stuck". This problem could motivate a need to refine the property so that it does exclude all non-examples.

Discussion

We found that the instructors in our study implemented three different moves to support definition refinements for the case of Eventually Constant Sequences. Two of these moves focused on the refinement itself (*suggest an edit with implicit mathematical reasoning* and *suggest an edit with explicit mathematical reasoning*) whereas the third move focused on a problem to motivate a need for a refinement (*ask a question to create a problematic situation*). We do not intend to claim that one move is always preferable. For instance, it might be appropriate for an instructor to suggest an edit with implicit mathematical reasoning when, for instance, the reasoning has been established and taken-as-shared within the classroom community. However, we conjecture creating problematic situations with drafts of students' definitions to be advantageous in many cases. Guided by Harel's (2008; 2013) theoretical perspective, we anticipate that focusing on the problem a refinement can solve rather than the solution itself could better support students in understanding the nuances of the formal mathematical language.

This study is an ongoing project and our results here motivated some additional questions that we wish to further explore. To start, we wonder about the context of the task. In our experience we have seen that students often create an informal definition of the Eventually Constant Sequence concept that structurally parallels a formal definition. Thus it is often the case that any needed refinements are less substantial or more stylistic. This context could explain why we did not see many instances of the last category (*ask a question to create a problematic situation*) especially in comparison to Vroom's (2020) case study. Hence, we wonder whether different defining situations afford more opportunities to create problematic situations. We are also aware that the type of move that an instructor might use to initiate a refinement could be influenced by previous classroom activities. For instance, as we mentioned above, an instructor could decide to keep the mathematical reasoning implicit since it had been established and taken-as-shared within the classroom community. With that in mind, we think it is important to also pay attention to the order the instructors use the moves and what, if any, previous norms had been established. We plan to explore these questions in future research.

Our results also suggest some practical implications. A majority of the instructor moves fell into the *suggest an edit with implicit mathematical reasoning* category. While we have discussed that this move could be appropriate in some cases, this should not be the only move instructors make. As such, when it comes to designing support materials for our curriculum, these results suggest to us that we need to better support instructors to have explicit discussion about the mathematical reasoning for edits. This will be particularly important in the defining tasks that occur early in the task sequence when relevant mathematical norms and conventions have not yet been discussed. We also see this ongoing work as contributing to efforts beyond our own materials, and in particular, we hope that this study will provide insights for inquiry-based instructors who aim to refine students' definitions, conjectures, or proofs.

Developing Network Modeling and Analysis Methods for First-Year Mathematics and STEM Student Course-Taking Sequences

Jennifer Nimtz

Jothi Ramesh
Western Washington U.

Student success is typically measured by grades in coursework and 6-year graduation rates (York, Gibson, & Rankin, 2015). The purpose of this exploratory data analysis is to develop statistical methods that will provide a deeper understanding of student success, specifically success in first-year mathematics (FYM) prerequisite courses as well as the STEM courses they serve. We consider the many possible student course-taking sequences (paths) as a complex network system. We model the paths that students take with a network of vertices (courses) and edges (links between courses) by using 10 years of registrar data to generate vertex and adjacency matrices, and associated graphical representations (e.g., heat maps and network graphs). We also will conduct relevant exploratory data analysis to determine the importance of certain mathematics courses and transitions to overall student success.

Keywords: student success, mathematics prerequisites, modeling, statistics

Introduction

Student success is typically measured by grades in coursework and 6-year graduation rates (York et al., 2015). Regarding the latter, we know that student placement and success in mathematics courses are some of the primary factors that mitigate student time to degree (Aiken, Bin, Hjorth-Jensen, & Caballero, 2020). In addition, students who have STEM interests and place into lower-level mathematics courses take longer to complete their degrees. Furthermore, they are more likely to change their majors or drop out completely (Klingbeil, 2013).

The long-term purpose of this research is to gain a deeper understanding of student success, specifically success in first-year mathematics (FYM) prerequisites as well as the STEM course they serve. To accomplish this, we consider the many possible student course-taking sequences as a complex network system. We model student course-taking sequences as paths through a network graph of vertices (courses) and edges (links between courses taken in consecutive academic terms). Next, we generate a vertex matrix (courses) and adjacency matrix (edges that link courses) from registrar data of student course taking and generate associated graphical representations (e.g., heat maps and network graphs). Lastly, we will utilize statistical analysis of networks to determine the importance of certain mathematics courses to overall student success.

In this paper, we first provide a brief background of network analysis followed by the prior use of network representations to analyze the complex system of undergraduate coursework. Second, we outline our long-term research goals and contrast our research with the prior research about using networks to analyze undergraduate coursework. Third, we present our current research results in relation to our long-term research goals. Lastly, we discuss our future research agenda in more detail.

Background

In this background section, we define what a network is, provide a brief overview of the history and uses of network analysis, and culminate with the use of networks to model undergraduate courses. Networks, represented as graphs of vertices and edges, have emerged as useful tools in the modeling and analysis of complex systems across a diverse range of applications. Vertices represent the objects of study and are illustrated by the nodes on the graph.

Edges are the links between two vertices and are illustrated by the lines or arrows connecting two vertices. Edges represent the connection or flow between the objects of study.

Networks are useful tools in a wide range of research. Kolaczyk and Csardi (2014) discussed the history and expanse of network analysis, summarized in this paragraph. Due to advances in computer science in the 1950's, the use of network analysis became prevalent in areas such as transportation, allocation of resources, and distribution of products. In this initial phase, a few sociologists also utilized networks to characterize interactions in social groups. Then, interest in network modeling and analysis increased significantly in the 1990's due to the expansion of the internet and associated social media platforms. In addition, network modeling and analysis has proved useful in research areas such as computational biology (Mason & Verwoerd, 2008), engineering (Chen, 1997), finance (Abrams, Celaya-Alcala, Baldwin, Gonda, & Chen, 2016), marketing (Webster & Morrison, 2004), neuroscience (Farahani, Karwowski, & Lighthall, 2019), political science and public health (Goodin, Moran, & Rein, 2008). Two factors have contributed to the proliferation of network modeling and analysis: the increased interest in the study of complex systems, and the ability to collect, store, and maintain large data sets. These two factors prompted the development of statistical methods to analyze large, complex, connected data sets.

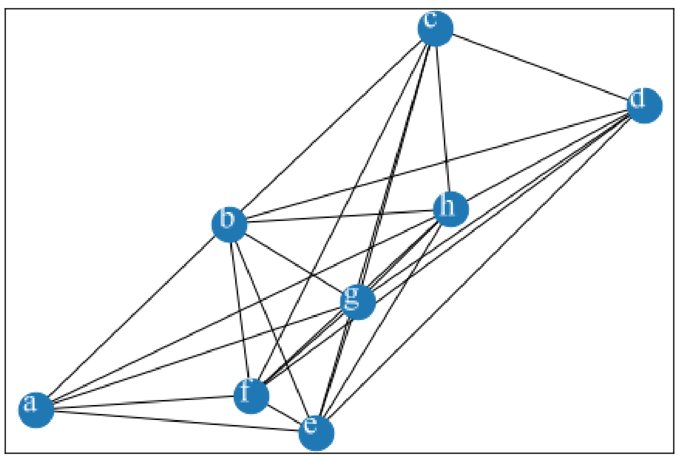

Figure 1. Network graph, G=(V,E) with vertices, V={a,b,c,d,e,f,g,h} and edges, E, that link any two vertices.

Recently, network analysis has been utilized as a method to examine the complex system of undergraduate coursework. For example, Aldrich (2015) and Ren et al. (2021) represented the intended sequences of courses using a directed network of vertices and edges in which each vertex represents a course and each edge represents a directional link between courses. To generate the course networks, university course catalogues (Aldrich, 2015) and program guides (Ren et al., 2021) can be used. In the context of undergraduate coursework network, the number of vertices represented the number of courses, and the number of edges represented the number of links between pairs of courses. They also discussed the general topology of the network by outlining the number of vertices and edges.

Long-Term Research Goals

Here, we present our long-term research goals to provide a context for our current research and results. In our research, we will utilize similar statistical methods as Aldrich (2015) and Ren et al. (2021), but our generation of the coursework network differs significantly. We define the *undergraduate course networks* presented in the referenced curriculum research as *intended* *course sequences* because those networks were generated by web-scraping data from a university course catalogue (Aldrich, 2015) and from a dental school program guide (Ren et al., 2021). In contrast, we define the *undergraduate course-taking network* we generate as the *enacted course sequences* because the network is produced from student course-taking data from a university registrar.

We currently have written a Python program to analyze registrar data of FYM course-taking, and we will expand this program to include STEM courses and General University Requirement Quantitative Reasoning courses. In our current research, we have generated a vertex matrix and adjacency matrix. Our long-term goal is to use such a vertex matrix and adjacency matrix to generate the *undergraduate course-taking network,* which will be a directed weighted network graph. In this *undergraduate course-taking network*, each vertex will represent a course and each edge will represent a directed link between a pair of courses. Each vertex will be weighted by the number of students taking that course and will contain a pie graph of the grade distribution for each course. Each edge will be weighted by the number of students who take linked pairs of courses in a sequence of terms. After generating the *undergraduate course-taking network*, we will conduct statistical analysis to determine different centrality measures of a network (e.g., degree centrality, out-degree centrality, betweenness centrality), which is discussed further in the Future Research section.

Research

To produce the *undergraduate course-taking network*, we utilized the Python programming language to generate a vertex matrix of the number of students who took each course (see Table 1) from student FYM course-taking data from a university registrar. Note that these courses are not necessarily taken in numeric order (see Figure 2). In addition, we utilized the Python programming language to generate an adjacency matrix in which each cell represents the number of students who took the sequence of the pair of courses referenced in the row (course going from) and column (course going to) (see Figures 3 & 4).

Research Questions

1. How can we represent the total number of students who take each course in a useful and flexible representation?
2. How can we represent the sequence of student course-taking in a useful and flexible representation?

Analysis

The analysis of the network of mathematics course-taking sequences is presented as follows:

1. Student course-taking is represented by a vertex matrix in which the total number of student enrollments for each course is tallied. Additional student summary data may be included in this matrix (e.g., grade distributions).
2. We generated an adjacency matrix from 10 years of registrar data. In the adjacency matrix, each cell consists of the number of students who took the sequence of the pair of courses referenced in the row (course going from) and column (course going to).

This adjacency matrix can be used in combination with the associated vertex matrix to generate a directed weighted network graph of student course-taking sequences.

Results

Our results thus far are represented in the Vertex Matrix (Table 1), Course Adjacency Matrix with Heat Map (Figure 3), and the Log Transform Adjacency Matrix with Heat Map (Figure 4). The log transform here is given by $\log_{10}(n+1)$, where n is the original number. The vertex matrix consists of a sample of FYM courses of interest and the student enrollment in those courses over a 10-year period. Note that course numbers do not necessarily indicate the prerequisite sequence. For example, a student who passes Math-90 can proceed to take Math-110 (Figure 2).

Table 1: Vertex Matrix.

Course Number	Course Name	Enrollment
090	Introductory Algebra	679
100	Quantitative Reasoning	3203
110	Functions and Algebraic Methods	5660
115	Precalculus 1	5750
116	Precalculus 2	2096
120	Calculus 1	3473
140	Business Precalculus	2334
141	Business Calculus	3270
200	Statistics	2008

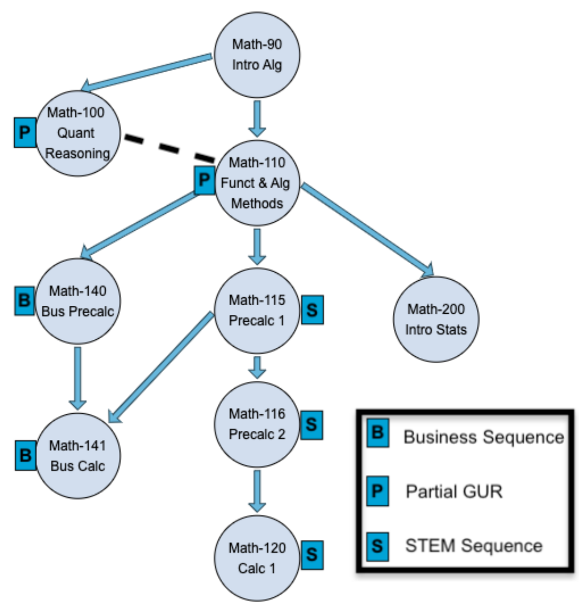

Figure 2: Intended Course Sequence.

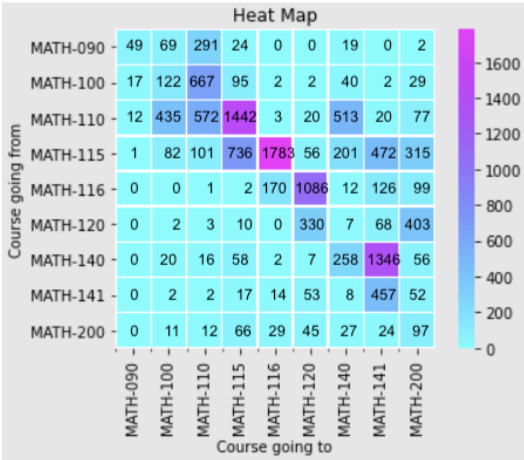

Figure 3: Course Adjacency Matrix with Heat Map

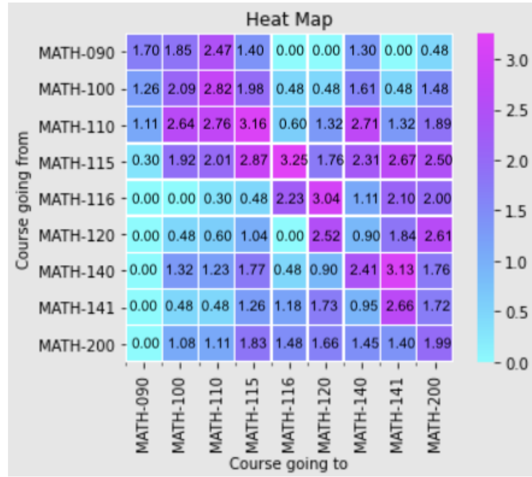

Figure 4: Log Transform of Adjacency Matrix with Heat Map

In the adjacency matrix (Figure 3), each cell consists of the number of students who took the sequence of the pair of courses referenced in the row (course going from) and column (course going to). For example, from prior data, we know that Math-110 has a higher DFW rate, so we may want to examine common course-taking sequences of those students. If we examine the row of cells indicating pairs of courses beginning with Math-110, we can determine the highest enrollment sequence pairs are [Math-110, Math-115] followed by [Math-110, Math-110]. In cell [Math-110, Math-115], we can see that 1442 students followed the STEM sequence, taking Math-110 as a prerequisite to Math-115. In cell [Math-110, Math-110], we can see that 571 students repeated Math-110, resulting in a loop in the network. Due to space limitations, we leave further interpretation to the reader and for the conference presentation.

Discussion

Our study builds on prior research that analyzed *undergraduate course networks* of *intended course sequences* generated from university course catalogues and programs of study. In contrast, we are developing methods to analyze the *undergraduate course-taking network* of *enacted course sequences* because the matrices that will be used to generate the network are produced from student course-taking data from a university registrar. The methods for generating and analyzing a directed weighted *undergraduate course-taking network* of *enacted course sequences* from actual student course-taking are the major finding of this research. Thus far, this study illustrates FYM course-taking as a vertex (course) matrix containing the number of students enrolled in the course and is useful in identifying courses with the highest enrollment. In addition, this study illustrates FYM course-taking as an adjacency matrix (transitions between pairs of courses). The adjacency matrix is useful in determining the most common course pairs taken in a sequence, which can be used to determine the emphasis of course content. The vertex matrix and adjacency matrix are generated as a first step in creating the *undergraduate course-taking network.*

Future Research

In our future research, we will conduct a network analysis on the *undergraduate course-taking network.* We will employ statistical techniques utilized by Ren et al. (2021) and Aldrich (2015) to produce the following measures of centrality: degree centrality, out-degree

degree centrality, and betweenness centrality. In the context of an undergraduate course network, these three measures of centrality signify the following: (i) degree centrality indicates the importance of a course in relation to all courses to which it is connected, (ii) out-degree centrality indicates the importance of courses in relation to those courses that follow, and (iii) betweenness centrality indicates the importance of the course in relation to the flow of information between other pairs of courses. For all three centrality measures, degree centrality, out-degree centrality, and betweenness centrality, the higher the measure, the more important the course is to an undergraduate coursework network. The degree centrality of vertices is calculated by the number of both incoming and outgoing edges to each vertex (Ren et al., 2021). On the other hand, the out-degree centrality of vertices is computed by the number of outgoing edges from each vertex (Aldrich, 2015). Lastly, the betweenness centrality is given by the extent that a vertex is situated between other pairs of vertices (Aldrich, 2015; Ren et al., 2021).

This ongoing network analysis will allow us to determine important courses in course sequences, to analyze student success in courses, and to prioritize courses in need of reform. These research techniques have the potential to apply across different departments, programs, and colleges of the university, as well as the university as a whole.

Establishing a Shared Vision of Effective Pedagogy to Sustain Networked Reform

Emilie Hancock
Central Washington University

Brent Hancock
Central Washington University

Allyson Rogan-Klyve
Central Washington University

Mark Oursland
Central Washington University

In this preliminary report, we share results from an ongoing project related to the professional development of K-12 math and science teachers in Washington state. The goal of this work is to establish and sustain a network of STEM teacher leaders who can support teachers statewide in using effective STEM pedagogy. In the project's first phase, we surveyed 290 stakeholders, including administrators, support specialists, teachers, and other community/industry partners, in order to identify attributes valued in a STEM teacher leader. Initial findings from this mixed-methods study indicated that STEM stakeholders prioritize teacher leaders' abilities to foster the incorporation of integrated, community-based STEM projects and culturally responsive pedagogy in theirs and their peers' teaching. We seek input from the RUME community on the project's second phase, in which we will study the efficacy of a particular change model in facilitating cross-institutional systemic change toward the adoption of STEM best practices.

Keywords: STEM teacher leaders, network, professional development of K-12 teachers

Networks are an established vehicle for effecting pedagogical change (Lewis, 2015). Networked communities exist in a variety of STEM education contexts; such diversity merits the investigation of a variety of network models that may contribute to large-scale pedagogical reform in STEM. For example, the Academy of Inquiry Based Learning provides a network for individual instructors seeking to adopt inquiry-based pedagogical practices in their classrooms (Yoshinobu et al., 2022), while the SEMINAL project established a network of university mathematics departments pursuing the implementation of active learning strategies in Precalculus through Calculus courses (Smith & Funk, 2021). The overarching goal of our WA-STELLAR project (NSF DUE #1950332, #2150054) is to grow and support a sustainable network of K-12 STEM instructional change agents (teacher leaders) across Washington state. Through this project, we will support the development of teacher leaders to mentor other STEM teachers in using effective STEM pedagogy (Objective 1); we will then support the systemic change efforts of the teacher leaders via network activities that promote collaboration among a range of STEM stakeholders (Objective 2).

Education networks vary in their motivations and goals, their participation and leadership structure, and their processes for catalyzing organizational change. Regardless of localized complexities, effective network collaboration is predicated on the following eight features: (1) focusing on ambitious student learning outcomes linked to effective pedagogy; (2) developing strong relationships of trust and internal accountability; (3) continuously improving practice and systems through cycles of collaborative inquiry; (4) using deliberate leadership and skilled facilitation within flat power structures; (5) frequently interacting and learning inwards; (6) connecting outwards to learn from others; (7) forming new partnership among students, teachers, families, and communities; and (8) securing adequate resources to sustain the work (Rincón-Gallardo & Fullan, 2016). In this report, we share preliminary results identifying a *stakeholder-informed* vision of "ambitious student learning outcomes linked to effective STEM pedagogy"

(Feature 1; Project Objective 1). In particular, we recognize that professional development associated with this project's second phase will only be effective if the aforementioned vision is truly *shared* amongst the network's constituents. Subsequently, we discuss implications for achieving project Objective 2 and conducting further research during this second project phase.

Theoretical Framing

This project is grounded in communities of practice theory (Wenger, 1998). Schools or districts form individual communities of practice. Through the WA-STELLAR network, we (the project leadership team) and teacher leaders act as *brokers* (Wenger, 1998) between these communities by translating, aligning, and facilitating coordination of perspectives, creating the possibility for collective meaning-making. Teachers' instructional strategies are simultaneously influenced by obligations to the discipline, themselves, others, and the institution or school (Herbst & Chazan, 2012). As such, changing practice is operationalized as "both building on existing instructional situations and breaching with some of their norms" (p. 611). With teachers from schools and districts across Washington state, the WA-STELLAR network can serve as a tool to breach existing norms while accounting for existing conditions. The network can unify strategies for supporting student success by leveraging the strengths of all members.

Methods

Research Questions and Design

The following research questions guided the first phase of this project (Objective 1) in order to determine what attributes WA-STELLAR network stakeholders value in a STEM teacher leader, and what program components the stakeholders view as likely to develop these attributes:

RQ 1: *What are principles and practices that advance STEM education and that a STEM Leadership program can support?*

RQ 2: *Who is the target audience for a STEM Leadership program?*

RQ 3: *What are the skills, certifications, and responsibilities necessary for an effective STEM leader, thus establishing guidelines for program curriculum?*

Utilizing a mixed-methods approach, we first surveyed 290 STEM stakeholders from four key groups: administrators, STEM support specialists, STEM teachers, and other STEM community and industry partners. Follow-up emails and phone interviews were conducted with seven survey participants, with four additional survey participants attending in a focus group. This report focuses on the first and a portion of the third research questions, as these results offer insight into how we might establish shared vision for "effective STEM pedagogy," an *essential feature* (Rincón-Gallardo & Fullan, 2016) needed to sustain the work of the WA-STELLAR network.

Participants and Sampling

To answer the research questions from the perspective of STEM stakeholders in Washington state, we developed and administered a survey online via Qualtrics. Stratified convenience sampling was employed to collect survey data. Members of the Apple STEM network, members of the South Central Washington STEM network, members of the Washington state Science Teachers Association, and graduates of our undergraduate STEM teacher preparation program were contacted until a minimum of 100 responses were received from STEM teachers and at least ten responses were received for each of the three other subgroups of stakeholders. In total, 290 participants consented to be part of the study and completed at least part of the survey. Their positions are summarized in Table 1.

Table 1. Summary of survey participants' educational positions.

Educational Position/Role	Count
Administration (District Superintendents, School Principals)	13
STEM Support Specialists (Curriculum and STEM Specialists, Coaches)	18
STEM Teachers (Math, Science, Technology, Computer Science)	208
STEM Partners (STEM community and industry advisors, Other)	51

Quantitative and Qualitative Data Sources

The skills and responsibilities included in quantitative survey questions were based on the characteristics of effective STEM leaders identified in literature on the topic (The Aspen Institute, 2014; National Council of Supervisors of Mathematics, 2008; Sublette, 2013; Tanenbaum, 2016; Toncheff, 2020). Prior to administering the survey, we incorporated feedback from other STEM educators to establish face validity (Gravetter & Forzano, 2012). In this preliminary report, we focus on results from two questions pertaining to establishing a shared vision of effective STEM pedagogy.

Qualitative data was collected to supplement and triangulate quantitative results from the survey and consisted of the following three data sources. At the end of the survey, participants were given an opportunity to share their thoughts in an open-ended question: *What would you like to tell us about STEM education? You can explain responses, add new ideas, or ask questions*. Follow-up phone and email interviews were conducted with seven survey respondents including representatives from all categories of stakeholders. Finally, we organized one focus group with four survey respondents including three STEM teachers and one STEM coordinator.

Results

Thematic Analysis of Qualitative Sources

In addition to triangulation of three data sources, we used analyst triangulation methods to strengthen the credibility of inquiry (Patton, 2002). Two of the authors independently analyzed qualitative sources, identifying repeated themes within and across participant subgroups. The two researchers then met to compare findings and understand any inconsistencies, generating a final list of four themes; three are related to a shared vision of effective STEM pedagogy:

1. All stakeholder subgroups stated STEM content needs to be integrated across disciplines.
2. All stakeholder subgroups identified the importance of promoting equity and diversity in STEM education. Several responses suggested meaningful community partnerships and project-based learning might help address equity issues.
3. From a curriculum standpoint, we need rich and engaging activities as well as meaningful applications connecting to industry.

Participant responses related to these themes are integrated into the next results section.

Quantitative Survey Results

In question one of the survey, participants were asked to rank a list of statements in order of importance for advancing STEM education. Table 2 provides average rankings of each statement for each stakeholder subgroup of participants. To determine the overall ranking, each stakeholder subgroup was treated as equally weighting the overall ranking. Thus, the ranking provided in each row of the 'Average' column is an unweighted average of the four numbers to its right.

Table 2. Statement rankings in order of importance for advancing STEM education (1=most important, 5=least).

Statement	Rank	Average	Admin	Support Specialists	Teachers	Partners
A. STEM projects should be integrated into all STEM courses.	1	1.89	1.85	1.71	2.14	1.86
B. STEM education principles are best advanced by hiring effective math, science teachers.	2	2.14	2.08	1.93	1.91	2.62
C. STEM education should focus on Career and Technical Education.	4	3.32	3.08	3.50	3.37	3.33
D. STEM education principles are best advanced through programs with industry, community partners.	3	3.15	3.46	3.29	3.13	2.71
E. STEM education principles are best advanced through extracurricular programs.	5	4.51	4.54	4.57	4.46	4.48

For all stakeholders, the two most important principles/practices for advancing STEM education were integrating STEM projects into all STEM courses (Statement A) and hiring effective math and science teachers (Statement B). These findings were further triangulated with qualitative results, in that all stakeholder subgroups mentioned that STEM content needs to be integrated across disciplines. In particular, as one STEM coach/coordinator expressed, “The trend and long-standing practice of trying to do each one of these [disciplines] exclusive of the other is the biggest hurdle we face.” Community partners, CTE support, and extracurricular programs help foster and grow STEM learning experiences; however, effectively implemented, integrated STEM projects must be the foundation of STEM education. Any STEM program must have integrated, project-based learning at its center. Additionally, STEM partners advocated for ‘integrating community projects, participatory science, and industry partners into schools.’

In question four of the survey, participants were asked: *How important are the following responsibilities for a STEM leader?* Table 3 provides a weighted average for each stakeholder subgroup and each responsibility. Each participant’s response was assigned one of the following weights: Extremely Important → 1; Moderately Important → 0.5; Not at all Important → 0. A score close to 0 indicates the subgroup views the feature as less important. A score closer to 1 indicates the subgroup views the feature as more important.

The most highly valued STEM leader responsibility was utilizing culturally responsive teaching practices. This finding was also substantiated in open-ended responses, where participants voiced a need for promoting diversity and equity in STEM education. For instance, one of the STEM coach/coordinator participants expressed “how important it is for students to see professionals they identify with in STEM professions. In order to draw more diversity into the STEM field, we need more STEM leaders with diverse backgrounds. Programs should promote diversity.” One STEM teacher felt that “STEM education that is hands-on problem solving has a better chance of bridging gaps with equity issues and schools that struggle with cultural responsiveness, better than most any other field.”

Table 3. Weighted averages for different stakeholder subgroups addressing question four.

Responsibility	Admin	Support Specialists	Teachers	Partners
Lead Professional Development in Designing and Teaching Problem-based Instruction	0.78	0.76	0.67	0.72
Initiate and Administrate Community-based STEM Projects	0.73	0.71	0.62	0.73
Coach colleagues in effective STEM Teaching	0.84	0.97	0.76	0.82
Coordinate STEM education district curriculum and programs	0.75	0.88	0.72	0.78
Lead professional development in integrating engineering practices for STEM courses	0.80	0.91	0.68	0.70
Utilizing culturally responsive teaching practices	0.90	0.94	0.79	0.87

Additionally, administrators, STEM support specialists, and community and industry partners identified initiating and administrating *community-based* STEM projects as an important responsibility of STEM leaders. However, STEM teachers felt support from their district and other STEM educators is essential to assist STEM leaders in both using STEM projects in their own classrooms and becoming STEM champions of district and community-wide projects.

Discussion and Implications

These results evidenced the need to redesign our (previously) traditional, content-focused master's degree in mathematics to train teacher leaders (Objective 1) in a way that better aligns with the values of the larger collective of STEM stakeholders. In our talk, we plan to provide a brief overview of the novel graduate STEM Leadership program we designed to serve as a *network hub* (Bryk et al., 2015) for the WA-STELLAR network.

As we move toward the next phase of our project (Objective 2), we will implement the Keck/PKAL change model (Elrod & Kezar, 2016) to facilitate the work of the WA-STELLAR network. This model has been used in higher education settings to coordinate multiple stakeholders and has eight stages, the first of which is: *establishing a shared vision for improving STEM student learning outcomes and success*. This next phase of our project will be guided by the research question: *What is the efficacy of the Keck/PKAL model in facilitating cross-institutional systemic change toward the adoption of STEM best practices?*

Our intended questions for the RUME audience concern ways in which we can leverage preliminary results to *maintain* a vision of effective pedagogy throughout implementation of network activities that is shared by all network stakeholders. We are interested in identifying potential opportunities/barriers to implementation that might impact the efficacy of our implementation of the Keck/PKAL model.

Introductory Calculus Instructional Practices Around Student Prior Knowledge

Amanda Mohammad Mirzaei
University of Delaware

Calculus is a pivotal course for postsecondary students and serves as a gatekeeper to advanced mathematics courses and STEM majors. This study considers the frequency with which instructors report engaging in practices that may help to strengthen introductory calculus students' prior knowledge. Using survey responses (N=136), this study reports on results from a set of questions that measures these practices. Results illustrate that instructors may use various practices to address students' prior knowledge in their introductory calculus classroom. Additionally, instructors provided examples of practices they use in response to student prior knowledge that are not explicitly considered in the literature. This implies that a closer look at what is happening in the classrooms may be key in understanding the current state of how instructors are dealing with student prior knowledge in introductory calculus.

Keywords: Introductory Calculus, Instruction, Student Prior Knowledge

Introductory calculus is an essential course for many students; it can bridge the secondary-tertiary transition. As such, it is often a culmination of students' K-12 knowledge and a gatekeeper to more advanced mathematics (Bressoud, 2015; Rasmussen et al., 2019). Despite its importance, students continue to struggle to make it through the course in postsecondary settings (Bressoud et al., 2013). One issue facing instructors at the postsecondary level, many of whom have been trained as mathematicians and not as teachers, is the varying levels of prior knowledge that students have when they enter the classroom. One reason for the difference in students' prior knowledge might be the various paths to get to postsecondary introductory calculus (i.e., having seen calculus in high school or not) (Sadler & Sonnert, 2018; Schraeder et al., 2019). Research has shown that student understanding of prerequisite knowledge connects to student success in calculus (Rasmussen et al., 2019); therefore, it is important to understand how instructors engage in practices that support the development of students' prior knowledge. Studying instructional practices that may strengthen student prior knowledge can help researchers understand more deeply practices that might be leveraged in the classroom to help more students succeed.

Theoretical Background

Introductory Calculus Instruction

Despite research on the impacts of and barriers to success in postsecondary calculus, mathematics instruction at the postsecondary level remains comparatively unexamined (Speer et al., 2010). Some researchers have looked at the instructional format in calculus, finding that calculus classes typically feature lecture and demonstration (Biza et al., 2016; Larsen et al., 2015). Other researchers have shown that instruction in introductory calculus classrooms may be more varied. For example, while lecture continues to be the most common mode of instruction for postsecondary mathematics, recent arguments suggest that this mode can help to model mathematical discourse (Viirman, 2021). In addition, Bressoud and Rasmussen (2015) found that while university instructors considered themselves fairly traditional (i.e., they thought that calculus students learned best from clear, organized lectures), they were open to trying other instructional approaches. Finally, several studies have pointed towards instructional practices in calculus courses that move away from lecture; recent work in math and related STEM fields has shown that university faculty do attempt to combine content- and student-centered practices and that these practices increase student achievement (Bressoud & Rasmussen, 2015; Hovey et al., 2019; Rasmussen et al., 2019; Tang & Titus, 2002).

Prior Knowledge & Introductory Calculus

In my dissertation study, I frame prior mathematics knowledge as the mathematical reasoning and skills students bring into the classroom from their previous mathematics classes or experiences. I draw here from Tobias' (1994) definition of domain knowledge: "domain knowledge deals with familiarity with general information in an area, even though it may not be specifically referred to in a particular passage" (p.39). A key difference between my definition of prior mathematical knowledge and Tobias' definition of domain knowledge is that I choose to include the idea of 'mathematical experiences' that may fall outside mathematics content. I borrow the concept of mathematical experiences as part of prior knowledge from Campbell et al. (2020), who put forth "how students understand core ideas based on their own lived and cultural experiences" (p. 68) as their definition of prior knowledge. By combining these definitions of prior knowledge, I can consider students' specific mathematics content exposure and how this exposure happened (e.g., procedural instruction in algebra courses). I also conceptualize prior mathematics knowledge as distinct from prerequisite knowledge because not all prior mathematics knowledge is important for calculus understanding.

One reason that instructional support of student prior knowledge is important is that it allows students to connect old and new ideas, creating opportunities to make sense of them. Neumann (2014) argues that student prior knowledge is brought to the surface in encountering new ideas. Furthermore, learning occurs when this prior knowledge and new ideas are worked through together. One way to understand where opportunities for prior knowledge and new ideas to be worked together is to examine instructional practices.

Building on Neumann's (2014) claims, Campbell et al. (2017) developed a framework to study how postsecondary courses might cluster by pedagogies and included instructional attention to supporting prior knowledge in their pedagogical characterizations. They found that both lecture and active learning strategies can be used to support student prior knowledge. Campbell et al. (2020) explain that while strides have been made in postsecondary institutions to have student-centered classrooms (which may promote discussions and use of prior knowledge), instructor attention to prior knowledge in college classrooms is still uncommon. This line of inquiry provides evidence that support of prior knowledge (though perhaps rare) does occur in postsecondary classrooms and that there may be observable instructional practices among those who consider prior knowledge in their instruction. I further this line of inquiry by asking the following research question: *How and to what extent do introductory calculus instructors report engaging in practices that promote students to make mathematical connections to their prior knowledge?* Results that answer this question help us better understand if and how these practices are being put into use by introductory calculus instructors around the U.S.

Methods

Participants and Procedures

The data for this study were collected using a survey distributed to postsecondary instructors at institutions across the United States in Spring 2022. The population of interest for this survey included full-time instructors at 4-year universities with a Carnegie classification of R1, R2, Doctoral, or Arts & Sciences Focused Baccalaureate who have taught introductory calculus at least twice. The choice to sample full-time instructors at these types of institutions was informed by research on where most students take introductory calculus (Blair et al., 2015). After excluding responses that did not participate past questions about demographic information, there was an analytic sample of 142 respondents. I received 42 responses from R1 instructors, 32 responses from R2 instructors, 39 responses from Doctoral institution instructors, and 29 responses from instructors at Baccalaureate Arts & Sciences focused institutions. In addition, 61 participants identified as female, 79 participants identified as male, 1 participant identified as non-binary, and 1 participant chose not to disclose gender identity. 13 participants identified as Asian, 3 participants identified as Black or African American, 117 participants identified as White, and 8 participants chose to not identify their race. In addition, 70 participants identified as Tenured Faculty, 15 as Tenure-Track Faculty, 57 participants as other full-time faculty. Finally, 23 participants indicated that they had taught introductory calculus 2-5 times before the survey, 32 had taught the course 6-10 times, and 87 had taught it more than 10 times.

Survey Construction

The survey data used here was intended to capture how often instructors engaged in practices that have been theorized to strengthen student prior knowledge. I developed a set of questions to measure this construct, drawing from the C-SAIL Mathematics Teacher Survey (California Version, 2017; Edgerton & Desimone, 2019). As written, this survey did not specifically measure practices that engage student prior knowledge. However, it was appropriate for this purpose because the questions were structured and validated to ask about instructional practices. I selected specific items based on theoretical grounding in prior literature. For example, I chose items asking about discourse in the classroom, teaching foundational skills, and presentation of multiple strategies (Chappell & Killpatrick, 2003). As the C-SAIL Mathematics Teacher Survey was written primarily for use in K-12 classrooms, I adjusted wording for the calculus and postsecondary contexts when necessary. It included 12 items measuring frequency on a 5-point Likert scale that indicated instructors engaged in these practices: Never, Once or Twice a Semester, Once or Twice a Month, Once a Week, or Almost Every Class Session. A higher score indicates that an instructor engages in the practice more often.

Additionally, data presented here was gathered from a single open-ended question at the close of the survey, "How, if at all, is your instruction affected by the mathematical understanding students bring when they *come into* your class at the start of the semester?" This question was intended to gather information on any instructional practices that my survey questions may not have caught.

Analysis

Analysis for this set of survey data occurred along three lines. First, de-identified data from the participants was used to validate the survey. Second, the survey data were analyzed to understand which practices instructors used more frequently. For these analyses, only data from instructors who had completed the full set of questions was considered (N=136). Finally, qualitative data was open-coded (Corbin & Strauss, 2014), to understand additional practices espoused by instructors; 127 instructors responded to this question.

Results

Reliability

Internal consistency of the items was analyzed using a correlation matrix and Cronbach's alpha. Inspection of the correlation matrix showed that all items except for one ("How often do you have students solve practice problems using explanations or solution strategies you have modeled in class?") had correlation coefficients greater than 0.3. The one item with no correlation coefficients greater than 0.3 was dropped from the analysis, leaving 11 items for analysis. These 11-items had a high level of internal consistency, as determined by Cronbach's alpha of 0.81.

Survey Response Instructional Practices

Overall, participants in this sample reported that they engaged in some form of instructional practice that may strengthen student prior knowledge. I calculated a composite score for each participant by averaging their item scores. I then calculated the mean across the participant sample. The mean was 3.77, indicating instructors in my sample participate in some of these instructional practices between once or twice a month and once a week. Additionally, there were practices that instructors were engaging in less or more (see Table 1). For example, instructors reported assessing students in prerequisite skills the least, with a mean of 2.93 (nearly once or twice a month). They also reported most often building calculus knowledge by connecting it to prior knowledge, with a mean of 4.42 (between once a week and every class).

Interestingly, the lower reported practices seem to align with a more procedural approach to strengthening student prior knowledge (e.g., reteaching or simplification of problems). In contrast, the higher reported practices involved a less procedural approach (e.g., engaging in discourse, connecting calculus content to students' experiences). Interestingly a one-way ANOVA showed no significant difference between instructors at different institution types for each item or across items. This implies that regardless of institution type instructors are engaging in similar practices.

Table 1. Means for Instructional Practices for Student Prior Knowledge.

"On average, across the span of a semester, how often do you engage in the following practices in your introductory calculus course?" (N=136)

Practice	Mean	Std. Deviation
Build calculus content by connecting it to prior knowledge	4.42	0.80
Correct or refine students' use of language when they are presenting their ideas	4.14	0.91
Provide opportunities for students to discuss their mathematical reasoning in class	4.20	1.08
Assess students in procedural skills taught prior to calculus	2.93	1.26
Reteach content using simpler numbers if students are struggling	3.47	1.15
Teach foundational skills students have not yet mastered	3.29	1.01
Have students apply prerequisite mathematics skills in the context of calculus concepts	4.40	0.82
Simplify the context of word problems by re-writing them	3.07	1.36

Present multiple solution strategies for a given problem or problem type	3.84	0.83
When a problem can be solved multiple ways, use strategies that students most often use	4.07	0.93
Connect calculus to students' experiences	3.68	1.01

Short Answer Responses

During the open coding of the short-answer responses to the question, "How, if at all, is your instruction affected by the mathematical understanding students bring when they *come into* your class at the start of the semester?" several themes emerged about how introductory calculus instructors perceive changes to their instruction based on their understanding of students' prior knowledge. Initially, this coding prompted me to divide the responses into five categories: instructors who said that their instruction was affected and gave me specific examples, instructors who said that their instruction was affected but gave me no or vague examples of instruction, instructors who said that it did not affect their instruction, instructors who gave an unclear response, and instructors who gave a student-focused response. Many (71 out of the 172 responses), instructors provided examples of instruction they engaged in response to students' prior mathematical knowledge. Although many of these align with the surveyed practices, a few new ideas came up. For example, explicit review was a common response. One respondent explains, "I assume most students need a "reminder" of the prerequisite topics. If they ask [or] seem to need more I do more review as part of my in-class explanations of problems." In addition, many instructors seemed to anticipate and build review into their plans for the course. This indicates that instructors can articulate practices they engage in to activate and connect to student prior knowledge and that they may do so in different ways than the literature has previously noted.

Discussion

These results are emerging as part of a more extensive dissertation study but indicate that introductory calculus instructors are mindful of the need to activate students' prior knowledge in the course. Additionally, they report engaging in practices that might help students strengthen their prior knowledge during introductory calculus instruction. Further, they might be engaging in more and less procedural instruction to support students (e.g., reteaching prerequisite skills versus engaging students in discourse). This finding is in line with previous research (Hovey et al., 2019; Rasmussen et al., 2019). Qualitative data supports the idea that instructors can identify and describe practices they engage in to respond to students' prior knowledge. Future research is needed to understand exactly how these practices are implemented and which are most accessible or provide the best student outcomes. Work in this vein can help the field move towards an incremental improvement approach (e.g., Litke, 2020) to better support calculus students without asking current instructors to overhaul their entire instructional approaches to introductory calculus.

Characterizing College Instructors' Attention During Peer Observations

Emily Jones
UT San Antonio

Stephen Lee
UT San Antonio

Jessica Gehrtz
UT San Antonio

Priya V. Prasad
UT San Antonio

Research has highlighted that actively involving students during instruction can lead to positive outcomes for students. However, college mathematics instructors may need support to develop the knowledge and skills necessary to effectively implement this type of instruction. This study looks at how college algebra instructors in a grant-supported professional learning community (PLC) focus on different aspects of their own and others' teaching. We leverage the instructional triangle as an analytical framework to characterize the foci of participants' observations. We analyzed PLC meetings where participants reported on specific aspects of each other's observed classes. Our analysis revealed that instructors each had a primary focus that drove their observations. We anticipate these different foci will inform future PLC meetings and lead to new questions about instructor thinking, and to continued development of the instructional triangle.

Keywords: Instructional Triangle, Peer Observations, Professional Learning Community

Research has repeatedly emphasized that teaching that actively engages students can lead to improved learning outcomes and conceptual understanding for students (e.g., Eddy & Hogan, 2014; Freeman et al., 2014; Kogan & Laursen, 2014; Laursen et al., 2014; Theobald et al., 2020). However, lecture remains a common form of instruction in many college mathematics classes (Apkarian et al., 2021; Stains et al., 2018). As such, it is important to support college mathematics faculty in developing the knowledge and skills necessary for teaching in a way that centers students and their thinking and moves beyond lecture.

This study is part of a larger ongoing funded project of collaborative instructional improvement at the university level, aiming to support the implementation of evidence-based instructional practices that actively engage students with the course content (funding information blinded for proposal). The project is a professional development experience for the instructors of all sections of a university-level college algebra course at a single institution. As part of this project, instructors work as a group to implement Continuous Improvement cycles (Berk & Hiebert, 2009) to develop and facilitate lessons on particular course topics. This process closely mirrors Lesson Study in that instructors work together to develop lessons, observe each other's lesson facilitation by watching video recordings, and then reflect on and revise the lessons (Dick et al., 2022). Instructors chose to create and use Desmos Classroom activities as a way to incorporate active learning in their teaching. Although instructors differed in how they used these activities (with some soliciting and leveraging student thinking more than others), they all gave students time to work individually or in small groups before discussing the activities in class. Notably, no instructors felt that they needed to lead students through the activities themselves.

This study centers on the discussions surrounding participants' observations of their peers' teaching. These observations were conducted in the style of a video club (e.g., Sherin & van Es, 2005), with each instructor watching the recording of another instructor's class and choosing clips to highlight for the whole group. Our research aims to answer the following question: What do college mathematics instructors notice when observing each other's teaching?

Theoretical and Analytic Frameworks

Teacher noticing informed the conception, data collection and analysis of this study. Noticing occurs when a teacher identifies important instances in a teaching situation, and then works to make sense of them (Jacobs et al., 2010; Sherin & van Es, 2005). Research on teacher noticing has highlighted that expert teachers tend to focus on noteworthy events, provide interpretive comments, and make connections between student thinking and pedagogical moves. In contrast, teachers with less developed noticing skills focus on general impressions and provide descriptive or evaluative comments about what was observed (van Es, 2011).

For this study, we used the "instructional triangle" as our analytic framework to capture what instructors were attending to as they observed one another's classes. Cohen and Ball (2001) argued that instruction consists of "interactions among teachers and students around content, in environments" (p. 122). These three components (teacher, students, content) are often represented as the vertices of the Instructional Triangle, with the edges of the triangle representing the relationships between each of these elements.

Recent research examining instruction at the college level has leveraged the Instructional Triangle to analyze instructors' reflections and discussions during an online working group centered on the teaching of Abstract Algebra using inquiry-oriented instruction (Kelley & Johnson, 2022). Specifically, Kelley and Johnson (2022) categorized instructors' comments as focused on the instructor, students, or mathematical content, and then connected this to instructors' roles during discussion in the working group. They found that over the course of the working group that individual instructor's foci shifted in different ways, but both instructors demonstrated a shift from a focus on content to a focus on the relationship between content and students. Our research aims to characterize instructors' foci when observing another instructor teaching a target lesson that was collaboratively developed, and then to use what we learn to inform how to support shifts in participant discussion for future observations.

Methods

The participants were four college algebra instructors at a large university who met weekly in a professional learning community (PLC) to share and discuss video clips of classroom observations and revise course curriculum for future semesters. For this study, we first recorded each instructor teaching an online lesson on algebraic properties. The PLC facilitators (who are the project's principal investigators) then asked participants to watch the video-recording of another participant teaching this lesson and select clips that caught their attention before the next meeting. Participants were paired, each watching their partner's recorded lecture in order to highlight specific aspects of each other's teaching. Participants were asked to consider things that would help improve the lessons for future classes and to identify any other interesting aspects of the teaching. At the next PLC meeting, participants showcased what they noticed from recordings of each other teaching this lesson, following a video club format. We then repeated this process for the lesson on fractions and the lesson on factoring. We recorded and transcribed the PLC meetings for analysis.

We utilized the Instructional Triangle (Cohen & Ball, 2001) to generate and assign codes to both the selected video clips and the participants' observations immediately following each video clip. Our aim was to gain insight into which aspects of a clip the participant was focusing on. We coded segments for the participants' focus on mathematical Content (C), Teachers (T), Students (S), and the interactions between the three: Teacher-Content interactions (CT), Student-Content interactions (CS), and Teacher-Student interactions (TS). We also differentiated between participant focus on teacher-student interactions about specific content, such as an instructor answering a content-related question (Teacher-Student Content interactions; TSC), and teacher-student interactions that were not explicitly related to content, such as discussions about classroom procedure or the instructor validating a student's contribution to the class discussion (Teacher-Student Non-Content interactions; TSN). Another addition we made to our codebook was creating the Content-Teacher-Student (CTS) code, which captured the participant tying all three corners of the instructional triangle together at once. This code differs from TSC by emphasizing the ways in which all three vertices interact at once, with each vertex engaging with the other two equally, while TSC highlights interactions between students and teachers where they are focusing on each other rather than engaging with the content individually.

The first and second author independently coded the transcripts, and then met to discuss all coding decisions. After reconciling all coding decisions, we calculated the frequency of codes that arose from each participant's comments about the video clips. By analyzing these frequencies and trends, we were able to identify focus profiles for each of the instructors.

Results: Participant Focus Profiles

Our data analysis allowed us to identify three distinct focus profiles demonstrated by the four participants, including a profile focused on Non-Content Teacher-Student interactions, a profile on Content-Teacher interactions, and a profile focused on Content interactions. In this paper, we provide a brief summary of each of the three profiles based on the participants' discussion from the algebraic properties lesson. Table 1 shows the frequency of specific codes assigned to each participants' discussion during the PLC meeting, highlighting what they noticed while observing the algebraic properties lesson.

Table 1. Frequency of Codes for Each Participant's Discussion on the Algebraic Properties Lesson

Participant		C	CS	CT	CTS	S	T	TSC	TSN	Total

Shay	*n*	0	0	10	1	1	1	0	4	17
	%	0.0	0.0	58.8	5.9	5.9	5.9	0.0	23.5	100.0

Focus on Non-Content Teacher-Student Interactions

Two participants, Nicholas and Alex (pseudonyms), tended to focus on Non-Content Teacher-Student interactions (TSN) as more than 65% of their discussion about the video clips were coded as such. Interestingly, both Nicholas and Alex appeared to have a secondary focus on the Teacher category, with 25% of Nicholas' and 13% of Alex's contributions receiving Teacher codes (T). Because of this, we characterized Nicholas and Alex as primarily concerned with the ways in which teachers conduct themselves in the classroom, and the interactions they have with students that are not related to specific pieces of content.

We find it interesting that these participants were so similar in their foci, because the other participants had very different foci in their discussions about the observations. We hypothesize that similar priorities and strategies between Alex and Nicholas' teaching may have contributed to the similarity of their foci during the video club meetings. For example, Alex spoke a lot about Nicholas' (and other participants') approach to gathering buy-in from students, saying, "He said, 'You know, no matter how we feel about the group work, there's a reason we're doing it.' He's… providing that… explanation of why we should do the group work [for students]." Alex also responded to Shay's comments about a clip of Ivy's teaching, saying, "I kind of just agree with everything that was said. I like, a lot the way that [Ivy] is kind of candid with her students. I think that helps encourage the buy-in. She just tells it like it is."

Similarly, Nicholas spoke about Alex's (and others') efforts to motivate students and the response from students those efforts garnered. Responding to a clip of Alex's teaching, Nicholas commented, "I liked that he actually gets his students to talk and discuss." Nicholas also responded to a clip of Ivy's teaching that Shay presented by saying:

> I think in general, even if we feel like we were on rinse and repeat, the more we say, 'This is why we're doing this this way. This is what we're trying to accomplish.' I think… it's enough throughout the semester to get the buy-in from the students … I think [Ivy] handled that perfectly - I always get the pushback of, 'Well, you're not teaching, you're not explaining something.' Well, we are. We're interacting and we're doing it together.

This focus on the interactions between teachers and students, and how those interactions can encourage students to participate fully in class, was a major component of Alex and Nicholas' contributions to the discussion.

Although Nicholas and Alex tended to focus a similar amount on Non-Content Teacher-Student interactions, we did identify some differences between Nicholas and Alex based on what else they focused on during the discussion of video clips. Nicholas' focus on Non-Content Teacher-Student interactions and Teacher comments accounted for 93.75% of his contributions, while Alex's focus on the same two categories accounted for only 78.26% of his. The remaining contributions from Nicholas fell under Teacher-Content Interactions (CT), while Alex's were spread between CS, CTS, and S. Note all of these codes involve interactions with students, which highlights that Alex was also concerned with the students' experience. This difference between Nicholas and Alex may be influenced by their standing within their instructional team. Nicholas is a course coordinator, so his primary focus on instructors may follow from that. Alex is a younger instructor, with preparation in secondary mathematics teaching and a graduate background in mathematics education research. We hypothesize that this may contribute to his focus on the experience of the students.

Focus on Content-Teacher Interactions

The second profile we identified is demonstrated by Shay (pseudonym), who was primarily focused on Content-Teacher interactions, with 59% of her observations focusing on the relationship between the instructor and the content they presented. Shay was secondarily focused on Non-Content Teacher-Student Interactions, with 24% of her contributions receiving that code.

A large portion of Shay's focus on Content-Teacher interactions was directed inward, reflecting on her own teaching. For example, after observing Ivy teach the algebraic properties lesson, Shay said:

> That's something that I never thought of … I'm like, when was the last time I actually did … teach the properties? And I'm like, it's been a really long time. So being able to see how … [Ivy] talked about these two [properties] was really nice.

We characterized Shay as Content-Teacher Focused because of this emphasis on her own and other instructors' relationship or interaction with the content they teach.

Focus on Content Interactions

Our third profile that we identified was characterized by Ivy's (pseudonym) primary focus on content and the ways in which individuals in the classroom interacted with said content. In particular, over 65% of Ivy's contributions were anchored to content, with the Content code consisting of 18% of her comments, Content-Teacher-Student interactions as 12% of her comments, and the codes Teacher-Student Content interactions and Student-Content interactions codes accounting for 6% each of her comments. Ivy's focus can be illustrated by this quote:

> Students got answers of 16, 8, 10, and 1, and [Shay] was asking for input … 'Would you mind sharing how you got your answer?' And that was after they had already established that 16 was the correct answer. So students actually did start answering and saying that this is what they did.

Because Ivy's focus is on the content in relation to both the instructor's words - "Would you mind sharing how you got your answer?" - and on the students' engagement with the content - "Students actually did start answering and saying this is what they did" - we characterize Ivy's contributions as being Content-Focused. We distinguish this from the Content-Teacher Interactions profile described above because Shay was focused on content and instructors, whereas Ivy was focused on both instructors' and students' relationship with the content.

Discussion

The diversity of participant foci in our results offers the opportunity to look into and pose questions about why certain instructors had the focus they did. We saw Alex and Nicholas both had a focus on Non-Content Teacher-Student interactions in their observations. This makes us wonder if they may have taken this observation opportunity to look for ways to further develop their pedagogical skills, specifically in relation to their interactions with students. This begs the following questions for further study: 1) Does this focus come from a perceived lack of those skills or from a perceived strength in those skills?, and 2) How does this impact the instructors' approach to soliciting and leveraging student thinking in class?

Further, during our coding and analysis of the transcripts we noticed a consistent focus of pedagogical observations relating to the use of technology, such as Desmos and Zoom. The prevalence of these observations leads us to consider the potential of adding technology as a fourth vertex to the instructional triangle in our analytic framework, especially for classes conducted online. Further investigation on the interactions between the three elements of the instructional triangle and technology could highlight how the mechanics within Desmos can be used to elicit student thinking in different ways. Finally, we intend to explore further the ways that instructors differ in their pedagogical and content priorities and their interactions in order to better shape professional development opportunities within the project and better support PLC interactions and discussions in the future.

A Survey of Programs Preparing Graduate Students to Teach Undergraduate Mathematics

Emily Braley
Johns Hopkins University

Jack Bookman
Duke University

Jessica Gehrtz
University of Texas at San Antonio

Natasha Speer
The University of Maine

In the last decade there has been a concerted effort to improve the preparation of graduate students for teaching undergraduate mathematics. Now, it is important to gauge the current state of the national landscape of graduate teaching assistant (GTA) professional development for teaching (PDT) and to assess the current needs of the community. To this end, a census survey was conducted in Fall 2021 of Ph.D-granting mathematics departments in the US. The survey followed up and extended a similar survey conducted in 2014. Some survey questions were duplicated, while others probed more deeply into the depth and extent of the GTA PDT being offered. In this paper we compare some results from the surveys, comment on how the landscape of GTA PDT has changed, and highlight areas that deserve additional attention moving forward.

Keywords: teaching professional development; graduate student instructors; teaching assistants

The need to improve success, retention, and graduation rates of undergraduate students in science, technology, engineering and mathematics (STEM) is clear (e.g., Holdren & Lander, 2012; Zorn et al., 2014). Efforts of education researchers have amassed evidence of the significant roles that instructional practices play in shaping learning outcomes for such students (e.g., Freeman et al., 2014; Laursen et al., 2014). Students' experiences in undergraduate classes also impact their views of mathematics, interest in persisting in their studies, and likelihood of completing a STEM major (Hake, 1998; Seymour & Hewitt, 1997; Seymour & Hunter, 2019). Moreover, findings from education research have illuminated disparities in how instruction can impact students who arrive in our courses with different sets of experiences and backgrounds (e.g., Ellis et al., 2016; Laursen et al., 2014; Reinholz et al., 2022).

Fortunately, the education research community has generated findings to guide improvement in the teaching of undergraduate mathematics (e.g., Bressoud et al., 2015; Laursen, 2019). Of note are impacts of active, engaged student learning approaches on achievement, retention, and equity. Professional societies and other groups have amplified these findings and provided guidance and resources for implementation (e.g., Abell et al., 2018; Laursen, 2019). However, for students to benefit, instructors need professional development for teaching (PDT). It is now quite common for departments to offer PDT to graduate teaching assistants (GTAs) (Ellis, Deshler & Speer, 2016). Yet there is still much to learn about the PDT that is offered and how programs have changed over time. To explore this, we focused on two research questions: 1) What are the characteristics of current GTA PDT programs in Ph.D-granting mathematics departments? And 2) Have those characteristics changed since 2014 and if so, in what ways?

Data Collection

Description of the 2014 Survey

In 2014, a survey was sent to all 341 graduate-degree granting mathematics departments in the US. The survey was conducted jointly by two projects of the Mathematical Association of

America (MAA). The first, College Mathematics Instructor Development Source (CoMInDS), provides support to those who prepare GTAs for their teaching responsibilities, including workshops and access to materials for instructor development. The second project, Progress through Calculus (PtC) aimed to further understand characteristics associated with students' success identified by the Characteristics of Successful Programs in College Calculus project.

The survey items related to GTA PDT were designed jointly by members of the PtC and CoMInDS teams. The survey included both multiple-choice and open-ended items designed to provide insights into characteristics of programs and to reveal the interests and needs related to GTA PDT. Department chairs were encouraged to have local experts respond to portions of the survey they were most knowledgeable about. Specifically, coordinators and providers of GTA PDT were considered ideal respondents for survey questions related to GTA PDT. The survey had a 75% response rate from Ph.D-granting institutions.

Results characterized GTA PDT programs offered in mathematics departments across the US (see Apkarian et al. (2017) for a report of the full 2014 survey). A cluster analysis of these data revealed nine models of GTA PDT that varied with respect to the activities included, and the amount and timing of the PDT (Bragdon et al., 2017). Additional analysis indicated that only 19% of departments considered their GTA PDT programs to be preparing GTAs "very well," and 33% of departments reported there was room for improvement in their programs (Ellis, Deshler, et al., 2016; Rasmussen et al., 2019). One area that was identified as needing further attention was program evaluation (Ellis, Deshler & Speer, 2016; Speer et al., 2017).

Description of the 2021 Survey

To understand how things have changed since 2014, and get additional information, a survey specifically about GTA PDT (based on the 2014 design) was distributed in Fall 2021 to Ph.D-granting institutions; the response rate was 69.5%. Again, department chairs were asked to have local experts complete it. Some questions were identical or like the questions asked in 2014 while others probed more deeply to better understand the nature of the PDT. New questions were added about the providers of PDT and how they are chosen for their positions. Mixed-methods analysis of the data is ongoing.

Results: Understanding the current landscape of GTA PDT

Here we highlight some notable similarities and differences between findings from the 2014 and 2021 surveys based on our descriptive and qualitative analysis. Both surveys generated data about roles GTAs play in undergraduate instruction and whether they participate in PDT. All respondents to the 2021 survey reported that graduate students assisted with instruction and over half reported that most, if not all, GTAs serve as instructors of record at some point in their graduate education. GTAs' roles in instruction have largely remained the same since 2014 (being graders, tutors, recitation leaders, instructors of record, and assisting with in-class instruction).

There was, however, a substantial increase (from 77% in 2014 to 88% in 2021) in the percentage of Ph.D-granting institutions that reported **all** of their GTAs participate in department-based PDT. PDT may be offered in the department, outside the department within the institution or outside of the institution. Currently, over half (57%) of responding institutions reported that over 90% of the PDT was offered within the department and only 7% report that less than half of the PDT is offered within the department.

There has been a notable change in the formats in which GTA PDT is offered. A majority of departments now offer term-long courses or seminars, short workshops or orientations, and additional occasional workshops or seminars. Table 1 shows changes from 2014 to 2021. Open responses indicate that some departments have changed their program's structure to include credit-bearing courses, regular teaching seminars, and have adjusted placement of GTAs in their teaching roles. New in 2021, institutions were asked to choose from a list of topics GTAs typically learn about in their formal preparation for teaching. Table 1 highlights the eight most frequently selected topics addressed in the PDT.

Formats offered	2014 (n=111)	2021 (n=118)	**Most addressed topics**	2021 (n=114)
Term-long course or seminar	60%	75%	University and or dept. policies	86%
Multi-day workshop	34%	48%	Grading strategies	78%
Short workshop or orientation (1-4 hours)	24%	79%	In-person classroom management	76%
Occasional seminars or workshops	16%	73%	Active learning	76%
One-day workshop	13%	39%	University resources for students	70%
Online modules	Not asked	43%	Equity and diversity in the classroom	65%
Other	13%	16%	Facilitating group work	64%
			Academic integrity concerns	64%

Table 1: Findings from survey questions: Which of the following formats are typically included in your GTA preparation program? Which of the following topics do GTAs typically learn about in their formal preparation for teaching? (Mark all that apply.)

The 2021 data allow us to better describe the community of providers of GTA PDT than was possible with the 2014 data. The providers are a mix of non-tenure track and tenure track faculty where a majority are non-tenure track. When choosing or assigning providers of GTA PDT, departments favored individuals who were willing to take on the role and were considered excellent teachers. Answers from the non-required open response questions indicated that other considerations included whether faculty work with GTAs in another capacity, like supervising or coordinating courses (40% of responses) or are involved in the graduate program (20% of responses). 25% of responses indicate that faculty were hired specifically with this responsibility.

Both surveys asked respondents to identify what additional supports are needed for providers to improve GTA PDT. In the 2021 survey, we asked "What resources would be most helpful to you, as a provider, in strengthening your GTA teaching preparation program, if desired?" Respondents were given six choices and asked to mark all that apply. Some of the results from Table 2 can be compared over time. One of the choices was "Tools for evaluating effectiveness of GTA teaching preparation"; 67% of respondents identified this as a need in 2014 and 80% of respondents checked that box in the 2021 survey. Respondents identified a critical need for the community to develop models, instruments, and methods to better understand the extent to which PDT efforts are effective and successful. This result suggests that a major effort in future work needs to be in developing tools and protocols for effective assessment of GTA PDT programs.

Most helpful to strengthen GTA PDT programs	2014 (n=91)	2021 (n=104)
Tools for evaluating effectiveness of TA teaching preparation	67%	80%
Research-based information about best practices in TA teaching preparation	74%	78%
Online library of tested resources	48%	72%
Professional development for TA teaching preparation staff	51%	53%
Online workshops for GTAs	Not asked	45%

Table 2: Findings from question: What resources would be most helpful to you, as a provider, in strengthening your GTA teaching preparation program, if desired? (Mark all that apply.)

The desire for the "Online library of tested resources" also stands out in Table 2. The CoMInDS project has created just such a library of materials to use in facilitating PDT (available via connect.maa.org). The CoMInDS Resources Suite contains materials for use in pre-term orientation sessions, semester-long seminars, periodic workshops and more. Resources, including assignments, activities, readings, syllabi, etc., are submitted and reviewed through an editorial process as the repository continues to grow. Given the existence of these resources, one interpretation of the survey finding is that the CoMInDS Resources Suite is being underutilized. Another interpretation is that folks would like a larger or differently accessible online library, or perhaps a different set of resources entirely.

Limitations and Future Directions

In the 2021 survey, 96% of institutions responded "yes" to the question "Do graduate students in your department participate in any formal preparation for their teaching responsibilities?" In any survey with less than a 100% response rate one should consider the effects of unit nonresponse bias (Bose, 2001). A response rate of 69.5% for a survey of this kind is very high. However, intuitively, one might suspect a higher response rate from departments with programs than from those without. It is likely that fewer than 96% of the non-responding institutions have a GTA PDT program, though it is difficult to quantify.

Another concern was whether there was a "CoMInDS summer workshop bias." At these multi-day workshops (running each summer 2016-2021) participants designed or revised GTA PDT programs. The workshops have served 203 participants from almost half (87) of the Ph.D-granting mathematics departments in the U.S., in addition to some masters-degree granting institutions (Bookman & Speer, 2021). Institutions that sent participants to a CoMInDS summer workshop might have been more likely to respond to the survey than those that did not. 73.6% of workshop-participating institutions responded compared to 65.4% of non-participating institutions. A 2x2 chi-square test revealed no statistically significant differences at the .05 level in those response rates ($p=0.223$). In future work, we may examine effects of differences between 'early' respondents to 'late' respondents and the effect of item non-response.

In both surveys, we collected data about the formative and summative feedback given to GTAs about their teaching and about how well providers feel their program does at preparing new GTAs. Analysis of these questions is ongoing, however the mixed-methods analysis of the 2014 survey data revealed that most programs used student evaluations of teaching (SETs) to evaluate the teaching of graduate students in their department and there were limited efforts undertaken to evaluate the effectiveness of the programming (Speer et al., 2017). From preliminary analysis of the 2021 survey data, it appears that SETs are still the most common method of formally evaluating GTAs' teaching (91% of institutions reported doing so).

As of 2021, graduate students in 88% of Ph.D-granting mathematics departments have opportunities to participate in PDT that is offered by their department. Although that certainly indicates that many GTAs are receiving preparation for their teaching-related responsibilities, programs vary in terms of enrollment. As a result, we do not know what percentage of all mathematics graduate students are participating in PDT. If the large Ph.D-granting programs are represented in the 88% then person-level participation may be even higher. However, if the 88% primarily includes small-enrollment programs, then the actual person-level participation rate may be lower. Knowing more about the size of the programs represented in the response sample could inform strategies used to increase the reach of efforts to departments that are currently not offering programs. On-going analysis will further examine this issue via other data provided on the survey as well as publicly available data from the CBMS survey of programs.

We anticipate that further analysis of responses to open-ended prompts will provide additional insights. Several comments highlighted major changes that have been implemented to GTA PDT programs, including hiring a GTA PDT provider and/or dedicated course coordinators. Course coordinators may be well-positioned to take on the role of providing PDT for GTAs (Martinez et al., 2021), and future analysis of the survey data could shed light on the ways coordinators are complementing existing GTA PDT programs.

Conclusions

The mathematics community has responded to calls for increased attention on professional development for those new to teaching. Now, 88% of departments offer PDT to graduate students whereas in 2014 only 77% did so. The scope and content of those programs has also changed and now better reflect what is known from research about effective design of PDT. The K12 education community has recognized that development of teaching practices and knowledge requires sustained engagement (Blank & de las Alas, 2009). In 2014, 60% of departments offered a term-long course or seminar and today, 75% of departments do so. Such courses or seminars may represent as little as 10-15 contact hours (for a 1-credit course) or as much as 30-45 contact hours (for a 3-credit course). This falls short of the 100 hours that is regarded as necessary for impact (Banilower et al., 2006), however, when taken together with other changes we see, the shifts since 2014 are encouraging.

We also see that current programs are focusing on issues of importance to the broader mathematics community (e.g., active learning, collaborative groupwork, and diversity/equity/inclusion, see Table 1). We lack comparison data but the presence of such topics in the majority of programs suggests that those involved in program design are well-informed about current needs of the mathematics community and findings from education research.

Those involved in GTA PDT continue to request tools to better understand the impact of their programs on teaching and learning. In 2014 this was expressed by a majority (67%) and today, 80% say this is something they need. While some of this increase may be a result of trends about assessment and evaluation seen throughout the mathematics community, the finding points to the need for ways of examining the impact of PDT on instructors (which also requires tools for assessing and evaluating instructional practices). This creates opportunities for increased collaboration among those with expertise in PDT programs for GTAs, research on the teaching and learning of undergraduate mathematics, and program evaluation.

Professed Beliefs of a Teaching Assistant of an Introductory Proof Course

T. Royce Olarte
University of California
Santa Barbara

Micah Swartz
Texas State University

Sarah A. Roberts
University of California
Santa Barbara

It is known that teachers' beliefs influence how they filter new knowledge and understanding of pedagogies and can directly impact their classroom practices. Moreover, the context can shape beliefs, and thus it is imperative to examine the beliefs of teaching assistants (TAs) of introductory proof courses because they play important roles in supporting student learning at this crucial mathematical junction. This preliminary study explored the professed beliefs of Lisa, a second-year, mathematics doctoral student. We qualitatively analyzed her responses in a semi-structured interview - with a particular emphasis on exploring her beliefs about teaching and beliefs about introductory proof courses. Overall, she believed that introductory proof courses pose new challenges and demands for undergraduate students. We saw connections to her beliefs about how TAs should deliver content and support students. Critical examination of TAs' beliefs can inform how mathematics departments prepare graduate students to be teaching assistants.

Keywords: Teaching Assistants, Beliefs, Introductory Proof Courses

Introduction

In the present preliminary study, we examined the professed beliefs (Speer, 2005) of a teaching assistant (TA) of an introductory proof course. Introductory proof courses mark a critical junction in the academic trajectories of many undergraduate students pursuing mathematics degrees. Students are confronted with significant challenges in proof-construction (e.g., Moore, 1994; Weber, 2001), because the demands associated with proof-construction are unlike those of courses such as calculus and linear algebra. Graduate students who serve as TAs play important roles in supporting student learning during this transition to upper division mathematics courses that heavily rely on proof-construction competencies. It is imperative that we better understand what mathematics TAs believe about students, learning, and teaching at this important junction. These beliefs can not only impact their current instructional practices (e.g., Pajares, 1992; Goldin et al., 2009), but they can also filter how TAs learn about and develop their pedagogies (Brousseua et al., 1988) to teach upper division coursework.

Prior work has illustrated how teachers of different domain areas (e.g., STEM, humanities, etc.) have described and exhibited differences in beliefs about aspects of their instruction (e.g. Patterson et al., 2016; Roothooft, 2019), and we posit that the specific content areas within the mathematics discipline (e.g., calculus, linear algebra, etc.) can uniquely influence what TAs believe. To date, there is limited work that is specific to examining the beliefs of TAs of introductory proof courses. As we move forward, findings from studies of this nature can inform how higher education institutions and mathematics departments can better support graduate students' professional development and teaching practices in proof-based courses. If we are to positively develop these dimensions of teaching and instruction, it is important that we first identify and examine the beliefs that graduate students bring into these courses and develop as they serve as teaching assistants or early instructors of record. The research question that guided this study was: How did a mathematics teaching assistant discuss their beliefs about teaching and mathematics in an introductory proof course?

Framework

We drew on a categorization of professed teacher beliefs (Calderhead, 1996; Carter & Norwood, 2010; Torff, 2011) to frame the present exploratory study. Research on teaching and educational psychology have previously described beliefs as being professed or attributed (Calderhead, 1996; Putnam & Borko, 2000). Speer (2005) stated, “professed beliefs are defined as those stated by teachers, while attributed beliefs are those that researchers infer based on observational or other data” (p. 361). We consider the beliefs of the focal TA as primarily professed beliefs because we as researchers did not observe their classroom practices nor inferred beliefs from observed actions. We built upon the work of Speer (2001) who previously connected teaching assistants’ beliefs to their teaching practices in reform-oriented calculus courses. Speer described and categorized teaching assistants’ *belief profiles* to encompass 1) what the teaching assistants believed about their students, 2) what they believed about teaching, 3) what they believed about learning, and 4) what they believed about mathematics.

Other scholars have similarly categorized beliefs as a way of identifying and assessing teachers’ professed beliefs (e.g., Carter & Norwood, 2010; Voss et al., 2013). Although beliefs are extremely interconnected, categorizing them is helpful in making sense of an individual’s broader belief system. Voss et al. (2013) provided a rationale for why researchers often classify and categorize teacher beliefs, writing: “These detailed taxonomies are helpful and necessary when it comes to addressing theoretical questions about specific components or painting a coherent picture of belief systems” (p. 252). In this preliminary study, we focus on two primary dimensions: beliefs about teaching and beliefs about mathematics. More specifically, we sought to identify how beliefs about teaching and mathematics are related to introductory proof courses and the extent to which the focal TA’s beliefs about her teaching and mathematics is shaped by the course content and her perceptions of the demands of introductory proof courses.

Method

Purposeful sampling (Miles et al., 2020) was used to recruit graduate students of an introductory proof course at a Minority-Serving Institution in California. It was part of a larger study about transfer students’ experiences in a department intervention involving a set of courses to help transfer students transition to a four-year university. The focal introductory proof course, Math A, was one of these courses. Participants were mathematics doctoral students who were TAs for the course during the Fall 2020 quarter. We focus on Lisa (a pseudonym) as a case for this preliminary study because she was revelatory (Yin, 2016) about nuanced professed beliefs regarding teaching and mathematics that were also related to the context of the introductory proof course. She self-identified as female and was a 2nd year doctoral student pursuing a degree in mathematics. Moreover, at the time of data collection, Lisa had two quarters of experience as a TA for the introductory proof course. The research team qualitatively analyzed her responses to a semi-structured interview protocol (Rubin & Rubin, 2011). The following questions guided our categorization, coding, and analysis of Lisa’s professed beliefs: (1) What does Lisa believe about her teaching practices and role as a TA? (2) What does Lisa believe about mathematics and introductory proof courses? We pair-coded the interview transcript, discussed our codes, and wrote memos throughout this preliminary analysis of themes in her professed beliefs. Code charting (Saldaña, 2021) using matrices was used to organize the categorization of her beliefs and this afforded insight into themes across the various dimensions of her beliefs.

Findings

We present initial findings highlighting themes in Lisa's professed beliefs about introductory proof courses and her role in teaching and supporting student learning. Lisa expressed some beliefs unique to the context of and circumstances around introductory-proof courses (e.g., it is a course mainly for mathematics majors, it is the gatekeeper to upper division courses, etc.). She also expressed beliefs related to characteristics and key practices of what she believed makes a successful TA of such courses.

Beliefs about Teaching

Lisa expressed beliefs related to her role as a content-deliverer and as someone who is a supporter of her students. Regarding the dimension of her teaching related to content-delivery, she recognized the constraints of her role as a teaching assistant and believed that she should reinforce the material already presented by the professor - but make it more personable and approachable for the students. She described the importance of being "less scary" than the professor and recognized the impact that instructors' demeanors can have on student learning and engagement. She said:

> I guess, I kind of view it as like I'm someone to reinforce the material that the professor is doing. So just like it can be more personal, reinforce ideas, because they're very abstract when they're first given to students. And then, just to be someone who is less scary than the professor. My job is just to be approachable.

Lisa frequently returned to this notion of being personable. She reflected on how she introduced herself to students at the beginning of the semester. Her goal was to convey the message: "I care about you as a person and I'm going to take the time to try and show it." She believed TAs should be clear about their intentions to support students and that this should be explicitly communicated. Another key belief associated with teaching and content delivery was her belief that a TA should present material in a way that is digestible and understandable for students, especially with material they had not seen before. She said, "I think knowing how to present the material in a way that you know someone who's just seen upper division math for the first time can do it, can understand it." Lisa understood that many students struggle in making sense of proof-construction and believed that TAs should strive to make material accessible and understandable to all students. This included actions such as exhibiting patience, breaking down complex concepts, and scaffolding students' proof construction by first showing easy examples, and moving to "hard interesting problems." She recalled noticing a difference in students' engagement and interactions when she expressed that she cares for them. She said, "I tried really hard to like, start off being with like, 'Okay, I care about you as a person and I'm going to take the time to try and show it to you.' and I think that worked well." Overall, Lisa believed that a TA needs to make the content relatable and accessible while also providing support and demonstrating care for students.

Beliefs about Mathematics and Introductory-Proof Courses

In examining her beliefs about teaching, we saw that there were some connections to her beliefs about the mathematical difficulties associated with introductory proof courses. Lisa primarily expressed beliefs about the nature of these courses - specifically that they mark a junction in the content, problem-solving, and sense-making demands that students encounter in these courses and beyond. She believed that constructing mathematical proofs are unique from the mathematics that students have previously seen and that this poses challenges that many students may not yet have faced. She said, “They’ve never been into, like a proof-writing, class everything's really different.” Moreover, in reflecting on her position as a teaching assistant for the Math A course, she expressed a concern and critique about the focus of introductory proof courses. Lisa believed that the emphasis of such courses is on the correctness of the final proof, rather than a deeper understanding of the conceptual and logical underpinnings of constructing proofs. She commented,

> I think my biggest thing about Math A is there's such, still such an emphasis on like the correct answer in Math A. But like ideally, from my point of view, [the] Math A goal should be: “Do you know how to write a proof?” So I think a lot more emphasis on like writing proofs well, and like having students actually get graded feedback.

She suggested that providing students with feedback, rather than just a grade would help attend to the concern and overemphasis on correct answers and proofs. Lisa believed that introductory proof courses should better prepare students to construct proofs – not just in rote and procedural ways, but rather with a deeper understanding that can support them as they continue to more advanced mathematics.

Discussion

Overall, we observed that Lisa placed importance on being approachable as a TA and engaging in practices that allow all students to access the mathematics content. Lisa believed that TAs should make content digestible and understandable and that the emphasis of Math A should be on supporting students’ deep and conceptual understanding of proof-construction. Altogether, we can infer that she believed that affect-oriented practices that attend to students’ motivation and fostering positive perceptions of TAs can support student learning in introductory proof courses. Wiesman (2012) previously found that some teachers believed that students’ motivation in the classroom are impacted by teacher actions and that demonstrating care can have positive impacts on academic achievement. This idea is echoed in Lisa’s reflections on how she should foster safe classroom environments where students feel supported and cared for. Also, Lisa’s consideration of students’ perceptions of TAs and providing more socio-emotional support is consistent with aspects of the work of Beijaard et al. (2000) who characterized some teachers as *pedagogical experts*, or those who base their sense of selves as teachers on supporting students’ social and emotional development. Ultimately, our preliminary findings of Lisa’s beliefs are consistent with existing research on how beliefs may be categorized (e.g., Ernest, 1989; Speer, 2001; Carter & Norwood, 2010; Voss et al., 2013) but are still interconnected and influence each other (e.g., Pajares, 1992) to form larger belief systems.

We also recognized that some of the professed beliefs were explicitly connected to introductory proof courses, which supports the notion that beliefs are informed by the mathematical contexts and domains. For example, her belief that proof-construction poses challenges and introduces a level of cognitive demand many students have not yet faced (i.e, a belief directly related to the specific course she was a TA for) was a significant part of her reflections on why she should be more personable and approachable to students. We also saw preliminary findings illustrating how course contexts can impact beliefs. We may expect a TA in a precalculus course and a TA in an introductory-proof course to have nuanced beliefs about mathematics and teaching that are reflective of their different experiences and content areas. Lastly, we also highlighted Lisa’s belief regarding the nature of introductory proof courses and their overemphasis on rote proof-construction and the correctness of the final answer. This belief can have implications for how Lisa develops her own pedagogies and practices as a TA and a potential faculty later in her career because it can serve as a lens through which she adopts or rejects new pedagogies. She may make the effort to combat the traditional emphasis on correctness and procedural understanding and make conscious effort to develop practices that better support deeper learning.

Limitations and Implications

One limitation of the study is that we only focused on the beliefs of one TA, which did not allow for a comparison of professed beliefs across multiple participants. Future work could perhaps examine more participants (i.e., more TAs of introductory proof courses) or more TAs across multiple courses (i.e., examine TAs of calculus, linear algebra, introductory proof courses, etc.) Secondly, a key limitation of research on beliefs is the extent to which participants can convey and articulate their beliefs. Future research should examine other dimensions of TAs' beliefs (e.g., beliefs about how students learn) or observe how TAs facilitate their sections to identify any connections between observed practices and their professed beliefs. A richer understanding of TAs' beliefs, uniquely situated in specific courses, has important implications for practice and research. It can inform department-level training, coursework, and other professional development opportunities for graduate students, and this can expand our understanding of the belief systems of individuals involved in undergraduate mathematics instruction.

Conclusion

We consider research on TAs' beliefs an important, yet under-researched, dimension of undergraduate mathematics education, especially in courses like introductory proof courses which are foundational to students' success in upper division coursework. Our preliminary findings highlight connections between a TA's beliefs about introductory proof courses and mathematics and her beliefs about teaching, and this sheds light on the complexity and interconnectedness of beliefs. A richer understanding of the beliefs of TAs of these courses can also be resources for mathematics departments because they afford insight into students' experiences from the perspective of those who often, more frequently, interact with students and see firsthand the challenges they encounter. With many graduate students continuing on to become faculty and may later teach proof-based courses, critically examining their beliefs when they serve as teaching assistants can inform how institutions and mathematics departments prepare them for careers as post-secondary educators.

Student Confidence and Certainty in Comprehension of a Proof by Induction

Michael Preheim — North Dakota State University
Josef Dorfmeister — North Dakota State University
Ethan Snow — University of Nebraska

Researchers typically utilize response correctness to interpret student proficiency in proof comprehension. However, metacognition has not been simultaneously analyzed alongside correctness to determine student competency in proof comprehension, yet it offers important information about performance behavior. The primary objective of this study is to investigate the accuracy of student confidence and certainty levels at local and holistic aspects of proof comprehension regarding a proof by induction. Students were given a three-factor proof comprehension assessment at the beginning and end of an undergraduate transition-to-proof course that collected student confidence, correctness, and certainty at each tier of an established proof comprehension framework. Results of this study highlight a critical distinction between high and low performers' metacognition throughout the host course. One outlying assessment item especially illuminates additional considerations for future application of metacognition in proof comprehension research.

Keywords: Proof comprehension, Proof by induction, Confidence and certainty, Metacognition, Multidimensional competency assessment

1 Introduction

The present study investigates the interplay between students' confidence and certainty (states of metacognition) with response correctness within proof comprehension assessments. The discussions presented in this paper operate on the following definitions of confidence and certainty. *Confidence* refers to an individual's level of belief that they *can provide* a correct response to an assessment item pertaining to a given set of clearly defined criteria, whereas *certainty* refers instead to an individual's level of belief that they *have provided* a correct response to an assessment item. Confidence and certainty are differentiated by their context and timing at which they are measured. Confidence, measured prior to viewing assessment items, is a self-assessment for anticipated performance, while certainty is a self-assessment of past performance measured after providing a response to an assessment item.

1.1 Metacognition and Multidimensional Knowledge Assessment

Metacognition includes any way of monitoring of cognition (Kitchener, 1983) and thus the term has been applied with a wide variety of interpretations. Commonly, metacognition is categorized into two broad areas – metacognitive knowledge and metacognitive skills (Veenman & Spaans, 2005). Metacognitive knowledge involves one's beliefs about the interactions of person, task, and strategy knowledge (Flavell, 1979), whereas metacognitive skills refer to the "procedural knowledge that is required for the actual regulation of and control over one's learning activities" (Veenman & Spaans, 2005). Confidence and certainty as previously defined address a subcategory of metacognitive knowledge (relating person knowledge to task knowledge) wherein an individual self-monitors their cognitive performance.

Knowledge is information which is both true and justified (Hunt, 2003). Student certainty has been well studied for providing response justification during assessment (Gardner-Medwin and Gahan, 2003; Ghadermarzi *et al.*, 2015; Hunt, 2003; Snow, 2019). The authors of the present study have investigated simultaneous evaluation of confidence, certainty, and correctness (the

"3Cs") within an undergraduate linear algebra course and established corresponding accuracy indices for identifying outlying student metacognitive behaviors and providing new insights for assessment item analysis (Preheim *et al.*, 2022; Preheim *et al.,* 2023). The 3C assessment structure and analysis has yet to be used to investigate student competency in proof comprehension.

1.2 The Role of Confidence and Certainty in Proof Comprehension and Proof Writing

An individual's confidence and certainty in proof comprehension may impact decisions which occur throughout proof writing tasks wherein they must make strategic choices on how to proceed (*e.g.*, deciding which method of proof to initially employ, which strategy to use to satisfy a particular case, *etc.*). For example, consider a student who does not feel confident in their comprehension of proof by contrapositive as a technique. When posed with the task of proving "if n^2 - $(n\text{-}1)^2$ is not divisible by 8, then n is even," this student might shy away from a proof by contrapositive and be led to attempt a direct argument (which would be more tedious). Similarly, an individual's certainty in their proof comprehension has the potential to influence their willingness to move to a next step in a proof-writing task or impact their conviction in the truth of the mathematical statement being proved.

While the role of proof in establishing mathematical conviction (*i.e.*, belief in the truth of a mathematical statement) has been discussed and investigated by researchers such as Weber or Mejía-Ramos (Weber & Mejía-Ramos, 2011; Weber *et al.*, 2014; Weber & Mejía-Ramos, 2015; Weber *et al.*, 2022), student confidence and certainty regarding proof comprehension has not been thoroughly investigated. Mejía-Ramos *et al.* (2011) developed a model by which to construct assessment items for proof comprehension assessments (PCAs) in undergraduate mathematics. This proof comprehension framework (PCF) identifies seven aspects of proof comprehension separated into two tiers: local and holistic (Mejía-Ramos *et al.*, 2012). Assessment items at the local level are intended to assess an individual's comprehension of a small number of statements contained within a proof. At the holistic level, items assess an individual's understanding of the proof as a whole (Mejía-Ramos *et al.*, 2012). Student metacognitive behavior at each level of the PCF has not been empirically investigated to measure student competency or assessment item validity.

The objective of this study is to investigate students' confidence and certainty levels and their accuracies at local and holistic aspects of proof comprehension regarding a proof by induction. Distinctions between high and low performers' metacognitive behaviors from the beginning to end of the host course are also presented and discussed.

2 Methods

2.1 Course Information and Assessment Structure

The introduction to abstract mathematics course which hosts the focused student population in the present study serves as the transition-to-proof course for undergraduate students at North Dakota State University. This course focuses on proof-writing tasks and proof comprehension amidst various topics in abstract mathematics. 3C data was collected via two assessments per section from 36 students in four sections of the course.

The PCA used in this study assesses comprehension of a proof by induction that every third Fibonacci number is even. This multiple choice PCA developed by Mejía-Ramos *et al.* (2017) which adheres to the PCF (Mejía-Ramos *et al.,* 2012) was adapted to include 3C assessment methodology. This same 40-minute in-person assessment was administered near the start of the course (the initial assessment) as well as near the end of the course (the post assessment).

Each assessment item from the PCA was mapped to one PCF subitem. Immediately preceding each assessment, student confidence levels were collected for pertinent PCF subitems. The prompt requested students to indicate their level of confidence in each PCF subitem (4=High confidence, 3=Somewhat high confidence, 2=Somewhat low confidence, and 1=Low confidence). In the first semester of collected data, students provided their confidence levels prior to viewing the proof or assessment items. During the second semester, students were given five minutes to read the proof prior to providing confidence levels.

Once the confidence self-assessments were completed, students were given an assessment packet which contained the 12 multiple-choice questions. Following each multiple-choice question, a corresponding certainty prompt (similarly structured to the confidence prompt) instructed students to record their certainty in their response before moving on to the next item.

2.2 Accuracy Indices and Metacognitive Accuracy Plots

An individual student response yields the following three values: c_1 = confidence level, c_2 = correctness (1 for correct and 0 for incorrect), and c_3 = certainty level. Two similarly defined functions were developed to measure the alignment of confidence with credit (AccConf) and the alignment of certainty with credit (AccCert). The formulas for each are shown in Figure 1.

$$\mathrm{AccConf}(c_1, c_2, c_3) = \begin{cases} 1 & \text{if } \mathrm{c}_2 = 1 \text{ and } c_1 = 3 \text{ or } 4 \\ -1 & \text{if } \mathrm{c}_2 = 1 \text{ and } c_1 = 1 \text{ or } 2 \\ -1 & \text{if } \mathrm{c}_2 = 0 \text{ and } c_1 = 3 \text{ or } 4 \\ 1 & \text{if } \mathrm{c}_2 = 0 \text{ and } c_1 = 1 \text{ or } 2 \end{cases} \qquad \mathrm{AccCert}(c_1, c_2, c_3) = \begin{cases} 1 & \text{if } \mathrm{c}_2 = 1 \text{ and } c_3 = 3 \text{ or } 4 \\ -1 & \text{if } \mathrm{c}_2 = 1 \text{ and } c_3 = 1 \text{ or } 2 \\ -1 & \text{if } \mathrm{c}_2 = 0 \text{ and } c_3 = 3 \text{ or } 4 \\ 1 & \text{if } \mathrm{c}_2 = 0 \text{ and } c_3 = 1 \text{ or } 2 \end{cases}$$

Figure 1. The metacognitive accuracy formulas AccConf and AccCert. A weighted average of these accuracy values produces the accuracy indices AIConf and AICert.

Accuracy values of 1 indicate accurate confidence/certainty while accuracy values of -1 indicate inaccurate confidence/certainty. A weighted average of accuracy values across responses was computed for each assessment to generate an accuracy index for confidence (AIConf) and an accuracy index for certainty (AICert). For this weighted average, responses reporting confidence/certainty levels 1 and 4 were weighted at three times the weight of those corresponding to levels 2 and 3. Metacognitive accuracy plots were produced to display the transitions in AIConf and AICert from the initial to post assessment among all students, high performers (students in the top 25th percentile of course standing), and low performers (students in the bottom 25th percentile of course standing).

3 Results

Among all students, AIConf increased from the initial assessment to the post assessment for all local items except item Q4 (Figure 2a). Among high performers, AIConf increased by more than 0.20 from the initial assessment to the post assessment for ten of the twelve items (excluding Q4 and one item with near maximum accuracy) (Figure 2b). Among low performers, AIConf and AICert decreased from the initial to post assessment for all holistic items (Figure 2c). Furthermore, Q4 showed substantial decrease in both AIConf and AICert among low performers (Figure 2b) and substantial increase in AICert among high performers (Figure 2c).

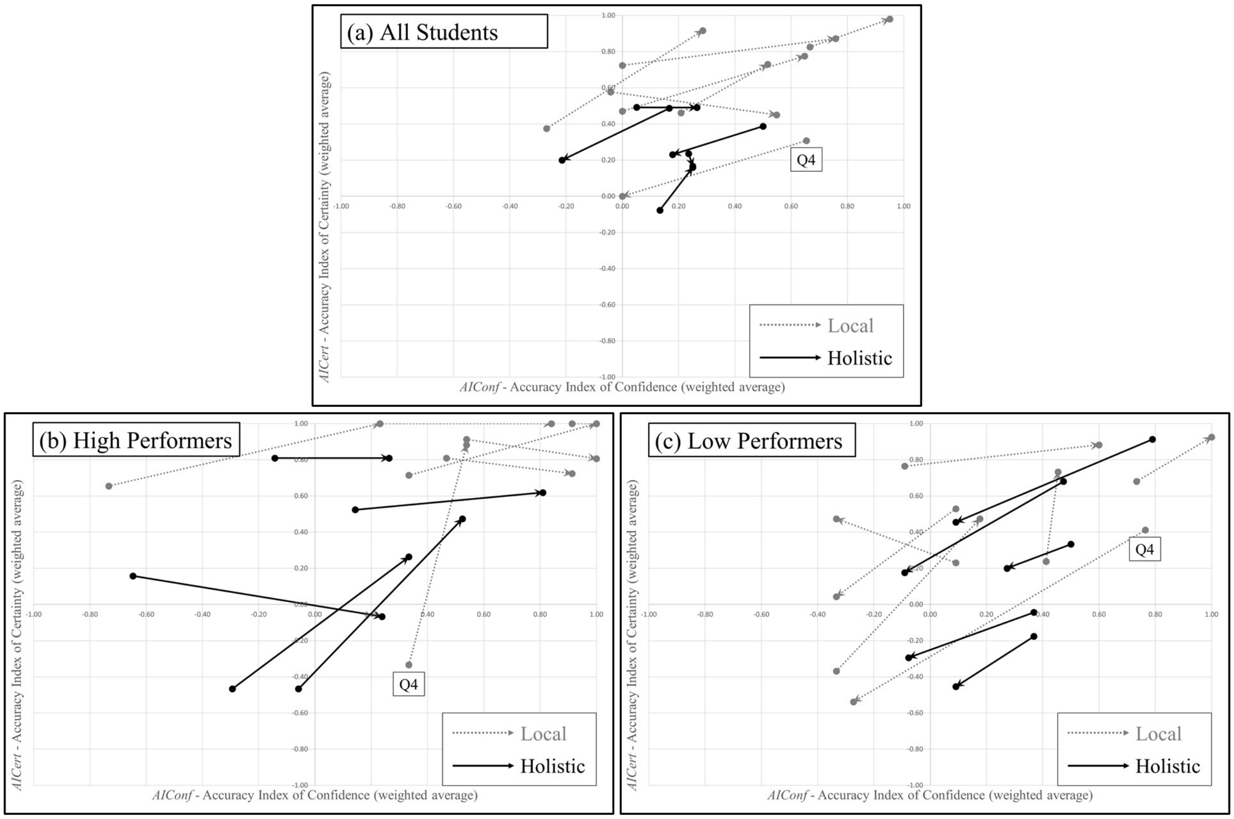

Figure 2. The transitions of AIConf and AICert for each assessment item from the initial to the post assessment are plotted as arrows on a graph of AICert vs AIConf. Items addressing local aspects of the PCF are represented with gray dotted arrows while those addressing holistic aspects are represented by black solid arrows.

Reported confidence and certainty levels demonstrated significant ($\alpha<0.05$) increase from the initial to the post assessment for all and eleven of the twelve items, respectively. Certainty levels were higher than confidence levels on average among questions pertaining to local aspects of the PCF for both the initial assessment and the post assessment. However, certainty levels among questions pertaining to holistic aspects of the PCF were lower than confidence levels during the post assessment. On average AICert was higher than AIConf among both assessments for all items, local items, and holistic items. Average confidence and certainty levels as well as correctness scores increased from the initial assessment to the post assessment among all items, local items, and holistic items. Though average AIConf and AICert among questions addressing local aspects of the PCF increased from the initial to the post assessment, both decreased among questions addressing holistic aspects of the PCF (Table 1).

Table 1. The average confidence level, certainty level, score (correctness), AIConf, and AICert on the initial and post assessments among all items, local items, and holistic items.

		Confidence	Certainty	Score	AIConf	AICert
All	Initial	2.26	2.63	0.58	0.19	0.44
	Post	3.07	3.14	0.67	0.37	0.50
Local	Initial	2.56	2.92	0.70	0.17	0.53
	Post	3.26	3.40	0.75	0.53	0.67
Holistic	Initial	1.95	2.21	0.40	0.22	0.30
	Post	2.88	2.77	0.54	0.15	0.25

4 Discussion

Transitions from the initial to the post assessment highlight a critical distinction between questions addressing local aspects of the PCF and those addressing holistic aspects. Increased accuracy of confidence regarding local aspects of the PCF indicates that students' increase of confidence levels at the local tier (Table 1) was accurate to their performance. Though questions at the holistic tier also saw an improvement of confidence levels and score (Table 1), the varying shifts in students' accuracy of confidence (Figure 2a) suggest that the increase of confidence was not necessarily indicative of an increase in performance. This may suggest that students feel more comfortable reading mathematical proof by the end of the course, but it does not guarantee they are more competent in comprehending proof at the holistic level.

A further distinction between local and holistic aspects is made when comparing the shifts of AIConf and AICert among high versus low performers. The results shown in Figure 2 (b and c) demonstrate that while high performers exhibited increased accuracy of confidence among holistic aspects of proof comprehension, low performers experienced a decrease in metacognitive accuracy among holistic aspects of the PCF. These preliminary findings suggest that training student metacognition with respect to proof comprehension may be beneficial for improving student performance in abstract mathematics. Further investigation of this idea is merited.

3C data identified outlying metacognitive behavior on assessment item Q4 which would not have been detectable by correctness-only assessment methods. Qualitative evaluation of the question prompt and multiple-choice options indicates that while the prompt seems to address a local aspect of the PCF, the correct option requires holistic understanding of the proof. As these PCA items originated from open-response questions (Mejía-Ramos *et al.*, 2017), this discrepancy is not particular to the multiple-choice structure. Moreover, the most selected incorrect option includes a correct description of the proof's procedural structure followed by an incorrect conceptual justification for the final claim of the proof. This outlying behavior therefore supports an observation by Piatek-Jiminez (2004) that procedural knowledge and conceptual knowledge of proof by induction are not necessarily reliant upon each other.

5 Conclusions, Future Directions, and Questions for the Audience

The 3C assessment distinguished metacognitive behavior at the holistic level between high- and low- performing students. Development and use of methods for enhancing students' metacognitive accuracy in proof comprehension could improve student performance in abstract mathematics. Future directions of this research are focused on employing the 3C assessment methodology to improve students' metacognitive accuracy among holistic aspects of proof.

Adapting proof comprehension assessments to utilize 3C assessment methodology allows for the detection of interesting outlying metacognitive behavior. Investigating such outliers can aid in revising assessment items, generating new assessment items, and guiding directions for continued research. For example, the investigation of outlying behavior observed in this study made the distinction between conceptual and procedural knowledge observable. To more comprehensively analyze proof comprehension within the PCF, future studies might consider methods to further distinguish conceptual and procedural knowledge and study the 3C methodology in other related and unrelated domains.

The authors conclude this proposal with some intended questions for the attending audience:

1. How might 3C data be used to guide assessment item revision or PCA construction?
2. How might metacognitive behavior differ if PCAs utilized open-response questions?
3. Are there other methods of proof which you expect would generate critically different metacognitive behavior than that demonstrated in the present study?

Identifying Instructional Autonomy Approaches in Calculus and its Connection with Student's Perceived Classroom Climate

Kaden Liles
Clemson University

Matthew Voigt
Clemson University

Calculus courses are an integral component for STEM degree attainment yet are historically attributed to high attrition rates and lowering student confidence. Although prior research identified coordination of instruction as a successful characteristic of Calculus programs, there is a need to further examine the role of Instructor Autonomy (e.g., decision making on content and instruction) and its potential impact on student perceptions of the climate. We analyzed data from two national studies of introductory math courses focusing on instructor (N=321) reports of course decision making and student (N=14,488) reports of climate. Preliminary results indicated a great deal of variability in Instructor Autonomy across the Precalculus to Calculus 2 sequence within our sample and even within a department. Narrowing our focus to Calculus 1, variability in Instructor Autonomy persisted and student perception of climate was not unified; however, courses that utilized team-based decision making promoted higher student perceptions of climate.

Keywords: course coordination, calculus, instructor autonomy, student voice

Research indicates Calculus 1 is effective in lowering student's confidence, their enjoyment of mathematics, and their desire to continue in a discipline or future course where mathematics is needed (Bressoud & Rasmussen, 2015). Globally, Calculus 1 courses are associated with high failure rates and attrition (Cavalheiro & Grebot, 2021; Hagman et al., 2017). In the United States, Calculus 1 averages a 22 percent DFW rate, the percentage of students who receive a grade of D, receive a grade of an F, or withdraw from the course (Rasmussen et al., 2019)—about one out of every five students. As such, efforts have increased towards the recruitment and retention of students (Calleros & Zahner, 2021; Patrick & Borrego, 2016) through the improvement of introductory math courses.

From 2009 to 2015, a national study of college Calculus 1 courses was conducted to measure what characteristics of Calculus 1 influenced student success. The Characteristics of Successful Programs in College Calculus (CSPCC) study aimed to improve retention rates for students in Science, Technology, Engineering, and Mathematics (STEM) majors (Bressoud & Rasmussen, 2015). The CSPCC study launched a national survey (n=212) to two- and four-year institutions and conducted case studies of 16 institutions identified as having successful programs in Calculus. The study identified seven characteristics of successful Calculus programs: 1. Regular use of curricular and structural modifications; 2. Attention to the effectiveness of placement procedures; 3. **Coordination of instruction, including building communities of practice**; 4. Construction of challenging and engaging courses; 5. Use of student-centered pedagogies and active-learning strategies; 6. Effective training of graduate teaching assistants; 7. Proactive student support services.

As identified by the CSPCC study, coordination of instruction is a characteristic of successful Calculus programs. Course coordination, as defined by Rasmussen and Ellis (2015), consists of two features, uniform course elements and regular instructor communication. Uniform course elements are elements of a course that are the same for every student across a multi-section course (e.g., textbook, topics, common homework, common tests). Regular instructor communication are moments when instructors contact and support each other regarding aspects of the course. With these two features, course coordination aims to reduce variation across multiple sections of a course by providing consistent experiences (Rasmussen & Ellis, 2015). When it comes to the uniform elements implemented and the frequency of communication with instructors, there is not one blueprint for implementation (Apkarian et al., 2019).

Methods

Data from this analysis comes from two national studies of college Calculus, the Progress through Calculus (PtC) study and the Student Engagement in Mathematics through an Institutional Network for Active Learning (SEMINAL) study. PtC cataloged departmental efforts in improving student success and documenting the effectiveness of implementation efforts (Rasmussen et al., 2019), while SEMINAL researched systematic change in mathematics departments towards the use of active learning in introductory mathematics courses (Smith et al., 2021). Both studies conducted in-depth case studies at 20 universities and implemented the X-PIPS-M Survey suite (Apkarian et al., 2019) for instructor, student, and teaching assistants (both graduate students and undergraduate students) across several academic terms.

Through a case study approach with constant comparative methods, we explored and evaluated instructor autonomy and student reports of the perceived classroom climate. The PtC and SEMINAL data sets have three categories of courses namely, Precalculus, Calculus 1, and Calculus 2. All institutions were coded according to their institutional characteristic as a Historically Black College or University (HBCU), as a Hispanic Serving Institution (HSI), or as a Predominantly White Institution (PWI) to both anonymize the institution as well as provide another way to compare institutions and trends. In total we had instructor and student data from 20 institutions with a total response of 321 instructors and 14,488 students. For the 9 institutions that had teaching assistants there were a total of 328 responses.

Instructional Autonomy

To analyze instructor autonomy, we looked at the instructor responses to the Likert scale questions on who was making the decisions about the course content and the instructional approach. Specifically, instructors answered the questions;

1. "How are most decisions about <u>course content</u> (e.g., syllabi, exams, homework, pacing, grading) made for the course? Clarify if you wish." and
2. "How are most decisions about <u>instructional approach</u> (e.g., use of clickers, group work, active learning) made for the course? Clarify if you wish."

with answer options of *1 ("I make most decisions"), 2 ("I am part of a team that makes most decisions"), or 3 ("Someone else makes most decisions")*. To better help understand the data, we developed a classification table to categorize the level of autonomy instructors had in their course, see table 1 (Instructor Autonomy). To classify a site using the Instructor Autonomy table we looked per site per instructor autonomy question. For the two questions we noted which answer choice had the highest percentage of instructor response per site. Given the exploratory nature of this analysis, categorization based on highest percentage allowed for further exploration and reflected the lived reality of instructors but does fail to capture the level of agreement between instructors. Then we combined the classification of the highest percentage of responses for the approach and the content to get the overall instructor autonomy per site for the course. For example, if HSI 1 had 60% of instructors say someone else decides content and 52% of instructors say they are part of a team that decides the approach, the site would be classified as

"Collective Approach Top Down Content". Due to 1 institution having too much variability and low response rates we chose to exclude PWI 14 from the analysis leaving us with 19 institutions. For analysis, after determining the instructor autonomy classification we compared and contrasted across sites, course levels, and within institutional characteristic groupings.

Student Classroom Climate

To evaluate the perceived classroom climate from the student's perspective we looked at three 5-scale Likert questions asking the student to describe the overall climate. Questions asked about the intellectual engagement, academic rigor, and atmosphere the student perceived in the Calculus courses as seen below,

"How would you describe the overall climate within [Calculus 1]?

1. Excluding and Hostile (1) _ _ _ _ _ Including and Friendly (5) [Atmosphere]
2. Intellectually boring (1) _ _ _ _ _ Intellectually Engaging (5) [Intellectual Engagement]
3. Academically Easy (1) _ _ _ _ _ Academically rigorous (5) [Academic Rigor]"

For analysis we compared and contrasted institutions across the average of the three climate questions. We then looked for possible trends between the site's instructor autonomy classification and the student's perceived climate by use of the institutional characteristics. Through grouping institutions by their institutional characteristics we also examined the student data to note any trends within a particular group of institutions that could then be compared to the other institutional characteristics groupings.

Preliminary Results

Initial analysis of looking across course level (Precalculus, Calculus 1, and Calculus 2) revealed that as the sequence of Calculus progressed there was more instructor autonomy. 35% of all Precalculus instructors stated they choose their content whereas 44% of Calculus 1 instructors and 49% of Calculus 2 instructors stated they choose their own content. With decision on approach 67% of Precalculus instructors stated that they choose their own approach whereas 73% of Calculus 1 and 80% of Calculus 2 instructors stated they choose their own approach. With this trend of seeing more individual choice as the Calculus sequence progressed, we still witnessed variation within a course level on the type of instructor autonomy. Meaning that in our data set, Precalculus courses had a larger variety of instructional autonomy approaches (10 variations), compared to Calculus 1 (8 variations) and Calculus 2 (8 variations). It is worth noting that of the 19 analyzed institutions there are 16 institutions with Precalculus, 19 institutions with Calculus 1, and 18 institutions with Calculus 2 responses. Therefore, while Precalculus had the fewest institutions represented, it had the largest number of different instructor autonomy types.

Analysis of looking across courses within an institution determined that most institutions (15 of 19) have differing categories of instructor autonomy across their Calculus sequences. From those 15 institutions, six institutions had the same categorization for two of their courses with most of the same categorization being seen in the Calculus 1 and Calculus 2 courses - highlighting how Precalculus can often be disconnected from the course sequence. The remaining 9 institutions had no categorizations in common across their Calculus sequences. For the remaining four institutions that have the same categorization of instructor autonomy, three of those institutions only had data from two of the courses in the sequence, meaning only one institution (HBCU 1) had the same level of instructional autonomy across the entire sequence.

Given the variation in instructor autonomy within an institution across course level we decided to move forward with our analysis of just Calculus 1 courses across the 19 institutions.

We began the deep dive into Calculus 1 by categorizing the instructor autonomy (see Table 1), noting that there were many institutions that had a split highest percentage on who was deciding the content in the department.

Table 1. Categorization of Instructor Autonomy Approaches of Calculus 1 Courses

		Decision on Instructional Approach		
		I decide	*Team Decides*	*Someone Else Decides*
Decision on Course Content	*I decide*	Full Individual Autonomy- **PWI 1, PWI 5, PWI 11, PWI 7, HSI 1, HSI 3, HBCU 1**	Collective Approach Individual Content- **PWI 9**	
	Split Individual and Collective	Individual Approach Split Individual and Collective Content- **PWI 4, PWI 12, PWI 15**		
	Team Decides	Individual Approach Collective Content- **PWI 3, PWI 8, HSI 2**	Team Collective Autonomy- **HSI 4**	
	Split Collective and Top Down	Individual Approach Split Collective and Top Down Content- **PWI 10**		
	Someone Else Decides	Individual Approach Top Down Content- **PWI 6, PWI 13**		Top Down Highly Coordinated- **PWI 2**

By organizing the institutions into the Instructor Autonomy table, we can see that the majority of Calculus 1 instructors are getting to choose their own instructional approach but there is a lot of variety in who is deciding the content of the course. We see that 11 of the 19 institutions are experiencing a form of coordination with who is deciding content as there is another voice of a team or more of a top down coordination happening even within the split categories. To better understand what was happening in these varied Calculus 1 courses we analyzed student data about their perceived climate within the classroom.

For the climate questions on atmosphere, intellectual engagement, and academic rigor we looked at the means and standard deviations for instructor autonomy categories. Recall these climate questions are all based on a 5-scale Likert style question with 5 being representative of a more friendly atmosphere, more intellectually engaging, and more academically rigorous. Notice that the individual approaches seem to lead the student perception of the atmosphere to be lower (i.e. less friendly) and are exacerbated by also having top down content, as seen in the Individual Approach Top Down category. The highest ranking of the classroom atmosphere is in the Team Collective Autonomy approach where instructors are working in a team to decide the content and approaches in the classroom. We also see a similar pattern for the engagement question, highest ranking of engagement in the Team Collective Autonomy and lower in the individual approaches with an exacerbated effect when individual approach is paired with a top down content. Within the rigor question there is a less clear pattern which may be a result of the student interpretations of the questions and thus requires further analysis. It is noteworthy that we are not seeing a more unified student experience in the top down courses as the standard deviations are within the same relative range across all categories of courses.

Table 2. Student Perceptions of Climate by Instructional Autonomy Approaches

Instructional Autonomy Classification	Number of institutions	Atmosphere	Engagement	Rigor
		Mean (SD)	Mean (SD)	Mean (SD)
Full Individual Autonomy	7	4.13 (1.01)	3.57 (1.24)	4.07 (.99)
Individual Approach Split Individual and Collective Content	3	4.24 (.91)	3.59 (1.17)	3.93 (.96)
Individual Approach Collective Content	3	4.23 (.92)	3.61 (1.21)	3.62 (1.14)
Individual Approach Split Collective and Top Down Content	1	4.15 (.99)	3.59 (1.20)	3.90 (.99)
Individual Approach Top Down Content	2	3.95 (1.02)	3.49 (1.16)	4.11 (.98)
Collective Approach Individual Content	1	4.03 (.95)	3.57 (1.18)	4.03 (.955)
Team Collective Autonomy	1	4.48 (.80)	4.07 (1.05)	3.70 (1.04)
Top Down Highly Coordinated	1	4.06 (1.06)	3.40 (1.24)	3.74 (.99)

Discussion

From our investigation we found that when looking across the Calculus sequence there is a great deal of variation happening across the 19 institutions, with greater variability in Precalculus, and variability within an institution. It was seen in the student data that there was the same level of variability of reported climate even within the top down courses, but team collective approaches may support the highest levels of reported climate. These findings seem to support prior research on the efficacy of course coordination as a successful characteristic of Calculus programs (Rasmussen & Ellis, 2015). Additional analysis is needed to examine the perceptions of the students who are moving through an institution's Calculus sequence where each level of course has a different category of instructor autonomy. Lastly, we would like to examine institutions that do have the same level of instructor autonomy throughout to explore the instructor perceptions as well as the student experience.

Student Reasoning about Definite Integrals on a Calculus Concepts Assessment

Toni Hall
Oklahoma State University

Beth Cory
Sam Houston State University

Taylor Martin
Sam Houston State University

Vicki Sealey
West Virginia University

Michael Oehrtman
Oklahoma State University

Assessing student understanding of calculus concepts is of interest to RUME researchers and practitioners alike. This paper details the initiation of the development phase of a new instrument to assess student understanding of the central concepts in the introductory collegiate calculus course. We discuss a framework for defining "conceptual understanding" and make transparent our process for selecting and refining robust tasks to measure it. We provide discussion on interview responses that reveal how students may attempt to rely on memorized procedure and, as a result, discredit productive conclusions. Finally, we outline and seek discussion on future work to continue development of valid and reliable questions to assess the broad range of productive understandings in calculus.

Keywords: calculus, conceptual understanding, assessment

Introduction

Although notable strides have been made by researchers such as Epstein (2007) who created the Calculus Concept Instrument (CCI), no curriculum-independent concept inventory for Calculus I has been validated and found to conform to accepted standards of educational testing (Gleason, Thomas, Bagley, Rice, White, & Clements, 2015; American Educational Research Association, 2014). The purpose of our study is to initiate the development of a valid and reliable instrument to assess students' understanding of central concepts in an introductory college calculus course for Science, Technology, Engineering, and Mathematics (STEM) majors. Our goal is to make our process and criteria transparent so that (a) researchers and educators can make informed choices about what portions they want to include in their research and (b) others in the community can contribute to the instrument in a modular way. Our initial research focuses on interpretations of accumulation and area for definite integrals.

Literature Review and Theoretical Framing

Graphical representations of definite integrals as signed area under a graph are ubiquitous in introductory calculus courses. Research on students' understanding of integrals shows that while area interpretations are widely adopted by students, they are often misapplied and hinder further productive quantitative reasoning (Jones, 2015; Sealey, 2006). Past research has also shown that an adding-up-pieces conception of a definite integral is critical for successfully modeling and interpretation especially in STEM applications (Meredith & Marrongelle, 2008; Von Korff & Rebello, 2012; Jones, 2015; Oehrtman & Chhetri, 2015). Sealey (2014) documented the nature of such student understanding paralleling the mathematical structures of products, sums, and limits in the formal definition, and Jones (2015) labeled the application of such reasoning as a Multiplicatively-Based Summation (MBS). Simmons and Oehrtman (2017) extended this analysis to Quantitatively-Based Summation (QBS) in which the basic models used to construct the parts to be added in the definite integral are not necessarily conceived as a product of the integrand and change in input.

Tallman, Reed, Oehrtman, & Carlson (2021) found that the productive meanings assessed on calculus exams at colleges and universities in the U.S. are sparse. The concept of a definite integral as area is not always supported by quantitative reasoning. Students often approach integration as simply finding the area of a planar region without considering an underlying meaning of accumulating a quantity. Tallman et al. (2021) identified key features of assessment tasks that improve their potential to assess students' productive understandings including that the items should require students to (a) coordinate interpretations, (b) provide explanations or justifications, (c) make comparisons, or (d) draw inferences. Such features require students to make strategic decisions in the problem-solving process rather than only select and apply a memorized procedure.

Methods

After reviewing the literature on student understanding and learning of definite integrals, we identified clusters of particularly consequential meanings and reasoning, based on comments in the literature and our own judgment as teachers and researchers. We selected those involving accumulation and area for our first round of developing assessment items. We collected variations of conceptual questions from the literature and available homework and exams then selected and refined seven of these questions that we felt best addressed the meanings and reasoning identified in the literature. We then developed interview protocols which included contingencies for anticipated student responses.

We conducted and video-recorded one-on-one interviews with 12 students at three institutions. These students were either completing a first-semester calculus course or currently enrolled in a second-semester calculus course. The interviews were approximately 90 minutes in duration and consisted of the seven open-ended questions with ample space for students to show their work. Each interviewer followed the protocols and encouraged students to elaborate their meanings and reasoning. In cases with unexpected responses, the interviewer probed for additional reasoning or allowed the student's reasoning to take its course then provided additional information or suggestions to see how they would proceed. We created detailed summaries of the students' work with notes about potential underlying meanings and reasoning. The entire research team then met to discuss the notes and create a model of productive understandings and the meanings with substantial evidence in the data.

Results

In this paper we discuss and contrast two pairs of tasks. The first pair (Tasks 1 and 2) requires an MBS and a QBS conception of the definite integral, respectively. The second pair (Tasks 3 and 5) illustrates students' conceptions and reasonings about area when interpreting integrals given a graphical representation.

Task 1

Carl was driving on the highway when he saw a sign that said ROAD ENDS 250 FEET. He slammed on his brakes and came to a stop in 4 seconds. Below is a table of data from his truck's computer while he was braking.

Time (seconds)	0	0.5	1	1.5	2	2.5	3	3.5	4
Speed (ft/s)	98	96	92	84	74	60	43	23	0

Given the table, what is your best estimate for the total distance Carl traveled before coming to a stop?

Most students approached this problem heuristically, drawing the graph of a function and finding the area under it. They often reached a correct conclusion using memorized procedures and associations rather than expressing any meaningful quantitative reasoning. Some applied a simple unit analysis to verify their computations but did not support this analysis with associated quantitative reasoning. Others, with prompting, did eventually invoke some quantitative meanings, which however did not alter their approach or answer.

Student 1: Multiply…feet per second…times one second. How much the area is underneath that [graph]…that's how many…feet.

$$0.5(\cancel{98}+96+92+84+74+60+43+23+\cancel{10})$$

Student 2: The speed, feet per second times second is just feet. All of this times .5.

Student 3: Speed is feet a second and time is just measured in seconds, so if I multiply time times speed, it can obviously give me a distance. Then obviously, the value under the curve is the entire…estimate.

Task 2

A train travels along the monorail at a theme park and is programmed to change speed according to where it is on the track, to make turns, stops, etc. The train passes a sign that says the next stop will be in 30 meters. The speed of the train is $v(x)$ meters per second at a point x meters along the track from the sign. As it approaches one stop, its speeds at 5-meter increments are given in the table below.

Distance from sign (m)	0	5	10	15	20	25	30
Speed (m/s)	8	6	5	4	3	2	0

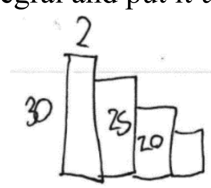
Given the table, what is your best estimate for how long it takes the train to stop from 30 meters out?

Some students guessed the correct integral using unit analysis. Without the underlying quantitative reasoning that is necessary in a problem such as this, however, they were unable to make accurate associations and generate the appropriate Riemann sum. This discrepancy is partly due to their perception that the answer should be the area under whatever curve they have.

Student 1: [manipulates formula and tries switching axes and using slope] Slope is rise over run. You could take the integral and put it under 1. You can just set distance as the *y*..

$T = \frac{D}{S}$

$\text{Slope} = 1/T$



$$2(30+25+20+15+10+5)$$

Student 2: [using non-quantitative unit analysis and manipulating ratios]: I'm multiplying distance times speed and that's meters times m/s…but distance times speed does not equal…time. If 8 is to 1, then what is that to 5 over *x*.

$m \cdot m/s$

$\frac{m}{m/s}$ $\quad m \cdot \frac{s}{m}$

$\frac{8}{1} = \frac{5}{x}$ $\quad 8x = 5$ $\quad 0.625\,s$

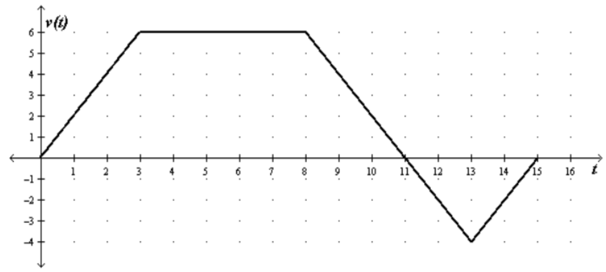
$0.625 + 5/6 + 1 + 5/4 + 5/3 + 5/2 = 7.875\,s$

Task 1 vs. Task 2

Most students approached Task 1 procedurally without any quantitative reasoning about (a) the distance-velocity-time relationship or (b) the structure of a definite integral. This type of problem invoked an instant association with computing a Δt, multiplying by function values, adding the results, areas of rectangles on a graph, area under the graph, and an integral representing area and/or distance. However, there was no connection between these associations and meaningful quantitative reasoning. In contrast, Task 2 required students to reason quantitatively in the context of the problem rather than simply use formula manipulation and/or unit analysis. Those who successfully completed the task, developed a QBS interpretation that enabled them to break up the scenario into pieces of time and create an appropriate Riemann sum. Further, these correct answers differed from their initial procedural approach.

Task 3

Assume that the graph of $v(t)$ shown below represents the velocity of a car (in meters per second) that is traveling along a straight road. Positive velocity corresponds to traveling straight north.



1. How far is the car from its starting point after 15 seconds? Explain.
2. How far does the car travel over the 15-second interval? Explain.
3. Write down integrals that correspond to the numerical answers for #1 and #2.
4. Compute $\int_0^{15} v(t)dt$.
5. Is there an interval on which $\int_0^{15} v(t)dt \int_a^b v(t)dt = 0$? If so, where, and what does it mean in terms of the context of the car?

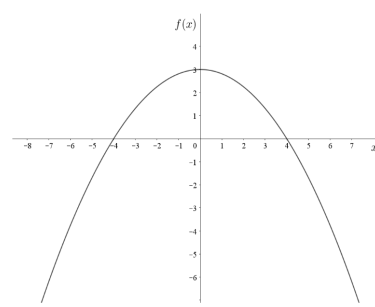
Draw a graph of position vs. time and relate it to each interval of the velocity vs. time graph.

Most students were able to interpret the movement of the car correctly. However, when finding displacement or distance traveled, many relied on memorized procedures with no productive understanding of the situation.

> *Student 1:* I'm not even really reading the words. I'm just seeing graphs. Find area.
> *Interviewer:* Does it matter that velocity is the *y*-axis and time is the *x*-axis?
> *Student 1:* No. That helped, I suppose.
> *Student 2:* Why would I set up an integral when I could just like use shapes?
> *Student 3*: I just found the difference of those areas.
> *Interviewer:* What led you to compute areas?
> *Student 3:* That was just my go-to…start finding the areas. I just remembered doing it from other problems.

Task 5

Use the graph below for this item. For each pair below, determine which one is larger or if the quantities are equal. Explain how you know.



a) $\int_0^2 f(x)dx$ _____ $\int_0^4 f(x)dx$ (fill in the blank with <, >, or =)

b) $\int_3^4 f(x)dx$ _____ $\int_4^6 f(x)dx$ (fill in the blank with <, >, or =)

c) $\int_0^4 f(x)dx$ _____ A left-hand Riemann sum on the interval from *x*=0 to *x*=4. (fill in the blank with <, >, or =)

Determine if each expression below is positive, negative, or zero. You do not need to evaluate the expression. Explain how you know.

d) $\int_{-4}^{4} f(x)dx$ e) $\int_{-3}^{3} f'(x)dx$ f) $\int_{3}^{1} f(x)dx$

This question revealed flawed reasoning that can result when students lack a meaningful basis for their understandings. Imagistic reasoning led some students to misinterpretations.

Student 1: [explaining his correct answer (>) on part (b)] 4 to 6 isn't even above the *x*-axis, I don't think it makes it negative. It's still area. I just put that because since 3 to 4 was above the *x*-axis, it'd be positive, and this 4 to 6 wouldn't really count in my mind…so I just discredited it. If you do think about if it keeps going below the *x*-axis, it would be…infinite. If you're just thinking about it being below this graph, it keeps going down.

Student 2: [explaining his incorrect answer of "0" on part (d)] Assuming it's a symmetrical parabola, the negative area [points to left of *y*-axis] is equal to the positive area [points to right of *y*-axis], so they cancel each other out.

Task 3 vs. Task 5

The use of imagistic and associative reasoning enabled some students to answer question 3 correctly but caused serious interpretive problems in question 5. For example, student 1 (above) conceptualized the area below the curve extending to negative infinity yet obtained the correct answer to question 3 (with bounded regions). Student 1 seemed to think that all area is positive and "discredited" the area that was below the *x*-axis.

Discussion

Although we may be tempted to be complacent about students' memorized associations and procedures, these questions reveal that when not backed by productive understandings of the underlying mathematical concepts, they are merely arbitrary rules. Without a meaningful basis, students are likely to invoke highly inappropriate variations of these procedures alongside or even displacing appropriate ones.

We reviewed Tallman et al.'s (2021) analysis of productive meanings assessed on calculus exams in the United States. Results showed that the exams generally required low levels of cognitive demand and students were rarely required to demonstrate or apply their understanding of concepts. Therefore, the need arises for exams to contain discerning questions to assess students' quantitative conceptions. To facilitate this assessment, students must be required to model the accumulation of quantities using a localized adaptation of a basic model relating the multiple relevant quantities. They must also explicitly connect definite integrals with the approximations generated from the resulting Riemann sums.

Ultimately, we aim to develop an instrument that will (a) identify aspects of productive understandings that are both broadly and effectively adopted by students to make sense of calculus content, (b) evaluate broad-scale interventions which seek to identify instructional practices that lead to productive understandings of calculus content, and (c) convey important characteristics of productive understandings to the general mathematics faculty in order to illuminate effective and ineffective instructional practices in calculus.

Examining the Interplay Between Self-Efficacy Beliefs, Emotions, Stress Mindset and Achievement in Different Assessments in University Mathematics

Kaitlin Riegel
University of Auckland

Tanya Evans
University of Auckland

There is currently little research that examines the interplay between various affective constructs, particularly within the context of mathematics assessment. This longitudinal study seeks to understand how student assessment-related affect changes across a university mathematics course and seeks to identify latent or explicit factors that play a role. We collected data on achievement emotions, self-efficacy, stress, and stress mindset across three time points, in addition to measures of academic performance, specifically on different forms of assessment. Without accounting for interactions, preliminary results considering the constructs individually demonstrate an increase in negative and decrease in positive affect. However, incorporating path analysis suggests that engagement on low-risk summative assessment has the potential to promote self-efficacy. As a consequence of this research, we hope to pinpoint suitable interventions that may have a positive influence on affect and achievement. The disentangling of these relationships will have practical implications for course design and assessment structure.

Keywords: assessment, affect, higher education

Social-cognitive theory (SCT) posits that personal affective factors, such as beliefs and emotions, have reciprocal relationships with learning behaviors and educational environments (Bandura, 1997). From this perspective, understanding assessment-related affect is critical to the design and delivery of assessments conducive to student achievement. Based on findings that different assessments elicit different affective responses (Riegel & Evans, 2021) and that frequent, low-risk assessment may enhance self-efficacy (Evans et al., 2020), we identified two broad research objectives: (1) To gain a deeper understanding of assessment-specific affective constructs, including why and how they change during a mathematics course, and (2) To gain a holistic view of the relationship between affect and assessment through examining students' assessment-related *affective field*, defined as, "the bundles of affective factors involved in particular situations in their intraplay" (Schindler & Bakker, 2020). This research particularly seeks to consider relationships between student assessment self-efficacy, emotions, and stress mindset in both an online quiz and final exam, amongst other measures, such as gender and achievement. We chose these affective variables as their relationships and interplay have been underexplored in the context of mathematics assessment. We hope to formulate generalizable implications for assessment practice.

Literature Review

Achievement Emotions in Assessment

Achievement emotions are emotions experienced by learners pertaining to achievement activities and outcomes (Pekrun, 2006). Positive emotions have generally been shown to correlate positively with engagement, attention, motivation, and performance, while negative emotions correlate negatively with these constructs (Mega et al., 2014; Peixoto et al., 2017; Pekrun et al., 2002; Reeve et al., 2014; Schukajlow & Rakoczy, 2016). Most research on achievement emotions with respect to assessment has focused on test-anxiety, with studies generally demonstrating a negative correlation between test-anxiety and achievement (e.g., Lang & Lang, 2010; Steinmayr, et al., 2016; Zeidner 2014). Little attention has been paid to other emotions in this context. When considering online assessment, studies have generally indicated that students experience less stress and anxiety (Cassady & Gridley, 2005; Dermo, 2009; Engelbrecht & Harding, 2004; Stowell & Bennett, 2010), as well as more positive and fewer negative emotions (Daniels & Gierl, 2017; Riegel & Evans, 2021). In line with SCT, Pekrun (2000) argues that repeated experiences of emotion in recurring scenarios, such as assessment, can cause cognitive appraisals to be bypassed and lead to the emotion becoming habitualized. Research has shown there are reciprocal effects between emotions and achievement (Ahmed et al., 2013; Pekrun et al., 2017; Pekrun et al., 2019). More studies are needed to understand how emotions in assessment change and interact with other affective constructs over time.

Assessment Self-Efficacy

Self-efficacy is a construct in SCT defined as, "the beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1997, p. 3) and is a known predictor of achievement (Pajares & Graham, 1999; Zimmerman, 2000). Experiences of success support the development of self-efficacy while experiences of failure hinder it (Usher & Pajares, 2009), indicating that success or failure in one assessment may impact students' beliefs about future assessments. Few studies consider assessment-related self-efficacy, despite Bandura's (1997) proposal that self-efficacy measures must be both context and content specific. Since summative assessment is the foremost way tertiary institutions gauge students' progress (Iannone & Simpson, 2011), it is vital for research to understand and operationalize student assessment-related self-efficacy.

Stress Mindset

Crum et al. (2013) present a new construct of stress mindset, defined to be the extent of one's beliefs that stress has enhancing or debilitating consequences. The few existing studies in education indicate significant relationships with student affect and performance (Jenkins et al., 2021; Keech et al., 2018; Kilby & Sherman, 2016; Riegel et al., 2021). A further study by Crum et al. (2017) concluded that adopting an enhancing view of stress may be beneficial by altering how individuals respond in stressful scenarios over time. Research demonstrates that self-efficacy associates positively with positive emotions and negatively with negative emotions (Luo, et al., 2016; Pekrun et al., 2004; Pekrun, et al., 2011; Usher & Pajares, 2009). No studies have yet incorporated stress-mindset as a moderator for these relationships.

Methods

Setting and participants

The participants in this study were students enrolled in semester two of 2020 at a major New Zealand university in a second-year service mathematics course. The course featured frequent online quizzes to be completed any time between each lecture. These were designed to be low-risk through the use of multiple-choice questions, 30 minute completion windows, two attempts with instant feedback, and keeping best 27 out of 31 quizzes throughout the 12 weeks term. They amounted to 13 percent of the final grade. The course also had a test and a two-hour, invigilated, 50 percent final exam. After data cleaning, 277 of the 410 students enrolled at the start of the semester had consented to their data use and completed all three surveys. This study was approved by the University of Auckland Ethics Committee (approval number 024710).

Data collection and analysis

The research design is a repeated measures design with no control group. As part of the coursework, there were three ten-minute questionnaires administered online (via Qualitrics), each worth 0.1% of the final grade. During the twelve-week semester they were administered in week one (Q1: before any assessments), seven (Q2: after the mid-semester test), and eleven (Q3: before the final exam), and student achievement measures were collected throughout the semester. Participants were removed from the analysis if their responses demonstrated sufficient evidence of straight-lining or the survey was less than 50% completed. Missing data was inserted using EM-imputation. All analyses used version 27 of SPSS and its AMOS programme.

Measures

Achievement Emotions Questionnaire (AEQ). All three questionnaires included an adapted version of the test-related section of the AEQ (Pekrun et al., 2011), with statements pertaining to achievement emotions experienced before (χ^2/df = 2.09, CFI = .92, RMSEA = .06, n = 18) and during an exam (χ^2/df = 2.72, CFI = .90, RMSEA = .08, n = 18). Our adapted version consists of statements measuring anxiety, enjoyment, hope, and hopelessness on a Likert scale from 1 (*Strongly Disagree*) to 5 (*Strongly Agree*).

Measure of Assessment Self-Efficacy for Quiz (MASE-Q) and Exam (MASE-E). All three questionnaires included the newly developed MASE-Q (χ^2/df = 2.38, CFI = .99, RMSEA = .07, n = 7) and MASE-E (χ^2/df = 1.47, CFI = .99, RMSEA = .04, n = 7) (Riegel et al., 2022), designed to assess the participant's beliefs in their *comprehension and execution* and *emotional regulation* abilities while studying and during an assessment. Responses to statements were measured using a slider scale from 1 (*Cannot do at all*) to 100 (*Highly certain can do*). The participants were randomly presented with two assessment scenarios, a low-stakes online quiz and a high-stakes final exam to respond to the MASE-Q and MASE-E, respectively.

Stress and Stress Mindset Measure (SMM). To measure assessment stress, participants were asked "How stressful do you perceive this mathematics QUIZ/EXAM to be?" following each scenario. They responded on a nine-point scale from *Not stressful at all* to *Extremely stressful*. Using the scales developed by Crum et al. (2013), we included an adapted general version of the SMM in the first questionnaire (χ^2/df = 2.67, CFI = .97, RMSEA = .08, n = 7) to obtain an overall measure of students' perception of stress. Additionally, an adapted SMM was designed to measure participant stress mindset in relation to the quiz (measured in Q2 and Q3) and exam scenarios (measured in Q1 and Q3). The scales consist of three stress-is-enhancing statements and four stress-is-debilitating statements. Participants responded on a five-point scale (*Strongly Disagree* to *Strongly Agree*).

Achievement. Student prior achievement was recorded as a self-reported prerequisite grade. We also collected performance results, which contributed to their final grade (quizzes, tutorial participation, assignments, test, and exam).

Demographic Information. We collected self-reported gender, ethnicity, and major.

Preliminary Results and Discussion

Several analyses have already been conducted using this data, including the validation of the MASE-Q and MASE-E (Riegel et al., 2022). Riegel et al. (2021) found stress mindset to be significant and achievement emotions dominant in predicting exam self-efficacy. As understanding the consequences of the pandemic became crucial, Riegel and Evans (2022) included new variables and found engagement with online quizzes, prior achievement, positive affect, and wellbeing were predictors of how students evaluated the impact to their learning.

We now seek to use the longitudinal data to understand how different affective constructs interact and individually change over time for students, as well as investigate students' affective fields in assessment. To address the first part of this goal we ran repeated measures ANOVAs and *t*-tests, which largely suggested a significant increase in negative and decrease in positive affect across the semester (Table 1). This raises interesting questions around 'trait' affect, which we hope to unpack, but also fails to illuminate why these constructs change. To investigate further, we employed path analysis. We first examined the unexplored construct of assessment self-efficacy, incorporating the effects between and within assessment and self-efficacy.

Table 1. Repeated measures ANOVAs and t-tests for affective variables.

		1	2	3

**Note.* ***p* <.001, *<.05; CE = comprehension and execution, ER = emotional regulation.

Acceptable models are presented in Figure 1. Anticipated reciprocal effects between exam self-efficacy with a similarly high-stakes test are seen. However, quiz *comprehension and execution* self-efficacy does not demonstrate a reciprocal relationship with quiz achievement following the test. Moreover, for quiz *emotional regulation* self-efficacy, there is no reciprocal relationship with performance. These findings may suggest that the relationship between self-efficacy and performance is weaker in low-risk assessments, which elicit less of an emotional response, and the effects are overwhelmed by the affective influence of a high-stakes assessment.

Generally, we see simultaneous effects between different forms of assessment self-efficacy, suggesting performance in one assessment may indirectly influence self-efficacy in another. In the first half of semester, exam self-efficacy more strongly predicts quiz self-efficacy. However, in the second half of the semester (after the mid-semester test) quiz self-efficacy is a stronger predictor of exam self-efficacy. This in part indicates that repeated experiences on low-risk assessments can influence the efficacy of students going into an exam, though high-stakes assessments during the semester can overwhelm these effects. The quizzes were designed so participating students were likely to receive full marks, meaning performance on quizzes largely reflects student engagement. Thus, it is plausible to suggest that through incorporating the intervention of regular quizzes, educators can indirectly promote exam self-efficacy and achievement. To further support this hypothesis, we intend to conduct a cross-lagged panel analysis so to determine directions of influence between the types of assessment self-efficacies.

Questions

We have presented some of the results of our preliminary analyses and seek to discuss with the attendees of RUME the following questions:

- We can perform similar path analyses to the ones presented here for other variables collected to look at affective relationships with achievement, but how might we retain the interplay between affective variables with our limited sample size?
- Certain affective constructs (e.g., beliefs) are considered slow to change. How can we use our data to provide insight into our understanding of “trait” or “global” affect?

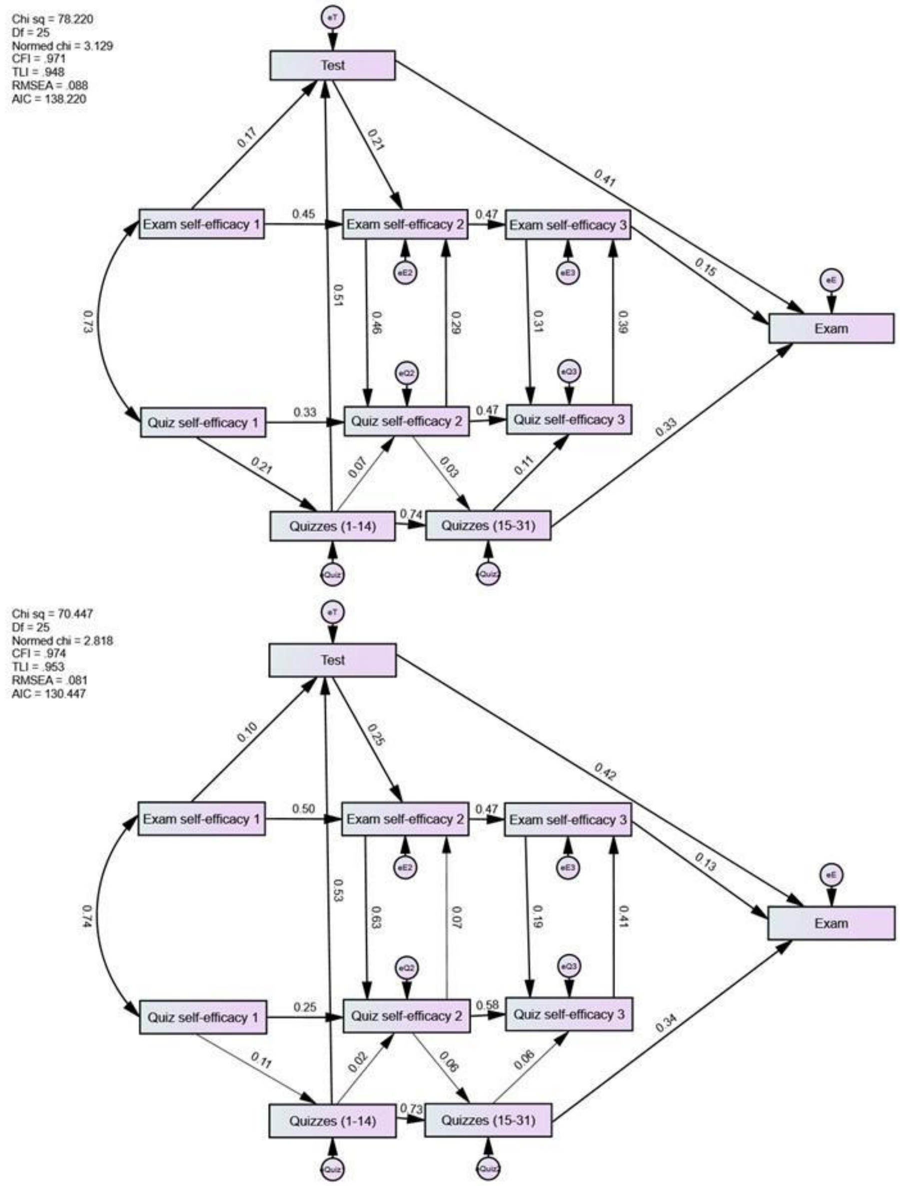

Figure 1. Path analyses of comprehension and execution (top) and emotional regulation (bottom) self-efficacy.

Changing the Conversation: Building Success in a Community College Mathematics Classroom

Megan Selbach-Allen
Stanford University

Calculus remains a major barrier of entry into STEM for students without strong mathematics backgrounds. This study looks at one implementation of the STEM Core model, which provides an accelerated pathway through developmental math classes along with extensive support to get students calculus ready in one year. Viewing this program as a community of practice around math learning I examined course completion data and conducted interviews to understand how the model is impacting student success. Furthermore, I seek to understand what aspects of the model matter most to the students. Initial results of student success rates in the course sequence show significant positive outcomes, with nearly 65% of STEM Core students reaching Calculus I in one year. Interviews with students reveal how their success goes beyond course completion and the importance of the relationships they built with their instructors and one another.

Keywords: Community College, STEM pathways, Developmental Mathematics, Calculus

Within the context of science, technology, engineering, and mathematics (STEM) many studies have shown the reality of the "leaky pipeline" with students dropping out of STEM majors along the way to completing a degree or dropping out of school (Flynn, 2016). Historically, many faculty in these disciplines promoted this culture as they thought it was a filter removing students who would not be capable of succeeding, but this is not the case (Seymour & Hewitt, 1997). Unfortunately, the students who drop are not weaker academically but do have backgrounds already underrepresented in STEM fields and cite the realities of a "chilly climate" as a significant factor in why they step away from finishing their STEM degrees (Jorstad et al, 2017). Addressing the issues creating the leaky pipeline and students not persisting in STEM degrees is crucial to improving broader issues of diversity in STEM.

Research has shown the importance of teachers and effective teaching in students' academic outcomes (Burroughs et al., 2019; Christe, 2013; Goe, 2007; Goh & Fraser, 1998; Sonnert et al., 2015). This research spans grades K-16 and all subject areas. Unfortunately, undergraduate mathematics often serves as a barrier for students attempting to pursue STEM degrees (Bressoud et al., 2015). Improving mathematics instruction and classroom environments is an important part of addressing the leaky pipeline and equity in STEM (Boaler & Selling, 2017).

Public two-year colleges educate roughly 35% of undergraduate students in the United States (Community College Research Center, 2022). They educate a disproportionate share of minority, first generation and low-income students. Community colleges are an important starting point for many students entering the college pipeline and 49% of students completing bachelor's degrees had attended community college at some point in the previous 10 years (National Student Clearinghouse Research Center, 2017). While this is an important context of study because of its large share of the undergraduate student population in the US, it is also an understudied context (Mesa et al., 2014a; Fletcher & Carter, 2010).

To work on improving the environment of STEM classrooms in community colleges we need to know both what effective teachers are doing in their classrooms and how students are responding to their instruction. Related to that it is necessary to understand the social environment of these classrooms and what students are learning.

Theoretical Framework

Of greatest interest for this work is understanding the mathematics classroom learning environment in this school. The environment is impacted by broader structures of the NSF funded STEM Core program of which it is a part, but it is also uniquely shaped by the instructors, staff and environment of this particular school.

This work is situated in the idea of learning as a community of practice (Wenger, 1999). The STEM Core model changes the mathematics learning environment for the students to engage them not only in the classroom as an individual, but in all aspects of their life and as a part of a community. With a cohort model, students spend a full year with consistent instructors who know them and each other. The student cohorts become a community with genuine relationships forming among the students themselves and the teachers and staff who support them. With the funding provided by STEM Core students also have access to a dedicated student support specialist.

This study is conducted in partnership with the mathematics course instructor and seeks to better understand what is working with this implementation of the STEM Core model. The research questions for this work are:

RQ1: How is this implementation of the STEM Core model affecting student success rates?

RQ2: What do student interviews reveal about the most impactful aspects of the program over time?

Success is defined by the institution as obtaining a C or better in a course. This definition in assessing the impact of STEM Core on academic outcomes for students aligns with requirements for taking follow-on courses and meeting transfer requirements. However, in this work success is also defined more broadly. Student persistence in the face of failure or adversity along with taking up identities as knowers and doers of mathematics, engineering or computer science are also markers of success for this researcher and the administrators of the program.

Literature Review

In 2012, Ann Sitomer and colleagues (2012) laid out a research agenda for mathematics education researchers specifically focused on community colleges. They acknowledged that there is much overlap with the long history of mathematics education research in K-12 classrooms and with the more recent research in undergraduate mathematics education (RUME) work, but they also note ways in which community colleges and the math learning they encompass are distinct. In a research commentary written a few years later Mesa and colleagues (2014a) also called for the need to expand research specifically in the math classrooms of community colleges. They note the difficulty and limitations of transferring the findings of work done in one setting (ie K-12 classrooms or 4-year colleges) to another (ie community colleges) as while there may be some similar characteristics there will also be many differences. In their commentary they also explicitly note the lack of research conducted specifically within classrooms and focusing on instruction. The research in classrooms that did exist tended to be conducted by practitioners and focused on particular interventions and more in line with sharing "what works" with other practitioners and not producing generalizable knowledge. They described the state of math education research in this setting as having, "the same feel of disorganized guerrilla warfare" (Mesa et al., 2014a, p. 179). Community colleges are constantly under pressure to improve student outcomes and are often looking for a quick fix. While instructors want to do better for their students, there is a lack of an organized research agenda to help them know the best ways to do so. In laying out their research agenda they reiterated the same four areas highlighted earlier by Sitomer and colleagues (2012).

Since the writing of these two commentaries additional important work in understanding community college mathematics instruction and learning has been done. A large video study of community college instructors sought to connect how they talked about instruction to their actual instructional practices in the classroom (Mesa et al., 2014b). While this study provided a significant amount of insight into instruction the authors note the need for more studies focusing on what students are learning, “what do students learn and understand as they experience particular teaching approaches” (Mesa et al., 2014b, p. 146). A further study of community college faculty teaching developmental math that sought to apply the framework of mathematical knowledge for teaching resulted in a proposal for the need to add an amendment of “the Caring Map” to make sense of the concept at the community college level (Nabb & Murawska, 2019). Studies using quantitative longitudinal methods have considered the variance of students’ pathways through developmental mathematics and what drives varied student outcomes (Howell & Walkington, 2022). However, community college mathematics students themselves, especially their individual experiences, remain understudied.

Methods and Data Sources

This study uses past-performance data from 2015-2019 on student success rates in Algebra II through Calculus III, success is defined as obtaining a C or better in the course. It should be noted all course completion data is from before the implementation of AB705 in California which dis-incentivized colleges from offering developmental mathematics classes and led to a restructuring of the course sequence at this college along with changing the placement system for students. Updated course completion data is not yet available.

These course records are supplemented with student interviews (n=10) to understand what students viewed as the most salient aspects of their experience with the program. The students interviewed were alumni of STEM Core who had completed the one-year program up to four years prior. Volunteers were sought through messages on a facebook group for alumni in the program. Due to this sampling methodology the views expressed by students in the interviews may be biased but they still provide useful insight into what mechanisms might be driving the program success rates revealed by institutional data. Student demographic characteristics matched roughly with the overall demographics of the program, 8 students were male identifying and 2 were female identifying. The students also held a diversity of racial and ethnic identities. Further details of students’ demographic characteristics are not included to protect student privacy and confidentiality.

During the roughly 30-minute interviews students were asked about many different aspects of the program. By interviewing students from multiple cohorts of students the researcher sought to better understand the longitudinal impact of this program for students after their first year of classes and when the intensive support structures of the program were no longer present.

Preliminary Results

Research Question 1

The first 5-years of the STEM Core program at this institution has produced results that show significant increases in student success in the courses from developmental math through calculus. Table 1 shows the results for cohorts of students in the program from four cohorts. As stated earlier in this paper success is defined as passing the course with a C or better. The number of enrolled students for a given course may exceed prior course numbers because students may take the course multiple times before obtaining a C or better and students are able to join the STEM Core cohort at any point in the pathway as long as they have met the prerequisite. Of students who start the STEM Core program with Algebra II 64% complete Calculus within one year compared to only 16% percent of students statewide (Mejia, Rodriguez, & Johnson, 2016).

Additionally, preliminary data shows that students in the STEM Core have higher success rates in English courses 77% versus 71% for the institution, even though English is not a part of the program. This difference indicates that the impact of the STEM Core model goes beyond helping students perform better in their STEM classes but may be helping them become better students overall.

Preliminary data also shows that success rates, while still high, decrease for courses that come after the program. Specifically, Calculus II success rates are significantly lower for students in their first attempt at the course but data shows that students who are not successful in their first attempt are taking the course again. The overall success rate for Calculus II for STEM Core students was 40% versus the overall institutional rate of 64%. However, a deeper look at the data revealed an interesting pattern. The results for one cohort show the success rate listed as 48% because 22 students passed in 46 attempts. However, this STEM Core cohort only included 29 students who had completed Calculus I, thus 76% of the STEM Core students who completed Calculus I also completed Calculus II, but some required multiple attempts.

Table 1: Shows student success rates in math courses in the institution as a whole and in the STEM Core cohort.

Course	**Typical success rates (3-year average)**	**STEM Core students**
Algebra II	56.4% (n=3311)	93.8% (n=145)
Trigonometry	60.9% (n=1542)	95.7% (n=164)
Precalculus	75.7% (n=1209)	89.7% (n=156)
Calculus I	65.8% (n=1376)	79.4% (n=136)

Research Question 2

Interviews with students revealed that nine of the students identified as still being involved in STEM either in their educational or career trajectory. Nine of the students had attempted calculus II with eight completing the course. One student dropped the course the first time and intends to retake again in the future and four of the eight who completed the course required more than one attempt to do so.

Students' discussion of their various experiences in calculus II shared a common theme of the drastic drop in the support they felt from their prior year taking calculus as a part of the STEM Core program. One student shared how her STEM Core instructors had warned their class not to expect the same level of support in future classes and worked to prepare them. Three of the students mentioned going back to their STEM Core instructor to seek advice and support. He encouraged them that failure was okay and that they would ultimately succeed.

The importance of the community they had found in the STEM Core program was a common theme among interviewees. They talked about how they trusted the faculty and staff in the program and built relationships with their classmates that extended beyond the classroom. One student mentioned that he was currently at a 4-year university and rooming with friends from the STEM Core program.

Another common theme in the interviews was how the program helped students connect with internships that helped lead to other jobs. These students who generally came from low-income families and were the first in their family to attend college appreciated how the STEM Core program provided guidance on the importance of internships and how to apply to them. They shared how these real-world connections have helped set them up with practical experiences and networks that they can leverage as they move forward in their careers.

Discussion

For students entering college at a developmental mathematics level the research says their chances of succeeding in a STEM major are very small (Bullock et al., 2017), but this work interrogates that 'truth.' It reveals through the success of students in one program how a model that supports students as whole people and builds community can lay the groundwork for long term success.

An important point to note about this program is that it is not 'remedial.' Any student who has an interest in pursuing a STEM degree can be admitted into the program. The main, initial appeal of the program to most of the students interviewed was that it would help them complete their math courses faster. This program leverages students' motivation and desire to succeed instead of labeling them as in need of remediation.

The instructors and staff of the STEM Core program studied in this work are incredibly dedicated and experienced. Their work may not be possible to replicate in all circumstances, but this work should lead institutions to consider whether implementing cohort models, emphasizing community building and considering wider supports for students might lead to higher success rates.

Finally, from a theoretical perspective this work could be seen as an empirical example of the mathematical knowledge for teaching (MKT) revised framework offered by Nabb & Murawska in their 2020 paper. They shared how understudied the domain of community college classrooms is and looked at the MKT framework that had arisen from K-12 instructional research, but they added one important area based on interviews with instructors: caring. The instructors and staff in this program care deeply for their students and that care is clear to the students in the program. While the students did learn content, the much more important messages they received was about their capabilities as students and that while they might struggle along the way they had a path to success.

Questions and Points for Audience Discussion

This work has served as a pre-study to a more in-depth study that will be undertaken during the upcoming 2022-23 academic year. I will be conducting a full ethnographic study of a cohort participating in this program and will attend and observe the mathematics classroom throughout the program. I am interested in what questions this work raises for audience members that I can consider in more detail in the longer study and what additional insights could be gleaned from further analysis of the interview data already collected.

Courtney Donovan
CU Denver

We address the transformation of instruction in entry-level college mathematics courses, such as College Algebra. Our research question is: What do instructors view as benefits and challenges when implementing novel digital graphing activities in College Algebra? We report on a case study of two instructors who implemented the activities during both semesters of one academic year, drawing on instructors' individual interviews at the end of each semester. The instructors viewed it as beneficial to implement these activities as part of a community. They also found the activities' focus on reasoning helpful for their students. They found integrating the new activities with existing online learning management systems challenging at times, and they wished their students were more engaged when implementing activities asynchronously. Overall, the challenges were not roadblocks, and the benefits outweighed the challenges. We conclude with discussion and implications for research and practice.

Keywords: undergraduate education, instructional activities, communities of practice, technology

The transformation of instructional practices in introductory college math courses, such as College Algebra, is important for students' persistence in Science, Technology, Engineering, and Mathematics (STEM) degrees (e.g., Freeman et al., 2014; Henderson et al., 2011; Herriott & Dunbar, 2009). Yet, instructional materials in such courses tend to privilege a status quo of finding numeric answers at the expense of promoting reasoning (Mesa et al., 2012). When instructors implement digital activities designed to press against a status quo of answer finding, there can be tension regarding the status of the activities within the course (Olson & Johnson, 2022). For this preliminary report, we investigate the question: What do instructors view as benefits and challenges when implementing novel digital graphing activities in College Algebra? We report on a case study of two instructors, Riya and Carol (pseudonyms), who implemented activities in both semesters of one academic year in conjunction with their participation in a faculty learning community (FLC) (Cox, 2016).

College Algebra is an entry-level undergraduate course at many U.S. institutions. The Committee on Undergraduate Programs in Mathematics (2015) has recommended revisions to College Algebra, including rethinking the class to better support students as logical and quantitative thinkers. However, change has been slow to develop (Tunstall, 2018). Working with innovative digital activities can make room for instructors to question conventions in their curricular materials (Sinclair et al., 2020) and deepen their understanding of mathematical relationships (Moore et al., 2019). By incorporating novel digital graphing activities into College Algebra, we work to affect change in the course. Our case study provides insight into instructors' views on the benefits and challenges of implementing such activities while discussing implications for research and practice.

Background

To explain how instructors may make changes to their instruction via implementing novel digital activities while participating in an FLC, we draw on Wenger's (1998) Community of Practice (CoP) theory. From this perspective, practice is not something people hand down from one group to another; it is ongoing and continually evolving. One way to engage instructors in new practices is to make room for negotiation between the core members of a community and those along the periphery (Wenger, 1998). This way, instructors can "dip their toes" into practice without demanding full participation. For example, instructors may participate by listening to others implement the activities or trying out a new digital activity in their class.

FLCs are common in higher education (Cox, 2016; Kezar et al., 2018). They can form when instructors connect through a common scope of practice and come together to learn and share about a concept or process over time. Communities of Transformation (CoTs) are a special type of FLC. Kezar et al. (2018) define CoTs as "communities that create and foster innovative spaces that envision and embody a new paradigm of practice" (p. 833). CoTs include three aspects: an idea to challenge the status quo, the space to carry out practices, and a group with which to sustain those practices (Kezar et al., 2018). For example, focusing on reasoning rather than finding answers is one way to challenge the status quo in early undergraduate mathematics courses. Interacting with CoTs allows instructors to have space to conduct new practices with colleague collaboration and support.

Methods

Our case study (Yin, 2016) stems from a larger, National Science Foundation-funded project spanning multiple institutions. The project intends to address the overemphasis on finding the correct answer in U.S. undergraduate mathematics education by prioritizing mathematics reasoning. The project aims to transform instruction in College Algebra via instructors' implementation of digital graphing activities, *techtivities,* that emphasize students' reasoning over answer-finding. We report on a case of two College Algebra instructors, Riya and Carol, who participated in the project for one academic year.

Techtivities

The techtivities are digital graphing activities developed in the free, Desmos platform (Desmos, n.d.). Each techtivity starts with animation, such as a "Cannon Man" propelled out of a cannon and then parachuting back to the ground. Students explore the change in two attributes identified in the situation (e.g., height from the ground and total distance traveled) and create a Cartesian graph relating the attributes. They compare their graph to a computer-drawn image and graphs generated by their classmates and reflect on their observations. Then, students sketch another Cartesian graph representing the same relationship between attributes but with the attributes on different axes.

Data Collection

Instructors participated in the project while receiving stipends on a semester-by-semester basis. In their first semester of implementing the techtivities in their College Algebra courses, instructors attended four professional development (PD) sessions via videoconference to accommodate participants from multiple institutions. During these sessions, participants explored features of the techtivities, discussed strategies for implementation, and reflected on the role the techtivities played in their instruction. Co-investigators of the larger project held PDs roughly once per month. After the first semester, instructors met in small group CoT meetings at their institution to debrief their implementation of the techtivities and share related ideas.

At the end of each semester, instructors participated in 30-minute, individual, semi-structured interviews conducted by video conference. In an instructor's first semester of participation, the interview had four topics: benefits and challenges of teaching College Algebra, benefits and challenges of participating in the project, instructors' views of students' interactions with the techtivities, and the instructors' perceived impact of the techtivities on their teaching. In subsequent semesters, the interview revisited benefits and challenges and student interactions, as well as three additional topics: instructors' views on what constitutes a techtivity and how the techtivities fit within their course, instructors' collaborations with others about the techtivities, and instructors' takeaways from working on the project. Graduate research assistants produced verbatim transcripts for each of the instructor interviews.

Analysis

Instructor interviews were our source of data, analyzed using a modified form of open coding (Corbin & Strauss, 2008). We entered the analysis process with two broad codes, "benefits" and "challenges." By a benefit, we meant something an instructor perceived to be good, helpful, or enjoyable. By a challenge, we meant something an instructor perceived to require thought, skill, or innovation to address.

Whitmore and Knurek led the coding and data analysis. They began by reading the transcripts and watching the videos. Then, they identified excerpts (uninterrupted speech turns from instructors), which they coded as benefits or challenges for the instructor. For each excerpt, they wrote a short field note explaining how they viewed the excerpt to represent a benefit or challenge. To vet the codes, they met in pairs to agree and brought the codes to the larger author team, who weighed the codes against the evidence in the interview and refined the themes emerging from the excerpts and codes.

Results

Our analysis revealed four themes related to benefits and challenges. Instructors' views of the benefits related to the techtivities outweighed the challenges they faced. Benefits included their participation in an instructor community and the value of focus on reasoning. Challenges included integrating the new activities with existing learning management systems and engendering student participation in asynchronous settings.

Benefits

Participating in an Instructor Community. Riya and Carol acknowledged the value of meeting regularly with other instructors while implementing the techtivities. In her second interview, Riya described structuring their small group CoT meetings around discussions about instruction.

> Riya: In terms of me as a faculty, we've been doing something different this year by like visiting each other's classes to check how these go with other instructors. And our schedules were in conflict, so we really didn't get the chance, but we all recorded and met after that. We discussed the recording and giving kinds of answers also about the set of questions, what was our challenges, what we like, what we faced, how things were going.

> And also, you see like the same video from a different instructor perspective, that was really helpful.

Carol found the CoT meetings to be a space where she saw other instructors' practice. She stated, "It was nice to see how other instructors, well, it was just Riya so far, but it's nice to see how they implement this." Their comments pointed to the ongoing nature of developing new practices, as put forward by Wenger (1998). Their implementation of the techtivities was something that continued to develop, not something the research team handed down for them to replicate.

Focusing on Students' Reasoning. Riya and Carol saw benefits for their students as well as themselves. In their view, the focus on reasoning over answer-finding was a positive aspect, which Carol stated that she appreciated in both interviews. In her second interview, Carol shared that this focus was something she wanted to expand in her teaching.

> Carol: I really liked the techtivities, and I would try to continue to have the students focus more on the reasoning and what they think rather than whether they get the right answer, so I'm hoping to maybe do this longer, um, incorporate this into my course, to get them to think versus just trying to find the right answer.

Riya and Carol felt that the techtivities impacted their students' mathematical thinking. In the first interview, Riya described how her students' responses gave her evidence of their learning and engagement.

> *Interviewer*: Do you think that the techtivities impacted your students' math thinking?
>
> *Riya*: Yeah, sure. I am sure about that one. Most of the answers they were saying that they "didn't think about that." Y'know, or "We didn't know that there is such a relation." or "That's very nice." So, so they were likely engaged with what they have learned from the new skills.

Riya and Carol's comments provided evidence that they were comfortable making room for students to think and hear each other's insights from their work on the techtivities. Notably, their comments suggested that the broader project's focus on reasoning is something that they valued as part of their instruction.

Challenges

Navigating multiple online platforms. Implementing the new activities meant that instructors needed to navigate both the Desmos platform and their learning management system, Canvas. Sometimes the challenges were specific to the platform, and sometimes they involved integration within the system. During her second interview, Riya talked about difficulties she experienced when trying to switch between techtivities on the Desmos platform. She stated: "Sometimes it's very hard to go back to, to go back it takes a while to go back to the techtivity you want, because I was doing two techtivities. So I cannot go from one to another quickly." Both instructors were new to using the Desmos platform, and the research team worked to help them navigate the online venues, both with facilitation guides and online modules.

The research team created a Canvas module for instructors to support different delivery formats. The first semester, Carol had a major challenge integrating the module into her Canvas course. Her upload inadvertently overwrote her course settings. She was quite frustrated and thought about quitting the project. Yet, she appreciated the research team's help troubleshooting the problem and decided to stay on with the project. She reflected on this in her second interview, stating, "Well, the challenge is initially, you know, that I had problems with, with the Canvas site. There was just a technical problem that I had, but it was something that I had last semester." Carol's and Riya's challenges pointed to the complexities of implementing new digital activities. Not only had they needed to learn the activities, but they also needed to learn to navigate and connect within different online platforms.

Encouraging student participation with asynchronous implementation. Both instructors had autonomy in implementing the techtivities in their courses. When the activities were asynchronous, even in face-to-face courses, instructors found it challenging to encourage student participation. During her second interview, Carol talked about decreased student participation when she assigned the techtivities asynchronously through Canvas.

> Carol: They were always lower for the ones that I assigned through Canvas, where I just tell them, here, this is what you need to do. And I'm just wondering whether there's anything I can do to get them to actually do the ones through Canvas.

Riya's comments also supported her value of synchronously implementing the techtivities when possible. She said in her second interview, "They worked really good this semester, better than last semester. I think the plan is to have the time for all of them to be implemented in the class so we can discuss them in more detail with the students." Riya and Carol's comments spoke to the utility of having the techtivities be something more than an "add-on" to the course, as recommended by Olson and Johnson (2022).

Discussion/Conclusion

We investigated a case of two instructors' views of benefits and challenges when implementing the novel techtivities in their College Algebra classrooms. While the instructors encountered challenges, they were not roadblocks to their implementation. A key benefit was instructors' participation in small group CoT meetings, in which they could discuss and reflect on their practices.

Our case study aims to illuminate how implementing novel digital activities can engender instructional transformation in College Algebra. We offer three emerging contributions. First, instructors' participation in a community, beyond just a researcher-led PD, is crucial for instructors to develop agency in their practice and to allow for new approaches to take hold. When the community is also a CoT (Kezar et al., 2018), instructors have a space to develop new practices to push back against the status quo of answer-finding and to promote students' reasoning in courses such as College Algebra. Second, the status of the new activities makes a difference in students' participation (Olson & Johnson, 2022). Riya and Carol found it difficult to encourage student participation when implementing the activities asynchronously within a synchronous course. Third, implementing new digital activities involves navigating new online platforms, and instructors need to have space to learn that navigation.

Our analysis is ongoing. To further develop the case of Carol and Riya, we will analyze their small group CoT meetings to learn more about how their interactions support their evolving practices. Then, we will triangulate those analyses with evidence from their classroom practices.

Questions for Audience

1. What are your experiences implementing digital activities (or active learning elements) into early undergraduate mathematics courses? What were the benefits and challenges?
2. How do you see FLCs, specifically CoTs, contributing to instructional transformation in undergraduate mathematics?

Physics Student Understanding of Divergence and Curl and Their Constituent Partial Derivatives

Zeynep Topdemir, University of Maine
Michael E. Loverude, California State University - Fullerton
John R. Thompson, University of Maine

This work is part of a broader project to investigate student understanding of mathematical ideas used in upper-division physics. This study in particular probes students' understanding of the divergence and curl operators as applied to vector field diagrams. We examined how students reason with partial derivatives that constitute divergence and curl of the vector field diagrams. Students' written responses to a task on derivatives, divergence, and curl of a 2D vector field were collected and coded. Students were generally successful in determining the sign of some of the constituent derivatives of div and curl, but struggled in one case in which components were negative. Analysis of written explanations showed confusion between the sign, direction, and change in the magnitude of vector field components.

Keywords: Partial Derivatives, Divergence, Curl, Vector Field Diagrams

Introduction

Many physical quantities, such as force and momentum, are represented with vectors. For several topics in physics, e.g., interactions in gravitation and electricity and magnetism, it is useful to define a vector field: a vector quantity is assigned to every point of a subset of space. Vector fields can be represented in different ways, with field lines, an array of arrows, or a symbolic expression like $\hat{V} = ay\hat{\imath} + bx\hat{\jmath}$. Students are introduced to vector fields in introductory courses, typically in the contexts of electric and magnetic fields. These vector fields vary in space, and vector calculus provides several ways to describe this variation, including the gradient, divergence, and curl of the vector field. Several significant physical quantities are associated with vector derivatives: Maxwell's equations for electromagnetism describe relationships between the divergence or curl of electric or magnetic fields and other physical quantities, and the fields themselves can be expressed in terms of derivatives of scalar and/or vector potentials. While most students have not encountered vector calculus the first time they study vector fields, those who go on to major in physics and electrical engineering will use these ideas extensively in a junior-level course in electricity and magnetism. Students encounter vector field representations for electric and magnetic fields in an electromagnetism course, and research involves electric and magnetic fields and even gravitational fields. Students are expected to reason with symbolic equations but also with vector field representations of divergence ($\nabla . \vec{V} = \frac{\partial V_x}{\partial x} + \frac{\partial V_y}{\partial y}$) and curl ($\nabla \times \vec{V} = det \begin{vmatrix} \hat{\imath} & \hat{\jmath} & \hat{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ V_x & V_y & V_z \end{vmatrix}$). We expect students to look at the vector field and find the appropriate components and see how the proper components are changing as we move to certain directions.

Several previous studies in physics education research (PER) have examined student understanding of divergence and curl in post-introductory courses (Baily & Astolfi, 2014; Bollen et al., 2015; Gire & Price, 2012; Singh & Maries, 2013). Generally these studies have involved a two-dimensional representation of a field as an array of vectors. Singh and Maries (2013) reported that even though graduate students successfully calculated divergence and curl of the vector fields, they were unable to interpret the div and curl of vector field plots. Baily and Astolfi (2014) and Bollen et al. (2015) repeated the previous study with different diagrams, reporting that around 50% of their students could correctly determine divergence and curl given the vector field diagrams. Bollen et al. (2015) also qualitatively studied students' responses, categorizing them into three approaches: description based, concept based, and formula based. For example, determining div or curl based on a description of its meaning was categorized as description based. If students used concepts like flux or the "paddle wheel" to determine div or curl, respectively, it was categorized as concept based.

While previous studies have focused on the divergence and curl, the classroom experience of one author of this study suggested that reasoning with the partial derivatives that constitute these operations, e.g., $\frac{\partial V_x}{\partial x}$ and $\frac{\partial V_y}{\partial y}$ for divergence or $\frac{\partial V_x}{\partial y}$ and $\frac{\partial V_y}{\partial x}$ for curl in Cartesian coordinates, might be one element of the challenges faced by students. Previous studies have asked students to determine the sign or value of the divergence and/or curl for a given field diagram, but there has not been as much focus on their constituent derivatives.

Prior PER studies have documented student difficulties with partial derivatives, often in thermal physics contexts (Bajracharya & Thompson, 2016; Thompson et al., 2006). Student understanding of derivatives is studied widely in RUME. Zandieh (2000) developed a theoretical framework for student understanding of derivatives, which was extended by Roundy et al. (2015) to include partial derivatives. Wangberg and Gire (2019) investigated student understanding of partial derivatives of scalar fields represented as surfaces using Zandieh's framework.

The derivatives in the expressions for divergence and curl have the additional complication that they are derivatives of vector components. In these partial derivatives, V_x refers to the x-component of the vector field, so $\frac{\partial V_x}{\partial x}$ is the partial derivative with respect to x of the x-component of the vector V. Extracting information about the derivatives from a vector field diagram involves multiple steps. Existing frameworks are restricted to derivatives of scalar functions, and need to be extended to deal with the derivatives of vector quantities. While prior frameworks have offered insights into student reasoning, they do not account for functions of multiple variables, nor for the vector nature of the derivatives.

We set out to develop and implement tasks that used similar questions to prior studies investigating div and curl for vector field diagrams, but with added explicit questions about the constituent partial derivatives. The goal is to begin to answer the following research questions:

- To what extent can students determine the sign of the constituent derivatives of divergence and curl given a vector field diagram?
- To what extent are student responses to tasks focused on the signs of constituent derivatives related to success in determining the sign of divergence and curl?

Methods

Written data were collected at two universities in sections of Mathematical Methods for Physics, post-introductory courses for physics and engineering physics majors and minors that are intended to cover the advanced mathematics students will encounter in upper-level theory core courses like Electricity and Magnetism or Quantum Mechanics. All students (N=32) had completed introductory sequences in both physics and calculus, and the data were collected in the course after instruction on vector calculus. One campus serves a diverse student population in the southwest, the other is a predominantly white institution in the northeast. Responses from the two universities were similar and are thus combined and reported together in this paper.

In each course, the students had considered similar representations of vector fields in class and answered questions relating the features of a field to its divergence and curl. In one university, students had completed a research-based instructional tutorial; in the other, these questions were presented as a whole-class discussion. After instruction, the questions shown in Fig. 1a were posed on a course midterm exam. Students are shown a 2-d field representation and asked to determine the signs first of the divergence and curl, then of the constituent derivatives.

In the broader study, different versions of this task were used. In this report, students responded to a task asking first about the derivatives and then about div and curl. With this sequence, we hoped to see whether the reasoning for div/curl included derivatives or if other reasoning would emerge.

The coding process began with general codes for both correctness of the sign and the correctness of reasoning provided by students. After the lead author generated the initial codes, other members of the team independently coded several student responses to refine the coding scheme. Answers without explanations (i.e., "$\frac{\partial V_x}{\partial x}$ is zero") or explanations that were not clear enough to be understood were coded as unclear reasoning.

Figure 1b (not given to students) shows which components students are expected to use to determine the sign of $\frac{\partial V_x}{\partial x}$.

A slice of **a vector field V** (for z=0) is shown. Assume that the field has no components in the z-direction (into and out of the page) and that other slices for other values of z would look the same (i.e., ignore z components or direction).

Results and Discussion

The numbers of students that correctly determined the constituent derivatives and the distribution of correctness of student reasoning are shown in Table 1.

Only 4 of 32 (13%) students answered all parts of the question (all derivatives, divergence, and curl) correctly, suggesting that the set of questions was especially challenging. Most students successfully identified the constituent derivatives in three out of four cases: for $\frac{\partial V_y}{\partial y}$, $\frac{\partial V_x}{\partial y}$, and $\frac{\partial V_y}{\partial x}$, success rates were over 75%. For two of these derivatives the vector field component was not changing in the indicated direction, and for the third it was positive and decreasing.

In contrast, only 21% of the students correctly determined that $\frac{\partial V_x}{\partial x}$ was positive with correct reasoning. Because this derivative was the most challenging, we examined the reasoning required in some detail. The first step was identifying the appropriate components; Figure 1b shows the components that students were expected to examine to determine $\frac{\partial V_x}{\partial x}$. Analysis of student responses showed that most (<90%) used the correct components to determine $\frac{\partial V_x}{\partial x}$. For the given vector field diagram, the absolute value of V_x is getting smaller with respect to the x-axis, but due to the direction of V, the change in V_x (∂V_x) is positive. Written responses did not show evidence of explicitly attending to subtracting the two components. Instead, students wrote about the trends in the magnitude of the components, whether that component was increasing, decreasing, or staying constant when you move in a certain direction. In one incorrect student responses, shown in Figure 2a, the student wrote "arrows getting smaller" and seemed to associate this with the resulting negative value for $\frac{\partial V_x}{\partial x}$. This response, while incorrect, included some correct reasoning. Responses that associated the component with the appropriate direction but reversed the sign were coded as correct reasoning with a sign mistake. However, this student wrote about change in magnitude rather than change in component.

Table 1. Performances and distribution of student reasoning for $\frac{\partial V_x}{\partial x}, \frac{\partial V_y}{\partial y}, \frac{\partial V_x}{\partial y}$, and $\frac{\partial V_y}{\partial x}$ of the diagram. Correct answers for the derivatives are given in parentheses. (C: Correct, I: Incorrect).

N=32	*Constituent derivatives for divergence*				*Constituent derivatives for curl*

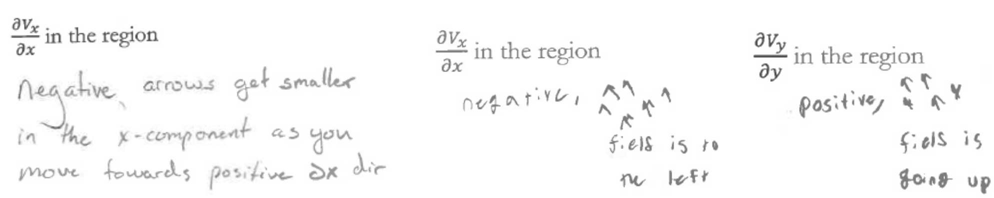
Reasoning	*C*	*I*	*C*	*I*	*C*	*I*	*C*	*I*
Correct	7	17	21	2	18	2	19	1
Incorrect	1	4	0	1	1	3	3	2
Unclear or none	3	0	4	4	6	2	1	6



a b c

Figure 2. (a) Incorrect response to $\frac{\partial V_x}{\partial x}$, reasoning about the decreasing arrow length to justify the response. (b) and (c) Example responses of students relating derivatives with the direction of the vector field component.

Previous studies conducted in introductory physics courses reported student difficulties in subtracting negative vectors when given as a graphical representation, even though students were very successful enacting the procedure of subtracting when vectors are provided in an equation with coordinates (Barniol & Zavala, 2014; Susac et al., 2018). Our results suggest similar difficulty among students in this more advanced context.

While students had good success with many of the constituent derivative tasks, only 38% of students determined the correct signs for divergence and curl with correct reasoning, as shown in Table 2. For the divergence, most of the responses coded as incorrect signs with correct reasoning stem from finding $\frac{\partial V_x}{\partial x}$ as negative, as described above. Student responses included several alternative forms of reasoning for divergence, such as inferring flux from the vector field diagram, or identifying changes relative to a perceived "source" of the arrows.

There was also no clear relationship between success on derivative task and on the curl task. Many of the students coded with incorrect reasoning for curl answered that the z component of curl was zero and referred to the problem statement that the vector field had no z component. This may reflect a misinterpretation of the question or a misunderstanding of the relationship between components of the vector field and those of the curl. A previous version of this question did not include this text and more students did find the curl correctly for the diagram.

Table 2. Student performances for divergence and curl of the diagram (C: Correct, I: Incorrect).

N=32	*Divergence*		*Curl*	
Reasoning	*C*	*I*	*C*	*I*
Correct	12	10	12	3
Incorrect	1	6	1	13
Unclear or none	2	1	1	2

Another small set of student responses show confusion between the direction of the vector field component and the change of the vector field component, as shown in Figure 2b and 2c. Similar confusion between a quantity and its change or rate of change has been widely reported in both mathematics and physics contexts at the introductory level (Meltzer, 2004; Trowbridge & McDermott, 1981). Our data show examples in a more advanced population, suggesting the persistence of this confusion.

Conclusions and Future Work

Our results were consistent with previous studies that reported that divergence and curl are challenging for students. For this task and population, students were largely successful in determining the sign of the constituent derivatives of div and curl. Incorrect responses showed confusion between the sign, direction, and change in the magnitude of vector field components; this confusion seems reminiscent of previous findings in both introductory physics and mathematics classes.

Determining the constituent derivative incorrectly did result in an incorrect divergence sign, but correct responses on constituent derivatives were not sufficient for success on divergence and curl. Students seemed to confuse components of curl with components of the field itself.

Explicit attention to the derivatives in expressions for divergence and curl seems to be a fruitful direction for future research and curriculum development. We plan to collect additional data, including student interviews, to further investigate the understanding of these derivatives as well as of divergence and curl, including relationships between quantities. We also intend to re-examine existing data through the lens of covariation (Carlson et al., 2002) and to examine whether it is possible to extend existing frameworks to vector derivatives.

Why Mathematicians 'Fully Understand': An Exploration of Influences on Their Understanding

Kyle Flanagan
Virginia Tech

One of the primary mathematical practices of many professional research mathematicians is engaging with highly advanced mathematical concepts in their research. As mathematicians engage with these concepts in their work, they may or may not 'fully understand' them, which could include not being able to deduce why each step in a proof logically follows from the next. This preliminary study investigates what reasons professional mathematicians give for not 'fully understanding' mathematical concepts in their own work. One mathematician researching coding theory was interviewed, which utilized one of the participant's own research journal articles as a launching point for discussion. Various reasons for the participant's conceived amount of understanding were observed, including authoritative reasoning and academic pressures. Implications for future research on professional mathematicians are discussed.

Keywords: Advanced Mathematical Thinking, Professional Mathematician, Understanding

Introduction

Professional research mathematicians are constantly engaging with highly-abstract, advanced mathematical concepts in their academic endeavors, especially if they study pure mathematics. Nevertheless, even with the heavily abstract nature of the mathematics, mathematicians are successful at answering mathematical problems and publishing new research. Therefore, it is worth investigating how professional mathematicians engage with and understand highly-abstract, advanced mathematical concepts. Some research has investigated how mathematicians understand mathematical concepts (e.g., Flanagan, 2022; Shepherd & van de Sande, 2014; Sinclair & Gol Tabaghi, 2010; Soto-Johnson et al., 2016; Wilkerson-Jerde & Wilensky, 2011). Despite this, there is certainly a need to further analyze the intricacies of how mathematicians understand these concepts, and specifically what factors influence how mathematicians engage in this understanding. This preliminary research study aims to address this need.

Literature Review and Conceptual Framework

The study of mathematical understanding has been addressed in a variety of ways, including procedural versus conceptual understanding (Hiebert and Lefevre, 1986), intuitive, relational, symbolic, and logical understanding (Byers & Herscovics, 1977; Skemp, 1976, 1987), and the Pirie-Kieren dynamical theory of understanding centered on how one experiences growth in understanding mathematical concepts (Pirie & Kieren, 1989, 1994). Additionally, distinguishing between different types or levels of understanding has appeared in the research on proof, such as the distinction between semantic and syntactic proof productions (Weber & Alcock, 2004) and the need for strategic knowledge (Weber, 2001). Furthermore, research has demonstrated that professional mathematicians sometimes choose to not 'fully understand' all the mathematics they work closely with. Fully understanding a mathematical concept is impossible to define precisely, but a demonstration of a lack of full understanding could include choosing to use a theorem in a proof without knowing why the theorem is true, or accepting a proof is valid without being able to deduce why each step logically proceeds from the previous one.

In the context of proof-reading and validation, there is strong evidence that professional mathematicians will accept a proof as true or valid without using deductive reasoning (e.g., Weber et al., 2014; Weber et al., 2022). For example, Weber (2021) provided evidence that even set theorists, who work closely with the building blocks of mathematics, are sometimes content without being able to construct certain details of their derivations. In addition, professional mathematicians have demonstrated that they sometimes use authoritative reasoning when reading and validating proofs (e.g., Inglis & Mejía-Ramos, 2009; Mejía-Ramos & Weber, 2014; Weber, 2008; Weber & Mejía-Ramos, 2011). Harel and Sowder (1998) defined an authoritarian proof scheme to be when the source of an individual's truth claims come from a place such as a teacher or a textbook. Instead of teachers or textbooks, mathematicians sometimes appeal to the authority of reputable journals and famous mathematicians.

Research Questions

Two primary research questions guided this research study. The first question captures the broad purpose of the research, while the second pertains to the specific goals of this study.

1. (Broadly) How do mathematicians successfully work with and understand highly-abstract, advanced mathematical concepts?
2. (Specifically) What reasons do professional mathematicians give for why they believe they 'fully understand' or do not 'fully understand' the mathematical concepts they use in their own work?

Methodology

To address the above research questions, a one-hour, semi-structured Zoom interview was conducted with one professional research mathematician. This mathematician, Callie (pseudonym), was a female algebraist who specializes in coding theory. She was specifically chosen for this study because her area of research was tangentially related to my own mathematical expertise, which would allow for me to better understand the mathematics she discussed in the interview. This interview was video-recorded, and the audio was transcribed for data analysis. Furthermore, this interview consisted of three phases. Callie was first asked some basic questions to better understand her mathematical background. Afterwards, we discussed specific components of one of her own research journal publications. Questions were centered around aspects of the article where she referenced mathematics from other sources, to help assess whether she believed that she understood the mathematics she was using from other sources that she did not publish herself. The final phase consisted of questions directly pertaining to the research questions, two of which are provided below for reference.

1. Are there any times where you believe that you have encountered a new advanced or highly-abstract mathematical concept where you were able to successfully work with it, but did not 'truly understand' the concept?
2. Have there been any incidents where you read a research paper relevant to your own research where you utilized some of the mathematics in the paper, but did not understand why it was true?

The interview transcript data was subsequently coded in two phases. The initial phase of coding looked for general codes pertaining to the research questions. These initial codes were then refined and grouped together into more precise codes, which were applied to the transcript in a second phase of coding. After final adjustments were made, these codes were organized into four themes, which will be discussed in the following section.

Results

The results from the data analysis will be presented as a thematic analysis (Braun & Clarke, 2012) of the reasons that Callie provided for having certain levels of understanding for the mathematical concepts she uses in her own work. The coding process revealed four major themes, which are (1) authoritative reasoning, (2) external pressures, (3) academic influences, and (4) intellectual factors. Each of these themes will be addressed individually, with supporting evidence provided from the interview.

Authoritative Reasoning

One pattern that appeared frequently in the data was authoritative reasoning. This consists of when Callie stated that she believed or accepted something was true because it came from a trustworthy or authoritative source, such as a reputable journal. In the case of appealing to the authority of journal articles, Callie stated that "I also think that because of the peer review process, and all of that, typically I feel confident that results that have appeared in the literature are correct. You know sometimes that's based on journal reputation, right?" Moreover, in addition to the peer review process providing Callie with confidence in the validity of results, she expressed that if a result is important, then likely enough people have looked over the result to verify its correctness. Regarding a particularly important result in her field, she mentioned, "And so it's had lots and lots of eyes on it, so there's something that comes from people believing that this is true and knowing that other people have checked it…it's received a lot of attention." Another facet of authoritative reasoning came in the form of believing results were true because certain people were involved. When discussing an area of her own field of research where she did not understand all of the results, she stated that this is "an example of where we're looking to use something and we trust that the people who have done the work have done it correctly."

External Pressures

Another theme that came out of the interview data with Callie was external pressures. This theme consists of when her choice to try to understand a mathematical concept was directly influenced by external factors, such as time constraints due to academic duties. The most common type of external pressure was time constraints. Callie's busy schedule and its influence on her ability to take time to deeply understand all the mathematical concepts in her work was summed up when she stated:

> And you know now, there's just not the time to do that. I mean I have my own students I have to worry about. I also have an administrative role that's practically a full-time job, in addition to the faculty member role. And so, so that's part of it, it's the time.

Moreover, she emphasized that "it'd be hard to confirm every single thing that we use and actually create something new ourselves at the same time." In actuality, highly advanced mathematics can take time to understand, and there is a lot of it being produced. According to Callie, this makes it unrealistic to produce new results and 'fully understand' all related results.

Another type of external pressure is the natural influence of what the current research community believes is important. For example, Callie described how she and her colleagues were looking to find a sufficient condition for a mathematical result, even though they were not entirely sure what they were looking for. However, they did that because they "knew it would be well-received by the research community" if they could find it. Additionally, she mentioned that her research pursuits have shifted because she wants to "stay current." Specifically, she stated:

> The field has moved a bit, and so I kind of like to move a little bit too in order to stay current, you know, in terms of applications and things that people actually care about,

> like for funding agencies or journals...because I'm having to pivot. I shouldn't say having to; I'm choosing to pivot based on some internal motivation to follow external factors.

Even though these are reasons why a mathematician might choose to pursue certain research questions, they also demonstrate that there are academic pressures that influence what one chooses to focus on and try to better understand.

Lastly, Callie shared how her level of understanding on certain mathematical concepts has likely been affected by the availability of resources now versus when she was starting her career. In particular, now there are a whole host of relevant journal articles that we can access on the internet with minimal effort. However, twenty years ago, Callie described in contrast to having twenty-five online articles, “If I had gone to the library and I only have two papers related to a subject…I’m going to really pour into those in ways that I wouldn’t do with the twenty-five.” This comment is especially interesting because it highlights that the extent to which mathematicians choose to understand mathematical concepts for their own research may be changing due to technological advancements, which would need further research to verify.

Academic Influences

A third pattern that emerged from the data is academic influences. This consisted of when Callie discussed anything influenced how the actual mathematical results would be used or the nature of the mathematical content itself, including what field of study that the mathematical content came from. Callie explained how the field of study influences what she chooses to ‘fully understand’ by stating, “And in order to follow all that reason, I mean it might be a series of many many papers, you know, traversing other fields. So, it might be outside of what would be easily doable without help.” This means that sometimes it may be difficult to understand the mathematics you are using, if you need to use advanced concepts that are outside of your area of expertise. Moreover, it is also possible that the field of research you engage in might influence the breadth of what you are able to understand, as suggested by Callie. She stated that “Different research areas are different as well…Coding theory’s evolved a lot in the last twenty years. And so that means lots of different types of things go into my research program.” She contrasted this with a mathematician who focused deeply on one idea for the entirety of his career, where he may deeply understand everything that he uses in his own work.

Another factor that appeared in the data was the influence of one’s stage of career or current mathematical experience. Callie described how she believes she is “more comfortable now not knowing things than she once was,” and questioned whether that is a “natural career progression” or not. Lastly, Callie expressed instances where the mathematical purpose of a concept for a journal article influenced how much effort she put into understanding it. Generally, she stated, “I use material from the literature and assume that it’s correct, and I think that how far down that we go into that depends on what we’re trying to do with the material." In the context of the journal article from the interview, she mentioned:

> You know there are times when you know, maybe you need to reference something and, you know, the results are there or you can see them, but you don't have full awareness of the supporting evidence. It certainly happens a lot, but in this case, you know we were trying to really nail down this value, and so I had spent some time with the techniques in that paper.

This sentiment was reoccurring in our discussion of her journal article, because she said that she understood the important references well but did not fully read or understand some of the references that were only provided for context or background.

Intellectual Factors

The final theme from the interview data was intellectual factors, which were any mentions of mental or intellectual influences on one's understanding, including Callie's mental capacity and how reasonable a mathematical statement appears. For instance, Callie expressed how the reasonability of a mathematical statement influences how much effort she needs to put into deeply understanding the mathematics.

> So sometimes my knowledge and awareness might come from hearing a talk about it and feeling like "Okay those techniques make sense; it seems reasonable; that's all I need." Other times, you know, it might be deeper confirmation if you feel like "Well that sounds surprising. I didn't think something like that could be true."

It is possible that when a mathematical statement appears reasonable, that this is influenced from other mathematics you know. In this case, one might believe that the statement is probably true based on other mathematical expertise or intuition. In addition to reasonability, Callie mentioned how she only has so much mental capacity to understand mathematical facts. She discussed this phenomenon by stating that most mathematicians cannot know everything in their field, and verbalized, "But to know the whole field is just not, at least for me, possible. I don't think it's possible for most people." These remarks provide support that mathematicians may not be able to 'fully understand' everything they work with, even if they would like to.

Discussion

The above thematic analysis provided supporting evidence that professional mathematicians do not always 'fully understand' the mathematical concepts they use in their work. Moreover, there are a plethora of reasons for why mathematicians have certain levels of understanding for these concepts. However, despite this, this study was preliminary in many ways and has some limitations. Most noticeably, this study only consisted of one mathematician researching coding theory. To further support these claims, it is important to research other mathematicians in similar ways, to see if Callie's experiences are shared among other mathematicians. A second limitation was that the chosen journal article was written over fifteen years before the interview. Due to this, some of Callie's remarks may have been misremembered, and she was not able to share as much detail about aspects of her producing the paper. In turn, much of the data came from the third phase of the interview. I believe that utilizing mathematicians' journal articles for interview data collection is valuable, but further data collection is certainly needed.

Moreover, the results from the analysis support the claims of the aforementioned literature that mathematicians appeal to authoritative reasoning and have reasons for not 'fully understanding' certain mathematical concepts they use (e.g., Inglis & Mejía-Ramos, 2009; Weber, 2008). In addition, this study contributed a concrete example of a mathematician who demonstrated numerous reasons for the understanding she had. However, further research is needed to delineate these various reasons why mathematicians do not 'fully understand' concepts. Is it mostly because of external and academic factors? Or is it also due to mathematical factors, such as using the concept in rich, mathematical "inventising" (Pirie & Kieren, 1994; see also Hadamard, 1945) or that the concept is too advanced or abstract for the individual? The above analysis provided some evidence that these could all be at work, but further research needs to be conducted. Lastly, the evidence in this study has implications for the teaching of advanced mathematics to students. If professional mathematicians are influenced in various ways on what they choose to 'fully understand,' we should not be surprised when students are similarly influenced. Instead, focus should be given to helping students learn to navigate what mathematical concepts should be 'fully understood' and what could be postponed until later.

Student Strategies Playing Vector Unknown Echelon Seas, a 3D IOLA Videogame

David Plaxco
Clayton State University

Matthew Mauntel
University of New Hampshire

Michelle Zandieh
Arizona State University

We present preliminary results of students' strategies playing Vector Unknown: Echelon Seas [VUES], a 3D videogame intended to support student reasoning about vectors. Our team designed VUES by drawing on theories from Inquiry-Oriented Instruction (IOI), Game-Based Learning [GBL] and Realistic Mathematics Education [RME]. VUES builds from a prior 2D game by giving players vectors with 1, 2, or 3 components, depending on the level. We use codes from our team's prior analysis (Mauntel et al, 2020) to analyze strategies in the 3D game. Early results show that students develop similar strategies during 3D gameplay as other students developed while playing the 2D game. However, we have also found new strategies that we did not witness with 2D gameplay, requiring us to extend our coding scheme. Further, early results emphasized the need for design changes to the 3D game to better support players' progress.

Keywords: Linear Algebra; Mathematical Play; Inquiry-Oriented Instruction; Game-Based Learning; Realistic Mathematics Education

The importance of Linear Algebra in undergraduate STEM students' degree progression is well-established (Stewart et al, in press). In this on-going design-research project, we have iteratively implemented and re-designed a browser-based video game intended to support student experiences with vectors before entering (and early during) a first course in Linear Algebra. Our team has drawn on a combination of design principles from Game-Based Learning (Gee, 2003; Gee, 2005; Gresalfi & Barnes, 2016; Williams-Pierce & Thevenow-Harrison, 2021), Inquiry-Oriented Instruction (Rasmussen & Kwon, 2007; Kuster et al, 2018), and Realistic Mathematics Education (RME; Freudenthal, 1991; Gravemeijer, 1994) to iteratively refine and develop the videogame (Zandieh et al, 2018; Mauntel et al, 2019; Mauntel et al, 2020; Mauntel et al, 2021). We have iteratively re-designed this video game to better support players' algebraic and geometric understanding of linear combinations of vectors and vector equations. In this paper, we present the newest iteration of the video game, discuss early results of clinical interviews with undergraduates playing the video game, and discuss what implications these results have for future iterations of this game and educational game design more generally.

Literature Review and Theoretical Framing

Game-Based Learning (GBL) is a growing area of education research that shows promise for supporting meaningful gains in student thinking outside of high-stakes classroom environments (Gee, 2003; Gee, 2005; Gresalfi & Barnes, 2016). With this project, our team set out to blend best practices from GBL and mathematical curriculum design theory to create a video game based on the Inquiry-Oriented Linear Algebra curriculum (IOLA; Wawro et al, 2013). Our game design leverages the key idea of using vectors as modes of transportation in the Magic Carpet Ride task from the IOLA curricular materials, which use the curriculum design theory of RME (Gravemeijer, 1994; Freudenthal, 1991). Using vectors as modes of transportation provides students and, now, video game players with an experientially real setting for using and understanding linear combinations of vectors. Our team has also incorporated theoretical framing from the Inquiry-Oriented Instruction (IOI) literature (Rasmussen & Kwon, 2007; Zandieh et al, 2017) to inform how student/instructor roles translate into designing a video game interaction.

The current version of the video game, Vector Unknown: Echelon Seas [VUES], takes place in a 3-dimensional environment with the player controlling a pirate avatar who runs between stages and puzzles. In this paper, we focus on Stage 4 of VUES, which we designed as an extension of the original 2-dimensional Vector Unknown game (VU). VUES Stage 4 is subdivided into three different difficulty levels, all of which are played via the same controls and format, but differ based on the number of components in the vectors used (i.e., whether the vectors in the level have 1, 2, or 3 components) and each difficulty level consists of 6 puzzles in which the player helps the pirate aim a grappling hook at an anchor. The player uses the vectors to create a linear combination equal to a goal location by dragging vectors (represented as column vectors in a given collection of cards) into a vector equation and using sliders to adjust scalars in front of each vector. To provide just-in-time feedback (Gresalfi & Barnes, 2016; Williams-Pierce, 2019), the game calculates the appropriate linear combination of those vectors, shows (1) a geometric representation of that linear combination consistent with a "tip-to-tail" representation of linear combinations and (2) a numeric representation of the vector equation with the calculation on the right of the equal sign, labeled as "Answer".

Figure 1. Images of gameplay in Vector Unknown Echelon Seas.

Using the earlier iteration of the game, Vector Unknown, we characterized the strategies that participants used to play the game (Mauntel et al, 2020, 2021). These strategies focused on two main components of the game, geometric and numeric. Geometric strategies related to the generated geometric display of the linear combination of two vectors. Numeric strategies involved focusing on a vector equation. There were four core strategies each with a numeric and geometric variant. ***Focus on one vector*** involved selecting a vector, scaling it to be as close to the goal location as possible, and then choosing another vector to reach the goal. ***Focus on one coordinate*** involved choosing an x- or y-coordinate in the goal vector and adjusting the scalars on each of the two vectors to first match one coordinate, and then adjusting as necessary to reach the goal. When a student employed ***quadrant-based reasoning*** they chose vectors to reach the goal based upon the quadrant of the goal (geometric) or by the signs of the goal (numeric). ***Button-pushing*** was characterized by adjusting scalars and switching vectors rapidly as a trial-and-error strategy. While not officially characterized as a strategy, participants also tended to choose vectors that had a zero to help them solve the puzzles. Our current work seeks to identify whether and how these identified strategies might emerge as students play the newer version of the game and also what new strategies we might encounter students using.

Methods

One member of our team conducted clinical interviews with five students from a small, four-year undergraduate university in the American Southeast. Each interview lasted between 60 and 120 minutes and consisted of the participant playing at least four puzzles in each difficulty setting as time allowed. Three of the participants had completed an introductory course in linear algebra, but had not yet played any version of the video game. Two participants had. Recently completed a Calculus I course and had not yet taken any course in Linear Algebra. Interviews occurred virtually over Microsoft Teams. Players shared their screens and maximized the window in which they played the game. Each interview was recorded and transcribed using the embedded features of MS Teams. The interviewer guided the participants through gameplay with written prompts and asked follow-up questions to encourage participants to explain their reasoning and to clarify strategies and rationale as they played the game. After data collection, the authors met to discuss analysis methods and narrowed our focus on using one participant's video for an initial coding pass. Our initial analysis is driven by the research question: *How might student strategies while playing VUES be similar or different from the strategies we identified with students playing VU?*

In the next section, we will discuss some of the results from our data collection, exemplifying them with key excerpts from our interview with Kyah (pseudonym, pronounced "KAI–yuh"; a woman, who is African American, majoring in mathematics). We will first briefly discuss some of Kyah's responses during gameplay on Level 2 and explain how we use the codes from prior analysis (Mauntel et al, 2021) to categorize her activity. We then provide examples from Kyah's Level 3 gameplay to highlight how some of her 2-D strategies persisted into her 3-D gameplay. We will then highlight aspects of her 3-D gameplay that did not fall into our existing categories. We expected such strategies would exist and, thus, will necessarily extend our existing taxonomy to include new types of activity that students engage in in the newer iteration of our game.

Results

Kyah spent the first 22 minutes of the interview working through five puzzles of Level 1, which uses vectors from $\mathbb{R}^1$. Across these levels, Kyah correctly articulated numeric strategies for using multiplication and addition to reach the goal and described a general solution for how she could find more than one possible correct solution when asked. When Kyah moved on to Level 2, the 2-dimensional version of Stage 4, the interviewer prompted her to notice the visual aspect of the game which they referred to as blue, red, and green lasers. Kyah at first was surprised that "a whole three different lasers" appeared. She added, "We just need one, right." The interviewer confirmed that "the green is the same as the Final Answer." Kyah then realized "oh, so the green needs to be on the white line." Although Kyah primarily used numeric methods in five puzzles of Level 2, she did explicitly return to the idea of matching the green line to the white line later when playing Level 3.

The majority of Kyah's Level 2 (vectors from $\mathbb{R}^2$) gameplay involved the strategy ***focus on one coordinate***. This worked especially well for her when she had a vector with a 0 in the second coordinate. In this case she could scale a vector with a non-zero second coordinate until its second coordinate matched the second coordinate of the "Goal" vector. Then she could add the vector with the 0 in its second coordinate and scale it until the first coordinate of the "Answer" vector matched the "Goal" as well. For example, Kyah solved Level 2, Puzzle 4 using the linear combination (4)<-1,3> + (-5)<1,0> = <-9,12> by first scaling <-1,3> to get <-4, 12> and then adjusting the scalar on the <1,0> vector. This is consistent with the ***focus on one coordinate*** strategy we identified from analyzing student gameplay in VU (Mauntel et al, 2021). In Puzzle 5, where no vector choice had a 0, Kyah was unable to implement this exact strategy, though she did attempt to modify it. She articulated this clearly when asked, "I'm looking at the Final Answer. I always aim to go for the bottom number first for some reason. Try to get the bottom number … [then] adjust to match the top." It was not until the interviewer said, "I'm looking at the lasers," that she changed her focus, "Oh! I forget about the lasers. … I wasn't even thinking about the lasers.” She did agree that the lasers could help. She and the interviewer then worked together, combining geometric and numeric strategies to solve Level 2, Puzzle 5.

When Kyah transitioned to Level 3 (vectors from $\mathbb{R}^3$), she was presented with the vectors: <1,3,1>, <-1,1,1>, <-3,-2,0>, and <-1,2,2> to reach a goal of <-7, 7, 5>. Similar to level 2, we coded Kyah’s initial strategy as Numerical Focus on One Coordinate. She moved the vector <1,3,1> into the equation and adjusted the scalar to 1, stating “I was looking at 7s first. I was thinking…oh wait. Actually, I think I should look at the bottom first. I’m going to go with the 5 first.” She adjusted the scalar to 5*<1,3,1> to match the z-coordinate of the “Goal”. Kyah then said, “[I] need the top number to be negative,” and chose the vector <-1,1,1> matching the sign with -7 in the x-coordinate. We coded this as Numerical Quadrant-Based Reasoning because she chose a prospective vector based upon the sign of the location she wanted to travel. She adjusted the scalar on <-1,1,1>, but was unable to get the first pair of vectors to work.

After this, the interviewer suggested that Kyah rotate the camera. Once she tried this, Kyah focused more on the geometric aspects of the game, especially the “lasers” that represented the scaled vectors and their linear combinations. She then adapted the strategy that she used in Level 2 and described her goal by saying “the green line is supposed to go on the white line”. Because the prior version of the videogame did not include geometric representation of the resulting linear combination, we did not have a code for this strategy. After describing her intentions, Kyah adjusted the scalars until the green line looked like it overlapped the white line (Figure 2, left). She then rotated the camera view and discovered that the view “can be very misleading” (Figure 2, right). This highlights an important difference between Levels 2 and 3. Solving a puzzle on Level 3 with a geometric strategy requires viewing the vectors from a variety of viewpoints and coordinating these viewpoints to make sense of the linear combination. In this moment, Kyah used this to determine if it was possible to find a solution with these two vectors.

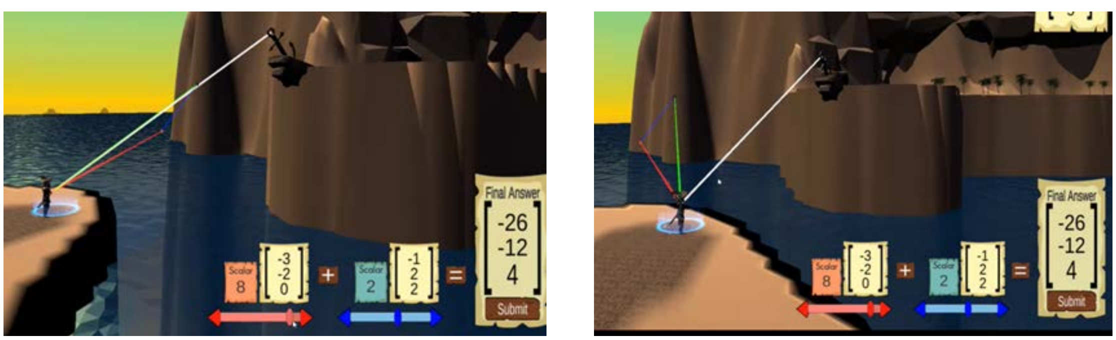

Figure 2. Kyah’s “close” linear combination on Level 3 (left) and the same combination with camera moved (right).

Kyah adjusted the scalars several more times and then switched vectors repeatedly with the other two in the list. She arrived at the vectors <1,3,1> as the red vector and <-1,1,1> as the blue vector she tried to figure out how the red and blue vectors affected the green vector. After playing her conclusion was that “the red one is just shifting left and right” and “the blue, that is going to shrink it [the green vector].” From this we can infer that the Kyah’s strategy is to try to shift and shrink [or expand] the green line until it lands along the white line. We call this new strategy geometric shrinking and shifting. Kyah experimented with this strategy, but was unable to find a solution and returned to a more numeric strategy.

Kyah had the vector <-3,-2,0> as the red vector and tried several vectors for the blue coordinate. The interviewer asked asked how having a zero in z-coordinate for the red vector affected the coordinate choice for the blue vector. Kyah realized that the scalar for the blue vector had to result in a 5 for the z-coordinate since the red vector contributed nothing to z-coordinate. Kyah tried multiple vectors setting the blue scalar to 5 for the vector <-1,1,1> and then adjusted the scalar on <-3,-2,0> to see if it would work. After trying several scalars for <-3,-2,0> she kept the vector <-3,-2,0>, swapped <-1,1,1> for <1,3,1>, adjusted the scalar for <1,3,1> to 5 so the z-coordinate would work, and finally adjusted the scalar on <-3, -2, 0> to -10 and then increased it to 4 and found that number worked. While Kyah explored geometrically, her final solution was the result of returning to a focus on one coordinate and combining it with a vector with a zero entry in the final coordinate. In the next level there was a vector with two zeros in it, and Kyah employed a similar strategy to reach the goal position by selecting the vector with two zeros, selecting another vector, adjust it to reach the z-coordinate, and then adjusting the vector with two zeros to get the final solution. Thus by this point, Kyah was employing a strategy similar to using vectors with zeros in several coordinates.

Discussion

First, we note that Kyah used several strategies consistent with those we observed students using with previous versions of the game, including Quadrant-Based Reasoning and choosing vectors with zeros in order to Focus on One Coordinate (Mauntel et al, 2021). Further, Kyah extended strategies from Level 2 to Level 3. However, when prompted to notice the geometric aspects of the game, she employed a new strategy, Green Line on White Line, but needed to develop a sense of how to assess whether this strategy was successful and how to manipulate the vectors to achieve this goal. Rotating the camera view allowed her to determine if the strategy was working. This points to a core difference between VU and VUES: adjusting the camera allows a player to solve puzzles in Level 3 of VUES geometrically that was not necessary for players to solve levels in VU because the earlier game only used vectors in $\mathbb{R}^2$. Kyah also found the most success using numeric strategies. We hypothesize this may be due to a key difference between VU and VUES, specifically how the game generates the vectors on any given level. In VU, players could always reach the goal as long as they selected a pair of vectors that were not scalar multiples of each other. In VUES, four vectors are provided and the player is only guaranteed that one pair of the vectors can reach the goal. This means that players could choose linearly independent vectors that do not reach the goal with the available integer scalars. This makes geometric strategies that were employed frequently during VU less effective in VUES.

Questions

We will continue to analyze Kyah's and the other student's gameplay. During the conference presentation, we anticipate presenting more robust findings from these data, including analysis of other participants' strategies and more focused coding of 3-D game strategies. We expect that the presentation will prepare audience members to engage with the following questions:

1. How might these results inform our game design and GBL design theory?
2. What theoretical and methodological approaches could help us analyze how players move the camera and interact with the computer program's 3-D environment?
3. How does the shift from vectors in $\mathbb{R}^2$ to vectors in $\mathbb{R}^3$ within VUES inform how students use the camera?

Creativity and Subjectivity: Two Researchers' Poetic Re-Presentations of Critical Student Perspectives of Mathematical Success

Rachel Tremaine
Colorado State University

Jessica Ellis Hagman
Colorado State University

Dismantling notions of objectivity in the qualitative research process necessitates engaging research subjectivity in meaningful and explicit ways. Poetic transcription methodology allows for an entry point into conversations around research subjectivity. In the context of a critical exploration into students' definitions of their own mathematical success, the poetic transcription results of two researchers are comparatively analyzed to highlight structural and thematic (mis)alignments in researchers' poetic interpretations of students' definitions of mathematical success. We emphasize both the scholarly value and uncertainty that the results of such a comparison produce and discuss how future work might build on these comparisons and on our understanding of what poetic transcription can bring to mathematics education.

Keywords: Methodology, Student Success, Subjectivity

Within qualitative research processes, researchers themselves are the "primary research instrument" (Corley, 2020, p. 1023). This positioning makes clear that researchers and their collection, framing, analysis, and presentation of qualitative data are deeply intertwined. One way this manifests is in recent academic discussions on how identity impacts mathematics education scholarship, and the acknowledgement that mathematics education is *not* culture-free nor is the knowledge it produces disjoint from socio-cultural and socio-political notions of power and oppression (Gutiérrez, 2013; Ladson-Billings, 1997; Martin et al. 2010).

By resting on the research axiom that neutrality is fundamentally nonexistent within qualitative mathematics education research, space is opened to explore ways to make explicit the discussion of subjectivity. Corley (2020) writes that "the goal for researchers should be to write in such a way that challenges mainstream knowledge claims and that values the subjective, contextual, relational nature of both reality and inquiry" (p. 1024). In this work, we aim toward this goal through comparatively analyzing the results produced by our independent engagement with poetic transcription methodology.

Poetic transcription draws from the literary tradition of a *found poem*, in which excerpts from existing written media are juxtaposed to create poetry with distilled meaning. In poetic transcription, participants' words from interview or focus group transcripts are pulled in such a way as to honor and reflect the participant's meaning and narrative style (Glesne, 2007). Prendergrast (2009) emphasizes that these poetic transcriptions are built from the participants' words but filtered and "re-presented" through the lens of the researcher by referring to these poems as "participant-voiced poems." Via the artistic embodiment of experiential knowledge, poetic transcription can present nuances of qualitative data in a way that the quoting and analysis of traditional prose may not, particularly when viewed through a lens of feminist theory (Faulkner, 2018) and critical, justice-oriented qualitative research (Fernández-Giménez et al., 2019; Keith & Endsley, 2020).

Poetic transcription is utilized in meaningful ways in educational spheres (see, for example, Thunig & Jones, 2020; West & Bloomquist, 2015; Mercer-Mapstone et al., 2019; Vannini & Gladue, 2008). It has a particularly rich history in regards to re-presenting the narratives of Indigenous participants through its existence as an "embodied meaning-making practice that is consistent with more holistic Indigenous approaches to teaching and learning which engage the heart, mind, body, and spirit" (Madden et al., 2013, p. 215; see also Ambo, 2018; Thunig &

Jones, 2020). In mathematics education spaces specifically, poetic transcription has been used to understand the structure of students' mathematical thinking (Staats, 2008), interrogate the intersection of theological beliefs and beliefs about mathematics (Norton, 2001), and examine mathematical identity in the face of "low attainment" labels (Helme, 2022). The poems constructed in the context of this work centered around re-presenting narratives of mathematical success shared with us by three first-year undergraduate women students who also identified as first-generation students, Pell-grant eligible students, and/or women of color.

Poetic transcription as a methodology lends itself well to a critical exploration of marginalized students' experiences of mathematical success because it (a) promotes "evocative critique and resistance of the status quo" (Faulkner, 2018, p. 23) and (b) lends itself to "topics that lead into the affective experiential domain" (Prendergast, 2009, p. 546). Students' own conceptualizations of their mathematical success align with both attributes; centering students' voices in the defining of their own mathematical success both provides critique of traditional neoliberal measures through implicit or explicit misalignment (Tremaine, 2021), and student definitions and narratives of student success are deeply affective in that they are evidentially embodied and emotional (O'Shea & Delahunty, 2018).

The two authors of this work engaged independently in a parallel poetic transcription process using the transcript data from three participants, resulting in three pairs of poems. In an investigation into both the use of the methodology and how it allows for rich conversation regarding the student participants' experiences and definitions of mathematical success, we pose the following research question: In what ways do the poetic interpretations of two researchers, when constructed through a prescribed poetic transcription methodology, align and misalign, and what do these (mis)alignments teach us about this data analysis method?

Methods

The data used in this analysis are three sets of two poems, each set containing one poem constructed by Tremaine and one poem constructed by Hagman through the poetic transcription process depicted in *Figure 1.* As poetic transcription is inherently a creative process, there is no one *right* way to engage in this methodology– the methodology illustrated by *Figure 1* draws from the work of Prendergast (2009) and Glesne (1997), as well as Burdick (2011)'s notion of tandem poetic transcription, and is intended not as a definite guide to poetic transcription, but as a description of process undertaken by the authors. This particular method of poetic transcription consisted of three phases: Phase 1 (Initial Parsing of the Data), Phase 2 (Poetic Juxtaposition), and Phase 3 (Member Checking).

Poems were constructed using qualitative interview data from three participants- Ada, Isabel, and Kenzie- as collected and transcribed by the authors in January 2021. Ada, Isabel, and Kenzie are first-year, Pell-grant eligible women students and were asked in an interview context to (a) describe an experience in which they felt successful in mathematics and (b) define what *student success in mathematics* meant to them, with conversational room to elaborate on responses.

The analysis below, as it is preliminary, identifies themes in both meaning and style that align and misalign between the two researchers' poems. We then discuss the significance of this alignment and misalignment as it relates to poetic transcription as a methodology and in research more broadly, with the intent of bringing others into this conversation as this methodology (and what it means to do research) is continually refined.

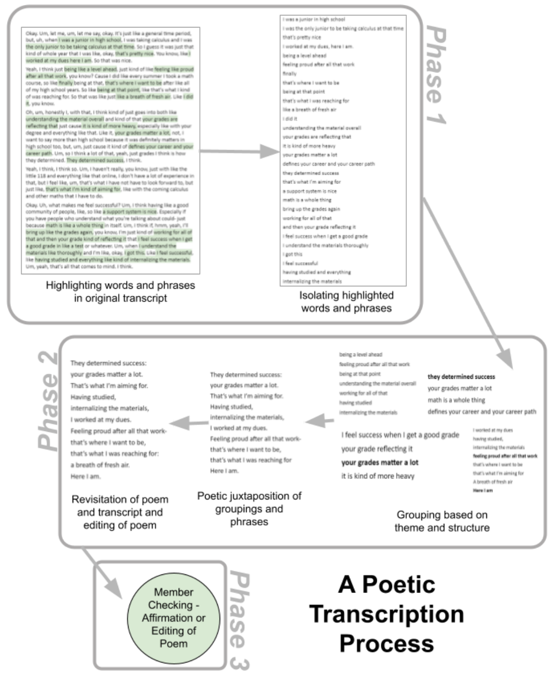

Figure 1. The poetic transcription process engaged in by both Tremaine and Hagman.

Analysis

In *Table 1*, we present the poems constructed by Tremaine and Hagman from each participant's data and invite the reader to contemplate what they tell us about the participants' definitions of mathematical success. We then follow the poems with a comparative analysis, diving more deeply into the analysis of Kenzie's poem and providing brief overviews of the others to account for succinctness in submission.

Table 1. Poems written by Tremaine and Hagman which draw from each participant's data.

Kenzie	
<u>Tremaine</u> They determine success: your grades matter a lot. That's what I'm aiming for. Having studied, internalizing the materials, I worked at my dues. Feeling proud after all that work- that's where I want to be, that's what I was reaching for: a breath of fresh air. Here I am.	<u>Hagman</u> Every summer I took a math course, that's what I was reaching for: being a level ahead, feeling proud, like a breath of fresh air. I did it. Just grades is how they determine success. Your grades matter a lot. It is heavy: your degree, your career, your career path,

	everything.
Isabel	
<u>Tremaine</u> It’s two different intelligences: being able to do well in school and being able to actually use what you’ve learned. Some people just enjoy doing math for the sake of math; I really enjoyed being able to know how much fabric to get. Being able to practically apply your math skills- this is what math was meant to be used for.	<u>Hagman</u> It’s two different intelligences there: There’s being able to do well in school and there’s being able to actually use what you’ve learned in school. Some people just enjoy doing math for the sake of math… I really like it when I can use math to do something: I have math skills to know how much fabric to get. To be able to calculate how much fabric you need- it’s successful because you’re using it for something.
Ada	
<u>Tremaine</u> I’ve had a lot of struggles in math. I’ve also had a lot of successes. We all fail, we’ve all been there. I had to take a step back and be resilient; work around it; put in the effort; learn critical thinking; I could pull through. I know how to do this. Cross it off a checklist? That’s not what college is. Further your education, get something positive out of the experience. I was still successful because I didn’t give up.	<u>Hagman</u> I was killing it. Getting nineties on my tests, I did so good on their finals. Running home to my parents- bragging to my friends- Hey, look, look at my scores, hahaha. Grades are important, but at the end of the day I’ve learned from college that grades aren’t everything. In a college math classroom, it’s more about learning something and getting something out of it. I need to get something out of it and still care about my grade, but not let that grade define me as much. At the end of the day, it’s not all about grades. Now it’s like, okay, I’m growing up.

As the reader is no doubt aware of after reading the poems, the set contains a myriad of alignment and misalignment, both in phrase, theme, style, and structure. In each pair of poems, we see stylistic differences between the authors' poems which emphasize different aspects of the students' interviews: a key distinction we see is the use of more abstract descriptions of student success versus more concrete descriptions of moments of success. The impact of this stylistic difference varies by set of poems, with the least differences for Isabel and most for Ada. Here we analyze Kenzie's poems to exemplify these differences and provide brief additional analyses of Isabel's and Ada's poems.

We see that several phrases from Kenzie's transcript were poetically juxtaposed in both authors' poems, such as the highlighting of how "they determine success", as well Kenzie's "feeling proud" and experiencing "a breath of fresh air" upon achieving her goals. However, one can see thematically that Hagman attends more closely to Kenzie's concrete experiences that led to mathematical success (in this case, taking a math course every summer), while Tremaine utilized more abstract imagery to illustrate how Kenzie discussed her experience of success. The reader may have also noticed Hagman's use of two stanzas, versus the single stanza used by Tremaine. In Tremaine's poem, this "they" entity is presented as having more influence on Kenzie's own perspectives and experiences by nature of being a part of a unified poetic narrative; the two stanzas utilized by Hagman present this entity as something which Kenzie discusses but perhaps does not have as direct an influence on her own experiences, as the experience of working hard to get "a level ahead" in mathematics is separate from what "they" define success as. Further, Tremaine and Hagman both highlight structural parallelism in Kenzie's narrative; Tremaine juxtaposes "that's where I want to be / that's what I was reaching for" and Hagman juxtaposes "your degree / your career / your career path." Thematically, both center on Kenzie's hard work in mathematics as central to her definition of success, while simultaneously painting nuanced interpretations of her transcript via poetic style and structure.

We see similar phrase and structure (mis)alignments in Isabel's set of poems. Interestingly, lines 1-6 in both poems draw from the same components of the transcript. Hagman splits their poem into two stanzas, allowing for a clear distinction between the two intelligences alluded to by Isabel, while Tremaine maintains a single stanza, reinforcing continuity of the overall theme found in both poems of the exaltation of mathematical applications as a means of mathematical success. Meanwhile, the most notably different set of poems are those constructed from Ada's narrative. Both in theme and in phrase choices, these two poems paint two different (albeit complementary) pictures of Ada's ideas of success. Tremaine's poem focused on the imagery and action phrases Ada used to describe her perseverance, attributing this perseverance as immensely relevant to how she was describing success. Hagman attended more to Ada's concrete experiences in mathematics, including "getting nineties on her tests." Both authors emphasize in their poems the salience of Ada's acknowledgement that she "needed to get something out of [her mathematics courses]"–something more than a good grade–to feel successful. We are left pondering these differences in what they tell us about students' own definitions of student success, and welcome this as a discussion point during the presentation.

Discussion

The comparison of two researchers' results when engaging with poetic transcription methodology enables multiple perspectives on how these students defined their mathematical success. A multitude of poetic interpretations of the data provides opportunity for nuance that could not have been captured by a singular poem. Further, it makes space for discussion around the ways in which participant data can be varyingly interpreted, necessarily incorporating discussion of the researchers' perspectives on data presentation. This is especially evident with the poetic interpretations present in Ada's poetry, in which each poem emphasizes differing components of her narrative of mathematical success. Glesne (1997) describes the creation of a *third voice* when engaging in poetic transcription—one which is constructed from both the participant's and researcher's experiences. Future work would more closely and critically interrogate our own *third voices*—how our experiences and identities as researchers, and what of the participant's own experience we drew from, enabled these two irreplicable poetic interpretations.

We also acknowledge the tensions brought forth in our experiences as researcher-poets; while poetic transcription offers an opportunity to work toward "healing wounds of scientific categorization and technological dehumanization" (Glesne, 1997, p. 214), it also maintains the hegemonic power of the researcher, and thus the potential to privilege perspectives that are already dominant in research spaces. In addition to explicit acknowledgement of this tension, other poet-researchers have illustrated ways in which to centralize participants' poetic voices in the process, either through researcher-participant co-construction of poetry (Levinson, 2020), tandem research poetry (Burdick, 2011), or with the researchers' own transcripts as data from which to engage in poetic transcription (Mercer-Mapstone et al., 2019). While not a possibility in the context of this study, future work with poetic transcription could entail comparison of multiple researchers' poetic interpretations with poetic interpretations written by the participants themselves to further highlight the subjective nature of research and deepen understanding of the research topic at hand.

We also find it important to emphasize the joy that engaging in this particular methodology brought to us as researchers; seldom is the researcher's experience of researching brought into academic discussion, but we find it particularly relevant here due to the inherent emotional nature of poetic transcription, and its evidenced potential to grow our own research practices (Romero, 2020). We find ourselves excited to discuss implications of the comparison of poetry and appreciative of the opportunity to deeply engage with our participants' perspectives in a poetic, artful way.

In addition, future work with this data will employ computational analysis to rigorously compare the poems, attending to differences in style, affect, and the use of concrete imagery (Kao & Jurafsky, 2012). This analysis will add to our understanding of the application of poetic analysis as a qualitative methodology for research in undergraduate math education, as well as the potential benefit of creating multiple poems by multiple authors to gain a richer analysis. In engaging in this comparison, we build upon prior scholarly work which challenges the notion of objectivity in mathematics education research and invite others to join the discussion of both the value of subjectivity and arts-based research to our field.

Connections Pre-Service Teachers Make Between Social Justice and Mathematics

Zareen G. Aga (Rahman)
James Madison University

This study explored pre-service teachers' (PSTs') initial experience connecting mathematics and social justice. This work is part of an on-going action research project on improving mathematics PSTs' experiences in their methods courses, specifically focusing on culturally responsive mathematics teaching. Research stresses the need to prepare teachers who can teach a diverse student body, are mindful of differences in student backgrounds and, are cognizant of their own biases (Mark & Id-Deen, 2020; Brown et al., 2019; Gallard, Mensah, & Pitts, 2014; Johnson & Atwater, 2014; Lemons-Smith, 2013; Leonard, 2008; Lewis, Pitt, & Collins, 2002). PSTs developed lesson plans balancing both mathematics and social justice goals. Lesson plans were analyzed to find initial connections PSTs made between mathematics and social justice.

Keywords: Pre-service teachers, mathematics for social justice, mathematics teacher education.

A focus on equity and social justice is needed in mathematics education (NCSM, 2019; AMTE, 2020; Kokka, 2020). Research stresses the need to prepare teachers who can teach a diverse student body, are mindful of differences in student backgrounds and are cognizant of their own biases (Mark & Id-Deen, 2020; Brown et al., 2019; Gallard, Mensah, & Pitts, 2014; Johnson & Atwater, 2014; Lemons-Smith, 2013; Leonard, 2008; Lewis, Pitt, & Collins, 2002). Teachers must be able to look beyond their classrooms and see their role as a teacher in a wider context. They must recognize their responsibility to prepare responsible citizens who can use mathematics to change the world (Aguirre & Zavala, 2013).

Existing frameworks can help mathematics teachers develop practices in line with this call. Examples of these frameworks include standards-based mathematics instruction (National Council of Teachers of Mathematics, 2000), complex instruction (Cohen, 1994; Cohen & Lotan, 1995; Lotan, 2006), culturally relevant pedagogy (Ladson-Billings, 1994, 1995a, 1995b), and teaching mathematics for social justice (TMSJ; Gutstein, 2003, 2006). All these frameworks build on each other and emphasize teaching for understanding (Rubel, 2017). However, even with the existence of these frameworks it is challenging to teach novice teachers about pedagogy that connects social justice, culture, and mathematics (Gutstein, 2018). Teachers need to be proficient in making connections between mathematics and community, as well as developing their students' awareness of the world (Gutstein, 2018; Freire, 1970). To prepare such teachers it is necessary to determine what skills they would need, and develop ways to cultivate these skills (Gutstein, 2018). To fill this need, the study focused on pre-service teachers' (PSTs') experience in a mathematics methods course. The guiding research question was: What initial connections do mathematics PSTs make between social justice and mathematics?

Theoretical Perspective

Teaching Mathematics for Social Justice (Bartell, 2013; Gutstein, 2006) or Critical Mathematics (Frankenstein, 1983; Gutierrez, 2002) is pedagogy that seeks to develop students' conscientização (Freire, 1970). This means helping students understand content and become academically proficient, develop an awareness of inequities around them and begin to take action (Ayers, 2009; Kokka, 2019). This kind of teaching requires teachers to set two kind of goals, mathematics pedagogical goals and social justice pedagogical goals (Gutstein, 2006).

Teachers need to be mindful of both these goals as they work together to guide their students' development of conscientização (Gutstein, 2006). Mathematics pedagogical goals include, reading the mathematical world, traditional mathematics success, and conceptual understanding of mathematics/learning how to use mathematics as a tool (Gutstein, 2006). To achieve the mathematics pedagogical goals, teachers can seek guidance from standards frameworks (e.g., national or state standards), textbooks or standardized assessments (Gutiérrez, 2002; Kokka, 2020). On the other hand, social justice pedagogical goals focus on, grasping sociopolitical situations, taking action towards change, and developing positive identities (Gutstein, 2006). These identities include both cultural and social identities and are of particular importance for students who are not part of the dominant culture (Gutstein, 2006; Kokka, 2020).

In addition to goals, teachers must develop and implement tasks that help students use mathematics to learn about their cultural context, such as, a task comparing students' own neighborhood to those with different socio-economic status (Kokka, 2019). When implemented well, such tasks allow students to see the power of mathematics to learn about local social issues (Yang, 2009). While powerful, these tasks are employed in tandem with a district/textbook curriculum, and are used only 15% to 20% of the time (Gutstein, 2006). It is challenging for teachers to develop and implement mathematics tasks that develop students' conscientização (Bartell, 2013; Gregson, 2013; Brantlinger, 2013; Rubel et al., 2016; Kokka, 2020), and as mentioned earlier, it is crucial to develop supports for them (Gutstein, 2018).

The goal of this study was to learn from mathematics PSTs' experience developing lesson plans that balanced both mathematics and social justice goals. PSTs' developed lesson plans and made videos implementing them. Their lesson plans were analyzed to find the initial connections they made between mathematics and social justice.

Research Methodology

This study employs action research (Sagor, 2000) methodology to develop supports for PSTs inside mathematics methods courses. In particular, the goal of this project is to develop PSTs' teaching philosophy and teaching practice connected to culturally responsive mathematics teaching (CRMT) and TMSJ. The study took place at a mid-sized university in the Mid-Atlantic region of the United States. Participants in the study were twenty-three PSTs enrolled in a middle school mathematics methods course during Fall 2021 and Spring 2022 semesters.

PSTs were asked to develop lesson plans guided by the CRMT lesson analysis tool (Aguirre & Zavala, 2013). The CRMT tool was developed to help PSTs contextualize the mathematics they teach and to help them see their role as teachers who prepare their students to engage in the society (Aguirre & Zavala, 2013). It includes 8 dimensions: (1) intellectual support; (2) depth of student knowledge and understanding; (3) mathematical analysis; (4) mathematical discourse; (5) communication and student engagement; (6a) academic language support for ELL; (6b) use of ESL scaffolding strategies; (7) funds of knowledge/culture/community; and (8) social justice. The PSTs were required to include both mathematics and social justice standards (Learning for Justice, 2016). Open coding (Strauss & Corbin, 1998) was used to analyze the lesson plans and learn about the connections PSTs made between mathematics and social justice.

Results

PSTs favored some social justice standards in their lesson plans over others (please see table 1). For example, standard 12 was used most frequently, *students will recognize unfairness on the individual level (e.g., biased speech) and injustice at the institutional or systemic level (e.g., discrimination)* (Learning for Justice, 2016). This standard was connected to the following mathematics topics, evaluating and simplifying algebraic expressions, equivalent fractions, graphing linear functions and identifying the slope and y-intercept of a linear function, identifying the components of the coordinate plane, histograms, rational numbers, and solving linear equations. In general, students favored Probability and Statistics over other content strands. This was followed by Patterns Functions and Algebra, Numbers and Number Sense, Measurement and Geometry, Computation and Estimation, and Expressions and Operations.

Table 1. The most commonly used social justice standards

Standard	count	SJ Standard
12	7	Students will recognize unfairness on the individual level and injustice at the institutional or systemic level.
6	6	Students will express comfort with people who are both similar to and different from them and engage respectfully with all people.
9	6	Students will respond to diversity by building empathy, respect, understanding and connection.
1	2	Students will develop positive social identities based on their membership in multiple groups in society.
8	2	Students will respectfully express curiosity about the history and lived experiences of others and will exchange ideas and beliefs in an open-minded way.
10	2	Students will examine diversity in social, cultural, political, and historical contexts rather than in ways that are superficial or oversimplified.

Here, I share examples to show connections that PSTs made between social justice standards and mathematics. In a 6th grade lesson, one PST connected, Measurement and Geometry to social justice standard 12. The lesson focused on identifying the coordinates of a point, and graphing ordered pairs in a coordinate plane. The PST planned to have students graph sets of ordered pairs. Each ordered pair would represent a residential unit, with the origin of the coordinate plane representing a hospital. Students would analyze the location of the housing units and their proximity to the hospital. They had prepared to ask questions such as: *Compare and contrast the consequences of living closest to the hospital and furthest from the hospital?* and *If you could move the hospital anywhere on the coordinate plane, where would you move it and why?*

The PST stated that they wanted their students to discuss, the various advantages and disadvantages of living in a specific location. Standard 12 focuses on recognizing unfairness either on a personal or a systemic level and the PST had planned for their students to investigate the map of their local area to find essential resources (i.e., hospital, police station, school) with the goal to discuss systemic injustice and raise students' awareness.

Another PST developed a 7th grade lesson plan, using social justice standard 6, *students will express comfort with people who are both similar to and different from them and engage respectfully with all people* (Learning for Justice, 2016). The PST connected this standard to solving two-step linear equations. They started the lesson with a problem frequently found in standard mathematics textbooks (please see figure 1). Following this problem, they planned to ask questions to foster discussion focusing on both mathematics and accessibility. Their questions for the mathematics discussion were, *What is the cost dependent on? How is this different for members vs. non-members? How does the membership fee affect the total cost? How* *can we represent this problem using algebraic terms? What does each part of the equation tell us? How will we know when having a membership is a better deal?* These questions would foster

The local amusement park sells summer memberships for $50 each. Normal admission to the park costs $25; admission for members costs $15.

a) If Darren wants to spend no more than $100 on trips to the amusement park this summer, how many visits can he make if he buys a membership with part of that money?
b) How many visits can he make if he does not?
c) If he increases his budget to $160, how many visits can he make as a member?
d) And how many as a non-member?
e) Based on what you found above, after how many trips would having a membership be a better deal? Why?

Figure 1. A Problem about student recreational activities.

discussion about what the algebraic equations represent and the meaning of each part of the equation. In addition to the mathematics discussion question, they had prepared questions for what they called an "accessibility and implications discussion." These questions were, *Are amusement parks widely accessible? What determines who is able to go to amusement parks and who isn't? What are other forms of entertainment/recreation that are not widely accessible? Why is this? What forms of entertainment/recreation are widely accessible? How do these differ from those that are not widely accessible?* The PST explained that their goal was for their students to study and explore the accessibility of different forms of recreation. They shared that students should become aware that some students might be able to spend more time and money on recreational activities than others. Their lesson focused on awareness of similarities and differences between peers.

In the last example, a PST developed a 7th grade lesson plan using social justice standard 9, *students will respond to diversity by building empathy, respect, understanding and connection* (Learning for Justice, 2016). They connected standard 9 to histograms, stem-and-leaf plots, line plots, and circle graphs. The goal of their lesson was for students to learn, *How do histograms allow us to interpret data? How can you use intervals, tables, and graphs to organize data? Why do refugees flee their own country? What opportunities do refugees receive when they come to the United States? What age are the majority of refugees?* At the beginning of the lesson, the

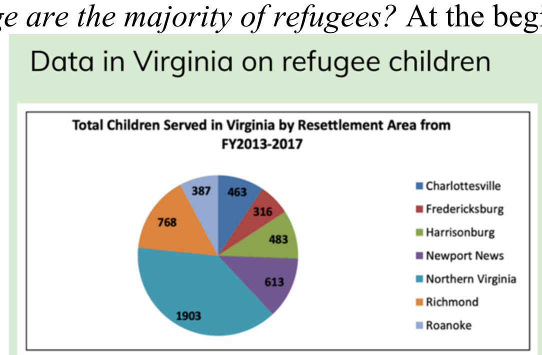

Figure 2. A graph depicting refugee data.

PST had planned to ask the students if they had any pre-existing knowledge on refugees and why refugees flee to other countries, and to have a class discussion. After the initial discussion, the PST had planned to show a video to the class on, *What does it mean to be a refugee?* (TED-Ed, 2016) followed by asking the following questions: *Why do refugees leave their home/country?*

What is the difference between migrants and refugees? What is a refugee camp? What data could be used on refugees to make a histogram? If I wanted to create a histogram on the age ranges of refugees, what would I label my x and y axis?

Following a discussion, the PST had planned to share graphs depicting state data on refugee children (please see figure 2 for one such graph). The PST had prepared the following questions for their students to answer, using data from the graphs: *Based on the histogram data what is the highest age range of refugees and what is the lowest? Why do you think so many refugees are young? How do histograms show the differences in distributions of data? List a couple of challenges that refugees could encounter at school? What are some actionable steps that you could take to help refugees in your local community? What is something new you learned today about refugees?* This lesson plan had the potential to have the students learn about mathematics as well as develop awareness. It is noteworthy that lessons such as these that focus on statistics lend themselves well to connections between mathematics and social justice.

Implications for teaching practice and future research

The process of developing lesson plans allowed the PSTs to research social justice topics that would connect to a middle school population, and they began to make connections between specific contexts and mathematics. PSTs also challenged themselves to develop questions that would lead to discussions in their classrooms. Such discussions would focus on unpacking the mathematics content and helping students become aware of the world around them. This exercise had the potential to help PSTs develop their own awareness of the world, potentially leading to their development of conscientização (Freire, 1970).

It was a challenging task for the PSTs to balance mathematics and social justice goals in a lesson. This finding is in line with existing research, as learning to balance mathematical and social justice goals is difficult and a long term pursuit (Harper, 2019; Bartell, 2013). Successfully balancing the two goals means being mindful during planning so that a focus on social justice does not take away from students' development of mathematical proficiency (Moses & Cobb, 2001; Harper, 2019). The PSTs began to experience this tension and would need further support to develop their own understanding of social justice in a mathematics classroom.

Teaching for social justice is a long journey that requires teachers to connect their teaching to contexts that are relevant to them and their students (Cochran-Smith, 1999). This process takes time, perseverance, and reflection (Darling-Hammond, 2002; Bartell, 2013). Teachers who begin this journey must understand that it is not a short-term goal (Gutiérrez, 2009), as their thinking and practice will develop and grow with practice and reflection (Bartell, 2013). As teachers develop an understanding of teaching mathematics for social justice, the changes are reflected in their teaching goals and teaching practice (Bartell, 2013). For PSTs it is particularly important to reflect on their teaching experience to develop a sense of who they are as teachers, this identity is necessary for them to employ pedagogies that connect culture, social justice, and mathematics (de Freitas, 2008, Leonard et al., 2010). Experiencing the challenge of connecting mathematics and social justice goals, allowed the PSTs to start thinking about teaching for social justice. At this early stage, most of their lessons aimed to have their students become aware of their selected context. The PSTs did not plan to have deep conversations about why the issues existed or to discuss actionable steps that can be taken to address the issues. With continued support PSTs can not only focus on awareness but also learn to discuss possible solutions so their students can take action and feel empowered. Such practice is necessary for PSTs to engage in repeatedly, for them to become experts (Nasir et al., 2008). Future research will focus on guiding PSTs to develop their identity as teachers who connect culture, mathematics, and social justice.

Physics Students' Interpretation of Matrix Multiplication

Pachi Her
Oregon State University / CSU Fullerton

Michael Loverude
California State University Fullerton

Most upper-division physics courses use mathematics beyond that encountered in the calculus sequence. Matrix multiplication and eigentheory are used by physics students in courses including classical mechanics, optics, and quantum mechanics. While there have been recent investigations of student use of linear algebra in quantum mechanics, no prior work has examined how physics students approach this mathematics in other contexts. In this paper, we investigated the extent to which student interpretations of matrix multiplication could be characterized by those from Larson and Zandieh (2013): linear combination, system of equations, and transformations. We have examined student responses to written questions and used the results to develop an interview protocol to examine how physics students interpret matrix equations using the three interpretations to classify their responses. Results are shown from an interview sample of six undergraduate physics majors.

Keywords: Linear Algebra, Mathematical Reasoning, Physics

Introduction

It is well established that upper-division physics courses have increased mathematical difficulty and that students in these courses encounter a variety of mathematical topics beyond calculus, including linear algebra and ordinary and partial differential equations. From linear algebra, matrix multiplication and eigentheory are used most in physics. The most well-known application is in quantum mechanics, but matrices are also used in other courses including classical mechanics and optics. Prior work on student knowledge of linear algebra in physics contexts has primarily focused on quantum mechanics (e.g, Wawro et al., 2020), which brings into play a set of conceptual and representational issues that may or may not reflect student understanding of the underlying mathematics. For this project, we have chosen to look at student interpretation of matrix multiplication in a broader array of topics, including some acontextual mathematical tasks as well as contexts drawn from classical mechanics and optics.

Theoretical Framework

Several models have been proposed to describe student use of mathematics in physics. In each, successfully executing the mathematical procedure in question is only one element of success. Redish and Kuo (2015) proposed a framework for student usage of mathematics in science courses describing stages of modeling, processing, interpreting, and evaluating. For the specific case of upper-division physics courses, Wilcox et al. (2013) proposed the ACER framework 'to guide and structure investigations of students' difficulties with the sophisticated mathematical tools used in their physics classes.' In this framework, students activate the appropriate mathematical tool in addition to constructing a model, executing the math, and then reflecting on results. For earlier work, we were guided by the physical-mathematical model developed by Uhden et al. (2012). This model describes three skills used at the boundary of math and physics: mathematization (converting a model into mathematical expressions), technical operation (executing relevant mathematical procedures), and interpretation (translating a mathematical result into physical interpretations and implications). In a previous study, we characterized student written responses to a number of tasks, and coded responses for each. Technical operation was seldom the most challenging for students; rather, more than half of the students had difficulty in converting a physical model into a matrix equation (mathematization) and relating eigenvalues to system behavior (interpretation) (Her & Loverude 2020).

Given that interpretation of matrix multiplication is both a critical skill and a source of student difficulty, we focused the next portion of the study on how students interpret matrix multiplication. Larson and Zandieh (2013) described three mathematical interpretations of the matrix equation A**x**=**b** among students in linear algebra courses: Linear Combination (LC), System of Equations (SOE) and Transformations (T). In previous work, Larson (2010) described two mathematical procedures to matrix multiplication, 'Matrix Acting on a Vector' (MAOV) and 'Vector Acting on a Matrix' (VAOM) which can be connected to (T) and (LC), respectively. The three interpretations have distinct conceptual and procedural interpretations [see Table 1].

*Table 1. A brief description of each interpretation from Larson & Zandieh (2013) for the matrix equation, A**x** = **b**.*

Linear Combination (LC)	**System of Equations (SOE)**	**Transformations (T)**
• Vector **x** components act as weights that modify the column vectors of matrix A • Associated with 'Vector Acting on a Matrix' (VAOM)	• **x** is a solution that coordinates the values for **b** with matrix A as coefficient entries	• Matrix A operates on input vector **x** where vector **b** is the modified output vector • Associated with 'Matrix Acting on a Vector' (MAOV)

Their work in the context of mathematics courses led us to consider the usage of these interpretations among physics students applying matrix multiplication in upper-division physics. In informal conversations with physics instructors, most expressed a strong preference for a transformation perspective, perhaps due to the use of matrix multiplication in quantum mechanics. This guided the formation of the following research questions, the first of which is addressed in this preliminary report:

To what extent do physics students use each of the three interpretations from Larson & Zandieh, and do they express preference for any of the three?

What relationship, if any, does the preference for interpretations have to solutions to physics tasks using matrix multiplication and eigentheory?

Methodology and Data Analysis

This project involves qualitative research on student learning. Data collection involved individual interviews with undergraduate physics students ($N = 6$) at a public university serving a diverse student population. All students were physics majors; one was a double major (computer engineering) and one had switched from engineering to physics. Their math and physics backgrounds were similar with some variations; in particular, three of the six students had taken a linear algebra course. All of the students had previously taken a course titled 'mathematical methods in physics,' intended to provide support in more advanced mathematics for later upper-level physics core courses. The mathematical methods course included a brief (2-3 week) introduction to matrix multiplication and eigentheory. Four of six student had subsequently completed a quantum mechanics course in which matrix multiplication and eigentheory were used frequently. The interview sample included three men and three women; three were white, two Latinx, one Asian.

Due to COVID-19, our standard routine of conducting interviews in-person had to be modified for an online setting. The first three interviews were recorded and conducted through Zoom, and the remaining three were in person. The interview protocol was designed to collect information on how physics students think about matrix multiplication and analyze the bridge between their mathematical interpretations and their physical interpretations. The interview consisted of nine questions that were separated into three sets. The first set were acontextual tasks intended to explore how students interpreted matrix multiplication without any physical context [see Figure 1] and were influenced by prior RUME studies (Henderson et al., 2010). The second set focused on reflection and rotation matrices along with the eigenequation. The last set of questions included three different physics concepts that used matrix multiplication and the eigenequation (optics, coupled blocks on springs, and a quantum spin operator), though some students did not complete all of these tasks. The first set of tasks was used to probe which of the interpretations, if any, were articulated by students Questions 1 and 2 provided examples of matrix multiplication and a matrix equation and asked students for their interpretation; question 3 provided three expressions associated with (LC), (T), and (SOE), respectively, and asked students to describe how, if at all, each expression represented the matrix equation.

Portions of the interview transcripts were coded iteratively by two members of the research team. Interview coding was in part emergent and in part driven by prior research. The primary focus of our analysis procedure was to investigate the students' interpretation

Question 1	**Question 2**	**Question 3**
Consider the expression $\begin{pmatrix} 2 & 1 \\ 5 & 6 \end{pmatrix}\begin{pmatrix} 3 \\ 4 \end{pmatrix}$. How do you think about this expression?	Consider the matrix equation $\begin{pmatrix} 3 & 5 \\ 2 & 7 \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} a \\ b \end{pmatrix}$. First, how do you interpret this?	$\begin{pmatrix} 1 & 2 \\ 8 & 4 \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} a \\ b \end{pmatrix}$ For each of the following expressions, explain how if at all, it represents the matrix equation. (i) $x\begin{pmatrix} 1 \\ 8 \end{pmatrix} + y\begin{pmatrix} 2 \\ 4 \end{pmatrix} = \begin{pmatrix} a \\ b \end{pmatrix}$ (ii) $\begin{pmatrix} 1 \cdot x + 2 \cdot y \\ 8 \cdot x + 4 \cdot y \end{pmatrix} = \begin{pmatrix} a \\ b \end{pmatrix}$ (iii) $x + 2y = a$ $8x + 4y = b$

Figure 1. The first set of interview tasks.

rather than assessing 'correctness'. The initial analysis was based on the interpretations described by Larson and Zandieh (2013); student utterances were coded as (LC), (T), or (SOE). The grammar of student utterances was part of the analysis; e.g., transformation interpretations were often characterized by transitive verbs like 'manipulated,' 'changed,' or 'rotated.' MAOV and VAOM were coded and associated with (T) and (LC), respectively. The transcripts were also examined for evidence of interpretations that were not accounted for by any of these codes.

Initial analysis suggested that additional refinements would be required. Some student responses seemed to shift depending on whether they were primarily procedural or conceptual. This led to creating a parallel set of codes in which responses were identified as being procedural (relating to the method used to evaluate the mathematical expression, e.g., 'the first row with the column of the second matrix'), conceptual (how they make sense or meaning of the expression or outcome, e.g., 'change a vector from one initial state to a final state'), graphical, or none of these. An utterance might be coded as, say, both procedural and LC. These distinctions mirrored analysis in Larson and Zandieh (2013) as well as other recent work (Serbin et al., 2020). The researchers worked to resolve differences in coding and adjusted the codes appropriately; one example of this process is described in the Results section. The analysis process consisted of grouping terms and sections of the interview transcripts and examining the resulting data set for trends and patterns. Responses were further examined for either, on one hand, consistency of interpretation or, on the other, fluid, changing interpretations across different tasks.

Results

Table 2 presents a summary of our analysis. Student descriptions of matrix multiplication were generally consistent with the three descriptions (T), (LC) and (SOE). Nearly all student statements were readily aligned to one of the three.

There was some degree of preference for the Transformation interpretation (T), with some variation. All six students incorporated the (T) interpretation at some point. Three of the six students consistently interpreted matrix multiplication, in a variety of tasks, in terms of the transformation interpretation and the associated MAOV description, with few or no codes for (LC) or (SOE). This was a clear signal throughout these three interviews, and was often accompanied by explicit rejection of, or confusion with, equations in Question 3 associated with other interpretations. Three of the six students showed signs of more fluid interpretations, with all articulating (LC) and/or (SOE) interpretations, though again all shifted to (T) at some point during the interview. Most of the students offered both procedural and conceptual support for their preferred explanations, but one of the six remained focused on procedural knowedge and offered little in the way of conceptual interpretation.

Below we present extended examples of responses given by students in different categories: student A, a consistent user of T interpretations, and student C, whose responses were coded as supporting all three of the interpretations at various parts of the interview.

Table 2. A summary of student backgrounds and responses. LA/QM refers to whether students had completed linear algebra and quantum mechanics, respectively. Conc/Proc = conceptual and procedural.

Student	A	B	C	D	E	F
Major(s)	Physics	Physics	Physics (formerEng)	Physics	Physics +CompEng	Physics
LA / QM	Y/Y	Y/Y	Y/N	Y/Y	Y/Y	Y/N
Initial / Final Interpretation	T / T	T / T	LC / T	T / T	SOE / T	LC / T
Stable/Fluid	Stable	Stable	Fluid	Stable	Fluid	Fluid
Conc/Proc	Both	Proc	Both	Both	Both	Both

Student A

Student A was coded as consistently using a (T) interpretation throughout the interview. For the first two questions, Student A immediately described characteristics (T) interpretations, e.g., using terms 'manipulated' and 'transformation matrix': "So uh I see this as we got some of vector quantity here and it's being manipulated by some sort of transformation matrix."

Student A's responses further suggested a strong association of the (T) interpretation with the procedure of matrix multiplication. On question 3 he immediately chose the second equation and commented that choices (i) and (iii) were difficult to parse conceptually. He was unsure whether these were even mathematically equivalent, stating that (iii) was 'divorced from the whole process of matrix multiplication.' After some discussion, student A performed procedures to reproduce the expressions, and once he was satisfied that all three were representations of the matrix equation, he reversed course somewhat and stated that choice (i), the (LC) interpretation, was the best representation. However, his conceptual description in support of choice (i) was coded as a (T) interpretation as he referred to 'transforming' the elements of the vector and 'what the matrix is doing,' rather than the weighting of column vectors associated with (LC). Indeed, he interpreted all three expressions in terms of (T), though the intent was that each expression mapped to one of the three interpretations.

Student A: "…number (i) seems like it is more representative…it represents what the matrix is doing more than the other two. So the fact that this [points to first column of matrix A] is transforming that [points at x] and this [points to second column of matrix A] is transforming that [points at y] kind of represents the idea of the matrix multiplication a bit more than—a lot more than this [option (ii)] and more than this [option (iii)] I would say. Because we see a component of the matrix acting on sort of a scalar."

Student C

Coding student C's responses could be challenging, in part because she used unconventional terminology. For example, in her response to question 1, she explained that while the knew the accepted terminology, she preferred to refer a 2 by 2 matrix as a "2 by 4." She gave responses consistent with each of the three interpretations at different moments in the interview, offering both procedural and conceptual explanations. In her initial procedural response, she showed multiplying the rows of the matrix with the column vector, consistent with MAOV. However, her subsequent conceptual description was coded as being consistent with VAOM and thus (LC). In question 2, she described the matrix equation as: "$\begin{pmatrix} x \\ y \end{pmatrix}$ is modifying $\begin{pmatrix} 3 & 5 \\ 2 & 7 \end{pmatrix}$ where $\begin{pmatrix} x \\ y \end{pmatrix}$ would be some arbitrary modification being performed to get an arbitrary outcome $\begin{pmatrix} a \\ b \end{pmatrix}$." The vector 'modifying' the matrix suggests VAOM, but written work was consistent with MAOV.

Ultimately, Student C concluded that choices (i) and (iii) were possible representations of the matrix equation but was ambivalent because she could not fully track their procedures. She identified choice (ii) as 'no representation' and rejected its validity altogether.

Conclusion and Implications for Future Work

Analysis reveals some patterns that may have implications for instruction as well as future research efforts. Three of the six subjects showed a strong and consistent preference for the (T) interpretation. While each of the choices in task 3 was intended to support one interpretation, these students provided (T) interpretations for all three. The other students all used (T) at some point but offered more fluid responses, shifting among the interpretations. The preference for (T) interpretations may reflect a difference in disciplinary usage, as recent experiences with matrix multiplication came in physics courses that likely emphasized the (T) interpretation above others.

While the sample is small, two additional patterns are of note. First, the three students who had the most consistent (T) interpretations had all completed two semesters of quantum mechanics, and two of the three who shifted among interpretations had not yet completed the course. Quantum mechanics instructors and texts frequently use language like 'the operator acts on the vector', which seems to be consistent with the (T) interpretation. Second, the two students with engineering backgrounds were both among those who used other interpretations; this may suggest additional disciplinary influences.

Analysis is ongoing and later publications will include analysis of later parts of the interviews including physical contexts, as well as written problems developed based on these interview tasks. Informal discussions with instructors for relevant physics courses suggest a marked preference among at least these physics instructors for the (T) interpretation, possibly suggesting a further avenue of inquiry.

Calculus courses should embrace innovative pedagogies that promote Latin students' mathematics identity development. One such pedagogy is specifications grading, which might foster students' growth-mindset and perseverance in mathematics. In this study, we examine the mathematics identity development of two Latin* students' in Calculus courses with specifications grading, and we compare this development to that of a student not enrolled in a specifications grading course. We compare the changes in the students' mathematical competence and the changes in their sense of recognition as a doer of mathematics. We discuss how aspects of the specifications grading pedagogy can contribute to students' mathematics identity development.*

Keywords: Alternative Grading, Specifications Grading, Mathematics Identity, Calculus

For many, mathematics is a formidable academic challenge, especially at the college level (Roska et al., 2009; Weisburst et al., 2017). Indeed, despite recent significant gains in Latin* students pursuing mathematically-oriented degrees (Crisp & Nora, 2012), still remaining is a significant underperformance of Latin* students in entry-level mathematics college courses (Otero et al., 2007; Solórzano et al., 2013; Sparks & Malkus, 2013). Even though Latin* students have the capability of succeeding in college-level mathematics (Cole & Espinoza, 2008; Crisp & Nora, 2010), the mathematical under-preparedness experienced by many Latin* college students has even led researchers to designate Calculus as a *gatekeeper course* (Norton et al., 2017; Pyzdrowski et al., 2013; Suresh, 2006), or a course that (un)intentionally impede many Latin* and other underserved students from pursuing mathematically-oriented degrees and careers (Convertino et al., 2022). Despite these hindrances, however, research has demonstrated that fostering mathematics educational spaces in which students develop a stronger sense of self, or *mathematics identity*, significantly impacts their mathematics perseverance and success (e.g., Authors, in press; Matthews, 2020; Miller-Cotto et al., 2020; Morales & DiNapoli, 2018).

To contribute to the ongoing efforts for more equitable educational experiences for undergraduate Latin* students, especially in gatekeeper mathematics courses, we must shy away from pedagogies that rely on archaic dispositions about how people learn. Instead, we must opt for pedagogies that foster stronger mathematical identities by adopting an asset-based orientation towards all learners, including Latin* students. For that reason, we report our pilot efforts in implementing *specifications grading* Calculus I courses in Spring 2022, a pedagogy based on the idea of viewing learning as a process achievable by everyone rather than a result obtained only by a few (Nilson, 2015). This study was guided as follows:

1. How does the mathematics identity development of Latin* students enrolled in a specifications grading Calculus I course compare to the mathematics identity development of Latin* students enrolled in a non-specifications grading course?
2. What aspects of specifications grading foster students' mathematics identity development?

Literature Review and Theoretical Background

Mathematics Identity and its Constructs

Adams (2018) gives a clear definition of *mathematics identity* as "the dispositions and deeply held beliefs that students develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics in powerful ways across the context of our lives" (p. 121). Furthermore, Cribbs et al. (2015) offer an explanatory model for mathematics identity by focusing on students' self-perceptions in three constructs, namely mathematics interest (i.e., how a student perceives their interest in mathematics), recognition (i.e., how a student perceives their external recognition, or lack thereof, as mathematics doers), and competence/performance (i.e., how students perceive their comprehension and performance of mathematics). As shared by Cribs and colleagues (2015), self-perceptions about these three constructs significantly informs students' mathematics identity, and this has the capacity to influence students' goals and participation in mathematics, including the degree of choosing, or not, their future careers in STEM. Therefore, it is crucial for educators to understand and empower students' mathematics identity, especially among marginalized student populations, and let that guide their classroom interactions and practices so that students' self-perceptions in relation to mathematics can be positively impacted (Boaler & Greeno, 2000; Cribbs, et al., 2015).

Specifications Grading

We argue that specifications grading as a pedagogical framework provides us with an educational space that can foster stronger mathematical identities. For instance, instead of awarding points for assessments, students are given specifications on assignments, or learning objectives, and these are assessed via a more asset-oriented process that measures progress rather than correctness. Students are also provided with ample opportunities to revise their work based on instructor feedback and resubmit it until they meet the learning objective at a satisfactory level. In other words, specifications grading adopts a growth-mindset orientation towards learners, believing that all learners have the capacity to overcome setbacks in their learning trajectories. As a result, specifications grading has been shown to provide students with a sense of agency as they obtain a greater control over their mathematical trajectories, not to mention with a more authentic and equitable reflection of their proficiency in their respective courses (Boesdorfer, et al., 2018; Katzman et al., 2021; Stange, 2016; Talbert, 2017; Tsoi et al., 2019). Empirical research in this regard, however, remains scarce (Beatty, 2013; Post, 2017; Toledo & Dubas, 2017;). The gap is even more notorious when we consider the positive impact that a specifications grading pedagogy can have on Latin* students' mathematical identity development. For that reason, we aimed to explore the effects that a specifications grading-Calculus I course could have on Latin* students' mathematical identities.

Methods

We collected data at a Hispanic-Serving Institution in the southwest. In Spring 2022, our institution had 14 sections of Calculus I with approximately 500 students. We implemented the specifications grading course design to 9 sections with approximately 300 students. We divided the content of the course into 29 learning objectives that were assessed throughout the semester. Our assessments consisted of group worksheets, exams, and online homework. The mastery of every learning objective was tested on both a worksheet and an exam. If a student failed to show mastery of a learning objective on a worksheet on the initial submission, we allowed the student to resubmit. If a student failed to show mastery of a learning objective on an exam, the student was provided with opportunities to retest. Retesting sessions were available weekly after the first exam until the end of the semester. In our traditionally-graded Calculus I sections, a student's grade was based on quizzes, group work, exams, and homework with no opportunities for re-assessments. All 14 sections were expected to teach the same content.

To compare the mathematics identities among our Latin* students, we adapted Cribbs et al.'s (2015) well-established, 12-item mathematics identity survey instrument. Following a 5-point Likert-scale, it not only quantifies the mathematics identity of an individual, but also the three subconstructs of mathematics identity: self-perceived interest, recognition, and competence/ performance in mathematics). Additionally, all individual scores were scaled between one (1) and (5) to facilitate its comparisons within and across students. This meant that each student who took the survey had four different scores representing each construct, all within a 1 – 5 scale. The surveys were given during the second week of classes and on the third-to-the-last week of classes, respectively. In all, the survey was taken by 218, mostly Latin*, students enrolled in Calculus I. Out of the total, 119 enrolled in one of the 9 courses that were implementing specifications grading. These students were mostly 1st generation college students pursuing an Engineering, Biology, or health professional-related major.

Eight survey participants volunteered to participate in an individual follow-up interview. We focus on three of these participants for this preliminary report. To exemplify the most diverse types of cases studies, a common methodology in case study research design (Seawright & Gerring, 2008), we selected three cases of Latin* students, Katie, Oscar, and Carlos (pseudonyms) who demonstrated low to mid-range mathematics identity scores in the pre-survey. Katie and Oscar were enrolled in a Calculus I course using specifications grading, while Carlos was enrolled in a Calculus I course without specifications grading. Individual semi-structured interviews (Bernard, 1988) were conducted virtually with each of the three participants. The interview protocol was designed according to the components of Cribbs et al.'s (2015) model for mathematics identity. Follow-up questions were asked as needed for clarification and elaboration. These interviews were recorded and transcribed.

We analyzed the interview transcripts by using inductive coding (Miles et al., 2013) to classify the themes present in the participants' interview responses. We performed axial coding to organize our codes according to the constructs of interest, competence, and recognition. We then considered the results of the overall survey responses to inform our decision regarding the focus of further qualitative analysis. In doing so, we found that students in classes with specifications grading had higher scores on competence/performance and recognition than those not enrolled in such courses. Therefore, we chose to focus our qualitative analysis on the three students' perceptions of their competence/ performance and recognition in doing mathematics.

Results

Spider-web charts of the participants' mathematics identity scores measured on the surveys are in Figure 1, with mathematics identity, competence/performance, interest, and recognition scores plotted on each of the four axes. The grey region on the charts represents the students' pre-survey scores and the teal region the post-survey scores. These charts illustrate the change in Katie's, Oscar's, and Carlos's scores on the pre- and post-surveys. Katie and Oscar, who participated in a specifications grading course, both demonstrated large increases of one to three points in every measured score of mathematics identity and its subcomponents. Carlos, who did not participate in specifications grading, had small increases in his mathematics identity, competence, and interest scores, but his recognition score did not change. In what follows, we discuss the results from the qualitative analysis of participant's interview responses, focusing on their perceptions of their competence and recognition in being a doer of mathematics.

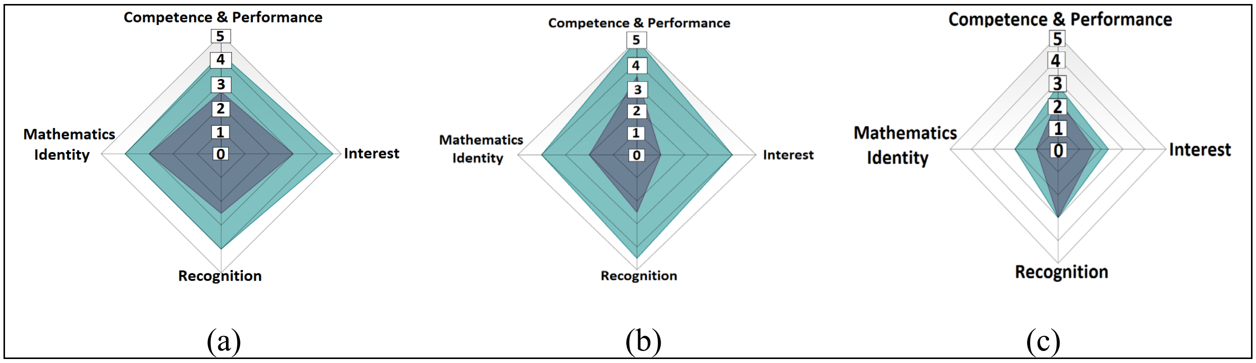

Figure 1. Spider charts demonstrating changes in Katie's (a), *Oscar's* (b), *and Carlos's* (c) *pre- and post-survey scores on measures of mathematics identity, competence, interest, and recognition.*

Students' Competence/Performance in Doing Mathematics

Katie and Oscar reported struggling in their prior mathematics courses: "I [Katie] had an overwhelming plate on my workload, and so I would either fall behind or just keep struggling with that part of the work. I kinda felt alone, I guess, back then… I had to drop the class." Similarly, Oscar referenced his prior Calculus course experience as "a dooming failure," sharing the negative feelings that failing had on him,

> "You're just like, 'Well I'm never going to finish. This is not working,' and you know, all those red X's and stuff like that, it's just puts you down man. It puts you down. You're like 'No I don't want to do this anymore. It's not worth it.'"

In all, they reported feeling overwhelmed and unmotivated to "deal with" their failures. Furthermore, Oscar referred to traditional grading as "either you pass or you don't pass," highlighting how traditional grading acts as gatekeepers for many.

Once in the specifications grading Calculus I course, however, Katie and Oscar demonstrated higher confidence in their competence in doing mathematics in their post-course-survey scores and during the interviews. As shared by Katie, "I am confident with myself…I know what not to do and what I'm capable of doing on my own." Oscar also described his change in confidence as, "You know I thought…I'm never going to pass Calculus. Yes, you can. You can pass it if we put hard work and dedication to it. It is reachable." To this, Oscar attributed his change in confidence to seeing his progression of passed learning objectives: "You start seeing that you're making progress. That motivates you, and that amplifies your performance and gives you more confidence…it gives me confidence like 'Hey, I'm doing it!'…It's a boost to your confidence in your performance to do math." Carlos, on the other hand, self-reported a decrease in his confidence from high school to his traditionally-graded Calculus I: "I'm doing these college courses, and they're more difficult, and there's not that much time… I'm struggling more to really grasp at it… specifically in math where I've been struggling the most."

Overall, Katie and Oscar, who were in a specifications grading course, demonstrated increased confidence in their competence in doing mathematics. Oscar, for example, attributed this change to aspects of specifications grading. On the other hand, Carlos, who was not in a specifications grading course, self-reported a decrease in confidence, which he attributed to his struggle with the fast-paced Calculus course that moved on to the next topic before he grasped the prior one.

Students' Recognition as a Math Person

Katie and Oscar both increased their measured recognition scores between the pre- and the post-survey, while Carlos showed no change in his recognition score. In the interviews, we further investigated their perceptions of whether their family, friends, and mathematics instructors recognized them as a math person. All three participants claimed that their friends and family recognized them as a math person, and they gave anecdotal evidence about helping their friends with doing mathematics problems. Carlos expressed frustration that his family and friends "definitely" perceived him as a math person: "It's frustrating because… I know that I'm *not* that much. But unfortunately, they keep this illusion, and I'm forced to be pushed down this path that they think I am on, but I'm not." Carlos did not perceive himself as a math person and was frustrated that others did because he thought he could not meet their expectations.

After taking the course with specifications grading, Katie and Oscar reported that their instructors recognized them as a math person. Katie explained, "I think [my instructor] gives me praise for things I do correct and asks me if I'm getting it correct, so I think she does." She referenced the feedback she obtained from the instructor, which is part of the specifications grading process that informs students' revisions. The instructor's positive feedback seemed to give Katie a sense of the instructor's recognition of her as a math person. Carlos, who was not enrolled in a specifications grading course, reported that his instructor saw him as a math person "no more than anyone else." This interview response aligns with Carlos's low score for recognition from the survey. Overall, Katie and Oscar reported that their instructors recognized them as a math person, but Carlos did not. The use of instructor feedback in specifications grading may allow students to perceive their instructor's recognition of them as a competent doer of mathematics.

Discussion

Implementing innovative pedagogies, such as specifications grading, has the potential to foster students' mathematics identity development. Specifications grading realizes this by adopting a growth-mindset that provides students with multiple opportunities to meet their mathematics learning objectives. However, preliminary evidence suggests that specifications grading may also provide Latin* students with educational spaces that may take advantage of Latin* students' *cultural wealth* (Yosso, 2005), or the idea that Students of Color possess a plethora of capital that, when channeled into their education, can serve as critical factors that contribute to students' success in STEM (Samuelson & Litzler, 2016). Because of this, future studies should also explore to what extend do Latin* students' *aspirational capital* (Yosso, 2005), or their ability to maintain hopes and dreams for the future despite the challenges faced as marginalized populations, may be catapulted when they are provided with low-stakes educational spaces in which they feel more in control of their academic trajectories. Furthermore, their *navigational capital,* or their abilities to traverse White-dominated social constructs, like traditional Calculus curricula, could allow them to traverse their specifications grading Calculus I course with more ease given that the learning space values *persistence*, yet another critical characteristic of many Students of Color. Combined, these two forms of capital could also have the capacity to bolster Latin* students' success in Calculus and STEM in general; however, further studies are necessary. We propose the following discussion question for the audience: What further analyses can help us explore the connection between specifications grading and Latin* students' mathematics identity development? Also, it seems that specifications grading may also take advantage of Latin* students' cultural wealth. If so, what specific characteristics of specifications grading accomplishes this?

Susana Brewer Castano
Florida State University

Small-scale teaching experiments focused on how students reason about exponential functions provide an incredibly useful foundation when thinking about the design of classroom tasks. However, scaling-up certain critical features of these experiments such as focused and prolonged instruction on a single topic is unrealistic for those teaching at the university level. Drawing on research on covariational reasoning, exponential functions, and design-based research methodology, we developed and implemented two interactive lessons with the goal of enhancing students' understanding of exponentiation and covariational reasoning. In particular, we sought to identify the quantities and relationships that students focused on during classroom tasks and the ways in which the tasks could be refined to support students' understanding of exponential covariation. From this analysis, revisions made to the curricular materials and other implications for research and teaching are discussed.

Keywords: Precalculus, Covariational Reasoning, Exponential Functions

Researchers in undergraduate mathematics have paved the way for the rise in conceptually oriented undergraduate mathematics courses throughout universities in the United States (e.g., Thompson & Carlson, 2017). For many universities, however, implementation of these courses is constrained by several factors such as large class sizes, lack of research-based curriculum materials, and lack of professional development and support for instructors (e.g., Deshler et al., 2015). While many theories exist about instructional means of supporting conceptually oriented undergraduate mathematics learning, there is still a gap in the knowledge of how to scale-up the research findings from these small-scale teaching experiments to instruction and curriculum design in large university courses. This study seeks to fill this gap in the literature by developing and modifying classroom tasks from small-scale teaching experiments to support students' reasoning about exponential covariation in the scaled-up setting of a large undergraduate precalculus course. In particular, we sought to identify the quantities and relationships that students focused on during the classroom tasks and the ways in which the tasks could be refined to support students' understanding of exponential covariation in this scaled-up context.

Literature Review

Quantitative and Covariational Reasoning

Quantitative and covariational reasoning have been shown to be foundational reasoning abilities important for learning about functions and other related mathematical concepts (e.g., Carlson et al., 2002; Oehrtman et al., 2008; Thompson & Carlson, 2017). When students reason quantitatively, they are able to "conceptualize measurable attributes of some object or situation" (Madison et al., 2015, p. 56) and the relationships between these attributes. This reasoning serves as a basis for covariation which entails coordinating how two quantities change in relationship with each other (Thompson & Carlson, 2017). Instruction aimed at the development of quantitative and covariational reasoning has been shown to improve student learning outcomes in undergraduate precalculus and prepare students for success in future mathematics courses such as calculus I (Carlson et al., 2010; Carlson et al., 2015).

Exponential Functions

Historically, instruction on exponential and logarithmic functions has been based on the ideas of exponentiation as repeated multiplication and as logarithms as either repeated division or simply as the inverse to exponentiation (Ellis et al., 2012; 2015; Kuper & Carlson, 2020). Recent studies (e.g., Kuper & Carlson, 2020) have found that students' understanding of exponential and logarithmic functions is greatly improved when they are given opportunities to reason quantitatively and covariationally.

Ellis et al. (2012; 2015) analyzed three 8th grade students' reasoning while working in the context of a magical growing cactus named the Jactus to explore the conceptual shifts that students made to reason productively about exponential growth. These shifts included moving from a repeated multiplicative view of exponentiation to the coordination of constant multiplicative ratios between consecutive output values with constant additive changes in consecutive input values. An example of this is students' coordination of the ratio between the Jactus' heights at different times and the elapsed growth time. In other words, when given the Jactus' height at weeks 1, 2, and 3, students were able to divide the successive heights and coordinate this multiplicative ratio with the elapsed growth time of 1 week to come to the conclusion that the Jactus' height doubles every week. Ellis and collaborators observed students' levels of correspondence and covariational reasoning for repeated consecutive input values greater than a one-unit change preceded their productive reasoning with non-natural exponents. For example, students had to understand how to reason about the ratio between the Jactus' heights at 2 or 3 week intervals (i.e., the Jactus triples every 2 weeks as opposed to every week) before they were able to productively reason about the ratio of heights at 1 day intervals. For example, the students were told the Jactus doubles in height every week and were asked to find its height at 0.25 weeks. Productive covariational reasoning about these non-natural exponents occurred after students were familiar with natural numbers larger than 1 as the exponent.

Methodology

The analysis presented here is part of a broader study aimed at identifying and analyzing the key features of task design and classroom instruction that are beneficial for student learning when attempting to scale-up teaching experiments to whole classroom settings. We begin this work by developing and modifying classroom tasks used in prior teaching experiments (i.e., Ellis et al., 2012; 2015) to support students' reasoning about exponential and logarithmic covariation in the scaled-up setting of a large undergraduate precalculus course. We used design-based research methodology because its purpose is to simultaneously "develop a class of theories about both the process of learning and the means that are designed to support that learning" (Cobb et al., 2003, p. 10). The strength of this methodology for the purpose of scaling up curriculum and instruction is that we are able to utilize the empirical evidence from studies such as those described in the literature review to analyze and test which features are most crucial for students learning when in the new setting of a large undergraduate precalculus course.

Setting

This study took place at a large research university in the Southeast United States. The participants were 30 undergraduate precalculus students enrolled in a six-week course which included both lecture and lab or recitation sessions. Due to the accelerated nature of a six-week course, students met daily for lectures and twice weekly for lab sessions. During one lab meeting students took a weekly quiz in lieu of unit tests. In the other lab, students worked in small groups of 3–4 on assignments created by the research team which drew on literature such as that described above. The purpose of these labs was to support development of quantitative and covariational reasoning as well as deepen their understanding of key mathematical concepts. For this study, the constraints of this course structure were a crucial part of the design of lab tasks. For example, lab sessions were limited to 60 minutes and the only assistance that students received outside of their small peer group were from their instructor, a graduate teaching assistant, and the first author of this report. Unlike small-scale teaching experiments where one teacher works consistently with 2–3 students, our design needed to account for having two to three instructors working with 30 students during a single lab section.

Data Sources

Students' anonymized written work from the labs were used as the primary source of data analyzed for this study. In total there were six groups of 3–4 students who worked through 6 lab activities. Each lab consisted of a brief pre-lab assignment, a lab activity, and an exit ticket. Additional data that informed our lab revision process and analysis came from field notes taken by the first author during labs and from debrief meetings with the instructor for the course and the research team. Since the focus of this particular study was primarily on students' understanding of exponential functions with an additional emphasis on quantitative and covariational reasoning, we decided to limit our analysis to the lab which introduced these concepts.

The Mathematics. The problem context of the lab was Alice in Wonderland. In the pre-lab activity, students were expected to find the number of sips of potion needed for Alice to fit through the door when given information about her original height and how a potion changes her height as she takes sips. During the lab, students worked through tasks which asked them to calculate the first and second differences in her heights as she sips the potion and to plot the data on a graph. Following this, students had to consider how Alice's height changes when half sips are taken and estimated her height at half-sip values. The second portion of the lab focuses on Alice eating a cake which makes her grow. Students are given a partially-filled table with her height after a number of bites of cake and are asked to fill in the missing height data. Then they are asked to graph their data and to again consider how Alice's height changes when taking half-bites of cake. For this report, we drew on data from two questions (See Table 1) which we felt had the highest potential for supporting students' covariational reasoning.

Table 1. Alice in Wonderland Lab Questions

Problem 2e
Students have the following information: (1) Alice shrinks to ⅔ her current size each time she takes one sip, and one sip is 0.5 oz. (2) Alice was 51 inches tall before drinking any potion, and 34 inches after 1 sip (or ½ oz) of potion. **Students are asked this question:** We know that after her first sip of potion Alice's height decreased by 17 inches. If Alice had instead only taken half a sip of potion (0.25 oz) what is a reasonable expectation for the decrease in her height? Would it have been more than, less than, or equal to 8.5 inches? Explain your reasoning.

Problem 3d

Students have the following information: Alice has eaten 8 bites of cake and we know Alice's height after various bites of cake (e.g., 0 bites, 4.5 inches tall; 2 bites, 8.85 inches; 6 bites, 33.88 inches).
Students have to find the following information: Alice's height after 5 and 8 bites
Students are asked this question: Based on our table of data we know that after two bites of cake, Alice's height increased by 4.32 inches. If Alice had eaten each bite of cake separately would each growth spurt be a 2.16 inch increase in height? Why or why not?

Analysis

Tyburski et al. (2021) argue that covariational reasoning is clearly delineated into levels with associated mental actions involved, but in practice there is little guidance for deciding what moment-to-moment student words or actions are evidence of their level of covariational reasoning. They offer lessons from their work to researchers who want to analyze and make claims about students' covariational reasoning. In the spirit of their work, we began our analysis by drawing on students' written work to identify the quantities that students attended to and evidence of the ways in which they coordinated those quantities. We used this along with the field notes and observations made by the research team to group students' responses into categories we felt were indicative of the types of quantities and covariational reasoning observed.

Findings

The intention of the lab was to support students' reasoning and foundational conceptions about the exponential covariation of quantities. We wanted students to coordinate additive changes in bites/sips with multiplicative changes of Alice's height. Additionally, we wanted students to understand that Alice's height would decrease (or increase) by smaller and smaller amounts (or larger and larger) as she continued to sip potion (or eat cake). In order to get students to think about this, we asked them to consider whether or not Alice's difference in height would be halved when she took a half sip instead of a full sip (i.e., Problem 2e). We anticipated that students would reason about this by noticing that when you multiply by ⅔ (the shrinking rate), that the number shrinks more when you begin with a larger number. In other words, Alice shrinks by larger amounts when she is taller, but her changes in height decreases as she gets shorter. However, we found that the resources embedded in the design of the lab leading up to problem 2e did not provide students with adequate resources to appropriately coordinate Alice's heights and the successive changes in heights with each sip of potion. Indeed, five of the six groups responded incorrected to problem 2e by reasoning in ways such as "In order [for] a full ⅔ decrease, she would have to take a full 0.5 oz sip, but she only took half; therefore the ⅔ decrease would be ½ [as] effective, so she decrease[d] by ⅓, so her height decrease[d] would be 5.66 [inches]," or that "Alice's height [would] decrease by 8.5 inches because 17 divided by 2 equals 8.5." The only group who responded correctly used a previously learned formula (which was not our intention).

In examining student responses to question 3d, however, we found that students had far more ways to reasoning productively about the quantitative relationships involved. Additionally, every group correctly answered that Alice's growth would not be in two equal spurts of 2.16 inches. We grouped the ways of reasoning about this into three (often overlapping) categories as shown in Table 2.

Table 2. Examples of Student Work on Question 3d

Reasoning	Groups	Response
Change is **not** constant	2, 3, 6	"It would not be constant, so she would not grow 2.16 each time, instead the second time would be greater."
Change is multiplicative	2, 5	"No, because we're not adding, we are multiplying."
Change is exponential	1, 4, 6	"No, the rate of change is defined as exponential growth. This means each bite stimulated a greater change in height than the preceding bite."

Discussion

Our findings support those from Ellis et al. (2015) in documenting the conceptual difficulty of reasoning covariationally with exponential functions. We observed a pattern in students' reasoning (and our own when designing and planning the learning trajectory) where one wants to use linear relationships when partitioning both quantities rather than coordinating additive and multiplicative changes. We found that students frequently described changes in height in terms of linear relationships in question 2e (when they had to reason about a partition of a single pair of values). In contrast, students more frequently conceptualized the relationship in question 3d multiplicatively (when they had to reason about successive changes of sips and heights). While it was our intent that both questions supported the coordination of additive changes in one variable with multiplicative changes in the other, students did not reason in the way we intended until they were forced to reason about iterative or successive changes.

In examining other features of the task design, we also noted that the resources available to the students at the time of each problem were starkly different. Prior to question 2e, students were told that Alice's height was 51 inches and that she would shrink to ⅔ of her original height with each sip of potion. Then students were given a table of values filled in with her height at one sip intervals from 0 to 10. In contrast, prior to question 3d students were given Alice's initial height and a partially filled table of values (See Table 1). The students were tasked with figuring out Alice's height given only the information from this table before being asked question 3d. When students had to reason about the quantities and their relationships to fill in the table, it appeared to also support their ability to reason productively in question 3d (where every group answered correctly).

Based on our observations, we refined the content of the lab so that students would have the opportunity to engage in reasoning about the coordination of quantities earlier. We also set up tasks that specifically brought out some of the reasoning from their responses in order to challenge their thinking about constant versus non-constant rates of change. This preliminary report offers one way that researchers might use the findings of small-scale teaching experiments to inform task design in larger classroom settings. Additionally, we can use these findings to further our understanding of when and how conceptual shifts occur for students when learning about exponential functions from the frame of quantitative and covariational reasoning.

Highlighting Student Voices: Perspectives on Active Learning Advanced Math Courses and Implications on Equity

Elizabeth Wrightsman
Texas State University

The relationship between active learning and equity is a prominent discussion within mathematics education, as it should be. There are conflicting findings on whether active learning promotes or detracts from equitable outcomes. This study aims to highlight student voices in describing the student experience in active learning advanced mathematics classrooms. This preliminary report outlines key themes that surfaced from a cursory analysis of the data; quiet students were seen as less confident or less competent by their peers during whole class discussions, and students were keenly aware of the knowledge distribution within small group discussions. It is important to understand the implications of the sociocultural dynamics that may be emphasized in active learning classrooms, thus being better equipped to attend to equity.

Keywords: active learning, inquiry-based learning, equity, advanced mathematics

It is understandable why advocates of student-centered, active learning instruction (e.g., inquiry-based learning) might purport active learning as means to achieve equity in mathematics education (Tang, 2017). Generally defined, active learning occurs in student-centered classrooms where students are actively engaged in doing mathematics during whole class discussions and collaborate with peers during small group discussions with the goal of building their own mathematical understanding; the instructor merely mediates student learning rather than acting as the sole intermediary of knowledge as is the case in traditional, lecture-based classrooms. As defined, active learning classrooms sound like idyllic classrooms in which equitable student outcomes are bound to occur. Clearly, if the best-case active learning classroom scenario were easy to employ *and* the norm, the answer to how to achieve equity in math classrooms would be more evident –simply implement active learning approaches. However, that is not the case. For the purposes of this preliminary report, my conception of equity focuses on how students position themselves and others in terms of equal access to participate *in* and *with* the mathematics, which is related to the assignment of competence (or power) and one's identity as a capable doer of mathematics (Gutiérrez 2002, 2013). Equity is an ideal that postsecondary mathematics educators strive for, but how we achieve this goal is elusive. There are some that report findings that active learning leads to equitable results, particularly for women (Freeman, 2014; Kogan and Laursen 2014; Laursen, 2014) and marginalized student populations (Fullilove and Treisman, 1990). On the other hand, others are more apprehensive or critical of the claim (Johnson et al., 2020; Ernest, 2019; Evans, 2022). These conflicting findings (and opinions) on the extent to which active learning achieves equitable student outcomes imply that more research is needed. The aim of this study is to highlight those most impacted by dramatic changes in teaching and learning practices, the students who experience learning in active learning classrooms. Much of the existing research on equitable implications of active learning centers around achievement results or learning outcomes, which are important when considering equitable outcomes. However, I believe that undergraduate students are equipped to articulate their perceptions of what works and what does *not* work for them in an active learning classroom. Furthermore, by highlighting student voices, the author answers the call to deepen our field's understanding of the impact of active learning approaches on equity within undergraduate mathematics (Laursen & Rasmussen, 2019; Melhuish et al., 2022). In this preliminary report, I outline the methods used to conduct this qualitative study, describe a couple of significant connections between student responses that have equity implications, and discuss the equity implications.

Methods

The data in this study are comprised of semi-structured interviews (approximately an hour in length) with students who completed an advanced math course taught using an active learning approach. To provide readers with a basic context in interpreting the preliminary results, the self-reported demographics collected from each of the ten participants are presented in Table 1. Six participants were from an abstract algebra (Fall 2021) course and the remaining four participants were from an introduction to proof (Spring 2022) course. Both courses were offered at the same large, public Hispanic-serving university in the southern United States. The selection of the two different advanced math courses was intentional. It was discovered through the first round of interviews with the students from the abstract algebra course, that many of them had previously taken an active learning course. Therefore, the decision to recruit from an advanced math course earlier in the math course sequence seemed appropriate. As hoped, for variety, none of the four students from the introduction to proof course had previously taken an active learning course. Since the interviews took place after the end of the semester, interview questions were provided one to two days prior to the interview to allow adequate time for students to reflect on their experiences. The interview transcripts were generated using an electronic transcription service. Transcripts were verified for accuracy and any repeated words and filler utterances (e.g., uh, um). For preliminary analysis, a single coder open-coded broad interpretations of students' descriptions of firsthand and secondhand experiences in students' respective classes. Codes were then grouped by theme and relationships between the themes were identified. In total, there were 20 questions asked during each interview. For the purposes of this preliminary report, the focus will be on the following subset of questions that are strongly relevant to equity: *Do you believe you had <u>equal access to participate</u> in the course during <u>whole class discussion</u> as your fellow peers? Why or why not?; Do you believe each student (other than yourself) had <u>equal access to participate</u> in the course during <u>whole class discussion</u>? Why or why not?; Do you believe you had <u>equal access to participate</u> in the course during <u>groupwork</u> as your fellow peers? Why or why not?; Do you believe each student (other than yourself) had <u>equal access to participate</u> in the course <u>during groupwork</u>? Why or why not?*

Table 1. Self-reported student demographics

Identifier	**Gender**	**Race/Ethnicity**	**Degree Program**
Rosie	Female	White	Applied Mathematics
Tyler	Male	White	Education; MS Certification
Stephen	Male	White	Mathematics
Nathan	Male	Caucasian	Manufacturing Engineering
Ivan	Male	Hispanic	Applied Mathematics
Jon	Male	Southeast Asian	Computer Science & Mathematics
Nora	Female	White/Hispanic	Mathematics with Teaching Certification
Mary	Female	White/Cuban	Mathematics
Lamar	Male	White	Mathematics
Carlos	Male	Hispanic	Economics

Preliminary Results

The presentation of the preliminary results will be segmented into two broad categories, Whole Class Discussion and Small Group Discussion, which were derived from the foci questions, as listed above. Relationships between codes surfaced from the interview questions related to whole class discussion and small group discussion. I briefly summarize a relationship finding within each broad category and provide support from the data.

Whole Class Discussion: "You Gotta Be Strong"

It is not unusual to have quiet students in any given mathematics classroom. In a lecture-based classroom, they may go unnoticed. However, it is more challenging to hide in an active-learning classroom due to whole class discussions being a focal mode of learning. In analyzing the data, the characteristics of shyness/quietness arose on multiple occasions whether it was someone acknowledging they were the quiet one in class (projected as a deficit), or someone stating that it was easy to identify the shy ones (also considered a deficit). How might this pertain to equity? A student's disposition for shyness was a reason for peers to redraw mathematical competence, or conversely, outspoken students were interpreted as having more competence. The following series of interview excerpts illustrate some social dynamics of vocal and less vocal students within an active learning environment. When Mary was asked whether she believed she had equal access to participate in the course during whole class discussion as fellow peers, she responded as such:

> Yeah, pretty much. I've never been a super talkative person in class. Um, like when it comes to talking to other people in the class one-on-one, I love doing that and I love working in groups where we're all just kind of putting our heads down, thinking about stuff. But then if you were talking about the part where [the instructor] would like ask for sort of ideas on what to do, I would let other people talk and usually I just watched them battle it out. Um, 'cause that was fun for me, but you know, I don't like to be the loudest person in the class or anything, but I do think I had equal access to participate. I just chose not to sometimes.

Participation in whole class discussions may take on different forms. Although instructors ought to challenge and encourage students to vocally contribute to whole class discussions, ultimately, students should have the autonomy to participate in ways that are comfortable to them. However, one trend that surfaced was the tendency to interpret shyness or quietness, a trait often attributed to women, as an indication of mathematical inability or lack of confidence.

> *Jon:* There tended to be those people who were bad at math, and I don't wanna say bad at math like that, but they weren't good at proofs. Like, they said it, it was relatively clear, you know, and those type of people tended to not talk as much.

Jon describes making a connection between math ability and quietness. However, Mary was content engaging, albeit quietly, in whole class discussions while actively participating in small group discussions. Her identity encapsulated a quiet demeanor, which is not a reflection of her mathematical ability as she suggests in the following excerpt.

> *Mary:* Um, I'm just comfortable not saying anything. I actually ended up talking to my really good friend that I made [from class] about this 'cause he said at some point during the semester." It's obvious that you know what's going on and you just prefer not to speak.' Yeah, that's true. It wasn't like, I was feeling like I didn't have equal access. I just kind of was like, I was chilling, you know?

Mary implies that there is a level of assertiveness and strength needed to participate in whole class discussion when she admits, "I didn't talk because I knew someone else was gonna answer, but you know, you gotta be strong. You gotta stand up for yourself if you wanna. If you really want to talk, like you can just do it."

Many of the participants mentioned being able to identify the talkers from the non-talkers, and in fact, stated there were more non-talkers than talkers. In contrast to the negative labels non-talkers were ascribed, the more vocal students were assigned competence. Rosie admits being nervous to talk when there were outspoken people in class, whom she attributed competence due to their perceived confidence. This led her to doubt herself and her potential mathematical contribution.

> *Rosie:* Yeah. I feel like if I wanted to talk, like I definitely had like the opportunity and chance to. It was hard sometimes because we definitely had some more outspoken people in the class and it always made me nervous 'cause sometimes I got different answers than them on stuff, right? And they were very like sure in like what they were saying. So, it kind of made me like a little bit more hesitant to talk sometimes even though I was like, mmm, I don't know. But I'm also just a little bit more shy like that.

When asked a follow-up question related to whether the vocal student referred to earlier in the interview affected Nora's learning, Nora explained that it was helpful to have a different perspective than the professor.

> *Nora:* Not at all. Because I think we all also like learned from him like 'cause he was very vocal about like things that were going through his mind. Like um, if there was like a pattern going on through like a proof that we were learning, he would kind of vocalize it. So, I think it also at points like helped the class learn a little bit more and to see his point of view, like a little bit different than the professor's, because then we're getting kind of like multiple points of view. And so, at times it really helped.

The more vocal students have ascribed competence in contrast to less vocal students who have their mathematical proficiency questioned. Due to the focus on peer-to-peer interactions in active-learning classes, this is important to note. The perceptions of peer competence affect how students work together in small groups, which are prominent in active learning classrooms.

Small Group Discussion: "There was clearly a knowledge disparity"

As a characteristic of active learning classrooms, small group discussions were paramount in both courses within this study. In response to the series of questions asking about equal access to participate in the course during group work, Mario described an obvious "knowledge disparity" between the groups. When the interviewer asked Mario what he meant by "knowledge disparity," he responds:

> The best way I could put it is that you could tell that there's like a team that just really understood everything. And there were other teams that were just kinda like struggling. There were some groups that were kind of like in the middle, they kind of understood some of the stuff, and then there were some teams that were just like… 'I need outside help essentially.' The group assignment remained the same for this course the entire semester. Mario described how frustrating it was to be in a group where everyone was lost, and they had to wait for the professor to make it to their group to offer assistance.

He goes on to explain how difficult it was to get assistance if the entire group was lost due to "knowledge disparity."

> *Mario:* If you had questions or you were stuck, you're just like waiting for the professor to just kind of like come and help you. So, you know, if every team is like, kind of like

needing help on a part, you're kind of just like in this queue trying to solve it, you know, you kind of stall.

By design, active learning is meant to distribute mathematical authority more evenly rather than being solely held by the instructor. However, if an entire group is unable to make progress on a problem or proof, the group may have to rely on the instructor, as was the case described by Mario. Thus, the knowledge disparity persists. If you were fortunate to be with group members who had a stronger understanding of a concept, there were sentiments related to the uneven distribution of knowledge within a group.

Ivan: There would be cases in which some of our other group members, they didn't really do as much because they were confused, or they were lost within the proof itself. So from there, what we would do is we would essentially guide one another and as to the right direction. And just to essentially give them the baby steps of other proofs to show them as a way to kind of help them to learn that proof per se, or topic.

But the consequences of leveraging your group members for instruction may lead to fellow group members feeling as Jon describes.

Jon: There was an effort, but I mean at a certain point you kind of have to stop so that you can actually get the work done. So yeah. I mean, there's a limited time to finish. We had probably, I think at the entire semester, there was like a hundred proofs or something. So, I mean, there was quite a bit to do, and we cannot like hold back because of somebody.

Group members may feel as though they are being held back due to the time it takes to explain mathematics concepts to peers. This shift in authority that occurs in active learning environments is powerful as long as there is an accommodation made for situations as described by the students within this study.

Discussion

This study is a direct response to the call by many (e.g., Adiredja, 2017) for additional research on issues of equity in postsecondary education and, particularly, research that investigates student perceptions of their active learning experiences. The findings from this preliminary analysis indicate that competence may be assigned to students based on their perceived level of participation in whole class discussions. Furthermore, that assigned competence is likely to transfer into small group discussions and affect peer interactions. Additionally, students are perceptive to the unequal distribution of collective knowledge between *and* within small groups. As was stated, it was obvious whether someone was in a group that possessed “less” knowledge. These groups would have to wait around for the professor’s assistance. In the case where there were more knowledgeable students in a group, the more knowledgeable students felt like they were being slowed by having to explain concepts to peers. It is speculated (Brown, 2018; Ernest et al., 2019; Johnson et al., 2020) that since active learning classes increase personal interactions through whole class and small group discussions, student beliefs and peer perceptions may play a more significant role in learning than in traditional lecture-based classrooms. Although instructors cannot eradicate stereotypes and beliefs students possess, instructors can take steps to mitigate the influence of these beliefs as long as we identify common student perceptions. It is imperative to understand the challenges of implementing active learning approaches to make necessary modifications or accommodations to simultaneously and consistently achieve equitable results.

Student Goals and Motivations in their Undergraduate Abstract Algebra Course

Megumi Asada
Rutgers University

Keith Weber
Rutgers University

Tim Fukawa-Connelly
Temple University

Mathematics educators assign important learning outcomes to abstract algebra classes. However, it is unclear whether students share these goals or whether they have different motivations entirely. Using the framework of expectancy-value theory, we highlight preliminary results from semi-structured entrance and exit interviews with six undergraduates enrolled in abstract algebra. This report centers around the following research question: What are students' expectations, motivations, and goals for their undergraduate abstract algebra course?

Keywords: abstract algebra, motivation, goals, expectations

Introduction

Abstract algebra is a foundational course in advanced undergraduate mathematics in which students are expected to learn proof technique and abstraction alongside content-specific material (e.g. group theory, field theory) (e.g. Dubinsky et al., 1994). However, it is unclear what students' own goals and motivations are. While there have been many studies on the role of motivation in mathematics courses, there have been comparatively few studies on motivation in advanced proof-based courses like abstract algebra. This distinction is important, as mathematics educators have noted that the content and style of advanced proof-based courses differs from previous courses such as calculus (e.g. Alcock & Simpson, 2002).

We highlight preliminary results from semi-structured entrance and exit interviews with six undergraduates enrolled in abstract algebra. Our central research questions are: *What are students' expectations, motivations, and goals for their undergraduate abstract algebra course? And how do students' motivations contribute to how they approach the course?*

Theoretical Constructs

We adopt the framework of Situated Expectancy Value Theory (SEVT), (Eccles & Wigfield, 2020) to elucidate the relationship between students' expectations, motivations, and perceived task value of abstract algebra. A key assertion of Situated Expectancy Value Theory is that achievement on a task is mediated both by students' expectations for success as well as the task's perceived value (Eccles & Wigfield, 2020; Rosenzweig et al., 2019). Task value is then further separated into the constructs of attainment value, intrinsic value, utility value, and cost.

Eccles et al. (1983) define *attainment value* as the personal or identity-based importance of doing a task. *Intrinsic value* (also referred to as interest value) refers to the students' enjoyment of the task and shares similarities to the constructs of interest (Hidi & Renninger, 2006) and intrinsic motivation (Ryan & Deci, 2016). Within this study, a task is intrinsically valuable when it is enjoyable or helps procure future enjoyment. However, the concepts have different theoretical traditions and focuses. For instance, intrinsic motivation emphasizes the rationale behind an activity as opposed to what makes it valuable (Eccles, 2005). *Utility value* refers to the degree to which a task would be beneficial for a students' present or future plans. For the purpose of this study, we specify that utility value accomplish tasks for reasons other than for one's enjoyment, such as credentialing or seeking employment. Finally, *cost* refers to what an individual must give up in order to accomplish a task. We define success as the student's realization of their goals and is not necessarily based external metrics such as performance on an exam, and is thus a student-centered relative construct.

Literature Review

While motivation has been studied within math education literature (Hannula et al., 2016), and in scholarship on undergraduate STEM education (Cromley et al., 2016), we found no studies attending to motivation in proof-oriented mathematics classrooms. Existing motivation literature has largely consisted of studies drawing correlates between motivation and related constructs like self-efficacy, achievement, and interest (Cromley et al., 2016; Jones et al., 2010). There has been a recent emergence of scholarship on EVT interventions intended to increase student motivation (Rosenzweig & Wigfield, 2016). Much of the interventional scholarship has focused on utility value interventions as it is perceived to be the most easily modifiable task value (Harackiewicz et al., 2014) (i.e., the interventions have focused on increasing students' perceived utility of the tasks on which they work). While there is extensive literature on the statistical relationships between students' self-efficacy, motivation and performance in mathematics courses (for a review, see Wigfield & Eccles, 2020), there is relatively little work on how these factors operate qualitatively.

Eccles and Wigfield adopted SEVT from Eccles and colleague's Expectancy Value Theory (Eccles, 1984; Eccles et al., 1983) as part of a call to attend more closely to the situatedness of motivation. Situatedness, for Eccles and Wigfield, refers not only in the macro sense to the student's sociocultural environment but also to their interpersonal context. We believe our work provides a contribution to SEVT by situating our understanding of our participants motivation within their specific context of undergraduate abstract algebra. Accordingly, previous studies of elementary schoolers point to the domain-specificity of situated task values and academic self-concept.

Methods

Our study consisted of two semi-structured interviews with six participants on their motivation and associated study habits halfway through and at the end of the semester. Our interview protocol contained questions of the form:

1. Why do you think it might be important to study math?
2. What do you expect to get out of studying math in college?
3. What do you expect to get out of Abstract Algebra?
4. In a perfect world what would you want to get out of Abstract Algebra?

The first question asked participants for their perceived task values of studying math while the second and third question ask for participants' expectancies for both math and abstract algebra. The fourth question draws a distinction between participants' expectations and what they perceive they could optimally get out of abstract algebra.

In the second interview, we asked students to reflect on their responses in the first interview and to comment on whether they felt their expectations and/or ideal ("perfect world") goals were achieved. Students were also asked for their perceived task value of abstract algebra. We used thematic coding (Braun & Clarke, 2006) to identify key themes from the interviews.

Results

We present preliminary results from our ongoing analysis. One emergent theme is that some students desired intrinsic value, had utility value, and appreciated but did not require utility value in the form of real world applications. When asked what he expected to get out of abstract algebra, Participant 1 stated:

> It does seem like you know, at least for group theory, that that comes up a lot in things so I'll have an understanding, very foundational conceptual understanding and in a field that does have applications to these, this theoretical work. Um, hopefully, I'll come out of it. Part of the anticipation is also I don't really know where it might be useful, but hopefully, the expectation is, a useful thing will present itself to me. And also, you know, everybody I've talked to has been like, "oh, wow, Galois Theory is really awesome". […] I think it's one of those subjects which is, I'm very good at when I have an intuition of it, but sometimes something will happen I'm like, "why is that? Why does that work?" Or like "what does that work and this not work" Actually, that's the worst thing. It's not "why does this work?" But usually, 'why does this work and that doesn't'

The student remarks that he is unsure in what ways abstract algebra would be useful for him but that he expected that "a useful thing will present itself." We interpret this as the student expecting a utility value even though he does not know what it is yet. Even in the absence of a concrete utility value, the participant still anticipates the class will be intrinsically valuable to him. The expectation of intrinsic value seems sufficient motivation for Participant 1. A different participant, however, anticipated he would struggle with the course in the absence of intrinsic value. When asked what he could get out of abstract algebra under ideal circumstances, he answered:

> Yeah, I'm not too sure. I mean, I think...I don't know. I mean, I think most importantly, *for me even more than like having real life application and would be just to find something I'm interested in*, because like I said, *I have to pass the course*. And I think courses are a lot easier for me when I can find myself getting really interested in them. So for me even more important than having a real life application, just be to have an interest in it because I think it would just kind of be easy to pass the class with an interest in it, but it's kind of going in the direction where it's, it's like I don't have an interest in it. So I'm expecting to be pretty difficult for me to kind of fully understand everything and get myself to study for it. And prepare myself for exams and other things. But I, I guess, like you know, like I said, like, I mean, I don't know that anything off the top of my head in the class so far that would have a realistic you know, real life application for me, but I do think that would be very nice. That would be very cool if I could kind of get something because I think that would motivate me in itself to know that like okay, this is going to be something you have to know and have to understand versus right now I'm kind of in the like, my mind, I'm just like, "Okay, I literally just have to pass this class. And that's it.

Like Participant 1, Participant 2 desired intrinsic value in the course. While "real life application[s]" would be a plus for Participant 2, the participant stressed that, "even more important than having a real-life application [is] to have an interest in" abstract algebra. An interesting topic would make it "easy to pass the class;" without it, he would find it difficult to "get [himself] to study." We interpreted this to mean that even though Participant 2 desired utility value, it was intrinsic value (i.e., personal interest) that was crucial. It is notable that Participant 2 had a high personal utility value for the course—he required it to graduate—but thought that this would not be sufficient motivation for him to do the work to study the material. Later in the interview, Participant 2 described how the effort required to pass would be substantial, requiring frequent personal meetings with the course professor for extra help. The intrinsic motivation seemed necessary for Participant 2 to put in this effort.

Participant 3 noted utility that advanced mathematics had, but found this to be an unattractive reason to pursue the discipline.

> I study it, in part because I like it. Which is a huge motivation factor. But, you know, there's always that question of like, 'what is the real world application of what I'm doing?' and and I did struggle with that for quite a while, especially in that like transition from community college to [university]. Because [in university], a lot of the recruiting programs that you know, try to try to hire students out of the math program, they are government based or like Lockheed Martin, or, you know, all of those other programs and I don't like that very much. You know, and so a lot of times at this higher level, the application of math is based on those kinds of programs. And so, okay, I can name that as an application but I don't like that as an application.

Participant 3 later clarified that while much mathematics is used for a military focus, one can use mathematics for a “community-based focus and to do good things” and learning “flexible thinking and critical reasoning”, so mathematics could potentially have high utility. Nonetheless, Participant 3 stated that this is not why they studied mathematics:

> I think at some point, I just determined that I do math because I like it. And I enjoy it. Just like, I don't have to have a real world application for doing like arts or poetry, or whatever. So personally, I like it.

Discussion and Conclusion

Our analysis is preliminary and speculative at this stage. The data require verification with closer analysis. Our data indicate so far that for some students, attainment value is critical. Participants 1 and 3 were confident they would find attainment value and were optimistic about their ability to succeed. Participant 2, however, anticipated he would struggle in the course due to the absence of intrinsic value. Furthermore, our data suggest a connection between student motivation and the way students approach abstract algebra. Utility value appears to be the least important construct; the students included in this preliminary analysis neither expected it nor needed it. Indeed, Participant 3 thought the utility of mathematics for military use was a negative feature of the discipline. One student, Participant 2, was worried he would be unable to pass the class without finding intrinsic value and stated that he needed to go to office hours. Participant 1 and Participant 3 cited enjoyment as a reason to pursue mathematics.

Much scholarship in undergraduate math education has focused on achieving the instructor’s goals without addressing whether this aligns with student goals. Our work demonstrates that for some students, intrinsic value is the most important factor among intrinsic value, utility value, and attainment value. We suggest more research on how intrinsic value can be fostered in students and, more generally, how students can experience the joy that mathematicians experience in doing mathematics.

Investigating Student Use of Representation in Quantum Mechanics Change of Basis Problems

Idris Malik
The Ohio State University

Warren Christensen
North Dakota State University

Meta-Representational Competence (MRC), first theorized by Andrea diSessa, has been used widely in Math Education studies. It has been recently used in Physics Education Research in the domain of Quantum Mechanics. Specific problems within Quantum Mechanics have a foundation in Linear Algebra, and may be approached or perceived differently based on the notation used (either Dirac, Matrix, or Spinor notation). Semi-structured interviews were conducted to present physics students with content questions and then ask them about MRC concepts directly, as it related to the content questions or other situations in Physics or Math. Student statements were coded to indicate both previously identified and novel facets of MRC in the context of change of basis problems in Quantum Mechanics. The preliminary analysis of two student interviews demonstrates each student's distinct utility of MRC concepts, and suggests extending the Wawro, Watson, & Christensen (2020) MRC statement codes.

Keywords: Quantum Mechanics, Meta-Representational Competence, Physics, Linear Algebra, Representation.

Literature Review

Notions involving representation and notation in Quantum Mechanics have often been investigated in Physics Education Research (PER). Fredlund, Airey & Linder (2012) noted that "the affordances of different representations determine the role they can play in communication, and thus in the sharing of knowledge." These affordances, or the "inherent potential of that representation to provide access to disciplinary knowledge", are said to "enable certain representations to become legitimate within a discipline such as physics. Physics learning then, involves coming to appreciate the disciplinary affordances of representations." (Fredlund, Airey & Linder, 2012). Additionally, Gire & Price (2015) identified the terms "*individuation, degree of externalization, compactness, and symbolic support*" as "structural features of quantum notations". This structural features framework was adapted by Schermerhorn et al. (2019) into a "Computational Features Framework", in order to "answer questions regarding how and why students use different methods". While PER literature has examined representations in Quantum Mechanics in the past decade, it often did so without leveraging diSessa's Meta-Representational Competence (MRC) Theoretical Framework (2002), (2004).

Investigations using MRC have been recently conducted in the context of Quantum Mechanics, specifically in units involving "spin" which tend to use Eigentheory concepts. In a 2020 study, Wawro et al. enumerated the different MRC concept-related codes that arose in their interviews which were structured around Eigentheory concepts. These codes were in part informed by the "Computational Features Framework" developed by Schermerhorn et al (2019), along with additional codes that were organized and explained through the MRC framework.

The Wawro et al. (2020) study has been cited in a recent paper by Corsiglia et al. (2022), which focused on QM Change of Basis problems. However, the Corsiglia study focused on a phenomenographical approach and did not implement the MRC theoretical framework used in the Wawro study. This current research seeks to incorporate MRC at a boundary between realms of RUME and PER in the specific context of QM Change of Basis problems. This is done through the coding of MRC concept statements that involve codes listed in Wawro et al. (2020)

and novel codes that were not found in this earlier study. We define "MRC concept/statement" here as a concept/statement that could be analyzed by the MRC Theoretical Framework.

Theoretical Framework

The work presented is attempting to make direct measures of Andrea diSessa's theoretical framework, Meta-Representational Competence (diSessa, 2002). Meta-Representational Competence (MRC) "...[describes] the full range of capabilities that students (and others) have concerning the constructions and use of external representations" (diSessa & Sherin, 2000). Iszák Iszák, Çağlayan & Olive (2009) mention regarding a diSessa paper (2002), "[diSessa] observed that students' criteria usually emerge in reaction to particular examples." Iszák also noted, "he reported that different students can make systematically different judgments about external representations."

This framework has seen significant use in the Research in Undergraduate Math Education community (Hillel, 2000; Arcavi, 2003; Iszák, 2003; Iszák, Çağlayan & Olive, 2009) but has seen little use in Physics Education Research. Notions involving representation and notation in Quantum Mechanics have been often investigated in Physics Education Research (PER), but only one paper incorporated Meta-Representational Competence as a framework, Wawro et al. (2020). In Wawro et al. (2020), MRC statement codes were created based on the data observed (see Fig. 1) and proved to be very fruitful in parsing the data observed. However, the theoretical framework was applied post-hoc. This work aims to use an interview protocol designed specifically to parse out student statements regarding MRC in the context of Quantum Spin states.

A. Value-based Preference	B. Problem-based Preference
1. Clarity 2. Speed 3. Familiarity 4. "Likeability" 5. Ease of writing	1. Useful in calculations 2. Makes more direct use of given relationships 3. Needs less information 4. Compactness 5. Individuation 6. Externalization
C. Purpose and Utility Awareness	
1. Has freedom to choose symbols 2. Has an ease with notation, writes symbols to mean what is personally desired 3. Aware of one's own progress in notation use 4. Able to "step back" and weigh options to decide which notation system is best	

Figure 1. Table of MRC categories and codes from Wawro et al. (2020)

Background

In Quantum Mechanics, spin is a property of some particles, often described as "when a particle behaves like it has angular momentum (is 'spinning'), even though the particle is not physically spinning". This often confusing concept is better understood mathematically through the use of Eigentheory. Spin states of a particle or system are represented by Kets (|Psi>), which function similarly to vectors. For Spin-½ particles, the most common type in Intro-Quantum Mechanics situations, applying a directional Spin Operator can only result in one of the two possible eigenvalues and its corresponding eigenvector. The result is either "spin-up" (a "+" eigenvector with a corresponding eigenvalue of $+\frac{\hbar}{2}$) or "spin-down" (with a "-" eigenvector with eigenvalue of $-\frac{\hbar}{2}$). In a certain coordinate direction (namely z, x, or y), a spin-½ particle's spin state can be described as a linear combination of these $|+>$ "spin-up" and "spin-down"$|->$ kets.

These state vector kets, defined as linear combinations of eigenvector kets, can also be written in terms of 2 by 1 matrices. Here, the first entry represents the $|+>$ ket (usually in the z-direction), and the second entry represents the $|->$ ket. Introductory units of instruction may present the same information in both Dirac and Matrix form, so that students can see how one notation is translated to the other. Additionally, "Spinor" notation is sometimes used to write statements without explicitly using a Dirac ket or a column vector for the eigenvectors.

In any notation, the relations of the eigenvector kets, the spin operators, and the eigenvalue kets can be written in eigenequation form: $\hat{S}_z\,|+> = \frac{\hbar}{2}|+>$. Figure 2 (below) includes an example of the 3 notations used in the context of a state vector equation:

Spinor: $\chi = \frac{3}{5}\cdot\chi_+ - \frac{4}{5}\cdot\chi_-$ Dirac: $|\psi\rangle = \frac{3}{5}\cdot|+\rangle - \frac{4}{5}\cdot|-\rangle$ Matrix: $\chi = \frac{3}{5}\cdot\begin{bmatrix}1\\0\end{bmatrix} - \frac{4}{5}\cdot\begin{bmatrix}0\\1\end{bmatrix}$

Figure 2: Equivalent state vectors, or wavefunction kets, written in different notations

Methods

A semi-structured interview was designed to provide participants with content questions and ask them about MRC concepts directly (Browner et al., 1988). Content questions were adapted from questions from the Corsiglia et al. (2022) study, which focused on Change of Basis, including concept-focused and computational-focused questions. The questions were adapted to provide a context for discussing MRC statements, rather than pure tests of conceptual understanding. For some of these content questions, multiple versions were made with different representations in the questions (See Fig. 2). After each set of content questions, a verbal follow-up question was asked. The follow-up questions were intended to target MRC concepts directly. At first, these follow-ups treaded lightly on MRC concepts and focused more on content, but as the interview progressed, the follow-ups were directly aimed at MRC concepts.

This interview structure was selected to organically ease students into talking about MRC concepts without directly explaining the MRC theoretical framework. To avoid dead-ends due to content issues, hints were structured into the content questions, or ready to be provided by the interviewer. The structure of the interview questions was meant to guide students through the most efficient path (Corsiglia et al., 2022) through answering the questions.

Three student interviews were conducted at a midwestern, land-grant research university, each lasting about one hour long. Of these 3 interviews, we elected to focus the preliminary analysis on the interviews of participants PS and CG, as their interviews were the most unlike each other. After the interviews were transcribed, one of the authors reviewed the transcriptions to code mentions of MRC statements, guided by the codes delineated in Wawro et al. (2020).

Preliminary Results

The depth and amount of MRC statements made by student participants with relatively little direct prompting were surprising and encouraging. While physics students may unknowingly make MRC-related statements with their peers (e.g., preferences for notation, etc.) while working on group assignments, there is little evidence that they are instructed or directly graded on MRC concepts within physics courses. However, the interview participants all had some form of vocabulary for expressing some MRC concepts, to varying degrees, without being explicitly introduced to the terminology. Additionally, interview participants seemed to accept and use vocabulary that was explicitly introduced during the interview with good facility.

We focused our preliminary study on Student Participants PS and CG, as they had distinct interview experiences from an MRC concept standpoint. They performed differently on the tougher content questions. They also articulated different preferences in notation. We share some preliminary analyses of each interview separately to best highlight the most prominent features of each participant's interview experience. Future work will aim to synthesize these and other interviews we've performed.

PS Interview: PS is a Physics Undergraduate student, who had taken two semesters of undergraduate Quantum Mechanics from a midwestern land-grant research university. PS identifies as a white, cis-gendered man. PS made fewer MRC comments in total, and it took them longer to 'warm up' to speaking freely about MRC in depth. PS was effective in elaborating on their thought process while working on content questions when prompted. Additionally, most of the MRC statements PS made were "Value-based preferences" (Fig. 1).

Within the first 10 minutes of the interview, PS made statements involving their belief in a "Hierarchy" of notations. PS stated that Dirac (and maybe Spinor as well) notation is just a "shorthand" for the Matrix notation. There was no existing code from Wawro et al (2020), so we defined a new code to encapsulate this. Much later in the interview, PS made a similar remark regarding the Spinor notation in Question 5 ("Q5"), after being given Question 7 ("Q7"), (emphasis added in **bold**):

PS: There's a reason that I already like this notation way better, I got to be honest.

Interviewer: Why do you like it better?

PS: But again, you know, **it's like, hey, spin up -- 1 0, spin down -- 0 1**, and like, like I said before, I just **I like the given** - what exactly **given values for just like shorthand** [points at Q5] like Psi, Psi plus that's the spin-up, and you know, I kinda get, like all screwed up in my mind, like - how do I do this again?

PS: **Where I can actually, like… work out the numbers?** Like, [points at Q5 page] can one over square root of three be multiplied times Chi spin up? **Whereas here [Q7] it's like, I know I can, you know?**

It's possible that PS views this hierarchy of Matrix notation as being the 'real' notation, with Dirac and Spinor notation as 'shorthands' because they prefer doing change of basis computations in Matrix notation. Additionally, PS made many MRC statements about "Clarity", where Matrix notation was often 'more clear', and Dirac notation was 'less clear'. They also mentioned "Likeability" often: liking Matrix notation, and disliking Dirac notation.

PS spent significant time on Q5 but was not able to complete it. They expressed that they did not have enough equations to solve for the constants they wanted. When given Q7, which was a Matrix notation focused instead of Spinor notation focused, PS responded with the reaction in the interview transcript above. Even though the problems were similar, PS was able to complete Q7. Afterwards, PS made conflicting statements regarding their success in Q7 compared to Q5. Initially, they made statements indicating that they understood the question better after they saw it presented in Matrix notation (Q7). However, a couple minutes later, they said that they couldn't be sure that the different notation made it easier. In their opinion, their success may have been due to just seeing the same question a second time. A goal of future work is to investigate the connection between struggling to answer problems and a person's understanding of concepts that fall under Meta-representational Competence.

CG Interview: CG, a current Physics graduate student, has taken Quantum Mechanics at both an Undergraduate level at a small, private college in the midwest, and at the Graduate level at a midwestern land-grant research university. CG identifies as a white, cis-gendered man. CG, who performed extremely well on content questions, spoke fluently about how they represented their work verbally, on the page through equations, and using hand gestures. Relative to PS, CG made

MRC statements earlier and more often over the course of their interview. Many of these statements involved a preference for Dirac notation. "Value-based preferences" MRC statement codes (Wawro et al. 2020) such as "Speed", "Familarity", "Likeability", and "Ease of Writing" were often made by CG in support of Dirac notation and against Matrix notation. CG also made "Problem-based Preference" statements, noting Dirac notation was "useful in calculations" because it had "tons of tricks."

While PS made few statements regarding "Purpose and Utility Awareness" (See Fig. 1), CG made many (at least 10) distinct statements in this category; the first one coming during an early follow-up question. Most frequent were statements that would fall under "Aware of one's own progress in notation use", which encompassed Dirac, Matrix, and Spinor notation. CG also made statements consistent with the "Able to 'step back, and weigh options to decide which notation system is best" code after one of the verbal follow-up questions and while considering how to begin working on Q5.

CG made many statements involving concepts of "Abstractability" and "Visualizability." To CG, Matrix notation was very visible. They used hand gestures to set up a 3-dimensional coordinate system to communicate state vectors. CG then mentioned understanding Matrix notation as applying a linear transform to a vector, to change the direction of the state vector. In contrast, CG viewed Dirac notation as being more "abstract" in nature. They stated that the Dirac Kets could represent anything, or be written as "smiley faces" or "frowny faces" without any loss of meaning. Because of CG's focus on these statements, and that they emphasized the wording, we believe "Abstractability" and "Visualizability" may be identified as new codes for extending the Wawro, Watson & Christensen (2020) MRC codes related to expectation values (See Fig. 1).

Discussion / Conclusion

MRC concepts, which involve the capability to use external representations (diSessa & Sherin 2000), are likely related to skills developed by individuals by the time they are considered an 'expert' in a particular type of problem. Interviewee CG, who performed extremely well on content questions, successfully represented their work verbally, on the page through equations, and using hand gestures. Interviewee PS struggled with several content questions and did not demonstrate many MRC statements outside of the Value-based Preference category. How and when MRC concepts are developed and the role it plays alongside content understanding in Upper-division Physics is still unclear. Future research may shed additional light onto the relationship between students' understanding of their thinking of how to use different representations and their performance on content questions in Upper-division Physics.

Questions for Audience

If students are not directly taught or coached regarding MRC concepts, how do they develop it in a Quantum Mechanics spins context which draws heavily on Eigentheory concepts?

Would directly instructing students on understanding their thinking of how to use different representations help students become adept at this and content understanding?

At what points throughout a mathematics or physics curriculum could instruction be initiated and subsequently revisited to support MRC concept development across a curriculum?

Acknowledgments

I would like to thank Dr. Megan Wawro for their expert input on this preliminary research. I am grateful to Sam Gisi, Jessica Searl, and Kristen Rodenhausen for their advice and insight throughout the research process. I would also like to thank the innumerable other individuals whose support culminated in my opportunity to conduct this research.

Exploring the Connection Between Women of Color's Values and Mathematical Identity in Undergraduate Mathematics

Ciera Street
Colorado State University

The growing call for more equitable and just mathematics classrooms includes supporting and strengthening students' mathematical identity. Recent scholarship proposes a connection between students' mathematical identities and their values (Kalogeropoulos & Clarkson, 2019). However, limited research acknowledges and explores mathematics identity at the intersection of gender and race (Leyva, 2021; McGee, 2016). Furthermore, undergraduate mathematics in the United States often does not reflect the cultural values of women or students of color (Fong et al., 2019; Leyva, 2016, 2021). Informed by sociopolitical theory and an intersection lens, this study explores women of color's mathematics education values and the connections between those values and their mathematical identity. Through interviews and mathematical autobiographies, participant examples indicate various values, including those related to learning from mistakes and social support. Preliminary results suggest that the presence of these values in mathematics environments may support women of color's mathematical identity.

Keywords: Equity, Mathematical Identity, Values, Gender, Race

In the growing call from research and professional organizations within mathematics education to create more equitable and just mathematics classrooms (e.g., Mathematical Association of Mathematics Instructional Practices Guide, 2018; National Council of Teachers of Mathematics, 2014), one area of interest focuses on supporting and strengthening students' mathematical identities. Mathematical identity encapsulates students' relationship with mathematics and their perceptions of themselves as a doer of mathematics, including their beliefs about ability and participation, sense of belonging, and institutional and interpersonal supports (Voigt, 2020). Research suggests that gendered and racialized mathematical discourses play an important role in students' development of their mathematical identity, however, limited scholarship exists that acknowledges and explores mathematics identity at the intersection of gender and race (Leyva, 2016, 2021; McGee, 2016).

Recent scholarship proposes a connection between identity and values, such as mathematics teachers' professional identities and their values and students' mathematical identities and their values (Kalogeropoulos & Clarkson, 2019; Mandt & Afdal, 2022). There is general consensus that values are sociocultural in nature, embodying cultural norms about what is bad or good, or worth avoiding or doing (Hill et al., 2021; Schwartz et al., 2011). Thus, values in mathematics education includes one's belief about what is important and worth doing in mathematics, as well as what drives one course of action over another (Hill et al., 2021; Seah, 2019). Given that "what we value reflect years of learning and influence from our historical experiences and social interactions as members of the culture we belong," (Seah, 2018, p. 564) I argue that the relationship between identity and values in mathematics must be similarly influenced by gendered and racialized mathematical discourses. To this point, undergraduate mathematics in the United States often does not reflect the cultural values of women or students of color (Abrams et al., 2013; Fong et al., 2019; Leyva, 2016, 2021). Various scholars recognize how mathematical discourses in the US often align with, and thus give power to, dominant masculine and white values such as competition, risk, and individualism (Bullock, 2019; Jaremus et al., 2020; Leyva, 2016, 2021; Martin, 2006). Thus, unique and possibly additional tensions within mathematical spaces emerge at the intersection of race and gender for women of color as they develop their mathematical identity while negotiating their values with dominant mathematics values (Carlone & Johnson, 2007; Leyva, 2017; Rodd & Bartholomew, 2006). Supporting and incorporating women of color's cultural values within undergraduate mathematics may help reduce these tensions and better support women of color's mathematical identity development (Battey & Leyva, 2016; Hunter, 2021; Seah et al., 2016). Thus, this research engages critical frameworks at the intersections of gender and race to challenge exclusionary adherence to dominant values and encourage counternarratives to white, masculine mathematical discourses. In this research I ask, (1) What do women of color STEM majors describe as valuable/important to their undergraduate mathematics education? And (2) In what ways, if any, are these valued/important components connected to their mathematical identity?

Theoretical Perspective

I utilize sociopolitical theory and an intersectional lens to inform this work (Adiredja & Andrews-Larson, 2017; Crenshaw, 1991). This decision stems from the sensitivity of mathematics educational values to both the culture of the learner and societal influences (Hunter, 2021; Lee & Seah, 2015; Zhang, 2019). Given the white, patriarchal discourses within undergraduate mathematics, an intersectional lens helps describe the ways in which interactions between race, gender, class, and other social constructs account for overlapping discrimination imposed on people with multiple marginalized identities within societal systems (Crenshaw, 1991). Within the cultural system of mathematics, we recognize that the values women of color hold are both individually unique as well as shaped by societal influences related to gender and race. In particular, sociopolitical theory emphasizes the ways in which knowledge, power, and identity emerge and are often constrained by the values and norms of the mathematics environment. This theory challenges the currently "accepted" values and norms within the culture of mathematics, which often inequitably affect students' perceptions of themselves as doers of mathematics (Adiredja & Andrews-Larson, 2017). Sociopolitical theory rejects student assimilation into the current dominant culture and instead promotes a system that considers, supports, and affords space to various backgrounds and identities. Thus, I chose to center women of color in this analysis to provide counternarratives to the white, patriarchal mathematical context without comparisons to the dominant group. Instead, I highlight the often submerged and undervalued variety of experiences of women of color related to mathematical identity and values.

Methods

Data Context and Participants

The data for this study include transcripts of follow-up interviews and mathematics autobiographies from participants who completed the *S-PIPS-M* survey instrument administered by the Progress through Calculus (PtC) project in 2017-2018. This survey collected information about undergraduate students' experiences in precalculus and calculus, including mathematical activities, interactions, and affect (Street et al., 2021). To recruit participants for this study, I sent out an interest survey in Spring 2022 to all women of color from the survey who consented to future contact (n = 1121). Women of color within this dataset includes any participant who selected at least woman from the following select-all response options related to gender: Man, Transgender, Woman, Not listed (please specify) and who selected at least one of the following select-all response options related to race and/or ethnicity: Alaskan Native or Native American, Black or African American, Central Asian, Hispanic or Latinx, Middle Eastern or North African, Native Hawaiian or Pacific Islander, Southeast Asian, South Asian. The recruitment email described the study as an exploration of women of color STEM majors' experiences in undergraduate mathematics and thus participants self-selected as a woman of color to participate in this follow-up study. The interest survey included questions about demographics, various experiences and feelings related to undergraduate mathematics, and how those experiences and feelings related to race and/or gender, if at all.

Of those who responded to the interest survey, I selected participants based on results from a previous analysis as well as aiming to diversify the sample in terms of gender, race/ethnicity, university, and major. Previous analysis using this dataset grouped the full *S-PIPS-M* survey sample of women of color into clusters based on components of mathematics identity. Thus, I selected 12 participants to interview that span across these clusters while attending to the characteristics listed above. For this analysis, I focus on two participants, Lyka and Callie. Brief descriptions of Lyka and Callie are presented in Table 1. The participants self-described their gender and racial identities through an open-ended question on the interest survey.

Table 1. Description of participants.

Lyka	Callie
Lyka (she/her) is a Filipino and white cisgender woman. She recently graduated with degrees in Biomedical Engineering and Multidisciplinary Studies from a public university in the Eastern half of the United States. Within the mathematics department at her university, she completed College Algebra, Trigonometry, Calculus I, Calculus II, Multivariable Calculus, and Ordinary Differential Equations.	Callie (she/her) is a Hispanic/Latino cisgender woman. She recently graduated with a degree in Biology from a public university on the East coast. Within the mathematics department at her university, she completed College Algebra, Precalculus, Trigonometry, Statistics, and Calculus I.

Data Collection

In Spring 2022, I conducted 60 - 90 minute, semi-structured virtual interviews with each participant. The interview protocol included questions about participants' experiences and feelings related to undergraduate mathematics, including their perceptions of themselves as doers of math and what they found to be supportive and valuable in mathematics spaces. I divided the interview questions into four categories, three of which were informed by Voigt's definition of mathematical identity and one focused specifically on the potential connections to gender and/or race. This categorization intended to bring forth participants' narratives around their mathematical identity as well as components they felt were important and valuable in their mathematics education. I also asked participants to write a brief mathematics autobiography using an open-ended prompt. The prompt encouraged participants to highlight memorable and influential moments in their life related to mathematics up to and including college, along with any ways in which race and/or gender interacted with these moments. I asked participants to complete the mathematics autobiography prior to their interview.

Data Analysis

To analyze the transcripts, I used Saldaña's (2013) pre-coding, first cycle, and second cycle coding methods. Pre-coding occurred during the interviews and during the transcription process, whereby I noted particularly interesting or powerful statements. During the first cycle I utilized open coding to label any statements related to the research questions, including statements related to cultural values, mathematics education values, and the components of mathematical identity. These codes became the basis of the second cycle coding process which involved categorizing the initial codes into theoretical codes to help describe the overall story connecting the data to the research questions. The coding process is still in progress and thus the results section that follows includes preliminary findings and developing themes.

Results

Initial findings suggest mathematics education values associated with learning from mistakes, connecting to the real-world and future careers, clarity in mathematical explanations, and social relationships, such as with their instructor and peers. There also appears connections between these mathematics education values and their mathematical identity. Intertwined within these mathematics education values and connections to mathematical identity, I also note the role of cultural values, especially related to gender and race. I present here two examples, one from each participant, to exemplify some of these points. Future analysis will provide more detailed and potentially addition results and overarching themes.

Lyka's Example

In her mathematics autobiography, Lyka describes a stigma she perceives in STEM, where "if you mess up that's not only reflective of you as a person, but women as well, the same goes for race." However, she describes how much she valued and enjoyed her mastery-based upper-level calculus courses where she felt that having the opportunity to work through her mistakes made the process "less stressful and made me enjoy doing math. I was able to focus on the meaning of the content." She attributes those courses as the reason she decided to pursue a mathematics minor. This suggests that seeing her mathematics education values reflected in her math courses improved how she felt about math and herself as a doer of math. In Lyka's experience, we see how cultural values around making mistakes in mathematics, and how those interacted with being a woman of color in STEM, were challenged within her mastery-based math courses. When instead the value of making mistakes aligned with her values around learning and improvement, she added a mathematics minor, suggesting a strengthened mathematics identity.

Callie's Example

Callie describes both positive and negative experiences within undergraduate mathematics. She acknowledges how her performance often related to her feelings toward the courses. However, how she describes the importance of social support emerges across these experiences. When detailing her math courses, she recognizes that for most part "you were kinda on your own, and it was up to me… I was really good at forming friends within those classes so we could study together." The role of social support also influenced her perceptions of herself within mathematics and her major. When describing a fellowship she engaged in during college specifically geared toward marginalized students in STEM, she emphasizes how "that fellowship that I had is like a very big reason why I continued to do so well in all these [math] classes… I probably would have changed my major completely if I wasn't in this fellowship." She continues to talk about how the importance of this social support intertwined with her gender and race, "because they did help me a lot with just like the reassurance of like, listen, this isn't a common thing like, you're a woman, you're a minority." Even though Callie describes overall having a negative feeling toward mathematics, having a space that reflected her values around social support and made her feel less alone as a woman of color in STEM provided a positive connection with mathematics and her major.

Discussion

The above preliminary results suggest various values women of color relate to their experiences in mathematics. These include social relationships, such as the importance of peer support and organizational support for Callie, learning from mistakes, such as Lyka described in her mastery-based math courses, connections to the real-world and future careers, and clarity in mathematical explanations. Additional values may emerge as I complete the analysis. There also appears to be a connection between these women of color's values and their mathematical identity. In particular, they both mention the importance of a value-related component in their STEM degree considerations. Future analyses will explore this connection in more detail, including when and in what way values relate to students' mathematical identity. These results also support the use of sociopolitical theory and an intersectional lens given the inclusion of statements regarding the influence of gender and race on their experiences. Once the findings and overall themes are established, I will more robustly consider in what ways these women of color's values connect with previous literature about women and people of color's values and mathematical identity and how these results intertwine with gender, race, and the tensions often present within dominant mathematical systems. The implications of this work aim to consider how women of color's values emerge in mathematical spaces and the role of the university to incorporate those values to better support women of color in undergraduate mathematics.

The Role of Language in Undergraduate Mathematics: Linear Independence and Limit

Ernesto Daniel Calleros
San Diego State University and University of California San Diego

As English is increasingly seen as the language of mathematics instruction in the United States and the world, it becomes important to interrogate the role of the English language in mathematical understanding. This article investigates this question in relation to linear (in)dependence and limit through clinical interviews with undergraduate students. Preliminary results indicated a relationship between students' conceptual understanding of linear (in)dependence and their ability to connect their mathematical and non-mathematical uses of the term (in)dependent. Moreover, students' unproductive conceptions of limit appeared to be influenced by non-mathematical meanings of limit.

Keywords: Linear Algebra, Calculus, Language, Student Thinking, Undergraduate Education

As English is increasingly seen as the language of mathematics instruction in the United States and the world (e.g., Gerber et al., 2005; Planas, 2018), it is crucial to interrogate the role of the English language in mathematical understanding. Prior research suggests that the structure of the English language may be less effective than some other languages, say the Chinese language, for facilitating mathematical performance at primary and secondary school levels (e.g., Han & Ginsburg, 2001). This paper investigates the role of the English language at the undergraduate level in the context of limits and linear independence, as these are two central topics of study in mathematics education (e.g., Larsen et al., 2017; Rasmussen & Wawro, 2017).

Literature Review

Most English mathematics words at the K-12 levels have been created from Greek or Latin (Milligan & Milligan, 1983). For example, the term *quadrilateral* comes from two Latin words: *quadri* which means "four" and *latus* which means "side." Unfortunately, most English-speaking students are not taught Latin or Greek, so many of them may come to see math terms as random combinations of letters with no inherent meaning (Johnston-Wilder et al., 2016). In contrast, Chinese math words appear to have been created as descriptive and conceptually clear compound phrases (Han & Ginsburg, 2001). For example, the Chinese term for *quadrilateral* literally translates into English as *four sides shape*, which clearly depicts the concept of quadrilateral.

Yet, many undergraduate math terms in English such as *linearly independent* already seem conceptually clear to the expert's eye. But are such terms also conceptually clear to the undergraduate learner? Research on linear (in)dependence and limit documents a diversity of student conceptions of these topics. For example, Plaxco and Wawro (2015) analyzed data from clinical interviews with students from a linear algebra course that used a travel-oriented curriculum (Wawro et al., 2012). They identified four student conception categories of linear (in)dependence: travel, geometric, vector algebraic, and matrix algebraic. The travel conception described linear (in)dependence in terms of movement. The geometric conception used language about spatial reasoning or graphical representations. The last two conceptions focused on operations on algebraic representations of vectors and matrices, respectively.

Williams (1991) investigated the following student models of limits: (a) dynamic-practical, (b) acting as a boundary, (c) formal, (d) unreachable, (e) acting as an approximation, and (f) dynamic-practical. He found that it was common for students to exhibit a dynamic view of limit and organized this view into three variants: squeezing a value from both sides, finding approximations, and coordinating changes in x with changes in y. Building on William's (1991) work, Oehrtman (2009) characterized students' spontaneous metaphors for limits and identified five often used student metaphors of limit: as physical limitation, with infinity as number, as proximity, as collapse, and as approximation. He also identified three less often used student metaphors of limit: as motion, as zooming, and as informal version of correct definition. Of all these metaphors, Oehrtman found limit as an approximation to be the most productive.

My study investigates the uses of the terms *limit* and *(in)dependent* in relation to student understanding of limits and linear (in)dependence. Here, student understanding is conceptualized as any or all of the following elements of mathematical knowledge: meanings, images, ideas, connections, ways of comprehending situations, and explanations (Lobato, 2014). With this framework in mind, the research question is: What is the role of language in student understanding of linear (in)dependence and limits?

Methods

To gather background information on student understanding of linear (in)dependence and limits, the research team conducted clinical interviews (Ginsburg, 1997) with two groups of undergraduate students across two universities in the southwest of the United States. One group consisted of 4 students who had recently taken linear algebra and was asked questions about their understanding of linear (in)dependence. The second group had 6 students who were enrolled in Calculus II or III and were asked about their understanding of limits. Student interview responses were transcribed and analyzed. Students' linear (in)dependence conceptions were inferred from the data using open coding from grounded theory (Strauss, 1987). To infer students' conceptions of limits, we used a list of a priori codes from prior research (e.g., Williams, 1991), while allowing room for other codes to emerge from the data within a grounded theory approach (Strauss & Corbin, 1990).

Next, we analyzed the previously identified student understandings of limits and linear (in)dependence, considering the role of language. First, we determined which, if any, student model of limit related to the non-mathematical meaning of *limit.* Then, we analyzed student responses to the interview question regarding why the words *independent* and *dependent* are used for linear (in)dependence. In each response, we determined if the student used meanings of (in)dependence from outside linear algebra to interpret linear (in)dependence. Finally, we analyzed the relationship between each student understanding of linear (in)dependence and their use of outside meanings of (in)dependence.

Results

Background Findings: Student Understanding of Linear (In)dependence and Limits

Three student models of linear (in)dependence emerged: (a) A set of vectors (viewed as a matrix) is linearly independent if and only if it is reducible to the identity matrix; (b) A set of vectors is linearly independent if and only if no two vectors in the set are scalar multiples of each other; and (c) A set of vectors is linearly independent if and only if at least one vector is a scalar multiple of another vector in the set. Student models (a) and (c) were used by one student each (Marco and Arletta, respectively), whereas student model (b) was used by two students (Edward and Alana). While none of these student models was completely correct mathematically, some were more correct and conceptually oriented than others. Student model (a) was more computationally oriented, focused on reducing a matrix through row or column operations. On the other hand, models (b) and (c) highlighted connections between linear (in)dependence and the idea of scalar multiples, with model (b) being more logically correct than (c).

Regarding the limit analysis, each student had multiple conceptions of limit in calculus. We identified eight student models of a function's limit: Coordinating x and y (n=6 students), approaching from both sides (n=5), function value (n=5), continuity (n=3), boundary (n=4), unreachable (n=6), exception (n=2), and stopping point (n=1). The model of limit *coordinating x and y* described a limit in terms of how the function value changes as x approaches a certain value. *Approaching from both sides* described 'limit as x approaches *a*' as the common y-value the graph approaches from the left and from the right of *a*. *Function value* treated the limit value and the function value as the same. *Continuity* viewed the limit's existence as equivalent to the function's continuity. *Boundary* conceptualized a limit as a number or point past which the function cannot go. *Unreachable* conceived of a limit as a number or point that cannot be reached by the function graph. *Exception* viewed the limit as something that does not follow a rule. Finally, *stopping point* conceptualized the function as motion along a graph and viewed the limit as the place where the function is constrained.

The Role of English on Student Understanding of Linear (In)dependence

The results indicated that Edward and Alana, the two students with model (b) of linear (in)dependence, connected their non-mathematical understandings of the terms *independent* and *dependent* to their understanding of linear (in)dependence, whereas the other students (Arletta and Marco) failed to make such a connection.

For example, when I asked Edward, "We've been talking about linearly independent sets of vectors…Why do you think the words 'independent' and 'dependent' are used?," he responded, "Well, dependent means they're *related* to each other. Right? Independent means they're not." Then, when I asked him to elaborate, he said, "Well, dependent means it's related to or reliant upon each other. So, if you have a dependent set of vectors, you can make one vector from another by scaling it. So, they're interconnected, I guess." Based on this excerpt, it appears Edward connected his understanding of the term *dependent* as used outside linear algebra (i.e., "related to or reliant") to his interpretation of that term in linear algebra (i.e., "make a vector from another by scaling it").

Similarly, when Alana was asked the same question, she said:

> Okay, I like that the words are the words they are, because they help me remember the definition. So, when it's dependent– just like, in general the definition of dependence, to me, is when you need something else, or, like, you rely on someone else. So, if you just, like, rely on something or someone– so then, thinking about it mathematically, like– I'll just use this example I've been using. Oops. This [vector] times two gives you this [vector], and so there's that, like, *relationship*. And then independence, to me, in general means completely on your own. So, like, there's no way that these two [vectors] can ever, like, work together and be the same or look the same.

Thus, she used her general knowledge from outside of mathematics that "dependence…is…when you need… or rely on someone else" and that independence means "completely on your own" to help create mathematical interpretations or examples of linear (in)dependence (e.g., "this [vector] times two give you this [vectors]" for dependence and "no way these two [vectors] can ever look the same" for independence).

In contrast, Marco did not leverage his understanding of the words *independent* and *dependent* from outside of mathematics for interpreting linear (in)dependence. When asked the same question above, he responded:

> Yeah, honestly, I've been going through the whole… linear algebra course. I didn't know why it was called independent and dependent. I just thought, well, if it reduces to identity matrix, it's independent. That's all the correlation I got from that.

Hence, Marco claimed that, in interacting with the concept of linear (in)dependence, he had not attended to the meanings of *independent* and *dependent* outside linear algebra. Not connecting his non-mathematical and mathematical understandings of *independent* and *dependent* might have led Marco away from attending to scalar multiples (for interpreting linear (in)dependence) and instead into rote learning.

Like Marco, Arletta initially claimed never connecting her prior linguistic understanding of (in)dependence to linear (in)dependence. However, when I later presented her with a traditional textbook definition of linear (in)dependence, she forcedly made a connection: "The words independent and dependent [are used] because they're depending on whether or not the input values are zero to get a[n] output of zero." Moreover, when I pressed her to exemplify this connection, Arletta responded:

> Um, I guess, just going back to the definition. Like if c_1x_1— Like if c_1, c_2 [the coefficients] were to equal 0, then that means they're [the vectors x_1, x_2] independent… and... in dependent ones [vectors], these values [the coefficients] can be anything, but they don't all have to be zeros.

Although Arletta made an interesting connection between the formal definition of linear (in)dependence and her prior understandings of terms *(in)dependent*, this connection was superficially (not conceptually) aligned with the topic of linear (in)dependence. This is not surprising, given that she admitted not connecting the formal definition to her understanding of linear (in)dependence. This may help explain why, in her model of linear (in)dependence, she labeled a set with at least two vectors which are scalar multiples of each other as linearly independent and a set with no scalar multiples as linearly dependent (which is mathematically reversed).

These results indicate that the students with the strongest conceptual understanding of linear (in)dependence (those with model (b)) were precisely those who connected their mathematical and non-mathematical understandings of the words (*in)dependent* in terms of a *relationship* between vectors.

The Role of English on Student Understanding of Limit

All six students appeared to connect their mathematical and non-mathematical conceptions of limit. All students had at least one mathematical conception of limit that related to the non-mathematical definition of limit as a restraint or limitation – "a measure or condition that keeps something under control or within limits" (2019, n.p.). This non-mathematical definition aligns with the following (mathematically incomplete or incorrect) student models of limit inferred from the data: boundary (n=4), unreachable (n=6), exception (n=2), and stopping point (n=1).

To illustrate the connection between the non-mathematical meaning of limit and student mathematical understanding of limit, consider one student, Joyce, who had a *boundary* model of limit. When Joyce was asked what came to mind when she heard the word *limit*, she said, "When something cannot be something anymore like 'I'm at my limit.'" Then, to elaborate, she sketched a graph and its highest point while saying, "Here's a dot… and there's like a function… and it's like a maximum, but I guess like, that's as high as it goes. Like that's what I'm picturing like it's the limit… like the dot [the highest point on the graph] is the limit." Thus, Joyce related her non-mathematical conception of *limit* as a limitation (e.g., "like I'm at my limit") to her mathematical understanding of limit as a function's "maximum" value (which is mathematically incorrect).

Discussion

Overall, the results indicated that students' non-mathematical language can play an important role in students' mathematical understanding of linear (in)dependence and limits. In particular, it may be that connecting the non-mathematical use of (in)dependence as a *relationship* to the mathematical meaning of linear independence afforded students a deeper understanding of this topic. However, not all students in the study who had taken linear algebra made such a connection, suggesting that there is still room for making the English term *linearly (in)dependent* conceptually clearer to students. On the other hand, the analysis of student understanding of limits suggested that extending non-mathematical understandings of the term *limit* to mathematical interpretations of this term without reflection may also direct students' mathematical understandings astray.

These results highlight the importance for teachers to help students reflect on the terminology used to describe the concepts they are studying. This reflection may encourage students to compare the mathematical and non-mathematical meanings of certain terms. Leading students to see conceptual similarities (when they exist) can allow students to build on their own linguistic resources, whereas encouraging them to see differences can re-direct students away from unproductive mathematical conceptions rooted in limitations of non-mathematical meanings.

For example, a linear algebra instructor could facilitate discussions about the non-mathematical meaning of *dependent* and its connections, not only to the idea of scalar multiples of vectors, but more generally to the concept of linear combinations. This could help students interpret the idea of "a vector being expressible as a linear combination of other vectors" as a relationship in which that vector "depends" or "relies" on the other vectors. Likewise, a calculus instructor could facilitate discussions about the similarities and differences between mathematical and non-mathematical meanings of the term *limit*, so students may confront potentially unproductive conceptions and build productive models of *limit*.

To prompt or enrich such reflections, features of other languages, such as Chinese, could be leveraged. For example, if linear algebra students don't bring up the idea of a "relationship" on their own in class discussion, the instructor could promote such idea by asking students to consider the literal translation of the Chinese term for *linearly dependent* (线性相关: linearly related to each other*)*, which explicitly invokes the idea of a relationship. Similarly, to enhance the discussion about limits in a calculus class, students might be asked to reflect on the constrains of the literal translation of the Chinese name for *limit* (极限: maximum magnitude limit). This literal translation appears to reinforce the mathematically incorrect idea (held by students like Joyce above) that a limit is the maximum value of a function.

Ultimately, whether the multiple meanings embedded in certain mathematical terms support or hinder student mathematical understanding may lie on how students and instructors leverage these meanings. One promising way is for instructors to promote student reflection over the similarities and differences between multiple meanings of important mathematical terms. More research in language and undergraduate mathematics may shed more light on this promise.

Acknowledgments

I would like to thank Dr. Amelia Stone-Johnstone and Mike Foster, my colleagues and friends, for contributing to the design and implementation of the clinical interviews on limits and the initial coding of the data on limits.

Calculus I Instructors' Use of Representations in Instructional Tasks: Introducing Derivatives with Inquiry

Saba Gerami
University of Michigan

I present preliminary results from my dissertation research that investigates how eight college Calculus I instructors used representations in an instructional task intended for introducing derivatives with inquiry. Using Zandieh's (2000) framework, the instructors were asked to propose and sequence eight tasks for introducing derivatives to their students. This paper focuses on the instructors' utilization of various representations of derivatives in the first task they proposed in the sequence. The findings show how all instructors found graphical and physical representations appropriate for introducing derivatives, with some of them also reaching out to other representations (symbolic, numerical, and verbal) simultaneously.

Keywords: Instructional tasks, derivatives, representations, inquiry, calculus teaching

Research on the impacts of inquiry teaching suggests positive student outcomes, such as learning and persistence in STEM (Freeman et al., 2014; Kogan & Laursen, 2014; Laursen et al., 2014; Johnson et al., 2019; Rasmussen & Ellis, 2013). It is also known that the implementation of inquiry methods varies considerably among instructors (Laursen & Rasmussen, 2019). Research on the variability of inquiry-oriented teaching in undergraduate mathematics has mostly focused on characterizing and measuring how instructors and students interact in the classroom (e.g., Laursen et al., 2011; Mesa et al., 2020; Shultz, 2020). While showing the range of pedagogical variability in these classrooms is necessary for understanding inquiry teaching, this strand of research overlooks the content instructors and students interact with.

In my dissertation study, I investigate how college calculus I instructors, who use inquiry in their teaching, shape students' mathematical work during instruction of one specific piece of content: derivatives. As one of the basic and core concepts in calculus, derivatives' multiple representations and conceptualizations make its teaching a rich area for investigation. I bring my attention to the content during instruction by looking into the instructional tasks and their sequencing that instructors use to introduce derivatives to their students. For this preliminary report, I focus on instructors' use of mathematical representations, specifically addressing the following research questions:

1. Which representations do college Calculus I instructors, who teach with various inquiry approaches, use within instructional tasks to introduce derivatives with?
2. What patterns exist, if any, in their use of representations in instructional tasks for introducing derivatives?

Research on Representations of the Concept of Derivative

Research on representations of the concept of derivative has mostly attended to student understanding via using various representations, making connections among representations, and extending student understanding to applications of derivatives in other contexts (e.g., Feudel & Biehler, 2021; Jones & Watson, 2018; Maharaj, 2013; Roorda et al., 2007; Siyepu, 2013). Despite this enduring research on students' understandings of the derivative, there is less research on the teaching of derivatives through using representations. The scarce research in this area focuses on the student outcomes of instructional treatments. Kendal and Stacy (2000) compared high school students' competency in derivative representations from two classes. Although both teachers used identical curricular materials, students from the two classes became proficient in different representations (graphical versus symbolic) based on their respective teachers' emphasis on one representation. The authors claimed that "students had different cognitive experiences and acquired different differentiation competencies which related directly to the ways they were taught" (p. 133). Similarly, Hähkiöniemi (2006) carried out a teaching period based on the APOS theory, during which he emphasized visual and symbolic representations. He agreed with Kendal and Stacy's (2000) claim, as he found that students could recognize derivative visually early on and calculate derivative at a point symbolically. Hähkiöniemi (2006) concluded that visual representations are a good fit for introducing and developing understanding of derivatives. Also using the APOS theory, Borji et al. (2018) designed a teaching intervention focused on graphical representations. While both the experiment and the control groups spent equal time on the concept of derivative, the students in the experiment group spent some time using a programming software with graphing facilities, and later performed better on a written tests on derivatives. In another study, instead of emphasizing visual and symbolic representations, Dwirahayu et al. (2017) prioritized physical representations, specifically analogies to the speed of a vehicle, to introduce derivatives to students. Compared to the control group, the authors showed that teaching with analogies resulted in higher student understanding of other representations of the derivative.

These interventions are promising in explicating the relationship between teaching and learning of derivatives using different representations. However, the research has yet to investigate how instructors, outside of interventions, think about their use of representations for teaching derivatives and how they design and sequence their instructional tasks based on their insights about student conceptions of derivatives.

Theoretical Framework

In this study, I use Zandieh's (2000) framework (Table 1) to: 1) ground instructors in both the knowledge at stake and students' conceptions of derivative; and 2) organize instructors' use of representations when proposing tasks for teaching derivatives with inquiry.

Table 1. Zandieh's (2000) adapted framework for the concepts of derivative.

		Representations			
		Graphical (Slope)	Verbal (Rate)	Physical (Velocity)	Symbolic (Difference Quotient)
Process-Object Layer	Ratio	Slope of the secant line	Average rate of change	Average velocity	Difference quotient
	Limit	Slope of the tangent line	Instantaneous rate of change	Instantaneous velocity	Limit of the difference quotient
	Function	Graph of the derivative function	Rate of change of a function	Velocity as a function of time	Derivative as a function

Zandieh (2000) organized students' conceptions by representation (graphical, verbal, physical, symbolic) and process-object layers (ratio, limit, function). The process-object layers are hierarchical, as each layer is found by taking the process of that layer over the previous layer as an object. For example, the limit layer is found by the *process of* finding the limit of the ratio as an *object*. Although not originally captured in the framework, Likwambe and Christiansen (2008) and Roundy et al. (2015) added two new representations: numerical and instrumental.

The numerical representation of the derivative corresponds to the ratio of change ($\frac{y_2-y_1}{x_2-x_1}$) is written with values, often with a table. The limit layer corresponds to when the denominator approaches zero; the function layer is presented as an array of numbers or set of ordered pairs of differences. The instrumental representation of the derivative is the rules of differentiation and lives only at the function layer.

Methods

This qualitative study uses data collected through interviews with eight college calculus instructors who were purposefully selected. To select the interviewees, I administered a survey, including the INQUIRE instrument (The INQUiry-Oriented Instructor REview; Shultz, 2020), to 48 college instructors who teach Calculus I with inquiry. I then used INQUIRE to purposefully select eight interviewees with different patterns of inquiry-oriented practices in the classroom. The final interview sample included eight participants (all pseudonyms): Justin, Adrian, Barry, Matthew, Gopher (he/him pronouns); Monica (she/her pronouns); Max (they/them pronouns); and Alex (all pronouns). All participants were tenured with more than four semesters experience teaching Calculus I with inquiry. I conducted four remote semi-structured interviews (1-2 hour long each; Figure 1) with each instructor, as they proposed up to eight tasks. Instructors could use their teaching materials to choose tasks they had used or to create new ones.

Using Zandieh's (2000) framework, I dedicated an interview to each representation. During each interview, the instructors were given two prompts and were asked to propose a task for each prompt that would transition students' conceptions from one layer (as pre-conception) to the next (as post-conception, see Figure 1). For example, as Prompt 1, participants were asked to propose a task situated within the physical representation of derivative that would help transition students' conceptions from the ratio to the limit layer (without the framework's language):

> Assume that you have already taught students about average velocity and want students to learn about instantaneous velocity at a point. Propose a task with the position of an object varying as a function of time, where students figure out the velocity of the object at a given moment.

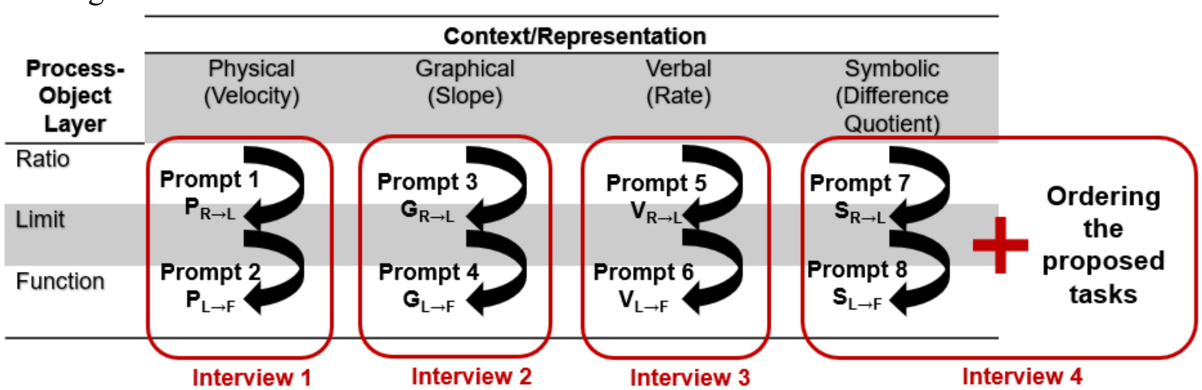

Figure 1. Structure of the interviews using Zandieh's (2000) framework. The code under a prompt, $X_{A\to B}$, gives: the representation X (P = Physical, G = Graphical, V = Verbal, and S = Symbolic), and the process-object layers A and B (R = Ratio, L = Limit, and F = Function). The arrow between the layers indicates the layer's precedence.

At the end of the final interview, I presented each instructor with all their proposed tasks and asked them to order them for introducing derivatives using inquiry. For the analysis reported here, I identified the representations and layers used within the proposed tasks without looking at the prompts' representation/layer code (those in Figure 1). I also coded representations of the derivative not in Zandieh's (2000) original framework. After coding, I listened to the interviews and read the transcripts to identify representations/layers that were mentioned but not written down in the task, as many instructors did not have enough time to write down all task details.

Findings

Due to space limitations, I present the representations used in the instructional task that instructors chose to use *first* when introducing derivatives to their students with inquiry. Because at the end of the final interview and after proposing eight tasks, the instructors re-arranged their proposed tasks in their preferred sequence for teaching derivatives, each instructor's *first task* is not necessarily the product of the *first prompt*. Figure 2 shows the prompts that generated each instructor's first task and the representations and layers identified in each. As their first task, the instructors chose to either use the task proposed for Prompt 1 (physical representation from the ratio to the limit layer) or Prompt 3 (graphical representation from the ratio to the limit layer). As shown in Figure 2's "Other reps/layers row", Gopher, Max, Barry, and Matthew reached out to representations and layers not mentioned in the prompts.

<table>
<tr><td>Prompt</td><td>Prompt(s) with reps/layers given</td><td colspan="4">Prompt 1
P: R → L</td><td colspan="2">Prompt 3
G: R → L</td><td>Prompts 1 and 3
P + G: R → L</td></tr>
<tr><td rowspan="2">First Task</td><td>Task's reps/layers used from prompt</td><td colspan="3">$P_{R/L}$</td><td rowspan="2">P_R</td><td rowspan="2">$G_{R/L}$</td><td>G_L</td><td>$P_{R/L} + G_{R/L}$</td></tr>
<tr><td>Other reps/layers</td><td></td><td>$G_{R/L}$</td><td>$N_{R/L} + S_L$</td><td>$G_F + S_{R/L}$</td><td>$V_{R/L} + S_{R/L}$</td></tr>
<tr><td></td><td>Participants</td><td>Alex
Monica</td><td>Gopher</td><td>Max</td><td>Adrian</td><td>Justin</td><td>Barry</td><td>Matthew</td></tr>
</table>

Figure 2. Derivative's representations and layers in the prompt that generated each instructor's first task, and representations and layers identified in their first tasks. Reps/layer is short for representations and layers. Each task has rep/layer codes similar to those in Figure 1. The task's layers are separated with slash (/) instead of arrows (→) here because I do not claim that the tasks necessarily transfer students' conception from one layer to another.

Alex, Monica, and Gopher provided similar tasks with tables of data for the position of a falling objects at various times and asked students to find the average velocity for various intervals. They then asked their students to find an estimate for the velocity at somewhere arbitrary between the existing data points. Gopher also used the graphical representation by defining secant and tangent lines, asking students to draw them on the curve of best fit for the data in Excel and finding connections between the lines' slopes and the velocities.

While Adrian and Max started their tasks similarly by providing the equation of the position of an object as a function of time, Adrian's task stayed within the ratio layer, as it asked students to only explain the physical meaning of some ratios (e.g., $\frac{R(5)-R(3)}{5-3}$). Max however provided multiple tables with times approaching $t = 5$ (e.g., 4.5, 4.75, 4.875) and asked students to complete the tables with average speed between the given times and $t = 5$. Max then asked students to estimate and write a formula for the object's speed at $t = 5$, thus using the limit layer of multiple representations (numerical and symbolic).

Looking at all representations used by instructors in their first task, everyone, except Justin, used the physical representation for introducing derivatives to their students, either encouraged by the prompt or by choice. Staying within the graphical representation only, Justin used an interactive GeoGebra applet to ask his students to find the slope of a secant line between two points on $f(x) = x^2$, as the distance between the points decreased. He then asked students to calculate the slope if Δx is zero, see what happens, and think about what the calculations reminded them of. Being cognizant of not using the physical representation, Justin explained that he does not use velocity "as the gateway application to move to calculus" because students get trapped in thinking that "a derivative is always a velocity rather than a velocity is always a derivative" (Interview 1).

Like Justin, Barry also chose the task he proposed for prompt 3 as his first task. Using a variety of functions and without mentioning secants, Barry asked students to find slope of tangent lines at various points. He then asked students to consider 2^x and plot $\frac{2^{x+h}-2^x}{h}$ in Mathematica with h getting smaller, ending the task by providing the limit definition of the derivative. As the only instructor to do so, Barry did not include the ratio layer in his task, but used the function layer.

Lastly, Matthew was a special case in the sense that he proposed the same task for both Prompt 1 and Prompt 3, saying that he wants students to "associate graphical representations to various parts of their work in the context of distance, velocity, time" early on (Interview 2). He also was the only instructor that used all four original representations (within ratio and limit layers) in his first task. Starting the task with the equation of the height of a bolt fired from a crossbow as a function of time, Matthew proposed a series of subtasks that asked students to: approximate the speed for a specific *t*, explain their approximation "using words only" (verbal), use the limit notation to write their findings, and identify secant and tangent lines on the graph of the function and find their slopes. Wanting students to become aware of the four main representations of the derivative, Matthew said that the task makes them "repeat the same set of questions over and over in different representations" (Interview 1).

Discussion

The findings show that the instructors in this study found graphical and physical representations, within ratio and limit layers, appropriate for introducing derivatives. These results align with Hähkiöniemi's (2006) and Dwirahayu et al.'s (2017) suggestions of using these representations early on. Nonetheless, half of the instructors also used other representations simultaneously. Moreover, while most instructor's use of the representations reflected the hierarchical order of layers in Zandieh's (2000) framework, one instructor (Barry) chose to not teach in that order. Further inquiry is needed to understand the ways in which calculus instructors utilize representations, separately and in connection to one another, at various conceptual levels to teach derivatives.

The study extends our understanding of inquiry teaching by attending to the content, as opposed to pedagogy, through their use of instructional tasks. As more mathematics faculty implement inquiry-based methods, it is essential that we understand their decision-making at the content level so that their specific needs can be met through curriculum or professional development initiatives. By attending to instructional tasks, we also gain a better understanding of what is actually offered to students during instruction and how it might impact their learning.

Acknowledgement

Funding for this work was provided by the University of Michigan's Rackham Graduate School to the author. I sincerely thank Dr. Vilma Mesa, Dr. Patricio Herbst, and the RTMUS lab for their continuous guidance and feedback.

How Do Postsecondary Linear Algebra Instructors Implementing Inquiry-Oriented Approaches Address Goals of Instruction in an Online Work Group?

Minah Kim
Florida State University

Shelby McCrackin
Florida State University

Postsecondary instructors interested in inquiry-oriented instruction of Linear Algebra participated in a sequence of eight one-hour online work group meetings with other experienced inquiry-oriented linear algebra facilitators and teachers. Recordings from three meetings were analyzed for how two participants referenced goals of instruction in preparation for teaching a new instructional unit on subspaces. We identified four goals of instruction of teaching subspaces. We discuss the intersections of several goals of instruction and possible implications for those who want to transition to inquiry oriented instructional approaches.

Keywords: goals of instruction, inquiry-oriented instruction, online work group

Linear Algebra is a postsecondary mathematics course that is typically required of all mathematics and many STEM (Science, Technology, Engineering, and Mathematics) majors. The topics learned in this course are foundational for many other math courses. Tucker (1993) and Carlson et al. (1993) point out the importance of linear algebra in addressing not only the theoretical and practical aspects but also its applicability in modern computation in industrial science, technology, computer science, engineering, and economics.

The number of students required to take Linear Algebra provides motivation to search for ways to improve instruction. Active learning in undergraduate STEM education is linked to increased student performance, and some literature suggests it may be linked to more equitable outcomes (Burke et al., 2020; Freeman et al., 2014; Haak et al., 2011; Kogan & Larsen, 2014). Inquiry-oriented Linear Algebra (IOLA) is one approach to active learning in undergraduate mathematics education. Inquiry-oriented instruction derives from Realistic Mathematics Education (RME) with the intent to support students in reinventing key mathematical concepts (Freudenthal, 1991; Kelley & Johnson, 2022). To support the students in these courses with an engaging learning experience, teachers need to be supported (Andrews-Larson et al., 2019) because changing instructional approaches is difficult and long-lasting change requires shifts in instructional practice (Cohen, 1996; Henderson et al., 2011). Therefore, there is "a need for professional development programs that foster the development of undergraduate mathematics instructors' pedagogical reasoning" (Andrews-Larson et al., 2019, p. 129)

Thus, an online work group (OWG) created as part of a larger project to support college mathematics instructors teaching Linear Algebra, gave instructors an opportunity to collaborate with others interested in continuing their pursuit to enact reform-oriented instructional practices. In the OWG of this study, participants with inquiry-oriented instruction (IOI) experience work on implementation of a newly developed set of IOLA tasks and discuss their teaching practices with researchers and facilitators of the OWG.

In this analysis, we focus on the two undergraduate instructors who are not researchers or facilitators of the larger project because this enables us to examine how experienced IOI instructors discuss content and related pedagogical decisions they make before and during instruction. Their discussions can highlight how teachers' knowledge shapes teachers' practices (Borko & Putnam, 1996), in particular practices related to the preparation of a lesson. One of those practices is attending to goals of instruction (Wagner et al., 2007) which is the focus of our study. The practical goal (Maxwell, 2013) of this research is to continue the conversation initiated by Wagner and colleagues, whose focus was on a novice instructor's experience with the inquiry-oriented instructional tools, and extend this to a discussion including experienced IOLA instructors. This research will aid in understanding the reasoning of experienced IOLA instructors, particularly regarding their instructional goals and the challenges of IOLA curriculum implementation. Our research question is "What is the nature of the goals of instruction articulated by experienced Inquiry-Oriented Linear Algebra (IOLA) instructors as they work to implement a new instructional IOLA unit in the context of the Online Work Group (OWG)?"

Theoretical Framework

Wagner et al. (2007) identified four categories related to instructional goals in the context of inquiry-oriented instruction at the undergraduate level: classroom orchestration goals, cognitive/learning goals, assessment goals, and content goals. The four goals emerged as a result of continuous work on studying teacher knowledge, such as pedagogical content knowledge (Shulman, 1986) done by Wagner et al. (2007) that focused on teacher knowledge shaping teacher practices through analyzing data from a novice inquiry-oriented instructor. The goals of instruction are signified through questions that instructors ask in their "transition" to teaching in reform-oriented ways. While instructors are in transition, each goal is evidenced by the, but not limited to, following questions:

1. Classroom orchestration goals: "How does mathematics emerge in the classroom? What is the instructor's role or students' role?" (p. 257)
2. Cognitive/Learning goals: "What supports learning? Is there a correspondence between what students are learning and what the teachers want them to learn?" (p. 259)
3. Assessment goals: "What is evidence of learning? What determines pace?" (p. 261)
4. Content goals: "Specifically what mathematics ought to be covered?" (p. 263)

Using the work from Wagner and colleagues as a priori scheme, this proposal will work to identify the ways in which these kinds of goals were conceptualized by experienced IOLA instructors in the online work group.

Study Context: Inquiry-Oriented Linear Algebra and Online Work Group

Inquiry-Oriented Linear Algebra (IOLA) is a design-based research project in linear algebra education as one approach to active learning (Freeman et al., 2014) and inquiry-based mathematics education (Laursen & Rasmussen, 2019). Laursen and Rasmussen (2019) describe inquiry-based mathematics education as "student engagement in meaningful mathematics, student collaboration for sensemaking, instructor inquiry into student thinking, and equitable instructional practice to include all in rigorous mathematical learning and mathematical identity-building" (p. 140). Specifically, the IOLA-X project focuses on developing student materials composed of challenging and coherent task sequences that facilitate an inquiry-oriented approach to the teaching and learning of linear algebra (Wawro et al., 2013). There are five main phases in the Design Research Spiral: *Design*, *Paired Teaching Experiment* (*PTE*), *Classroom Teaching Experiment* (*CTE*), *Online Work Group* (*OWG*), and *Web* (Wawro et al., in press). The participants of our study come from the OWG in phase 4 of the research project.

The main purpose of the OWG for the IOLA research team is to learn from instructors how IOLA is implemented in various classrooms with various student populations and to gain insights to develop instructor notes and revise tasks (Wawro et al., in press). At the center of the

OWG for this study was the discussion of a unit of tasks about subspaces; the tasks were contextualized in a problem about students walking in one-way hallways past cameras monitoring their traffic (See Figure 1). To draw out the feedback from the instructors, the facilitators manage mathematical discussions about the tasks as well as facilitate discourse about the preparation and implementation of the tasks. Through examining discussion and input from the experienced undergraduate instructors participating in the OWG, questions and thoughts about the goals of instruction and challenges with implementation naturally arise.

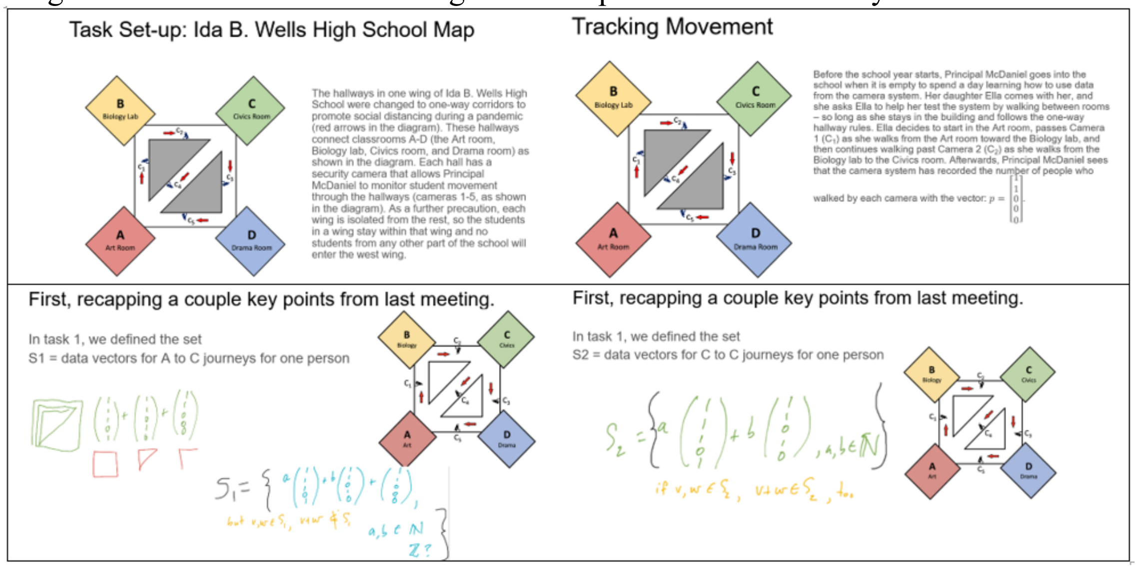

Figure 1. The inquiry-oriented linear algebra tasks in the subspaces unit

Methods

Our primary data source was the recorded videos of the OWG meetings (held and recorded via Zoom); group artifacts such as Google Slides and Jamboards served as secondary data sources. The OWG meetings were held in the Spring 2022 semester. During the first three meetings, participants worked through and discussed the mathematical progression of a new IOLA unit comprised of three tasks. The subspaces unit focused primarily on notions of closure of sets of vectors under vector addition and scalar multiplication, and on null and column spaces. Participants worked on the mathematical problems as a group, then discussed mathematical goals, approaches, and links to other ideas and topics. The remainder of the meetings took place throughout participants' implementation of the sequence, with each participant reporting on how the implementation went, what they liked, how their students reasoned about tasks, what they would change, and what they would do differently.

In the OWG meetings, there were six members. In this proposal, the members are coded as F1 and F2 (facilitators), R1 and R2 (IOLA researchers), and I1 and I2 ("pure" participants who are experienced inquiry-based instructors but not IOLA researchers). This team involved one graduate student (F2), one instructor (I2), three associate professors (F1, R1, and I1), and one full professor (R2). I2 taught linear algebra at a large public university in the Northeastern United States at the time of the OWG; and I1 taught the same course at a small private college in the Northwestern United States. The participation and contributions of I1 and I2 serve as the focus of our study.

Eight hours total of OWG meetings were conducted and recorded over several days. We analyzed transcripts of the first three videos. Narrowing these three videos allowed us to examine the ways in which participants worked through the mathematical tasks and identify the instructional issues that participants anticipated in their implementation. The videos were transcribed by Otter, an online artificially intelligent transcription application. Both authors separately coded all three videos for the four goals of instruction for all the participants of the OWG using Nvivo software. While coding, we assigned four codes, which mean four goals, at the level of a single turn of talk. Then, we compared codes to reach agreements to build inter-rater reliability. We identified common themes within each code in terms of broad questions and agendas that the set of codes seemed to address. Our findings highlight the themes in which each goal of instruction emerged from the two "pure" participants in our data set. Figure 2 summarizes these findings. Each goal of instruction is, not necessarily, but preferably described in question form in order to follow the original form of goals of our theoretical framework.

Findings

Generally, in the OWG meetings, the pure participants discussed classroom orchestration goals involving how to manage discussions of contextualized tasks about "closure". Also, cognitive/learning goals discussed in the OWG meetings are contextualized goals in subspaces and communication in engaging in IOLA tasks. Assessment goals are discussed in terms of pacing, timing, and grading of inquiry-based teaching. Lastly, content goals include curricular trajectories and mathematical content relevant to subspaces reorganized by instructors.

The participants talked about how to orchestrate the discussion of closure under scalar multiplication, considering irrational and complex scalars in the context of the IOLA task.

I1: We had a conversation we were talking about... here's a bunch of examples, what's the span of each of these sets? And, and I thought it was superfluous, but it turned out not to be. The last one I asked was span of the vector, <e, pi squared>. And that really freaked them out. And I was glad that I included [it] because we had already talked about magic carpet ride. Any real scalars are fine. If you want complex scalars, that's a different class, but any real numbers, great. And they seemed okay with that. But no, it was clear, we're going to have that conversation again.

From this excerpt, the instructor is unpacking a class interaction they have had before this OWG meeting where they introduce complex components of vectors in another IOLA task (magic carpet ride). I1 determined that interaction was relevant to the future implementation of the subspaces task because the idea of complex scalars will spark "that conversation again". That demonstrates the instructor's reference to orchestration goals, but also content and cognitive/learning goals. The instructor is connecting mathematical concepts across the IOLA tasks and using the tasks as an opportunity for elaboration beyond the initial exploration.

Furthermore, the participants shared their thoughts on student reasoning that may happen in class discussions and the contextualized goals in subspaces and sets of scalars, coded as cognitive/learning goals.

I2: And, but I think S2 is closed. […] Is it closed under scalars? Scalar multiplication of non-integer or negative scalars? I guess [it] depends on, do we require this to be walkable by number of persons? Right? Or does it just have to fit set description?

As Figure 1 illustrates, S2 is a set of camera vectors that pass through hallways from room C to room C. In this context, scalars mean the number of loops one person creates through one big square loop (through rooms A-B-C-D) and one small triangle loop (through rooms A-B-C). In the contextualized ways, S2 is closed under scalar multiplication but as I2 mentioned, the scalars depend on how much we address that real-life context. The non-integers or negative scalars cannot be defined in the contextualized goals, but this should be clarified to move on to the purely abstract mathematical definition of closure. During this conversation, participants discussed how they manage their trajectories of teaching linear algebra, how to address contextualized mathematical goals with IOLA tasks, and how they orchestrate discussions.

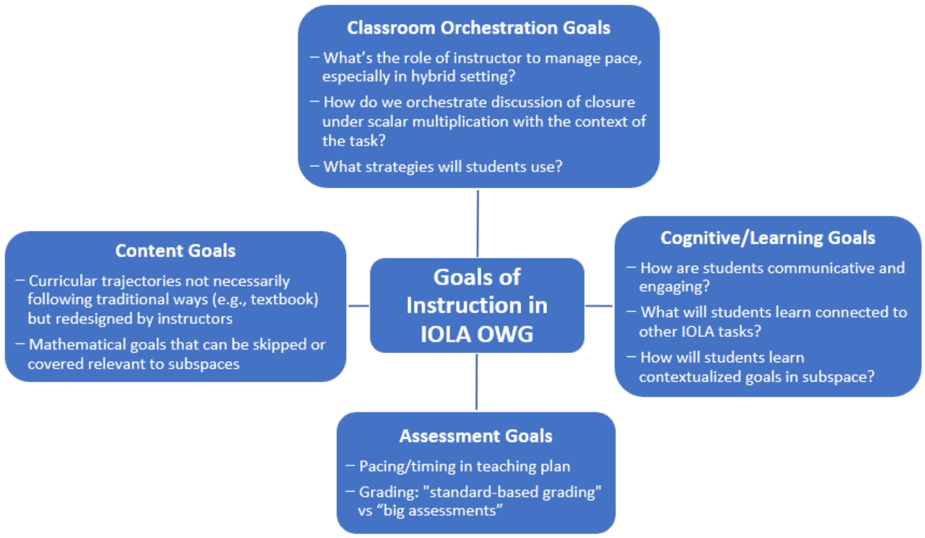

Figure 2. Goals of instruction in inquiry-oriented linear algebra online work group

Discussion

The two participants of our study asked questions and made comments in reference to all four goals of instruction introduced by Wagner et al. (2007). However, some dialogue from the participants were coded as referencing two or more goals. That made clear a separation of assessment goals from the other three goals. The results from the three goals - content, classroom orchestration, and cognitive/learning goals - show an overlap exposed by the instructors. The intersection of those goals may exist due to the contextualized nature of the IOLA tasks that the instructors work through in the OWG. In the task, scalars are constrained due to the context. Therefore, the scalars in the task would not be defined as scalars abstractly because other real numbers (like negative integers) could not be included. The instructors recognized the scope of the tasks and made plans to use the tasks as an opportunity to launch into more (abstract?) concepts chosen by the instructor and guided by student contributions.

On top of referencing goals of instruction as the novice IO instructor did in Wagner and colleagues' (2007) investigation, the experienced IOLA instructors of the OWG were able to expose tensions in instruction and mathematics that goes beyond attending to goals of instruction. The IOLA instructors addressed challenges of teasing through the tension between the aim of Realistic Mathematics Education (RME) and what mathematics is pursued in traditional linear algebra classrooms. This tension can be something to consider for new and transitioning inquiry oriented mathematical instructors.

Successes and Challenges in Supporting Calculus Students to Conceptualize and Express Distance on Graphs

Erika David Parr, Rhodes College
Samuel Lippe, Rhodes College
Jana Turner, Rhodes College

Conceptualizing and expressing distances on graphs of functions are central to understanding why integrals afford measuring areas and volumes in calculus. In this preliminary report, we share the results of implementing an intervention designed to support these skills with 31 Integral Calculus students. Initial results show that the activity did support some students in learning to accurately expressing the horizontal distance between two functions. However, a closer look at students' work revealed that the tasks may not have supported all of the ways of reasoning we intended. We discuss the instance of two students who successfully completed the activity yet displayed evidence of treating symbols as labels or parameters and following a pattern to complete the tasks rather than conceptualizing distance. We close with a discussion of how to improve the next iteration of the intervention.

Keywords: Graphical Representations, Calculus, Distance, Cartesian Coordinate System

One of the key results of Integral Calculus is the ability to find the area of curved regions and volumes of solids of revolution. In order for students to understand conceptually why the integral affords finding the value of such areas and volumes, students must be able to: 1) conceptualize distances within coordinate systems and 2) describe these distances with algebraic expressions from relevant functions. Prior research suggests that students, even at the undergraduate level, often struggle with one or both of these skills (David, 2019; Knuth, 2000; Parr, 2021), and may benefit from targeted interventions in these areas.

Previously, Parr et al. (2021) described the results of a small teaching experiment (Steffe & Thompson, 2000) that utilized a sequence of tasks designed to support students in conceptualizing and expressing distances algebraically, as part of a hypothetical learning trajectory (Simon & Tzur, 2004). Parr et al. (2021) reported that the tasks showed promise at supporting students and also clarified ways of reasoning that students may use when describing distances of segments. One of these interpretations is what Parr et al. (2021) refer to as a *composed magnitude interpretation* of distances on number lines. This interpretation involves conceptualizing a difference of the form $b–a$ (where $b \geq a$) as representing the distance in one-dimension between a and b. The interpretation of the difference $b–a$ is one of a *magnitude*, or amount of distance, within a graphical representation (Parr, 2021). The interpretation is *composed* as it includes the understanding that b and a themselves are magnitudes of distance. Thus, the difference $b–a$ yields the distance between a and b as a result of finding the difference between the distance between b and the origin, and the distance between a and the origin.

The current study is part of an ongoing effort to learn how to support students in conceptualizing and expressing distances for calculus. In this study, we investigate the effectiveness of implementing a revised set of these tasks in a classroom setting. The research questions this study seeks to answer are:
(1) *To what extent do these tasks support students in learning to conceptualize and express distances on graphs of functions in calculus in terms of the input and output variables?*
(2) *What are the affordances and limitations of these tasks in supporting students to develop a composed magnitude interpretation of distances?*

Methods

The data in this study were collected in Spring 2022 from 31 students enrolled in one of two sections of Integral Calculus taught by the lead author. The Integral Calculus course met three times a week and students participated in the study during two consecutive course meetings, ahead of the unit on Areas and Volumes. At this point in the course, students had been introduced to integrals through an accumulation model, without graphical applications. At the end of the first day of the study, students were given ten minutes to complete the pre-test item (Figure 1) individually. The next class meeting, students were instructed to work in groups of two or three to complete the *Interpreting Graphs for Calculus Activity* over the 50-minute meeting time, which included the same pre-test item as the final task. The instructor circulated groups answering clarification questions about the tasks as needed. Students recorded their group's activity via Zoom. Of the 31 students who consented to have their written work included in the study, 26 also consented to include their group's video recording in the data set.

Pre-Test Item & Interpreting Graphs for Calculus Activity

The pre-test item and the tasks comprising the *Interpreting Graphs for Calculus Activity* used in this study were a revised version of the tasks first described in Parr et al. (2021). The pre-test item (Figure 1) asked students to represent the length of the horizontal segment extending from a point labeled (x, y) on the function $y = \sqrt{x-1}$ to the vertical line $x = 2$ in terms of x, in terms of y, and to explain their reasoning for each response.

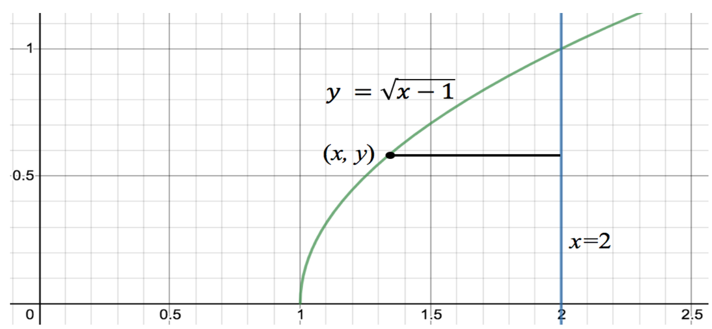

Figure 1. Pre-test item asking students to represent horizontal segment's length (black) in terms of x and y.

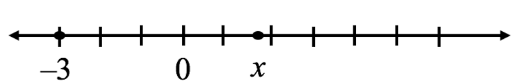
The three main goals of the *Interpreting Graphs for Calculus Activity* are to support students in (a) conceptualizing horizontal and vertical distances on number lines and the Cartesian plane, (b) representing these distances with difference expressions, and (c) using algebraic relationships among input and output variables to express distances flexibly in terms of either x or y. In this study, we focus on the first two goals and associated tasks. The first task asked students to use a ruler to mark specified distances from 0 on a provided number line, as well as distances between two values. The next set of tasks asked students to represent various difference expressions as segments, involving whole numbers, integers, rational numbers, and variables as distances on both horizontal (Task 2-Figure 2) and vertical number lines (Task 3).

h. Draw a segment to represent x– (–3) on the x-axis below.



i. Place another value of x on the number line above, and draw another segment representing x– (–3).

Figure 2. Portion of Task 2 from Interpreting Graphs for Calculus Activity.

Task 4 reversed this and provided students with horizontal or vertical segments, asking students to express the length of the given segment as a difference. Finally, Task 8, which we refer to as the post-test item, included the same items as the pre-test item to serve as a comparison for student responses before and after completing the activity.

Preliminary Data Analysis

To analyze our results, we first recorded students' responses to the pre-test and post-test items and developed basic categories for these responses, including correct responses, blank/I don't know, or other expressions. Based upon a student's response to the pre-test and post-test items, each research member selected 3-4 students who did not initially answer the pre-test item correctly and developed initial content logs and analytic memos of students' responses to the Interpreting Graphs for Calculus Activity and group videos of the students completing the activity. The goals of this initial analysis of students' work on the activity was to determine if we could identify shifts in the student's thinking about the tasks that may have supported or hindered them in responding to the post-test item correctly, especially related to their development of a composed magnitude interpretation of distances.

Results

The number of students who correctly represented the segment's length in terms of x and y increased significantly from the pre-test to the post-test item on the graphing activity (Table 1).

Table 1. Number of correct responses on the pre-test and post-test item.

Represent segment's length	Pre-Test	Post-Test
in terms of x: $2–x$	12/31 (38.7%)	24/31 (77.4%)
in terms of y: $2–(y^2+1)$	10/31 (32.3%)	20/31 (64.5%)
Both x and y correct	7/31 (22.5%)	20/31 (64.5%)

While the activity appears to be generally effective in its goal, our ongoing data analysis revealed that some students were limited in their use of variables to express lengths of segments, or may have avoided conceptualizing difference expressions as finding distances, even when they gave correct responses on the post-test items. (We note also that the post-test item was completed in groups and may not reflect each individual's understanding). These findings suggest that the activity may not promote some of the central ways of reasoning that we intended for students to develop and use. We illustrate these two issues using the case of two students who were partners for the in-class activity, Kevin and Amir. Kevin and Amir both incorrectly responded to the pre-test item but correctly expressed the horizontal distance in terms of x and y on the post-test item.

Symbols as Labels or Parameters

Both sets of responses from Kevin and Amir indicate that they tended to use symbols (such as x, y, and z) as either labels or parameters, rather than as variables to represent varying values. We found evidence of this tendency beginning with Amir's work on Task 1 in which he labeled segments with symbols x, y, and z that he introduced himself. This tendency was most apparent when it created some hesitation for Amir on Task 2i. Kevin asked Amir about this task and their discussion reveals the limitations of Amir's use of x. We provide their conversation below and Amir's work in Figure 3.

Amir: (*reading 2i*) Oh, so like place a value for x and just draw it, x equals 2…

Kevin: What is it asking, again?
Amir: Place another value of x, like 1, 2, 0, why did I put 0?... It doesn't make sense to place another value of x. I mean even if you put x over here, so x_0 equals x_1, it's the same thing.
Kevin: Ah (*leaning back*)
Amir: I mean, I like the zero thing.
Kevin: So, wait, what are you doing? (*looking at Amir's work*)
Amir: I'm saying x equals 0, I'm setting
Kevin: Okay
Amir: the segment from 0
Kevin: Yeah
Amir: I don't know.

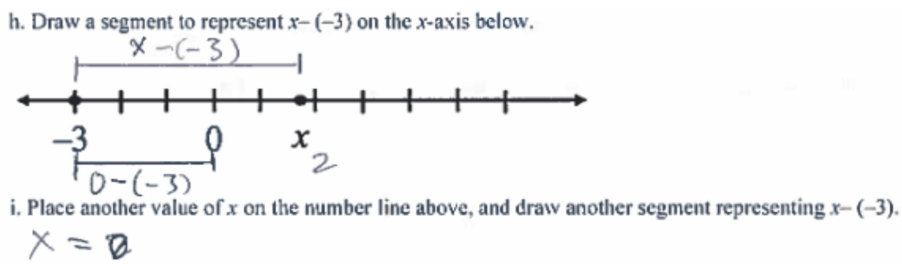


Figure 3. Amir's work, in which he wrote "x= 0," and then labeled "0–(–3)" on a segment below the number line.

Amir explained his interpretation of the directions to "place another value of x" as choosing a value for x, when he listed values "like 1, 2, 0." He goes as far to say that "it doesn't make sense to place another value of x" and continues to then describe different possible x's as "x_0" and "x_1." We infer from these comments that Amir is interpreting x as a parameter (Thompson & Carlson, 2017), in which x may take on different values in different settings, but may not take on different values in the same setting. This interpretation is distinct from interpreting x as a variable in which x may take on multiple varying values in the same context. Amir's interpretation of x as a parameter may help to explain why he thought that it didn't "make sense to place another value of x." Amir's interpretation of x as a parameter is also supported by his written work on this task, in which he sets x to 0, but then he labels the new segment as "0–(–3)" rather than "x–(–3)" as directed, not comfortable with using x to take on two different values in the same number line.

Following a Pattern for Expressing Distances

In addition to treating symbols as labels and parameters, Kevin and Amir also indicate that they may be simply following a pattern in order to express the indicated distances, rather than using a composed magnitude interpretation of distances. Specifically, this pattern involved using a minus sign because previous answers they found were also difference expressions. This issue came to light as Kevin suggested an alternative answer to 4c (Figure 4), a task which asked students to represent the distance between 5 and y on a vertical number line.

Amir: See directions matter. So now like, this above, 5 minus y and this is y minus
Kevin: Yeah. (*pause*) I guess you could say that it's also y plus 5.
Amir: y plus 5 (*slowly, thinking*). Well, yeah, you can say that, too. But because it's differences. Here it doesn't say differences, here it does.
Kevin: I'm just going to use minus for consistency.
Amir: Yeah

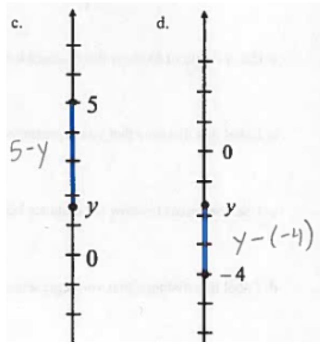

Figure 4. Kevin's work on Task 4c and 4d.

When working on Task 4c, Amir seemed to indicate that the ordering of the symbols mattered. In this case, whether 5 or *y* were on top indicated which was to be first in the expression. At this point, it is unclear whether Amir's distinction about the direction or order of the terms mattering was the result of a composed magnitude interpretation. However, Kevin's suggestion of "y+5" as an alternative expression, and Amir's agreement, indicates that they were not interpreting *y* as a distance from 0 to *y* and 5 as a distance between 0 and 5. Instead, they justify their decision to use the correct answer, 5–*y*, "for consistency," rather than with any reference to distances. This justification suggests that Kevin and Amir may have been learning to use a rule or pattern of "top minus bottom," since they could have just as readily used the expression y+5 to represent the distance between *y* and 5, and may have, if previous expressions had included sums rather than differences. We note that Kevin and Amir provided correct responses to the remaining tasks.

Discussion & Future Plans

At first glance, the *Interpreting Graphs for Calculus Activity* appears promising as an intervention to support students in expressing distances, based on the results of the pre-test and post-test items. However, as designed, they may be limited in the ways of reasoning they can promote. Kevin's and Amir's use of symbols as labels and parameters suggests that the tasks as designed may not effectively support students in conceiving of difference expressions involving symbols as representing varying values of distances. Kevin's and Amir's rule for using a minus sign in their expression to represent distances, to the avoidance of conceptualizing distance measurements given by the expression, may work in many contexts for which a "right minus left" or "top minus bottom" formula yields the correct answer. Yet, we anticipate this rule may not support students in expressing distances in coordinate systems beyond the Cartesian coordinate system. In our future work, we plan to conduct more teaching experiments with students with a next iteration of revised tasks designed to support students in conceptualizing distances more effectively. We hypothesize that it could benefit students to include more reflective prompts throughout the tasks, such as "what does this value represent?" after students calculate the length of each segment and to include some dynamic distances rather than only static distances for students to express with differences. We hope to further discuss with the audience ways to improve the task design to address the two issues we highlight in this study.

The Role of Ritual and Personalization in Students' Exploration of Subgroup Generation

Cody L. Patterson, Texas State University
Kathleen Melhuish, Texas State University
Michael D. Hicks, Virginia Tech

We share preliminary results of a commognitive analysis of the participation of twelve undergraduate students in an exploratory subgroup generation activity in an abstract algebra class. We find that while students' collaborative activity contains markers of both ritualized and explorative participation, their appeals to ritual and personalized formulations of inferences and insights about subgroups serve to broaden access to the conceptual substance of the activity. We discuss a possible asset-oriented interpretation of students' ritualized activity as an aid to exploration and reflective of the disciplinary activity of professional mathematicians.

Keywords: Discourse, Inquiry-Oriented Instruction, Abstract Algebra

Advanced mathematical courses such as abstract algebra provide a space where students are apprenticed into the norms and activity of mathematicians. These classroom spaces involve a complex interaction between student reasoning and activity and norms deriving from the professional mathematician community. Frequently, scholars have analyzed student activity in this setting from a deficit point of view, illustrating ways that students may engage in non-normative activity and fail to meet standards of communication associated with norms of formal proving (see Styliandies et al., 2017 for an overview).

To both illustrate this trend and contextualize our study, we use literature about students and subgroups. Subgroups are one of the fundamental topics in group theory (Melhuish, 2019) and have received considerable attention in literature. Some students have been shown to attend to subset properties but not operation. For example, students may suggest that "odds" are a subgroup of the integers (Brown et al., 1997; Titova, 2013). Similarly, several studies have shown students identify $\{0,1,2\}$ as a subgroup of $\mathbf{Z}_6$ (e.g., Dubinsky et al., 1994; Melhuish, 2018) because they unintentionally switch operation from addition mod 6 to addition mod 3. In contrast, Findell (2002) illustrated how a Cayley table could focus a student on the relevant operation, although generating subgroups from that table proved to be a significant challenge. There have also been some studies that pointed to specific issues with applying subgroup test requirements including production of proofs (Ioannou, 2018) or checking closure by only considering combinations of distinct elements (Hazzan, 1994). In general, we can state that the field has characterized a number of "errors" related to subgroups.

In this report, we attempt to re-examine student activity with subgroups through a more asset-based lens. We share analysis from one open-ended task designed to engage students in generating subgroups for a given, known group. We leverage the framework of Lavie, Steiner, and Sfard (2019) to characterize students' activity as exploratory or ritualistic, noting ways that students engaged productively with the task and identifying dilemmas students needed to resolve. We found that our students negotiated many issues reflective of the literature, but productively drew on personalization and ritual as they engaged in open-ended exploration.

Theoretical Framework

In this study we take a commognitive view of mathematics learning, in which thinking is conceptualized in terms of acts and processes of communication (Sfard, 2008). Central to the commognitive perspective is the notion of *routine*, a repetitive pattern of action that retains some invariant features across different performers and implementations (Lavie et al., 2019). Lavie and colleagues distinguish two types of routines: *rituals*, which are process-oriented and require performance of a rigid sequence of actions; and *explorations*, discursive routines guided by the performer's motivation to communicate an idea or pursue a line of inquiry. According to Lavie et al., students initially can only participate in mathematical activity in ritualized ways, because they must first familiarize themselves with the norms and meta-rules of disciplinary discourse. As they gain familiarity, they may begin to participate in "explorative" ways, generating new truths and pursuing inquiries borne of their own motivation and curiosity. Coles and Sinclair (2019) challenge the notion of ritualized activity as meaningless, arguing that participation in ritual can engender meaning for learners and is not mutually exclusive with exploration.

One specific discursive feature that has been associated with ritualized activity in mathematics is *personalization*, in which operations are presented as human actions on mediators rather than in terms of structural relations among mathematical objects (Ben-Yehuda et al., 2005). Personalization in mathematical talk has been associated with lower achievement in empirical studies of children's mathematical activity (Bills, 2002). Our study aims to challenge narratives of personalization as a marker of less sophisticated or less robust mathematical activity by exploring ways in which personalization can help students access algebraic concepts.

Guided by this theoretical framework, we address the research questions:

1. In what ways might collaborative student work on an open-ended task in an abstract algebra course resemble ritualized or explorative mathematical activity?
2. In what ways might ritual and personalization support students' explorative engagement in such a task?

Context and Method of Study

In this report, we analyze an activity on Lagrange's theorem developed by the Orchestrating Discussion Around Proof project which designed and field-tested abstract algebra lessons that engage students in authentic mathematical proof activity (Melhuish et al., 2022). The first activity in the task sequence involved students generating subgroups in order to anticipate the relationship between the order of a group and its subgroups. The participants in our study are twelve undergraduate mathematics majors who worked on the lesson in four teams (Table 1).

Table 1. Teams and group assignments for the subgroup generation activity.

Team	Group	Students	Team	Group	Students
1	$\mathbf{Z}_{10}$	Carlos, Romiax	**3**	D_4	Brad, Fernando, Mona
2	$\mathbf{Z}_{12}$	Diego, Jake, Paolo, Quinn	**4**	S_3	Alan, Eric, Nathan

Each team worked for 20 minutes to create a list of subgroups of their assigned group. In the previous class session, the instructor (Author 1) had demonstrated a possible approach for generating a subgroup of the group $\mathbf{Z}_8$: choose an element to place in a subset, and then use the closure and inverse properties to identify other elements that must be in the subset if it is a subgroup. Although he modeled how to identify elements that must be included in a subgroup, he did not demonstrate any systematic approach for generating all subgroups of a group.

We audio recorded each team's discussion and photographed all board work, then generated a transcript. To investigate the interplay between ritual and exploration in students' discussions, we analyzed all four team transcripts, noting any talk turns that contained instances of personalization or possible indicators of ritualized or explorative activity (see Table 2). For each instance we further described the problem-solving context, developing analytic descriptions of how personalization, exploration, and ritual supported the group's problem-solving process.

Table 2. Discursive indicators of personalization and ritualized and explorative activity.

	Indicator	Example
Personalization	Talk about human involvement with objects or symbols	"Yeah, we would need 1 and then we would need 11."
Ritualized activity	Description of subgroup generation routine as rigid algorithm with fixed, prescribed steps	"So you do have to add [an element to] itself?"
	Settling conceptual/procedural questions by appeal to authority or analogy with instructor-led example	"Last time over here, [Instructor] adds them, he adds the same element by themselves"
Explorative activity	Exploration of hypotheticals, as evidenced by "if-then" language	"If you compose [a transposition] by itself it just goes back to the identity?"
	Settling conceptual/procedural questions by definition or deduction	"Does 0 always have to be in here?" "Yes. Because it always has to contain the identity."

Preliminary Results

We found that each team's discussion contained some instances of personalization, though different teams used personalization in different ways. Each team's discussion contained some indicators of ritualized mathematical activity, but was largely reflective of explorative activity, with multiple members engaging together in exploration of hypotheticals. For this report, we present analyses of two cases chosen based on the contrast in their discursive features.

Team 1: A Progression from Ritual to Exploration

Team 1 first identified the singleton {0} and the entire group as subgroups of $\mathbf{Z}_{10}$. They then attempted to resolve the question of which operation (addition or multiplication) was the group operation by referring to the instructor's previously worked example. When this failed to clarify the issue, they asked the instructor, who specified that the operation was addition. We interpret this as pointing toward a ritualized form of participation; while it is possible to determine that $\mathbf{Z}_{10}$ is a group under addition but not under multiplication, the group considered the operation to be indeterminate without external specification ("Yeah, well, it could be any binary operation").

As they proceeded with subgroup generation, Team 1 used personalization to generate informal descriptions of subgroup properties, interpreting closure as follows: "So closed means whenever you're adding, whenever you get another element that's also in that set." Throughout the activity, the team frequently referred to a generic "you" operating on elements of subgroups to generate additional required elements.

At one point, Team 1 grappled with whether one should add an element of a subgroup to itself in order to generate additional subgroup elements. Rather than consult the definition of subgroup, Romiax attempted to resolve the issue by referring to the $\mathbf{Z}_8$ example: "Last time over here, he adds them, he adds the same element by themselves." Carlos appears to accept this as a warrant, then recalls an instance of this himself: "And then he did eight plus eight or something." It is possible that for Team 1 the ritual of subgroup generation had not yet fully fused with the team's understanding of the definition of subgroup. This is not to say that the team was inattentive to this definition; on the contrary, the team refers repeatedly to the properties that define a subgroup. We hypothesize that for this team, fluency in the application of the definition of subgroup was a work in progress, and the sense of a subgroup generation ritual or "game" (a descriptor used by the instructor and subsequently by some students) supported their exploratory efforts. After settling these procedural issues, Team 1 went on to fluently explore other subgroup possibilities, determining that the set of even elements of $\mathbf{Z}_{10}$ would form a subgroup, but deducing that the set of odd elements would not satisfy the closure property.

Team 4: Ritual Embedded in Explorative Activity

Team 4 began by identifying the trivial subgroup of the symmetric group S_3. Alan then asked, "Where do we start with the–?" Eric responded, "Yeah, just pick any couple of them and see what they generate." Eric thus explicitly frames his envisioned approach to the activity as an exploration, where they "pick" group elements and "see" what subgroup they generate. This explorative framing is consistent throughout Eric's portion of the transcript: "So if you include these ones, you need the whole group, is what we *discovered*." (emphasis ours).

However, Team 4's discussion is not without indicators of ritualized activity. At one point, Alan asks, "Dude, just a question, when we're composing, do we have to do it the other way too?" This question implicitly frames composition as a part of a prescribed routine that must be performed in a specific way. Assuming Alan's question is about whether closure requires one to be able to compose subgroup elements in different orders, this is a novel dilemma for the team: the instructor's prior example involved an abelian group. The team avoids the dilemma by discovering that the two permutations they used as starter elements generate the entire group, at which point the question is dropped; this suggests that the team's successful exploration supersedes the need to clarify procedural aspects of the subgroup generation "game."

In terms of personalization, we observe that while both Team 1 and Team 4 talk about the subgroup generation routine in terms of human actors performing operations on elements, Team 4 uses personalized language more often to refer to elements they "need": for example, "if we do this with all of them are we going to end up needing (1 3)? What if we did?" We hypothesize that the language of "needing" elements supports the team's communication about elements that must be in a subgroup without the use of conditional statements.

Discussion and Implications

In all four discussions, we see moments when team members are uncertain or disagree about the rules of the subgroup "game." We note two features in how students engage in the game.

Teams often attempted to resolve dilemmas by consulting a prior instantiation of the game, as one might when participating in a ritual whose rules are determined by an external authority. One might consider this antithetical to authentic mathematical activity: one powerful disciplinary norm in mathematics is that we resolve dilemmas by consulting foundational definitions and using deductive reasoning (see Dawkins & Weber, 2017). Second, we observed students engaging in personalization: rather than using abstract mathematical language, they introduce themselves or objects as acting agents. Again, this in some ways defies norms of valued activity in advanced mathematics. Further, literature on how students engage in abstract algebra content often suggests personalization as a deficit or lower level of reasoning (Hazzan, 1999). Others have suggested that using an "I" statement in reference to a quantified statement (in this case related to isomorphism) reflects the lowest level of development related to a quantified statement (Leron et al., 1995). If we were to use the standards of proof communication and disciplinary norms, we might view the student activity as lacking valued disciplinary qualities.

We wish to suggest an alternative, asset-based framing (cf., Adiredja, 2019) that interprets students' personalization and ritualized activity during an exploratory task not as evidence of a deficit with respect to acquisition of formal mathematics, but as resources that facilitate students' fluent participation in the task. We find that the students' personalization of the necessity of an element belonging to a subgroup due to the closure or inverse property (*e.g.*, "*You would need* at least the two [3-cycles] because they are inverses of each other"; emphasis ours) allows students to follow implications of hypotheticals without getting bogged down in the more demanding structure of conditional statements. Similarly, ritualization of the rules of the subgroup generation "game," and the opportunity to discern these rules from a worked example, offers students an alternative pathway to access the task even if, due to uncertainty about a definition or convention, they are unsure whether a certain "move" is permitted or required. This advances one of the goals of [*blinded project*]: to broaden access to mathematical activity beyond those students who quickly master the much more complex "game" of formal mathematics, whose rules are intricate and often difficult to decode. Further, we suggest that personalization and ritualized activity *are* reflective of disciplinary activity in meaningful ways. Weber and Melhuish (2022) argued that personalization is a key part of how mathematicians understand ideas highlighting metaphors and connection to their lives. Additionally, mathematicians also defer to outside sources of authority and have been shown to find arguments more convincing if written by respected authors (Inglis & Mejia-Ramos, 2009) and will defer to authoritative sources to assume validity (Weber & Mejia-Ramos, 2011). One of the main reasons mathematicians read proofs is to find ideas to transfer to their own research (Mejia-Ramos et al., 2012; Weber & Mejia-Ramos, 2011), which is also reflective of much of the students' ritualized activity.

Finally, we note that the instructor's choices of words in introducing the activity (*e.g.*, "game", action verbs such as "generate") likely had some influence on students' participation and discourse. We note that these word choices were reflected in student talk, and envision future work exploring ways in which careful orchestration of a task launch can invite students into exploration of open-ended problems with ritual playing a strategic and productive role.

Connecting Instructor Mathematical Knowledge for Teaching, Intercultural Competence, and Undergraduate Learning

Shandy Hauk
San Francisco State University

Billy Jackson
University of Wisconsin

JenqJong Tsay
University of Texas

We report on work to explore instructor intercultural competence and its relationship with the effectiveness of mathematics teaching in post-secondary settings. Results are from quantitative and qualitative inquiry into the mathematical knowledge for teaching and intercultural orientations of 15 instructors and 476 of their undergraduate students. Instructors participated to varying degrees in a professional short-course for faculty learning to teach mathematics for future grade school teachers. The greatest learning gains among undergraduates were in the classes of those instructor-participants who completed short-course activities about interculturally responsive mathematical knowledge for teaching future teachers.

Keywords: teacher preparation, intercultural competence, professional development, equity

Lee Shulman (1998), in reviewing the education of professionals (e.g., doctors, lawyers, teachers, clergy), noted six defining characteristics of a profession:

1. the obligations of *service* to others, as in a “calling”;
2. *understanding* of a scholarly or theoretical kind [e.g., mathematics, pedagogy];
3. a domain of skilled performance or *practice*;
4. the exercise of *judgment* under conditions of unavoidable uncertainty [e.g., instructional decision-making in classroom contexts];
5. the need for *learning from experience* as theory and practice interact; and
6. a professional *community* to monitor quality and aggregate knowledge. (p. 516)

These characteristics play out in a variety of ways. Item #1 includes the fact that:

> The professional educator’s challenge is to help future professionals develop and shape a robust moral vision that will guide their practice and provide a prism of justice, responsibility, and virtue through which to reflect on their actions. Medicine’s Hippocratic Oath, therefore, is a central manifestation of the moral foundations of a profession. (Shulman, 1998, p. 516)

Now, consider the current state of the art in the professional education of college mathematics instructors. What is clearly and explicitly offered to instructors for how to make morally and contextually complex judgment calls? Not much, yet (Braley & Bookman, 2022). Certainly characteristic #2 is accepted as essential (Herman, 2011) while #3, and how to measure it, has had increasing attention in the recent past (e.g., Castro Superfine & Li, 2014). If characteristic #4 is not well addressed early on, then the alternative is #5: Learn it from experience. Learning from experience requires a multifaceted mirror of reflective practice, one that instructors can use to see encounters with others as opportunities for professional learning about mathematics teaching. Both #5 and #6 are emerging as areas for research and development (e.g., among graduate students and novice faculty in their early teaching experiences).

Theoretical Perspectives

Professional growth is shaped by professional and personal cultures: dynamic social systems of values, beliefs, behaviors, and norms for a group, organization, or other collectivity in which the shared values, beliefs, behaviors, and norms are learned, internalized, and changeable by members of the group (McGrath et al., 1995). Many reports indicate that culture is a significant factor in the inequities of persistence and disparities in achievement in mathematics (e.g., Greer et al., 2009; Laursen & Rasmussen, 2019). University programs are responding (e.g., see Equity Alliance, equityalliance.stanford.edu). From anti-racism training to culturally responsive pedagogies, post-secondary instructor professional development efforts have emerged largely from the same arena as K-12 teacher education: psychology. Yet there is another area of the academy from which professional educators can draw insight: anthropology (Ladson-Billings, 2001). Psychology tackles professional education through an approach based in a teacher's *disposition,* attempting to change it through focused reflection on *behavior*; social anthropology offers the idea of movement along a developmental continuum of *orientation to differences* through focus on *relationships* and *communication*. In particular, healthcare and international relations professions offer theories of intercultural development and conflict resolution that are now being applied in education (e.g., Bennett, 2004; Hammer, 2009; Hauk et al., 2021; Hauk & Speer, 2022; Leininger, 2002; Wolfel, 2008). The core of intercultural orientation development is building skill at establishing and maintaining relationships in culturally complex situations.

Though some instructors have largely monocultural classrooms – in the sense that most students share experience of a particular set of cultural-general norms and practices – the nature of diversity in the U.S. is shifting from such segregated monocultural circumstances to cultural heterogeneity (Aud et al., 2010). We argue that intercultural competence is an essential component in the shift from teacher-centered to student-centered approaches to instruction. Knowing one's orientation, or the normative orientation of a group, can inform instruction. In particular, the authors are researchers in a project that has created professional learning for faculty new to teaching future K-8 teachers. Here we report on a small exploration into the results of infusing intercultural competence development into professional development.

Research Question: What evidence is there that intercultural orientation is part of the mathematical knowledge for teaching needed by post-secondary instructors to be effective in teaching future teachers?

Mathematical Knowledge for Teaching (MKT) and teaching future K-8 teachers

There are particular understandings and skills associated with effectively teaching children, a sociological synergy of mathematics and mathematics education called *mathematical knowledge for teaching* that encompasses types of *subject matter knowledge* and *pedagogical content knowledge* (MKT; Ball et al., 2008). Subareas of these include knowledge of the intended curriculum (Herbel-Eisenmann, 2007), "content knowledge intertwined with knowledge of how students think about, know, or learn this particular content" (Hill et al., 2008, p. 375); and knowledge about teaching actions and decision-making (e.g., productive ways to respond in-the-moment to students to support learning). All of the components of MKT are situated in a seventh aspect, *knowledge of discourses,* about communication in/with/through mathematics among people in and outside of the classroom (Hauk et al., 2014; Scheiner, 2019).

A related idea at the post-secondary level is *mathematical knowledge for teaching future teachers* (MKT-FT; Castro Superfine et al., 2013, 2014). A deep MKT-FT is vital in the student-centered and inquiry-oriented approaches to teaching shown to improve learning, increase persistence, and reduce inequities (Bressoud et al., 2015; Laursen et al., 2014). Generally, instructors build MKT-FT by learning from experience and professional community: grading, examining their own learning, observing and interacting with students or colleagues, reflecting on and discussing their own practice *and* the practices known to be effective in teaching (Kung, 2010; Speer & Wagner, 2009). Those with advanced degrees in mathematics who teach future teachers are faced with a need to connect mathematical learning by their future-teacher-students to the special mathematical knowledge needed for working with children as well (Castro Superfine & Li, 2014).

Model of Intercultural Competence Development

Our effort in applying the ideas of intercultural competence development to mathematics teaching and learning is based in the developmental model of intercultural sensitivity (Bennett & Bennett, 2004). The model ranges from a monocultural, ethno-centric view to an ethno-relative, intercultural view. Figure 1 is a schematic of the five benchmark orientations and developmental processes that support intermediate transitions.

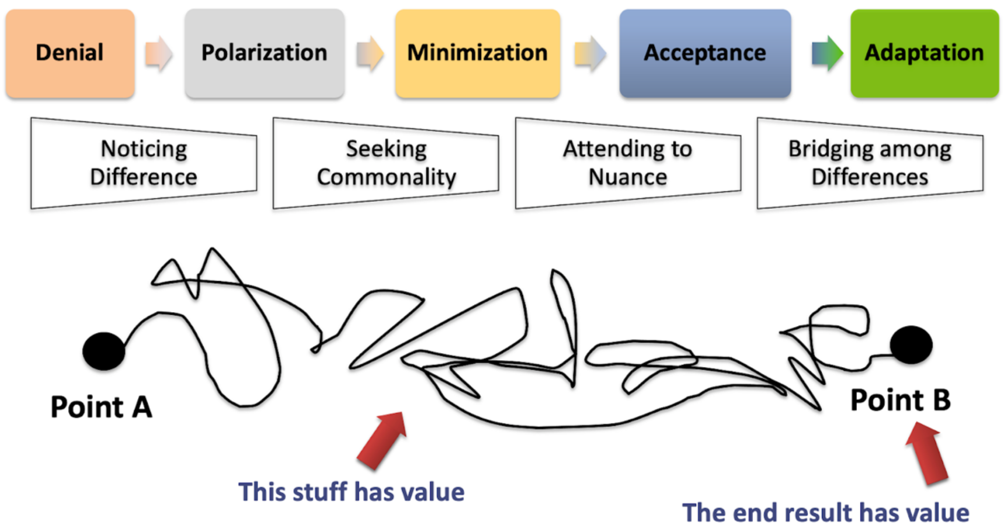

Figure 1. Milestones and processes for the intercultural development continuum.

The starting point of the continuum of orientations towards cultural difference, *denial*, is a lens for perceiving the world based on denying difference and assuming "Everybody is like me." A person with this orientation will avoid or express disinterest in cultural difference. The transition to the next benchmark, *polarization*, comes with the recognition of self as distinct from "other" through a noticing of difference. A polarization orientation can be driven by the assimilative assumption "Everybody *should* be like me/my group" where cultural differences is viewed in terms of "us" and "them." Transitioning *minimization* involves noticing commonalities beneath the surface differences, in particular a growing awareness of norms. This middle orientation is a minimization of difference, a lens for experience based on the idea, "Despite some differences, we really are all the same, deep down" and focuses on similarity and universals (e.g., biological similarities – we all have to eat and sleep; and presumed universal values). A minimization orientation will, however, ignore recognition and appreciation of subtle difference. Through increased attention to nuance in the differences that exist within noticed commonalities, one begins the transition to an *acceptance* orientation. Here, "accept" is used in its socio-cultural sense – the action or process of consenting to receive (rather than its psychological one – believe or come to recognize as valid or correct). Someone with an acceptance orientation has both some mindfulness of self as having a culture and awareness of moving among multiple cultures (plural). However, the importance of relative context, how to respond and what to respond in-the-moment of interaction with others is underdeveloped. The transition to *adaptation* involves developing culture-general frameworks for perception and behavioral shifts that are responsive to a full spectrum of detail in an intercultural interaction along with a concomitant awareness that one's own perceptions are limited and the whole picture is bigger than what is perceived. Adaptation is an orientation wherein one bridges cultural perspectives, without losing or violating one's authentic self, and adjusts communication and behavior in ways viewed as appropriate by each cultural group involved.

In the particular context of post-secondary mathematics teaching and learning, the continuum from ethno-centric to ethno-relative orientation may begin in a denial of difference (e.g., mathematics is acultural). Further development will go through a phase characterized by a tendency to polarize (e.g., there is one best or right way to solve every problem). From there, development can progress to a minimizing search for universals (e.g., there are "objective" or "mastery based" ways that are universally applicable to assess *all* students, and grades become the essential element of interaction for instructor and student, disconnected from students' mathematical funds of knowledge). With time and intentional development, one can learn more about mathematical ideas, contexts, and human interactions and reflect on teaching with greater attention to relational details (e.g., learning about implicit bias and suddenly noticing it in every word problem in the text), but how to use this knowledge to improve opportunities to learn, classroom climate, and interactions with others remains elusive. At its most developed, adaptation in mathematics teaching and learning involves networks of people and ideas; interactions can be anticipated (enough) that teaching responds to the needs of those involved (Hauk et al., 2014). Development along the continuum is not direct or linear. Folding back to previous orientations (particularly in times of stress) is common. Also, the time spent in learning about self and others during transitions and folding back hold value in developing more variety in the ways in which one perceives, makes sense of, and enacts culturally-informed relationships.

Methods

The *Professional Resources & Inquiry in Mathematics Education* (PRIMED) *for K-8 Teacher Education* project field-tested a 15-hour, 10-week online short-course for college instructors new to teaching future K-8 teachers. This online professional development (PD) experience covered topics such as mathematical knowledge for teaching, inquiry- and task-based learning, and tools for equitable instruction. The PRIMED experience was hybrid: Modules 2 and 5 included both asynchronous and live online activity-based work; the other three modules were sets of asynchronous web-based activities completed by instructors individually and in teams (see Figure 2). Participant teams rarely met in real-time and tended to check-in with each other by email or through online discussion boards.

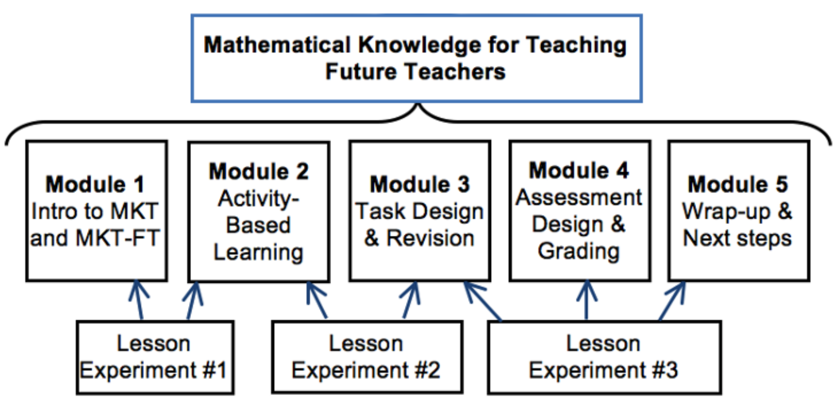

Figure 2. Overview of the PRIMED short-course for instructors new to teaching future teachers.

The short-course included consideration of MKT and MKT-FT in interculturally rich discourse contexts (e.g., examining a scenario where students are learning mathematics while also learning English as an additional language). Instructors had opportunities to learn about, witness (though video-clip-based activities) and practice (through lesson experiments) how to deal with the realities of negotiating the multiple experiences and relationships in a math-for-teachers classroom (see Jackson et al., 2020 for more on short-course development).

Each participating instructor agreed to complete research tasks and to include assignments in their course through which undergraduate students completed assessments of MKT. Instructors (n=15) and undergraduates (n=476) providing data for the study were from 12 different institutions of higher education (2 public community colleges, 7 master's granting universities [6 public, 1 private], and 3 doctorate-granting universities [2 public, 1 private]).

One of the project's main measures was the valid and reliable elementary grades number and operations *Learning Mathematics for Teaching* (LMT) assessment (Hill et al., 2008). Items on the LMT capture whether respondents correctly solve primary school mathematics problems as well as how they address teaching tasks (e.g., evaluating unusual solution methods, representing content to students, identifying adequate mathematical explanation). Instructors and their future-teacher-students completed the LMT at both the beginning and end of the semester in which instructors participated in PRIMED. Matched pre-post data were available for 12 instructors and 226 undergraduates. All also completed the Intercultural Development Inventory (IDI), a validated and reliable measure of intercultural development (instructor-participants did the IDI pre- and post-short-course, the undergraduates once, at the beginning). Also, each instructor had a PD involvement index (low, substantial, high) based on three characteristics: count of contributions to course online discussions, number of course tasks completed, and self-evaluation of effort. Though limited, these data allowed initial investigation of the relationships among PD, instructor and undergraduate MKT, and intercultural competence development.

Results

According to the LMT, faculty and their students gained MKT. The overall mean gain for instructors on the LMT was 0.5 standard deviations (sd) and for undergraduates was 0.29sd (see Figure 3, next page). Other research on prospective teacher learning has indicated that one semester of instruction in a course carefully designed and taught by an experienced teacher educator can lead to gains of up to 1sd (Castro Superfine et al., 2013). However, far smaller changes are usual (Phelps et al., 2016). When faculty have PD to strengthen their teaching, LMT gains among their students have been reported at about 0.25sd (Laursen et al., 2016). In the PRIMED study, when involvement-index is considered, average undergraduate learning gains were highest in the classes taught by instructors who participated most consistently in the short-course (student gain of 0.35sd), lower for those who skipped lesson experiments or modules (gain of 0.28sd for substantial participation group), and lowest for those who did only a few activities (0.13sd for this group).

The distribution of intercultural orientations for students was similar to that in previous research among pre- and in-service K-8 teachers (the majority at or before polarization). Figure 4 illustrates this along with the fact that the distribution of orientations for instructors was different from that of students (the majority at or after minimization) – which also is similar to results in other studies, (see Hauk et al., 2017 and references therein). That is, the distribution for students is rooted in polarization (seeing difference) while that for instructors is heaviest in minimization (minimizing difference and focusing on similarity). We have reported elsewhere on the challenges posed by the distinction (e.g., Hauk et al., 2015).

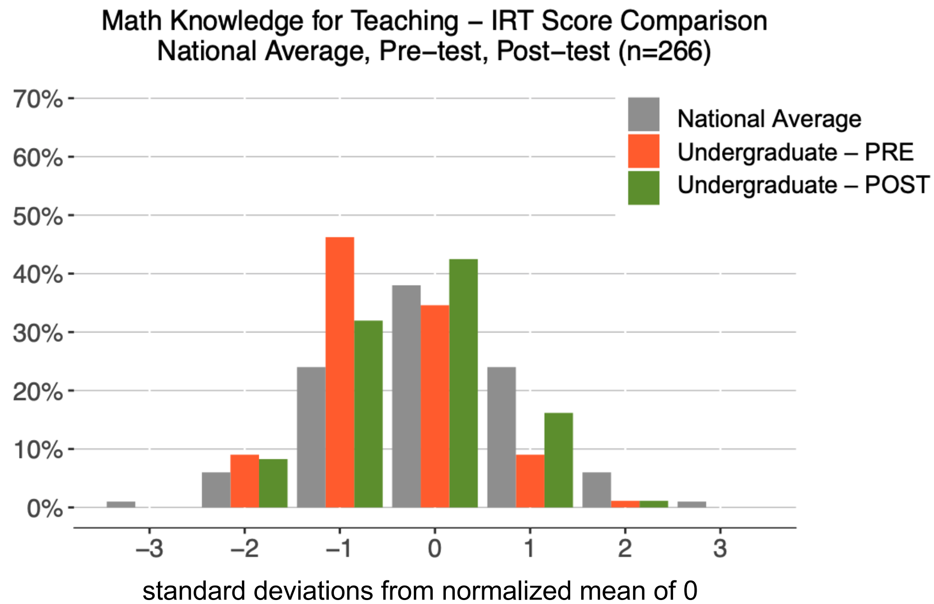

Figure 3. Comparison of LMT scores among future teachers

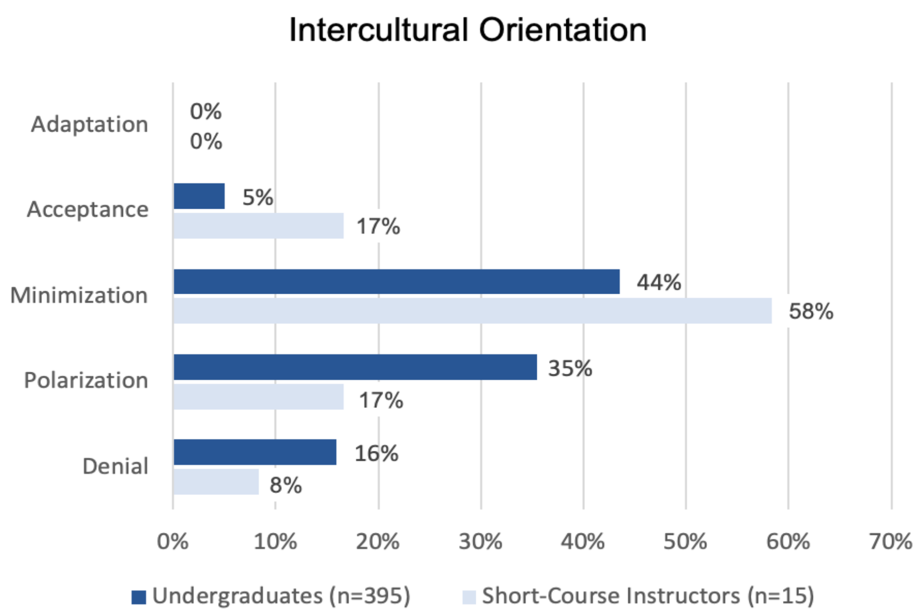

Figure 4. Pre-course IDI results as % of group for undergraduate students and instructor-participants.

Juxtaposing the two data sets, Figure 5 (next page) is a visualization of undergraduate student LMT average gains (horizontal) plotted according to the difference between the instructor and class average IDI orientations (vertical). The central boxed values indicate where the instructor and class (on average) had statistically insignificant differences in IDI score. Away from the central box the differences in IDI were statistically significant (p<0.5). For example, the dot furthest to the lower right is for a high-participation instructor (blue dot) whose class' polarization orientation was more interculturally developed than his denial orientation.

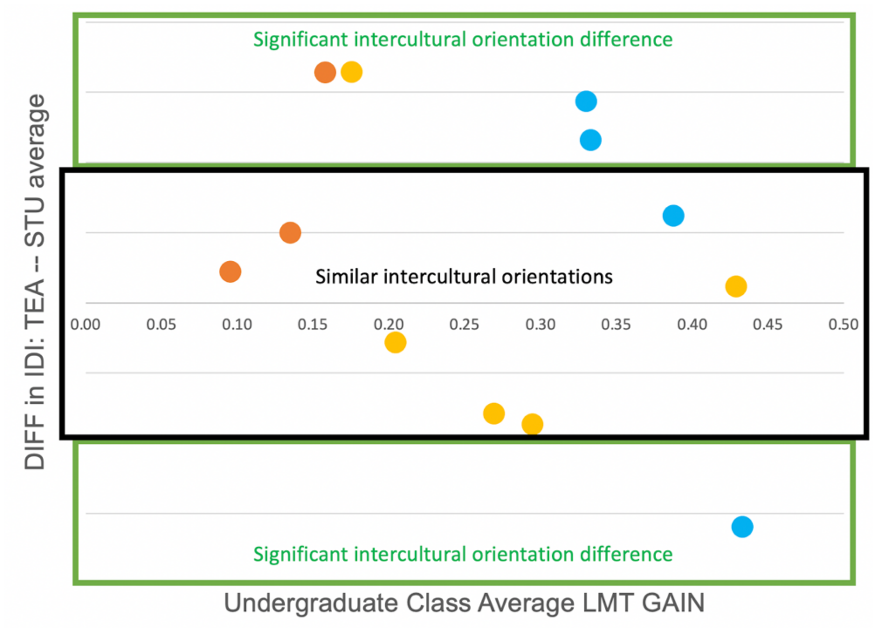

Figure 5. Scatterplot of student LMT gain by difference in IDI score. Dot colors indicate instructor level of participation in PRIMED (blue=high, yellow=substantial, orange=partial).

The research question driving the analysis sought insight into whether and how faculty intercultural competence development and MKT-FT development might be related to changes in undergraduate MKT. As indicated in Figure 5, instructors with high participation in the interculturally explicit PRIMED project had classes with the largest measured learning gains, even when there were significant differences between their own intercultural orientations and those of students. Figure 5 also suggests that PRIMED supported at least one instructor with a highly ethno-centric view to be effective with a diverse class group (rightmost dot in Figure 5).

Discussion and Conclusion

This study echoes, on a small scale, recent work on PD for inquiry-based learning in college settings that demonstrated an instructors' perceptions of their ability to enact behavior which they can control was positively associated with instructional practice aligned with PD aims (Archie et al., 2022). Our group continues to explore the relationships among intercultural competence, professional learning, and classroom practice (Hauk et al., 2017; Jackson et al., 2020). Finally, on a practical note, at the end of the short-course semester, three common goals for future professional learning emerged from participants, each related to interconnecting MKT and orientation:

(1) build *awareness of self as having a cultural lens for viewing the world* in a post-secondary mathematics/department culture that is distinct from the culture of K-12 teaching;
(2) find guidance in the transitions from minimization and into acceptance, particularly how to *be mindful of one's cultural filter(s) for interacting with the world*;
(3) engage in *building a knowledge base about equity*, including knowledge about culturally normative values and distinguishing these from essentializing or stereotyping approaches.

Acknowledgments

First, our thanks to the hundreds who participated in the PRIMED project. This material is based upon work supported by the National Science Foundation under Grant No. DUE-1625215.

Visualizing Conceptual Change: Using Lakatosian Conflict Maps to Analyze Problem Solvers' Structures of Calculus Definite Integral Tasks

William Hall
Washington State University

Serena Peterson
Washington State University

The work of Imre Lakatos has been influential in the philosophy of science and mathematics. His writings on how science and mathematics progress as fields have been utilized in mathematics and science education. In this study, we apply Lakatosian theory in analyzing task-based interviews. We use conflict diagrams to center the discrepant events participants experience while solving calculus tasks. In so doing, we illustrate how problem context plays a vital role in the evolution of problem-solver's structures in problem situations.

Keywords: Lakatos, Conceptual Change, Data Analysis

Qualitative data is rich. Researchers can present complex, nuanced perspectives on mathematical reasoning with interview data. However, rich data is often also dense and difficult to understand and/or overwhelming in scope. We present conflict maps as a tool for analyzing task-based interview data rooted in the Lakatosian theory of scientific and mathematical progress that illustrates the rich problem-solving that evolves over the course of a task-based interview. As an analytic tool applied to interview data, conflict maps present problem-solving strategies as they emerge and how they change. This highlights and makes evident moments of cognitive conflict.

Lakatosian conflict maps exist independently as pedagogical tools in science education (Tsai, 2000). In utilizing such maps, lessons are designed so that learners engage with discrepant events, moments where they perceive and must respond to a discrepancy between expectations and results. Specific discrepant events are regarded as critical events when alternative conceptions of science are engaged and evolve into traditional scientific conceptions. These critical events are identified by the instructor ahead of the lesson and result from the experiences of instructor and/or research on student thinking. Our research goal is to explore the usefulness of Lakatosian conflict maps as analytic tools for task-based interviews. In the current study, we illustrate their use in analyzing how undergraduate students solved calculus accumulation tasks. Our research question is what discrepant events emerge in the solving processes of individuals while solving calculus definite integral tasks?

Literature Review

Lakatosian Theory

In this study, we draw from the perspectives of Lakatos (1970). Lakatos claims that scientific theories do not progress linearly matching objective reality better as time goes on. Instead, Lakatos states that theories either progress or degenerate over time. Theory falsification does not happen immediately upon identifying a contradiction for Lakatos. Lakatos describes scientific theories as having both a "hard core" of central assumptions and a "protective belt" of auxiliary hypotheses (p. 133). Seemingly contradictory evidence can be redirected towards the protective belt instead of instantly disproving the theory outright. The hard core can be altered, but only after accumulating significant contradictory evidence that leads to the development of a new hard core and protective belt that explains the observations and makes new predictions. Within the domain of mathematics education, there have been several works to emerge utilizing Lakatosian principles. Larsen and Zandieh (2008) explore guided reinvention in abstract algebra using processes rooted in Lakatos' Proofs and Refutations methodology. Nunokawa applied Lakatos' theory to mathematical problem solving in many of their studies, specifically examining the "solver's structures of a problem situation" (Nunokawa, 1996, p. 274).

Enhanced Conflict Maps

Several researchers in science education have made explicit use of Lakatosian principles in their work. Specifically, they have connected these ideas with students' conceptual change and developed what are called (enhanced) conflict maps (Tsai, 2000; Oh, 2011, 2014). These maps serve as pedagogical tools for building effective science lessons. See Figure 1 for the template for an enhanced conflict map.

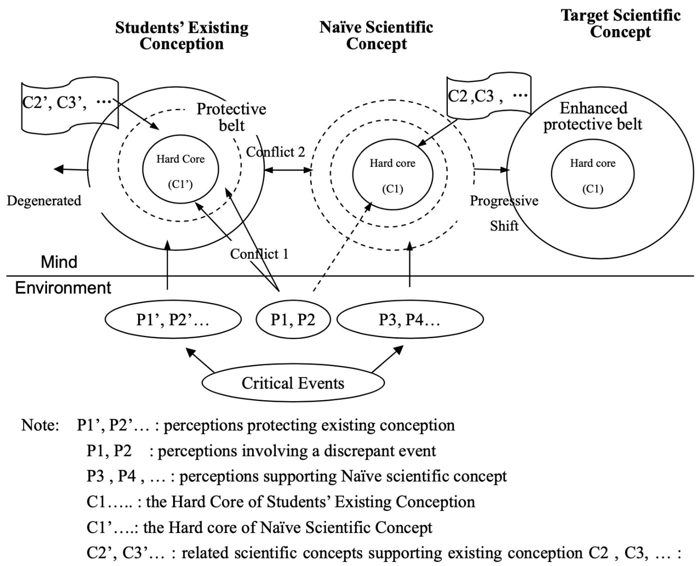

Figure 1. Enhanced Lakatosian conflict map Oh (2014)

Conflict maps have been utilized as pedagogical tools rather than analytical ones. These approaches map out how students are expected to move from one naïve or alternate conceptions to a scientific or mathematical one and include the planned events that (hypothetically) move students from one conception to the other. Ogbonnaya & Dimitriou-Hadjichristou (2022) illustrate such as approach in mathematics education, specifically for a student learning about surface area of a cone. We claim these diagrams can be used for the purpose of data analysis in research. Whereas discrepant and critical events have been presented intentionally by the instructor to move students through the various conceptions, we map these events as they occurred naturally during a task-based interview. This approach offers an alternative way to analyze qualitative data and provides an opportunity to reflect on analytic techniques in qualitative research based in visualization of data at several levels simultaneously, which may serve a researcher with neurodivergence better than traditional text-based techniques.

Theoretical Perspective

Problem Solving

Nunokawa (1994) defines problem solvers' structures as "structures given by the solver to the problem situation" and that "a solving process is described as a sequence of changes in the problem solver's representation structures" (p. 276). Nunokawa (1992) illustrated that the "sense" a problem-solver generates for a problem situation impacts the problem-solver's thinking during problem-solving. We use problem situation as Nunokawa does, to describe the in situ problem-solving environment as perceived by the participant.

Knowledge as an Adaptive Function

A view of knowledge as an adaptive function played a key role in the data analysis in this study. von Glasersfeld (1982) claims "knowledge for Piaget is never (and can never be) a 'representation' of the real world. Instead it is the collection of conceptual structures that turn out to be adapted, or as I would say, viable within the knowing subject's range of experiences" (p. 4). Viability is the crucial idea. Just as with the evolution of an organism in an ecosystem, what students learn is not driven by matching some objectively true reality, but what the student finds viable. For this study, the personal ecosystem is what Nunokawa calls the problem situation**,** and the problem-solver's structures exist (and thrive or perish) within that ecosystem. von Glasersfeld states that "in the sphere of cognition, though indirectly linked to survival, equilibrium refers to a state in which an epistemic agent's cognitive structures have yielded and continue to yield expected results, without bringing to the surface conceptual conflicts or contradictions" (p. 5). This is the heart of the concept of viability in constructivism, that learning is the development and application of stable cognitive structures.

Methods

This study concerns data from a broader study of the ways students reason in calculus accumulation tasks. In the broader study, twelve (12) undergraduate students participated in task-based interviews lasting approximately one hour. Participants in the study were undergraduate students from a large research university in the United States. All had majors or intended majors in the biological or life sciences and were solicited from across various upper and lower division undergraduate courses. Participants solved five calculus tasks concerning accumulation and rate of change set within contexts relevant for biological and life science students. In this study, we focus on one of the tasks and how students processed moments of conflict in their problem-solving work.

> Interview Task: The greenhouse effect is the rise in temperature that the Earth experiences because certain gases prevent heat from escaping the atmosphere. According to one study, the temperature is rising at the rate of $R(t)$=0.014$t^{0.4}$ degrees Fahrenheit per year, where t is the number of years since 2000. Given that the average surface temperature of the Earth was 57.8 degrees Fahrenheit in the year 2000, predict the temperature in 2200.

Diagramming the evolution of problem structures

Diagrams were created to visualize the evolution of problem solvers' structures during their work. Each diagram represents a student's full solution strategy for one interview task. Each diagram illustrates the central assumptions problem solvers made about the given rate of change function, this is referred to as the hard core of their problem structure. The hard core is surrounded by a belt of supporting concepts, assumptions, and calculations that the participant accepts as viable given their current assumptions. When contradictions arise, these are visualized externally to the current structure in the diagram. These are discrepant events for the participant. Each idea within the belt is presented chronologically how it appeared within the interview, read from top to bottom. The diagrams were first sketched by hand and then they were transferred to PowerPoint. The diagrams were validated using external checks, other expert researchers reviewing and providing feedback comparing the diagrams to the interview transcripts.

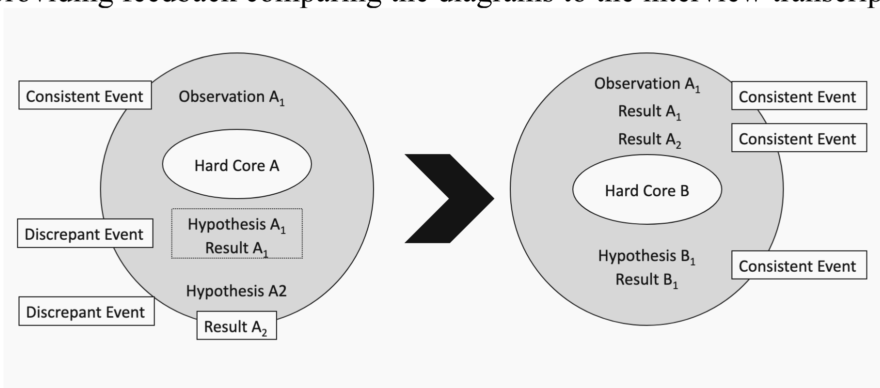

Figure 2. Theoretical problem structure diagram

In this report, we describe the discrepant events for eight of the participants. We focus on only those diagrams with discrepant events and identify the nature of those events and whether/how they were resolved. Figure 3 shows a theoretical problem structure diagram.

Results

We present the problem structure diagrams for two participants, Jake and Brenda. These visualizations capture the participants' full work on the task and what they recognized as viable and what discrepant events they experienced.

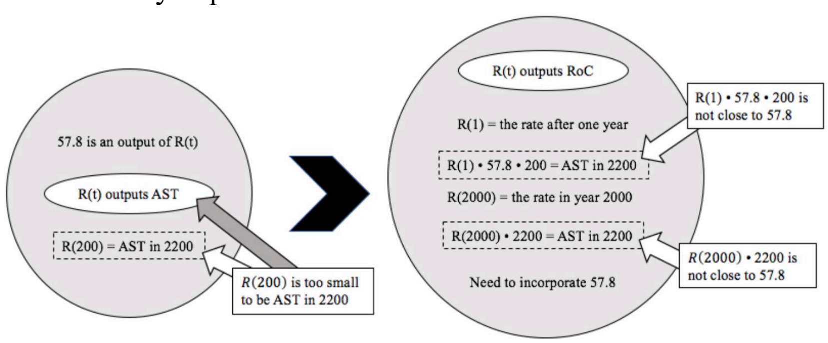

Figure 3. Problem structures diagram for Jake

In Jake's first problem structure, he claims the output of the function for t=200 will be the average surface temperature for the Earth in the year 2200. Jake's observation that R(200) is too small to the be average surface temperature is a discrepant event, similar to the case of Brenda. Jake formulates a new assumption about the values of the function R(t), namely that the outputs are rates of change. While this is accurate, his calculations lead him astray and new discrepant events result.

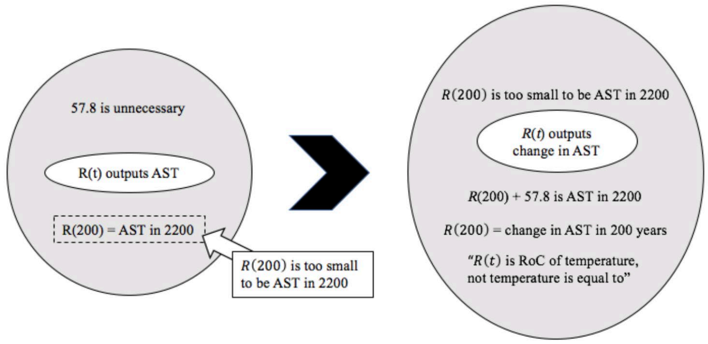

Figure 4. Problem structures diagram for Brenda

Table 1 contains a summary of the discrepant events observed in the eight participants under consideration. Each of the participants reasoned about the size of the value they calculated in relation to their expectations for climate change and the initial given temperature. Several others utilized the setting of the interview in reflecting on discrepant events or their work on other task.

Table 1. Summary of discrepant events

Participant	**Discrepant event description**	
Jane	Value is too low for AST(2200)	
	R(0) not 57.3	R(2000) very small
Anne	R(200) too small for AST(2200)	
	Interviewer direction	Work on Task 5
Shauna	R(200) too small for AST(2200)	
Andy	R(200) too small for change in temperature	
	Computed value too large for AST(2200)	Computed value too small for AST(2200)
Ron	R(200) too small for AST(2200)	
	R(200) too small for change in temperature	Work on Task 5
Jake	R(200) too small for AST(2200)	
	Computed value not close to 57.3	
Brenda	R(200) too small to be AST(2200)	
Gina	R(200) too small to be AST(2200)	

Discussion and Questions

Our research question is: what discrepant events emerge in the solving processes of individuals while solving calculus definite integral tasks? Most of the discrepant events observed involved the context of the task. Participants assessed the viability of their assumptions by using their expectations and knowledge of the context. The calculated values being either unreasonably low or high for the context of average surface temperature of the Earth was often a key indicator that assumptions were not viable. Questions for discussion: What are the benefits of adopting this analytical approach in mathematics education research? How can Lakatosian conflict maps benefit us in analyzing student thinking as they work through a task or broader concept? We feel visualizing interview data on problem solving math tasks leads to greater accessibility. We also believe the diagrams preserve the participants' voice, their authentic ideas as opposed to solely the researchers' perspective of the work.

A Genre Analysis of Mathematical Remarks

Valentin A. B. Küchle
Auburn University

This report describes the preliminary results of a genre analysis of mathematical remarks, which was conducted using Bhatia's (1993) seven-step genre analysis model. As part of the analysis, discussion threads on Mathematics Stack Exchange about mathematical remarks were analyzed as well as a corpus of remarks from first-year mathematics lecture notes of a British university. An overarching communicative purpose and seven non-mutually exclusive "mini communicative purposes" (Hyon, 2018, p. 30) of the genre of mathematical remarks are identified.

Keywords: Discourse, Genre Analysis, Mathematical Remarks

The American Mathematical Society's (AMS) Publications Technical Group (2017) observed:

> In mathematical research articles and books, theorems and proofs are among the most common elements, but authors also use many others that fall in the same general class: lemmas, propositions, axioms, corollaries, conjectures, definitions, remarks, cases, steps, and so forth […] (p. 2)

To account for differences between elements of this list, the amsthm package supports three theorem styles: plain (e.g., for theorems and lemmas), definition (e.g., for definitions and axioms), and remark (e.g., for remarks and notes). By being named alongside theorems and proofs as well as receiving their own theorem style by the AMS, "remarks" hold a privileged place in the writing of research mathematicians. The purpose of the study outlined in this report is to describe the genre of mathematical remarks using genre analysis, in particular by using Bhatia's (1993) seven-step genre analysis model.

As my work is of preliminary nature, I will only elaborate on a subset of the seven steps (i.e., steps 1, 2, 4, and 6). Further, in the interest of space, I will only report on findings regarding the communicative purposes of the genre of mathematical remarks, that is, I omit my findings regarding the form of the genre. This choice is motivated by the definition of genre I draw on (i.e., Swales's [1990] definition), which places communicative purpose at the center of a genre. Thus, this report's overarching question, which also guides much of the genre analysis, is: What are the communicative purposes of mathematical remarks?

Background Literature

As discussed by Hyon (1996) as well as Bhatia and Salmani Nodoushan (2015), researchers from three different (Anglophone) research traditions have sought to study genre: (a) New Rhetoric studies, (b) systemic functional linguistics (SFL), and (c) English for Specific Purposes (ESP). But, as Bhatia (2012) remarked, "[g]enre theory, in spite of these seemingly different orientations, covers a lot of common ground" (p. 241). For an in-depth comparison of the three traditions, see Hyon (1996) and Hyon (2018). In short, differences between the traditions that were more pronounced in the 1980s and 1990s have begun to fade in recent times with particularly the New Rhetoric and ESP traditions having ever-greater overlap (Hyon, 2018). I draw on the ESP tradition and provide a few brief remarks on this tradition below.

English for Specific Purposes

The ESP tradition of genre theory draws on Swales's (1990) definition of genre, which—in abbreviated form—reads:

> A genre comprises a class of communicative events, the members of which share some set of communicative purposes. […] In addition to purpose, exemplars of a genre exhibit various patterns of similarity in terms of structure, style, content and intended audience. (p. 58)

Building on Swales's (1990) definition of genre, Bhatia (1993) developed a seven-step genre analysis model attending to purpose and form: (a) placing the given genre-text in a situational context, (b) surveying existing literature, (c) refining the situational/contextual analysis, (d) selecting corpus, (e) studying the institutional context, (f) levels of linguistic analysis, and (g) specialist information in genre analysis. As Bhatia (1993) explained about these seven steps:

> These steps have been artificially separated for the sake of convenient formalization and systematic discussion. Moreover, it is not the intention to suggest that in all such investigations, the analyst must go through all the stages listed above and certainly not in that order. (p. 40)

For an application of Bhatia's (1993) model, see Singh et al. (2012). For four reviews of Bhatia (1993)—as well as his response to these reviews—see Nielsen et al. (2017).

Method

Data Collection

I collected two sets of data, each for a different step of Bhatia's (1993) seven-step genre analysis. For step 2 (i.e., surveying existing literature), I compiled all discussion threads related to mathematical remarks I could find on Mathematics Stack Exchange (MSE). The search was conducted on August 29, 2022 and consisted of searching for "remark" using the MSE search function. The top 500 results (sorted by "relevance") were then examined to determine whether the question asked pertained to conventions about writing mathematical remarks. I then inspected each discussion thread's "related" section to find any additional remark-related questions but found none. All ten relevant discussion threads were downloaded.

For step 4 (i.e., selecting a corpus), I compiled all remarks from the PDF lecture notes of all mandatory courses for first-year mathematics majors at my British undergraduate institution. These eight courses are: Foundations, Differential Equations, Analysis 1 & 2, Introduction to Abstract Algebra, Linear Algebra, Mathematics by Computer, and Geometry & Motion. These PDF files were written by the lecturers of these classes and uploaded or sold (in printed form) by the mathematics department (before or after the semester) for a small fee (£1–3). During the compilation process, three situations occurred: (a) remarks were the notes' only labeled exposition (in which case the remarks were included), (b) remarks were not the notes' only labeled exposition (in which case only the remarks were included), or (c) the notes contained no exposition labeled as remarks, only exposition labeled as "note" (in which case the "note"s were included). "Note"s were excluded (case b) or included (case c) to account for some authors possibly using the term synonymously with remarks, whereas others may have chosen to make a distinction. I ended up with a corpus of 31 remarks.

Given the preliminary nature of this work, rather than trying to create a large representative corpus of remarks (e.g., by compiling remarks from talks, lecture notes, textbooks, and research papers), I chose to focus on remarks from first-year lecture notes because this corpus was of a manageable size. Further, I suspected that this corpus might emphasize different communicative purposes than the discussion threads on MSE—a difference of pedagogical interest to me. Thus, for step 6, I am studying the communicative purpose(s) of a sub-genre of mathematical remarks: the remarks made to first-year British mathematics majors in lecture notes.

Data Analysis

To analyze the genre of mathematical remarks, I am using Bhatia's (1993) seven-step genre analysis model. The four steps I detail in this report are steps 1, 2, 4, and 6. For step 1 (i.e., placing the given genre-text in a situational context), I drew on my knowledge and experience. Step 4 (i.e., selecting corpus) has already been described in the Data Collection.

For step 2 (i.e., surveying existing literature), I analyzed the MSE discussion threads by using structural coding (Saldaña, 2009) to identify segments of the data that: (a) asked a question (or made an assertion) about the form of mathematical remarks (e.g., "Can I have a 'remark' after a 'lemma' before its 'proof'?"), or (b) asked a question (or made an assertion) about the purpose of mathematical remarks (e.g., "Remarks may also be used to provide motivation"). As described in the introduction, I will only report on the latter analysis in this report.

For step 6 (i.e., levels of linguistic analysis), Bhatia (1993) outlined three levels of linguistic analysis for analyzing one's corpus. I report on my level 3 analysis (i.e., the largest grain size), which Bhatia (1993) referred to as structural interpretation of the text-genre. Such an analysis may break down a genre into different moves, each of which has its own "mini communicative purposes" (Hyon, 2018, p. 30). Given that remarks are typically short texts of only a few sentences, I considered it unlikely to find a series of moves the genre follows. Nevertheless, I used the idea of "mini communicative purposes" to identify different sub-purposes that remarks can have. To identify these purposes, I process coded (Saldaña, 2009) the remarks in my corpus.

Preliminary Results

As Bhatia (1993) specified, researchers need neither follow all his steps nor follow them linearly. With this in mind, I share my preliminary results for steps 1, 2, and 6 below.

Step 1: Placing the Given Genre-Text in a Situational Context

To place the given genre-text in a situational context, Bhatia (1993) encouraged analysts who come from the relevant speech community to draw on their own experience and background knowledge. As a mathematics education researcher with a background in mathematics, I am familiar with the communication of proof-based mathematics and consider myself a member of the relevant speech community. Thus, in this section, I share experience-based observations I made before beginning my analysis. For the purposes of this report, I include only my observations about the communicative purpose(s) of mathematical remarks.

Context. Most of my relevant experience comes from studying mathematics at a British university. Lectures at the university consisted of a chain of labeled "blocks" (e.g., definition, theorem, proof, remark). These blocks—including remarks—were both spoken and written. Remarks were announced in spoken discourse (e.g., "Let me make a remark.") and written discourse (e.g., "<u>Remark:</u> The function …"). The only spoken discourse not recorded on the boards was unlabeled exposition, whose purpose it typically was to motivate material.

Communicative purpose. A remark's purpose is to highlight a piece of information that does not fit into the mathematical quartet of definition, statement-to-be-proved, proof, and example but is too important to be left as unlabeled exposition. Remarks can, for instance, relate one theorem/proposition/lemma to another (e.g., one being a special case of another), warn the reader about a potential confusion, indicate an alternative proof, highlight an idea or nuance that may have been lost amid mathematical notation, or share an alternative notation.

I suspect that the distribution of communicative purposes of remarks in a text depends on the intended audience. For instance, "highlighting an idea or nuance that may have been lost amid mathematical notation" might be a more prevalent purpose for remarks aimed at newcomers to proof-based mathematics, whereas remarks "relating one theorem/proposition/lemma to another" might be more prevalent when the audience is research mathematicians.

Step 2: Surveying Existing Literature

In his call to survey existing literature, Bhatia (1993) took an expansive view of possibly pertinent literature. Particularly relevant to this study is the inclusion of practitioner advice. Thus, as described under "Data Collection," I searched MSE for "remark" and found ten relevant discussion threads. After analyzing the discussion threads, I identified the following purposes of mathematical remarks:

1. to be able to refer to some piece of exposition (this requires that the remarks are numbered);
2. to draw attention to a piece of exposition;
3. to isolate (important or noteworthy) exposition tangential to the main exposition;
4. to give the reader a break (e.g., with an historical anecdote);
5. to provide motivation;
6. to state why some hypotheses are necessary or natural;
7. to state why one cannot hope to get stronger results;
8. to justify a seemingly unnecessarily circuitous route;
9. to address a potential distraction in the reader's mind;
10. to point out pitfalls; and
11. to point out (and possibly explain) the following of a certain convention.

Step 6: Levels of Linguistic Analysis

Analyzing my corpus of mathematical remarks, I identified the following non-mutually exclusive (mini) communicative purposes of remarks:

1. justify the author's choices on a meta-level (e.g., why they made a particular choice);
2. respond to a possible reader assumption or reaction (e.g., pointing out a pitfall);
3. point out something the reader may have overlooked (e.g., pointing out a border case, pointing out an additional implication);
4. introduce new or different notation and terminology;
5. point out an alternative (e.g., to a definition, an equation);
6. give advice; and
7. share background or additional context (e.g., historical anecdote, practical application, related concept).

As aforementioned, these "mini-purposes" of remarks are not mutually exclusive and, while studying their intersections, one combination of moves stood out due its frequency and structure: purpose 2 followed by purpose 7. That is, around half the time, in addition to responding to a possible reader assumption or reaction, authors chose to share background or additional context.

Discussion

Synthesizing across steps 1, 2, and 6, I observe that there are different grain sizes of communicative purposes of mathematical remarks. The overarching communicative purpose appears to be to separate some exposition from the main exposition—either for elevation or isolation. For example, whereas some remarks warn of a pitfall and are numbered to be able to refer to them more easily (i.e., elevated exposition), other remarks isolate exposition tangential to the main exposition to the extent that they can be skipped—one of the analyzed remarks even included the phrase “feel free to ignore this remark.” Discounting the possibility of reverse psychology, mathematical remarks are thus sometimes (almost) integral (elevated exposition) and at other times skippable (isolated exposition). I suspect this duality may leave novice readers of proof-based mathematical texts wondering whether remarks can be skipped or not.

Moving to the mini purposes (or sub-purposes) of mathematical remarks, I offer the following synthesized list of mini purposes from steps 1, 2, and 6 of my genre analysis:

1. justify the author’s choices on a meta-level (e.g., why some hypotheses are necessary or natural, why one cannot hope to get a stronger result, why one took a seemingly circuitous route, why one made a particular choice);
2. respond to a possible reader assumption or reaction (e.g., pointing out a pitfall, addressing a possible distraction in the reader’s mind);
3. point out something the reader may have overlooked (e.g., pointing out a border case, pointing out an additional implication, pointing out that B is a special case of A);
4. introduce new or different notation and terminology;
5. point out an alternative (e.g., to a definition, an equation, a proof);
6. give advice; and
7. share background or additional context (e.g., historical anecdote, practical application, related concept).

As the step 6 analysis showed, these purposes are not mutually exclusive and there may be some that combine more frequently (e.g., purpose 2 followed by purpose 7). As aforementioned, I also hypothesize that some purposes (e.g., sharing background or additional context) may lead to remarks which authors consider more ignorable than remarks with other purposes (e.g., responding to a possible reader assumption or reaction).

During the analysis, I also observed three differences between the mini communicative purposes identified in steps 2 and 6. First, the discussion threads seemed to emphasize purpose 1—a purpose only seen once in the lecture notes. Second, purpose 6 appeared in the lecture notes but did not explicitly appear in the discussion threads. Third, purpose 3 appeared in the notes but not in the discussion threads. (This last observation is partially in line with my suspicion voiced in pre-analysis step 1.) I am left wondering to what extent these differences are due to a difference in intended audience.

Compiling the corpus, I encountered a large variety of labeled exposition: “advice,” “aside,” “comments,” “digression,” “notation,” “note,” “observation,” and “warning.” Comparing these to the mini purposes, some similarities appear: warning (purpose 2), observation (purpose 3), notation (purpose 4), advice (purpose 6), and digression and aside (purpose 7).

Finally, I wish to share with the reader two of my wonderings: (a) What are the pedagogical ramifications of the mini purposes and the duality of the central purpose(s) of remarks? and (b) What possibilities would applying genre analysis to other mathematical genres offer?

Acknowledgments

I would like to acknowledge Dr. Jack Smith, who alerted me to the peculiarity of mathematicians announcing they were about to say something, that is, make a remark.

Utilizing Cognitive Interviews to Improve Items That Measure Mathematical Knowledge for Teaching Community College Algebra

Bismark Akoto
University of Minnesota

Dexter Lim
University of Minnesota

Irene Duranczyk
University of Minnesota

The Algebra Instruction at Community Colleges: Validating Measures of Quality Instruction project (VMQI) developed an instrument to measure mathematical knowledge for teaching community college algebra (MKT-CCA) and conducted cognitive interviews with 12 community college instructors of College Algebra. Thirty-six drafted MKT-CCA test items were reviewed with each item being reviewed by two instructors. This paper presents the lessons learned from this preliminary analysis of the cognitive interview transcripts.

Keywords: Cognitive interviews, mathematical knowledge for teaching, community college, college algebra

Introduction

The Algebra Instruction at Community Colleges: Validating Measures of Quality Instruction (VMQI) is a National Science Foundation-funded project that is developing an instrument to (1) measure mathematical knowledge for teaching community college algebra (MKT-CCA) and (2) identify the dimensionality of this knowledge. We began by situating our conceptualization of mathematical knowledge for teaching vis-a-vis one of the most common conceptualizations produced by Deborah Ball and colleagues (Ball et al., 2008; Hill et al., 2008). Ko and Herbst (2020) further proposed organizing the subject matter knowledge in Ball et al.'s framework by tasks of teaching. To move this work further in community colleges (CC), we have hypothesized to measure two main constructors, Tasks of Teaching (Choosing Problems and Understanding Student Work) and Function Types (linear, exponential, and rational functions that are foundational for advanced work in calculus) (see Figure 1). This conceptualization of algebra knowledge for teaching framed the instrument's development. Cohen and Swerdlik (2009) outline the development of an instrument in five main stages: conceptualization, construction, tryout, analysis, and revision. In the construction stage, cognitive interviews (CIs) play a significant role.

Cognitive interviews are an important qualitative method used by researchers to discern interviewees' understanding of survey items (Meadows, 2021; Willis, 2005). As part of the development of our MKT-CCA instrument, we conducted CIs with CC college algebra instructors to understand whether the items we developed to assess the dimensions (see Figure 1) are interpreted by respondents as intended and whether the participants used the intended knowledge (Mesa et al., 2020-2023). We used the following research questions to guide the analysis.

1. How do CC college algebra instructors interpret our developed items in relation to the dimensions of our blueprint?
2. What knowledge do CC college algebra instructors use to respond to the MKT-CCA instrument?

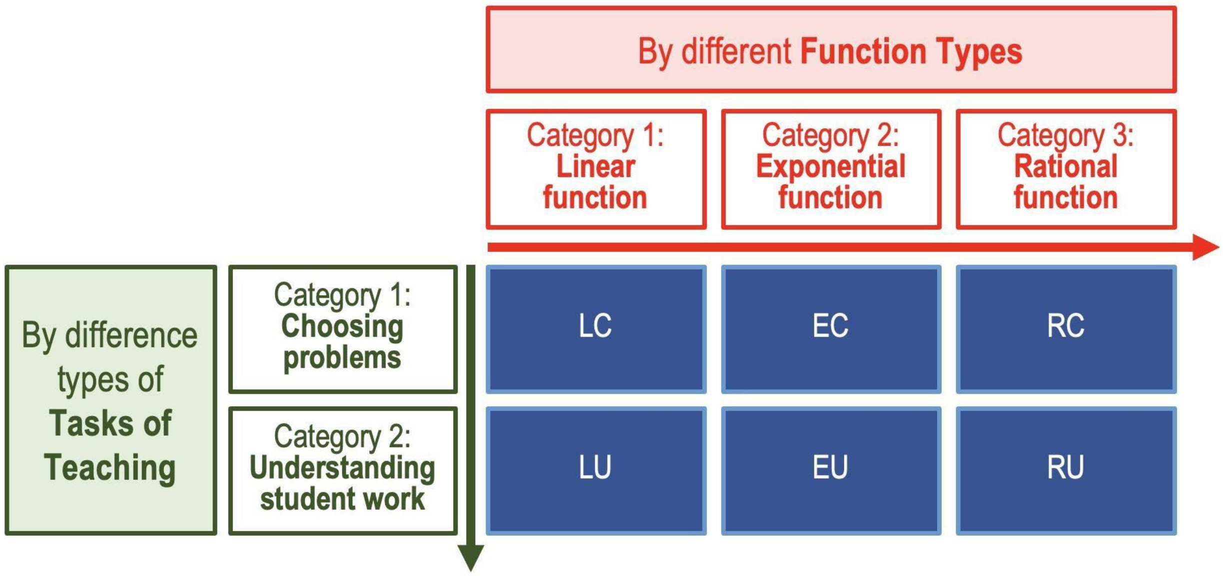

Figure 1. MKT-CCA blueprint showing its six dimensions.

Method

Materials and Procedures

Research on CIs suggest conducting "rounds" that consist of 5 to 15 interviews, which are ideally repeated following efforts to revise questions and eliminate problems (McColl, 2001; Willis, 1994, 2005). After the initial instrument construction and before piloting the instrument, CIs provide information to evaluate whether the items proposed uses the knowledge that is intended. Typically, CIs are planned to take a 3:1 ratio (Willis, 2015) of time (three times more than it would take to answer the item without think-aloud or probing). As a team, we decided to limit interviews to at most 90 minutes to eliminate fatigue (D'Ardenne, 2015). For this reason, we sent two items out of six planned for each respondent, ahead of time so that respondents could think about them and take notes beforehand. By doing this, we anticipated that we could average 12 minutes per item during the CIs. At the time of our CIs, our item pool consisted of 60 draft items that we had deemed ready for review. The 36 items selected (six items per dimension) would provide us with the information to understand whether the draft items were interpreted by respondents as intended, used the knowledge we thought was needed, and targeted the dimensions of the MKT-CCA blueprint.

We developed a protocol that we agreed to use for all interviews. Three teams of two researchers each performed the interviews (one person would be asking the questions, whereas the other was in charge of taking field notes and managing technical aspects). Each team interviewed four participants. We selected 36 items with the goal of having each item be reviewed by two participants. All interviews were conducted online in the last week of July 2021 using Zoom with screen sharing, and audio and video recording with transcription. We used Jamboard to present the items one at a time since it allows for real time documenting the participants' item solving process. We gave each participant two items to work on ahead of the interview and asked them to send us the documentation of their work before the scheduled interview. We asked them to keep track of how long it took them to complete each item. The interview protocol asked for their impressions of the content of the item, whether the content was relevant to their work, the answer they chose and their reasoning, and the reason(s) for eliminating other options.

Analysis

In this paper, we use the interview response from a respondent on an item as our unit of analysis. This gave us a total of 72 (one missing data point due to time restraint) interviews on 36 items. All the interviews were fully transcribed and summarized. The field notes were also coded. Analysis was done in two phases. The first phase focused broadly on answering whether respondents (a) choose the correct answer, (b) use correct reasoning in choosing the answer, (c) choose an incorrect option with correct reasoning, and (d) refer to the dimensions of the blueprint. This phase of coding was done by five members of the research team.

The second phase involved adapting Conrad and Blair's (1996) cognitive coding scheme and was done by the three authors. The coding scheme proposed attending to three categories: *Understanding the Intent*, *Performing the Primary Task,* and *Formatting the Response*. Conrad and Blair used *Understanding the Intent* to code the respondents' comprehension and appreciation of the researcher's objectives; *Performing the Primary Task* was used to code how well the respondents were able to retrieve information from memory, do mental arithmetic and evaluate a response. *Formatting the Response* was used to map how respondents responded to prespecified answer options. We adapted this coding scheme for our purposes as follows:

Understanding the Intent. This category examined whether the respondent was able to place the item in a dimension of our blueprint. Did the respondent recognize both the task of teaching and the function type? We coded a yes if the respondent recognized both the function type and the task of teaching, a partial if only one was identified and a no if neither was present.

Using Knowledge. This category examined whether the respondent understood the instructional goal embedded in the stem. Did the respondent reason about the stem in ways that conformed with our reasoning? Did the respondent use mathematical knowledge to make sense of the stem? Did the respondent's response indicate whether the stem was clear? Did the respondent give any indication of confusion of the stem? Did the respondent understand the context presented in the stem? This included instances where the wording was not clear but did not include situations in which the respondent did not understand the mathematical ideas or terminology in the stem. We coded the response as yes if it indicated a clear understanding of the stem, partial if the understanding was not clear and no if the response indicated that the respondent did not understand the stem.

The stem is the part of the item that defines the mathematical task. It is followed by possible solutions (optional answers).

Formatting the Response. This category examined whether the respondent's reasoning on the options was mathematically correct or aligned with our template. Was the respondent's correct or incorrect selection of options and elimination of distractors expected? We coded the formatting as expected if the justification matched our template intent or was found to be mathematically reasonable. It was coded as problematic when the respondent gave a correct answer or eliminated an option for the wrong reasons, when the reasons could not be mathematically justified, or when the justification given did not conform to our intent. It was coded as partial if the response was a mix of expected and problematic.

Findings

We present the preliminary findings of our analysis in this section. Table 1 shows the summary of the analysis using the three categories. Overall, 88.73% of participants' responses showed a recognition of the function type and task of teaching, 85.92% of responses showed an understanding of the stem and 61.97% of participants responses to the items had mathematically appropriate justifications.

Table 1: Percentage of Responses to the Individual Items (N=72).*

Dimension of Blueprint	Understanding the Intent			Using Knowledge			Formatting the Response		
	Yes	Partial	No	Yes	Partial	No	Expected	Partial	Problematic
EC (n=12)	100.0	0.0	0.0	91.7	0.0	8.3	66.7	8.3	25.0
EU (n=12)	91.7	8.3	0.0	91.7	8.3	0.0	66.7	0.0	33.3
LC (n=11*)	100.0	0.0	0.0	90.9	9.1	0.0	45.5	0.0	54.5
LU (n=12)	83.3	16.7	0.0	91.7	0.0	8.3	100.0	0.0	0.0
RC (n=12)	66.7	25.0	8.3	83.3	8.3	8.3	41.7	0.0	58.3
RU (n=12)	91.7	8.3	0.0	91.7	0.0	8.3	50.0	8.3	41.7

*One data point is missing. One participant only responded to five items.

Research Question One

Research question one sought to answer how CC college algebra instructors interpret our developed items in relation to the dimensions of our blueprint. This will be addressed using the *Understanding the Intent* code.

Understanding the Intent. As expected, preliminary analysis shows that participants mostly indicated a recognition of the function type of the items with only one exception. However, it was noted that the function type was mentioned in the stem of the item and is likely to be the reason the participant did not mention it in the interview. One main observation noted is that participants mostly were able to identify the task of teaching except in the case of choosing problems for rational functions where we observe a 33.3% of responses not indicating the task of teaching.

Research Question Two

We wanted to know what knowledge CC college algebra instructors will use to respond to the MKT-CCA instrument for research question two. We will apply the *Using Knowledg*e and *Formatting the Response* codes for this research question.

Using Knowledge. Participants demonstrated an understanding of the instructional goal in the stem for most of the items. With the exception of choosing an exponential function problem, we recorded high percentages for this category. We observed that the participants were distracted from the objectives of the items by the context of the item. For example, on an item to introduce students to interpreting the meaning of vertical asymptotes in a real world applied context, Justina (pseudo) stated, “I did not get where those numbers are coming from, 0.5 and 6380. I did not get . . . those assumptions being made about the surface or something”. Justina was clearly focused on the context rather than the mathematics in the item and was distracted by the source of numbers and assumptions.

Formatting the Response. Only a little over half the reasons given for the choice of options were expected or mathematically justified. This was concerning since we had recorded high percentages for the *Understanding the Intent* and *Using Knowledge* codes. Further analysis revealed that out of the 25 problematic codes recorded, 12 (about half) of them involved rational functions. About 39% of the reasons (involving 17 items) given were deemed problematic for varied reasons. The top reasons were (1) lack of knowledge needed to correctly answer items (especially with rational functions), (2) selecting familiar options over mathematically sound options, and (3) some also were distracted by multiple contexts in one item and tend not to reason through such items mathematically. Additionally, a few items were noted to be complicated.

Emmanuel (pseudo) gave the following reason for selecting an option: “I go with [option] A only because I already do it with my students. And it's one that they enjoy and it's one that I have expanded on over time.” Emmanuel does not offer a mathematical justification for his choice.

Conclusion

We learned some lessons from conducting these CIs. Respondents comprehend an item better when the item contains fewer applied contexts and confusions associated with parts of an item distract respondents from the objective. Additionally, items need to have more precise language when describing the stem and options.

Based on the feedback received from the CIs, four complicated items were discarded, the stems of seven items were revised, and the options of 14 items were revised to make them more focused, independent from each other, reasonable for the context, and possible to assess mathematically. Ideas collected from the respondents were also used to create new items and revise items that were not part of the cognitive interviews.

Questions for Discussion

1. Based on our review of the literature, isolating factors of mathematical knowledge for teaching has been elusive? What affordances or limitations do you see in our design to isolate two tasks of teaching? What else should be considered?
2. Is there another cognitive interview coding scheme that you have used to extract useful, reliable, objective, and quantifiable data from Cognitive Interviews? We may be doing cognitive interviews after our next version of the instrument. Any advice?

Co-Construction of Course-Taking Narratives in Undergraduate Mathematics Advising

Claudine Margolis
University of Michigan

Elena Crosley
University of Michigan

Maisie Gholson
University of Michigan

This study explores a mathematics department's advising process for incoming, first-year undergraduate students. Through the analysis of video-recorded advising sessions, the interactional dynamics of an undergraduate mathematics advising program are explored. In particular, we describe how student-advisor interactions co-construct students' course-taking narratives in ways that shape their mathematical opportunities.

Keywords: Advising, Discourse Analysis, Gender

Introduction

Mathematics coursework plays a crucial role for undergraduate students as a prerequisite for many programs of study, particularly in STEM fields. The continued underrepresentation of women in mathematically demanding STEM fields (Watt et al., 2017) has been attributed to attrition of women at various points between participation in early education and persistence in STEM careers (Blickenstaff, 2005). While research has linked women's attrition from the STEM pipeline to a variety of causes such as discrimination, societal gender inequality, gendered differences in academic interests, and differential high school academic preparation (Watt et al., 2017, p. 255), it has rarely demonstrated how these factors operate to impact academic and career choices for individual women at the timescale of moments (i.e., seconds to minutes). In this paper, we explore mathematics advising for incoming undergraduates as an undertheorized site of attrition along the STEM pipeline and illustrate how interactions at a small timescale can shape students' mathematical trajectories. Although we do not extend our analysis to examine the influence of gendered discourses or gender performances, we see this work as a necessary first step to learning more about the experience of women moving through the STEM pipeline. Our preliminary analysis of the impact of gender performance can be found in the poster sessions for this conference.

The Context of Mathematics Advising

Academic advising serves a critical purpose in the process of welcoming new undergraduates to the complex system of course offerings and institutional requirements at any university. While academic advising programs serve similar purposes across universities, they are uniquely structured to fit the needs of a particular institutional context. We use the term *mathematics advising* to describe academic advising programs for incoming undergraduates and offered by mathematics departments for the sole purpose of guiding students toward a decision about which mathematics course(s) to register for.

The mathematics advising sessions we examine take place over a very short timescale (five to ten minutes) and occur between an advisor and student who have no knowledge of each other. In this brief interaction, the advisor needs to learn something about the student and provide relevant information about available courses. At the same time, the student must share something about themselves and gather the information they deem relevant to the decision-making process. Course registration typically occurs within days of the advising session, so students have limited opportunities to seek out additional information or support before making a decision.

Mathematics Advising as Genre

We take a discursive approach in which written representations of advising sessions (transcripts) are thought of as *texts* that fit within a particular *genre*. The genre of a text is defined as “a staged, goal-oriented social process” (Martin & Rose, 2003, p. 7), meaning that instantiations of a particular genre generally follow the same steps to accomplish a specific goal and are enacted in social contexts. The genre of a text, and the stages that comprise that genre, constrain the range of discursive acts that are possible (or likely) to occur at various points within the text. Genre analysis provides a way of justifying the reader’s context-specific interpretations of discursive acts within a text. For example, the question *What do you think?* can be interpreted as referring to what the student is considering for an academic major or for a math course depending on when in the advising session it is spoken.

The genre of *mathematics advising* follows a particular logic in the pursuit of a clear goal. Namely, the purpose of an advising session in this study’s context is for the student to decide which course they will register for. To accomplish this goal, the advisor and student engage in a conversation that consists of three stages: Opening, Deliberation, and Closing. In the Opening, the advisor solicits information from the student about their prior mathematics experiences as well as academic and career goals. During the Deliberation, the advisor and student evaluate available course offerings in relation to the information shared during the Opening. Finally, the student and advisor arrive at a consensus during the Closing. The outcome of a mathematics advising session is an informal agreement between the advisor and student about which math course(s) the student will register for.

Mathematics Advising by Co-Constructing Narratives

We conceptualize mathematics advising sessions as sites in which the student and advisor co-construct a narrative about the set of courses that are appropriate for the student to take. The goal of a mathematics advising session is for the student to decide which math course to take, given the set of options made available by this co-constructed narrative. The act of registering for courses can then function as a collapse of students’ potential mathematical futures, particularly when they elect not to take a math course or to take a course that will not support their entry into a mathematically demanding field of study.

Stories told about the self by oneself are likely to have the most immediate impact on an individual’s actions (Sfard & Prusak, 2005). The stories that students tell about themselves during the math advising sessions that we observed are particularly likely to have an impact on their actions because students registered for classes within a day or two of their math advising sessions. Given that the explicit goal of advising sessions is to influence students’ action with respect to course registration, the stories that students tell about themselves in this context are very likely to influence their mathematical trajectories. Although students are narrating stories about themselves, they are doing so through interaction with an advisor. Advisors may ask questions that surface aspects of a student’s narrative that wouldn’t have otherwise entered the discursive space. Even seemingly innocuous utterances have the potential to shift the way a student’s narrative unfolds. In this study, we are trying to learn how the advisor-student interactions shape the narratives about students’ mathematical potentialities by influencing their actions with respect to course registration.

Theoretical Framework

Following Sfard and Prusak (2005), we take a narrative theory of identity that equates “identities with stories about persons” (p. 14), told by the self or others, each of which can exist simultaneously and change dynamically in response to contextual factors. In this view, the discursive construction of narratives comprise the identity of an individual rather than functioning as a window into some "true" sense of self that is represented by the narratives. Not all narratives about an individual count as identities, however. Sfard and Prusak (2005) define identities as collections of stories about a person that are *reifying* (they describe properties of the individual), *endorsable* (the narrator believes the story to be a faithful reflection of how things are in the world), and *significant* (changing some aspect of the story is likely to impact the narrator's feelings about the identified person). Identity-narratives are important in the context of mathematics advising because the goal of each session is to determine which course, out of a large number of options, is most appropriate for the students given who they are. In our conceptualization, *who the student is* is the collection of stories about the student that have been co-constructed within the advising session. In this study, we focus on the mechanisms through which students and advisors co-construct reifying narratives about the student during mathematics advising sessions.

Narratives have reifying qualities when utterances are about *being* or *having* (e.g., *I am a mathematician* or *I have a math brain*) rather than *doing* (e.g., *I do math*). Sfard and Prusak (2005) identify use of the *is*-sentence (e.g., *she is an able student*) as a particularly effective mechanism for reifying identity because it turns "properties of actions into properties of actors" (p. 16). In addition, they note that identity narratives can be analyzed for reifying qualities by looking for "verbs such as *be*, *have*, or *can* rather than *do*, and with the adverbs *always*, *never*, *usually*, and so forth, that stress repetitiveness of action" (p. 16). Additionally, given that the context of the interaction is an advising meeting where the information provided by the student is used to set an academic trajectory, sentences utilizing sensing processes like *love, hate,* and *want* also result in the reification of identities. For example, the statement *I hate math* functions like *I am not a person who likes math* which is a *being* process.

Given the potential impact of the reifying narratives co-constructed in mathematics advising sessions, this study seeks to address the following questions:

1. How are reifying narratives co-constructed through student-advisor interactions in mathematics advising sessions?
2. How do reifying narratives shape students' mathematical opportunities?

Method

Context & Participants

This study is part of a larger project exploring the mathematics advising program situated across three sites at Midwestern University (a pseudonym): the general student body in the liberal arts college, the honors program in the liberal arts college, and the engineering school. The participants included mathematics advisors consisting of faculty, lecturers, postdoctoral fellows, and doctoral students in the mathematics department, as well as incoming undergraduates. The data was collected over several weeks at these sites during the summer of 2019. In this study, we narrow our focus to examine 32 advising sessions from the honors program conducted by one man and one woman advisor.

Data Sources

The data corpus for the larger project consists of several sources: video-recordings of 100 advising sessions across six advisors at three sites, 100 web-based surveys from undergraduate students after their advising session, 1 video-recording and fieldnotes of the training session, and

4 audio-recordings of interviews with mathematics advisors after the advising sessions. For this study, we draw on video-recordings of the advising sessions as well as transcriptions constructed by our research team (Hammersley, 2010).

Analysis of the Co-Construction of Reifying Narratives

After applying stage and timeline codes to each transcript, we looked at the student's turns of talk and marked instances where reifying narratives were being constructed. In particular, we looked for markers of reification such as the first person equivalents of *is*-sentences, *I am* and *I was*; use of verbs such as *be*, *have*, or *can*; adverbs that stress repetitiveness of action such as *always*, *never*, and *usually*; and sentences utilizing sensing processes like *love, hate,* and *want*. After marking the reifying narratives constructed through the student's talk, we looked at the advisor's talk preceding each instance of reification to determine what the narrative was in response to. Looking ahead from each instance of reification, we created memos about how the advisor's talk took up (or did not take up) aspects of the student's narratives. For each session, we generated a diagram depicting the co-construction of narratives and indicated whether each utterance was a bid to move the student toward or away from mathematics coursework. Lastly, each session was placed in a two-dimensional matrix based on whether the student and advisor co-construction was cooperative (both moving toward or both moving away from math) or competing (moving in opposite directions), and whether the student was ultimately moved toward or away from mathematics.

Researcher Positionality

This analysis was carried out by a multi-ethnic, multi-racial (Black, White, and Latinx) research team, who identify as women. Each team member has an academic background in mathematics and is now focused on mathematics education. We use Black feminist perspectives to acknowledge the relationships between gender, race, and class within this analysis and draw on our own experiences as women working in and through mathematics spaces to inform our questions and interpretations of the data. Therefore, gender and gendered dynamics are taken as ubiquitous within social interactions and, thus, ground our analytical focus for the present study.

Preliminary Analysis & Discussion

Given constraints on space, we present an excerpt from one transcript and the accompanying diagram in Table 1. In the diagram, circles represent reifying narratives spoken by the student and squares represent responses to, and elicitations of, reifying narratives by the advisor. Arrows pointing left indicate narratives that move the student away from math, and arrows to the right represent narratives that move the student toward math. Shading is used to track particular narratives; white indicates *I plan to be a psychology major*, light gray indicates *I plan to take a math course*, and dark gray indicates *I plan to take a statistics course*.

In this session, the student repeatedly states that she enjoys math and would like to take calculus. The advisor, taking up the narrative of the student as a psychology major, repeatedly points out that math is not required and points the student toward statistics courses as more relevant. The student ultimately concedes that she may not take a calculus course, so we characterized this session as Away From Math. The co-construction in this session was classified as Competing to reflect the push and pull between the student's narrative of mathematical interest and the advisor's narrative of mathematics not being necessary.

Text	Narrative	Diagram
Advisor: Well you don't need any math for psychology. Did you want to take a math class or do you want to avoid math?	Psych majors don't need math Do you want to avoid math?	
Student: I did. I– **I do enjoy math** even though it's not really a part of psychology, but **I still really enjoy math**. Like **I am thinking of taking statistics**, but I wanted to. **I'm thinking also of including calculus** if I have enough room for it.	I enjoy math. I really enjoy math. I'm thinking of taking statistics. I'm thinking about taking calc.	
Advisor: So stats and math are two different departments here and I agree that if you're going into psych you're probably gonna have to take some stats and that's probably more relevant. But if you want to take math that certainly. (I encourage you to do that).	Stats isn't math. Stats is more relevant for psych. If you want to take math, I encourage that.	
Student: Yeah, **I really enjoy it**. […]	I really enjoy math.	
Advisor: [your AP score] means that you don't have to take calc one. So if you're going to take calculus, it would make sense to start with calc two. But you don't need that for psych. So, th- the only reason you should take calculus is if you really want to take more calculus.	You placed into Calc 2 You don't need Calc 2 for psych The only reason to take Calc 2 is if you really want to take more calc.	
Student: Okay. Yeah. I- **I'm pretty interested in taking it**, but **I think I'm actually going to talk to my advisor first**	I'm pretty interested in taking calc I may not take calc	
Advisor: I think that makes sense.	Not taking calc might make sense	

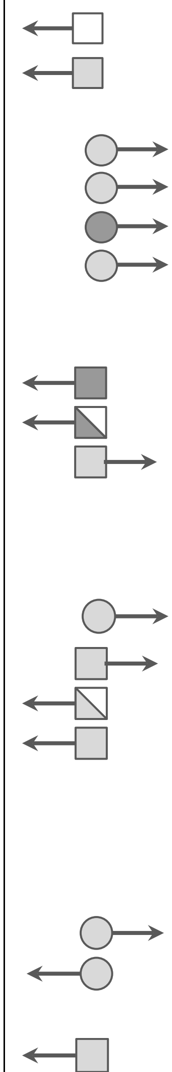

Figure 1. A transcript excerpt from a math advising session, reifying narratives, and diagram of co-constructed narratives.

This preliminary analysis included eight (of 32) randomly selected sessions from the honors college. Of those sessions, three were characterized as Cooperative/Toward Math and one was characterized as a Competing/Toward Math. All four of those sessions were with students who identify as men. Of the four sessions characterized as Away From Math, one was Cooperative (with a Woman student) and the other three were Competing (two women and one man). Although we expect to find variability as we analyze more sessions, it is notable that all three randomly selected sessions that have women students featured co-constructed narratives that moved these women away from further mathematics study. While there are many reasons for women to not pursue the study of advanced mathematics, that decision has long-term implications for the range of academic majors and careers that remain viable options. The results of this study illustrate how interactions at the timescale of seconds and minutes can impact the mathematical trajectories of students and act as a site of attrition for women in STEM.

Examining A Network of Communities Focused on Transforming Mathematics Instruction

Paula Jakopovic
University of Nebraska at Omaha

Kelly Gomez Johnson
University of Nebraska at Omaha

Chrstine von Renesse
Westfield University

Patrick Rault
Idaho State University

Nina White
University of Michigan

Communities of practice (CoPs) offer a structure for individuals with common goals to engage in collective learning (Wenger-Trayner & Wenger-Trayner, 2015). The CoMMIT Network was developed to support regional Math CoPs of undergraduate mathematics faculty interested in using active learning and inquiry teaching approaches in their courses. This study utilized the value framework (Wenger et al., (2011) to interrogate the value participating in the CoPs and COMMIT Network provides participants.

Key Words: communities of practice, active learning, inquiry teaching

Mathematics courses at institutions of higher education often act as "gatekeeper courses," leaving many students with minimal access to or interest in pursuing STEM careers. One strategy for increasing success is to use evidence-based teaching methods, like active learning (Freeman et al, 2014; Theobald et al, 2020). Despite research that supports this approach, traditional lecture-style teaching is still the predominant method of instruction in many college mathematics courses (Jaworski & Gellert, 2011; Laursen et al., 2019). Using networks and communities of practices (CoPs) to initiate, promote, and sustain change is one method shown to overcome these barriers to instructional change (Austin, 2011; Gehrke & Kezar, 2017). The COMMIT Network provides a flexible structure to support regional CoPs of undergraduate mathematics faculty in their mission to influence instructional change and improve student learning outcomes.

Methods

This study focused on two research questions: 1) To what extent does the COMMIT Network create value for the regional CoPs? 2) What aspects of the COMMIT Network model are most valuable to individual faculty participants, CoP leaders, and the Network? We utilized the value creation framework (Wenger et al., 2011) and descriptive analysis to qualitatively examine the layers of value identified by both faculty participants and CoP leaders to understand how the COMMIT Network can best support the sustained, systemic implementation of evidence-based teaching practices in institutions of higher education.

Results and Implications

Faculty participants shared finding immediate value in the ability to network with like-minded peers and share resources and ideas across their CoPs. CoP leaders expressed the importance of the COMMIT Network in providing a structure that supports: 1) regularly scheduled activities, 2) opportunities for networking, 3) structured channels of communication, 4) distribution of leadership, and 5) mentoring, which helps the CoPs within the Network to develop a sense of collective identity and legitimacy.

The Value of COMMIT-ing to Teaching with Inquiry: Examining a Network of Communities Focused on Transforming Mathematics Education

NSF-DUE #1925188 Project & Research Team: Patrick X. Rault, PI (Idaho State University), Paula Jakopovic and Kelly Gomez Johnson (University of Nebraska at Omaha), Amy Ksir (Anne Arundel Community College), Christine Von Renesse (Westfield State University), Nina White (University of Michigan),

Introduction

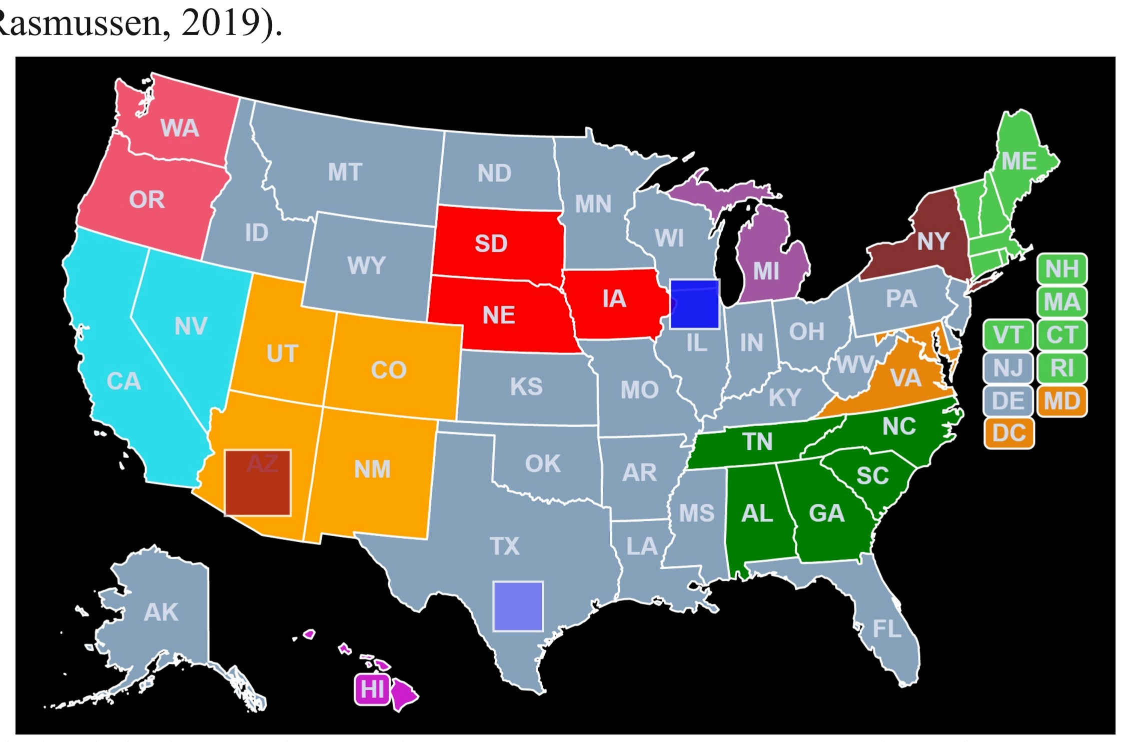
The 21st century workforce needs highly qualified STEM professionals. It is projected that STEM jobs will grow 8% over the next ten years (Seitz, 2021). Mathematics courses at institutions of higher education (IHEs) often act as "gatekeepers," leaving many students with minimal access to or interest in pursuing STEM careers. One strategy for increasing success, including for students from historically under-represented groups, is to use evidence-based teaching methods, such as active learning (Freeman et al, 2014; Theobald et al, 2020). Despite research supporting this approach, traditional lecture-style teaching is still the predominant method of instruction in many college mathematics courses (Jaworski & Gellert, 2011; Laursen et al., 2019; Nolan, 2006, 2010). Using networks and communities of practices to initiate, promote, and sustain change is one method shown to overcome these barriers to instructional change (Austin, 2011; Gehrke & Kezar, 2017) and is the focus and exploration of this project. Communities of practice (CoP) are groups of people with common interests who engage in shared learning via ongoing, regular interactions and collaborate toward a common goal(Lave & Wenger, 1991; Wenger-Trayner & Wenger-Trayner, 2015).

Context

The **COMMIT (COMmunities for Mathematics Inquiry in Teaching) Network** provides a common infrastructure and flexible structure to support regional communities of practice in their mission to influence instructional change, address faculty isolation, and ultimately, improve student learning outcomes. The COMMIT Network collectively spans over half of the United States, with over 800 educators actively involved. Each regional COMMIT brings high quality professional development to their local members, focused on infusing active learning, equity, and inquiry into college mathematics classrooms.

A regional **COMmunity for Mathematics Inquiry in Teaching (COMMIT)** is a local group of college mathematics educators interested in practicing and disseminating teaching and learning techniques centered on student inquiry.

COMMIT Members center their classrooms on the Four Pillars of inquiry that include: **(1)** ability for instructors to foster equity in their design and facilitation choices , **(2)** deep student engagement with coherent and meaningful mathematical tasks, **(3)** opportunities for students to collaboratively process mathematical ideas with peers, and **(4)** opportunities for instructors to inquire into student thinking (Laursen & Rasmussen, 2019).



The highlighted areas below are where current COMMIT communities are located.

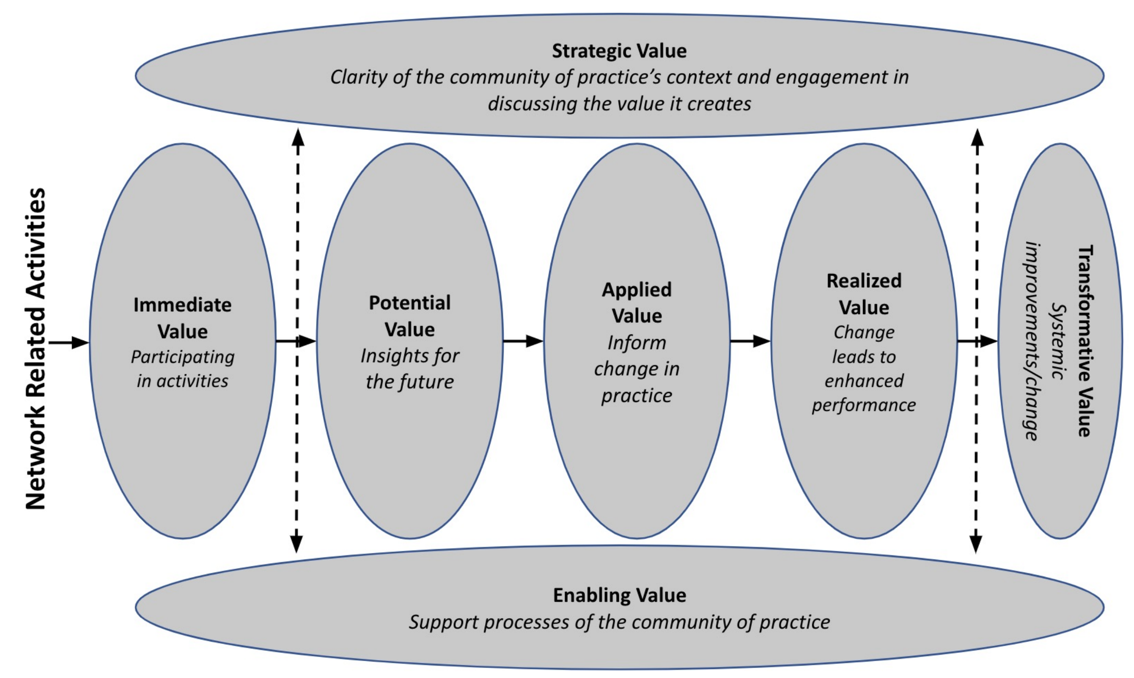
Research Questions

1) To what extent does the COMMIT Network create value for the regional COMMITS?

2) What aspects of the COMMIT model are most valuable to individual faculty participants, COMMIT leaders, and the broader network?

Theoretical Framing

Utilizing Wenger et al.'s value framework (Wenger et al., 2011), we examine the multiple layers of value identified by both faculty members and leaders as we seek to understand how the COMMIT Network can best support the sustained and systemic implementation of evidence-based teaching practices in IHEs. The framework incorporates five cycles of value creation - immediate (in the moment resources, information, connections), potential (for the future), applied (tested implementation), realized (actualized implementation), and transformative (broader dissemination to others). In addition to the cycles, value at the CoP level is also supported by strategic value (clarity of the context and vision, ability to engage in strategic conversations) and enabling value (support processes that make network life possible).



Findings

The Value the COMMIT Network Creates for Regional COMMITs

Interviews of COMMIT regional leaders in Year 2 of the project indicate that the ability to share resources and ideas and to develop interpersonal connections as the most prominent "in the moment" Immediate Value aspects of engaging in COMMITs. One CoP leader explained,

> *"We have been trying to learn from others and what they are doing…it has been inspiring for us." The opportunities to connect with like minded peer groups also surfaced as important to CoPs."*

Leaders shared that it was important to "...have access to the leadership teams and a shared voice" as they developed processes and events for their region and having access to other faculty and CoPs allowed them to build strong interpersonal relationships with colleagues, not only within their own COMMIT but also from across the network.

Findings (Continued)

Regional COMMIT leaders identified the role that the Network plays in fostering a sense of collective identity around utilizing teaching with inquiry practices. Leaders noted the importance of this in developing a sense of purpose and support to "change the way we think about effective teaching" in their CoPs and at their individual institutions. "Having the general CoP Network in the background helps us generate some legitimacy," explained a leader. "It is not something we are making up because it is fashionable...that support from the back is helpful. We have a more defined structure to what we were trying to do more organically."

Finding Value in the COMMIT Network Model

CoPs are often ephemeral—they develop organically out of shared need, but often dissolve, particularly when they do not exist within a formal organization. One of the goals of the COMMIT Network project has been to examine the structures and supports that individual CoPs need to sustain over time in order to facilitate long term, systemic change in mathematics education. As such, it is important to understand the aspects of the Network model itself that leaders and participants view as being integral to the health of their COMMIT.

- **Regularly scheduled, ongoing events**
- **Formal and informal opportunities for faculty to network and share ideas/resources**
- **Structured channels of communication within CoPs and across the Network**
- **Distributing leadership by recruiting and training new and upcoming leaders in each CoP**
- **Mentoring support for individual participants, workshop and activity facilitators, and COMMIT leaders provided by COMMIT members and the Network**

These forward-looking insights aligned with our consistent evidence of the value both individuals and regions find in the strong community connections within the network. When looking at the future goals of each region, it is often about engaging within the network in addition to continuing to expand the reach of the network and its regions.

> *"It's nice… our community has been around for awhile. We have a history of things we have done and tried, we could give that experience and share that history with new CoPs to help out."*

> *"There is something powerful about the regional anchoring of things but there is enough connection that regions can inform each other. There are many similarities to having a network where we can learn together what works well."*

Quick Facts About the Network

13 current regional COMMITs (8 included in the study), which expanded from the original 4 regions funded in 2019.

438 documented participants engaged in one or more COMMIT Network activities over the past 3 years (e.g. book clubs, teas, workshops, classroom observations).

213 mini-grants awarded to faculty to support their participation in activities such as peer classroom observations, course collaborations, and workshop planning/facilitation.

78.5% of surveyed participants indicated expanding their COMMIT Network with math faculty peers by engaging in at least one inquiry teaching activity

The Story of Sunny: Consequences of Faculty Mentoring for Perception of Mathematics Career Pathways

Seyda Uysal
Florida State University

Kathleen Michelle Clark
Florida State University

Keywords: pure mathematics majors, faculty mentorship, women in mathematics, perception of career pathways, mode of belonging

Numerous studies have underlined the persistent gender gap in mathematics related fields as a potential focus to be explored further with respect to learner identity, self-concept, stereotype threat, and sense of belonging in the discipline (Blackburn, 2017; Lahdenperä & Nieminen, 2020). The notion of belonging was cited as an important construct to investigate and understand factors in women's decision to pursue a career in mathematics (Good et al., 2012). Therefore, we investigated the "mode of belonging" of women with regard to engagement, alignment, and imagination components using Wenger's (1998) framework. For the purposes of this poster, we emphasize the imagination component of mode of belonging to address women's perception of career pathways in pure mathematics and its link to faculty mentorship.

We adopted narrative inquiry to examine women and underrepresented students' experiences in various mathematics environments (Clandinin & Rosiek, 2007). For the purposes of the study, we selected Sunny as the focus case among five participants. The study has longitudinal characteristics since Sunny participated in one-hour interview and weekly seminar discussions in Spring 2020. She also participated in three interviews and eleven weekly reflections in Spring 2022. Sunny graduated in Spring 2022. We focus on the case of Sunny, who began as a pure mathematics major, and then later pursued a career path in actuarial science. We concentrated on the aspects that led Sunny to switch from pure mathematics to actuarial science. Sunny's case was intriguing because she expressed a passion in pure mathematics and stated that up until her third year, she was interested in pursuing a research career in pure mathematics. Sunny changed her mind, though, after being discouraged by her Topology professor in her pursuit of research opportunities. Instead, she decided to pursue a career in actuarial science, which does not involve the pure mathematics and proofs that she most appreciated in her studies. Sunny remarked that this professor made it seem as though she lacked the ability to involve in research as an undergraduate student and was unhelpful in helping her find a suitable research topic for her directed independent study. Although Sunny had taken for granted a career in academia up until her third year, she considered this particular moment as a tipping point in which she realized she needed to shift her attention away from pursuing graduate-level study in pure mathematics.

It is worthwhile to examine the shift in Sunny's intentions: her initial plan to attend graduate school to pursue research, which morphed into a career path in actuarial science after an undesirable outcome from consulting with her Topology professor. We focused on Sunny's story because, despite her outstanding success in her major, Sunny's experiences revealed potential aspects of women's experiences in the mathematics major that could impact women's decisions not to pursue a career in pure mathematics. Despite earning a degree in pure mathematics, Sunny claimed that she did not feel valued or accepted in her program since she did not feel as a contributor to pure mathematics research. Our research indicates that faculty mentoring impacted women's decisions to pursue careers that are (or are not) in line with their academic background because women in STEM are more prone to social and institutional influences (Xu, 2017).

Gamification and a Leaderboard-Based Mathematics Game

Kimberly Cervello Rogers	Fei Gao	Camryn Grey
Bowling Green State University	BGSU	BGSU

One of the most used game design elements in gamification design is leaderboard, a scoreboard showing participants' current scores and rankings. Though many studies suggest the positive effects of leaderboard on participants' learning and motivation (Kalogiannakis, Papadakis, & Zourmpakis, 2021), research also shows that not all students benefit from the use of leaderboard (Andrade, Mizoguchi, & Isotani, 2016; Nicholson, 2013). Based on self-determination theory (SDT) (Ryan & Deci, 2017), we designed a study where undergraduate math students completed a leaderboard-based review, and addressed two questions: (**RQ1)** How are students' perceived autonomy and competence associated with their enjoyment and intention of continued participation? (**RQ2)** How is student actual competence associated with their enjoyment and intention of continued participation?

Method

In an undergrad math course, *Real World Math Skills,* we created a gamified quiz (Quizalize, n.d.) to review content that focused broadly on *Contending with Change* (e.g., linear & exponential modeling, & rates of change). During class, 47 students answered 24 Quizalize problems, while a leaderboard was projected in real time. Finally, students completed a survey with 19 Likert questions (1: strongly disagree to 7: strongly agree). These survey items also aligned with a specific sub-category (Competence, Autonomy, Enjoyment, & Intention of continued participation) and we considered the mean of students' ratings on survey items in each sub-category. We used student performance data (i.e., total number correct on quiz) to represent student actual competence.

Findings

Considering the correlations among variables, student actual competence was not correlated with either enjoyment or intention of future participation. Instead, student perceived competence was significantly correlated with both. We also found strong correlations ($r >= +.70$) (Creswell & Guetterman, 2019) between perceived autonomy and both enjoyment and intention of future use. Based on these correlations, we ran linear regressions to understand how well perceived competence and perceived autonomy predict student enjoyment and intention of future participation, respectively. The findings showed that perceived competence and perceived autonomy significantly predict student enjoyment and intention of future participation.

Significance of the Study

Our findings suggest that effects of leaderboard-based math practice on student enjoyment and intention for future participation are varied. These variations were not related to student actual competence. Instead, they were related to students' perceived competence and autonomy as predicted by SDT. Regarding Math Education and gamification implications, findings helped researchers and educators understand why and how students responded to gamified activities differently. Thereby offering a way to explain inconsistent findings in leaderboard research and providing insights about how to tailor leaderboard-based activities to optimize effects of intervention on all students.

SYLLABUS 2.0: USING VIDEO TO MAKE THE MATH SYLLABUS ACTIVE

John Kerrigan, Ed.D.
Rutgers University

Christina Bifulco, Ed.D.
Rutgers University

INTRODUCTION

There is a widely held view that a college course syllabus serves as a contract for students rather than a teaching and learning opportunity (Fornaciari & Lund, 2014). Earlier studies on syllabus development have focused on necessary components to include in the syllabus, such as professor information, course information, disability information, student support services, grading, and technology requirements (Doolittle & Siudzinski, 2010; Garavalia et al., 1999; Jenkins et al., 2014; Perrine et al., 1995). A second wave of studies focused on how the syllabus is presented in terms of professor tone (Harnish & Bridges, 2011) and length and use of images (Harrington & Gabert-Quillen, 2015; Nilson, 2002). More recent research on syllabus development has expanded on previous design considerations and has focused on accessibility and universal design for learning (Womack, 2017), the infusion of diversity, equity, and inclusion across the various components of the syllabus (Fuentes et al., 2021), and the inclusion of social justice elements across sections (Taylor et al., 2019). Given the wealth of research available on what components to include in a syllabus and possibly how that affects instructor perception, there is a lack of research on how to present the syllabus in a way that engages students in learning about the course. Our study examined the implementation of two multimedia syllabi developed for large lecture math courses: a graphic syllabus and a video version.

RESEARCH QUESTIONS

1) Which components of a video syllabus do students access the most frequently?

2) What are students' attitudes toward an undergraduate math course after reviewing its syllabi?

3) How does the syllabus modality (graphic or video) impact students' posttest performance on syllabus content?

CONTEXT/METHOD

Two sections of students in Precalculus College Mathematics (N=172) participated in the study. All students were first-semester School of Engineering students in a one-semester Precalculus course.

One section was assigned a graphic syllabus, whereas the other was assigned a video syllabus. After engaging with the syllabus, 107 students consented to take the syllabus survey, which represents 62% of the 172 students enrolled in the class. Sixty-one (57% of the sample) of these students had been assigned the graphic syllabus and 46 (43% of the sample) the video syllabus.

ANALYSIS

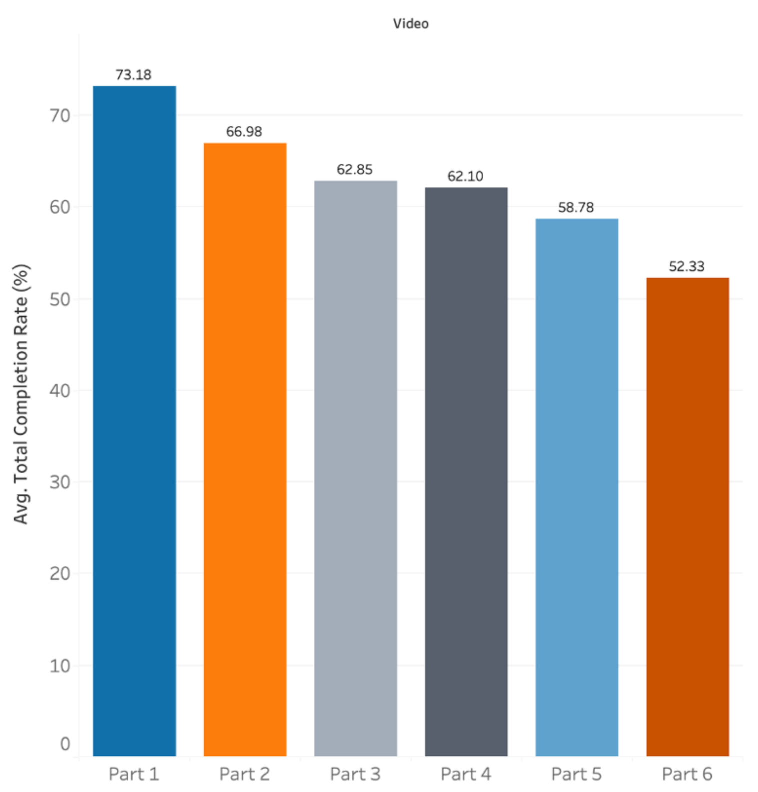
As most of our data was quantitative, we ran descriptive statistics for each of our survey and quiz questions to describe the data set. We also ran a t-test between groups to see if having either syllabus experience resulted in a significant difference in overall syllabus quiz score or a difference between each quiz or survey item. For the two survey questions that had qualitative responses, we used open coding to determine whether any themes emerged from the students' responses. For example, we classified both positive and negative reactions to the syllabi based on the one-word descriptions used to describe the syllabus. Video-watching data was extracted from Kaltura and organized into charts for ease of interpretation.

RESULTS

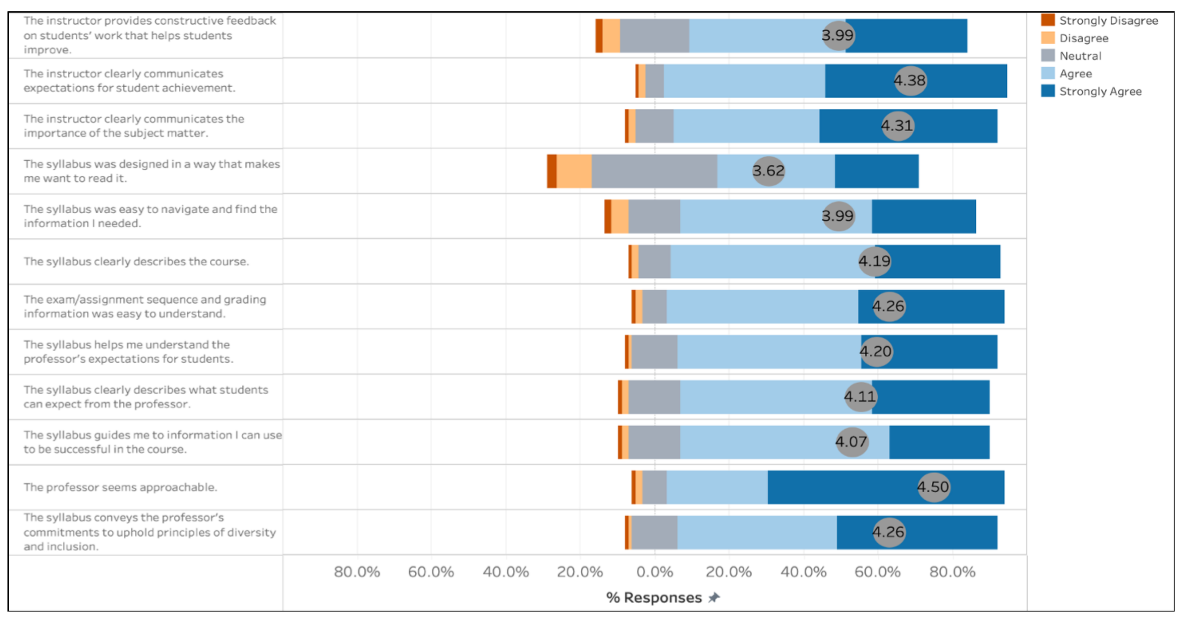
Findings indicate no significant difference between students' syllabus quiz performance and overall survey responses between groups.

Students responded favorably to the survey regardless of syllabus type (100% positive on graphic syllabus, 91% positive on video).

Last, there was no observed relationship between the length of each syllabus segment video and the frequency at which students watched each segment.



Distributions and Means of Responses to Syllabus Perception Questions



Note. The length of the bar denotes the percentage of instructors who selected that option. The center of the middle item (Neutral) is anchored at 0%. The gray circle on the bar shows the mean.

IMPLICATIONS

The results of our study indicate that first-semester college students may need additional explicit instruction on what a syllabus is, how to use it, and why it is important. Through our data analysis, we uncovered that there could be more effective ways of engaging students with the syllabus. When looking at this data coupled with some students' desire for a paper-based syllabus, we suggest offering students the option of viewing a graphic syllabus or video syllabus to accommodate learning preferences. To increase implementation fidelity and ensure students engage with the syllabus, we offer two suggestions for implementing a video syllabus and a graphic syllabus: a video-based syllabus quiz with embedded prompts and socially annotating the syllabus. Our next study will investigate this implementation.

Meritocrats, Wallflowers, and More: Characterizing Obstacles to DEI Engagement

Steven Ruiz
Arizona State University

Naneh Apkarian
Arizona State University

Estrella Johnson
Virginia Tech

Keywords: diversity, equity, inclusion, post-secondary STEM education

There is a pressing and continuing need to bolster equity and inclusion for marginalized people in all aspects of American society, including undergraduate STEM education. This paper draws on data from a broader study (Johnson et al., 2022) which collected survey data from postsecondary STEM instructors regarding their attitudes toward diversity, equity, and inclusion (DEI) efforts and how those views changed as a result of the events of 2020 (e.g., the onset of the COVID-19 pandemic, nationwide protests in support of racial justice). While many participants reported changes in their views, this report focuses on those who stated that their views were unchanged. In particular, we present profiles of the attitudes of 21 people who were not previously invested in social justice, and did not change their views in 2020. From these data, we identified archetypes of those who hinder DEI efforts in hopes of elucidating their motivations.

Theoretical Perspective

Both the original study (Johnson et al., 2022) and this one are informed by critical race theory (CRT), specifically where this framework intersects with education (Ladson-Billings, 1998). CRT posits that American educational structures are inherently beholden to a "White supremacist master script" (p. 18) under which minoritized students are seen as deficient. In particular, our study reports on the perceived differences in talent, opportunities, and interest in STEM fields among racial groups.

Data Reduction, Collection, and Analysis

Approximately 1300 post-secondary mathematics instructors were originally surveyed (Apkarian et al, 2022), 305 of whom responded to a follow-up survey. Of these respondents, 21 indicated that they had no DEI engagement prior to 2020 or thereafter. For these individuals, we compiled their race, gender, and beliefs on racial differences in STEM. We also captured their free responses which elaborated on their lack of engagement. In the spirit of grounded theory (Corbin & Strauss, 1998), these responses were coded to find themes to their motivations.

Results and Discussion

Of the 21 respondents in our data set, 18 were white men, perhaps suggesting that a privileged position obscures the need for DEI advancements. Five archetypes emerged from analyses of their responses – *opponents* who actively resist DEI efforts, *meritocrats* who believe that STEM is inherently neutral (e.g., Alvarado, 2010; Au, 2013; Liu, 2011), *good apples* who suggest that respect for all is sufficient (Martin, 2003), *wallflowers* who cite higher priorities elsewhere, and *exceptionalists* who posit that DEI engagement is only needed elsewhere. Understanding the motivations behind DEI hesitance is essential in order to overcome them.

Meritocrats, Wallflowers, and More: Characterizing Obstacles to DEI Engagement

Steven Ruiz, Arizona State University
Naneh Apkarian, Arizona State University
Estrella Johnson, Virginia Tech

Background and Original Study

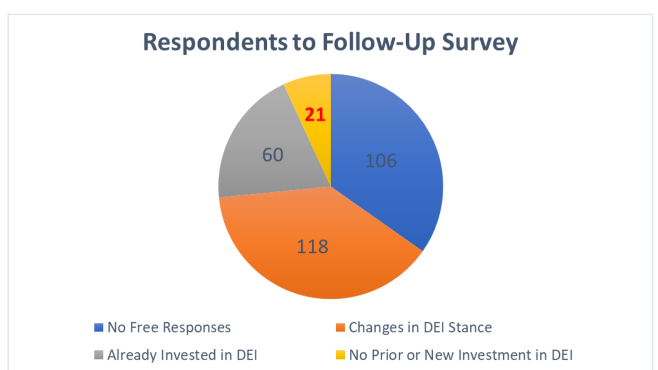
- Data taken from **Evaluating the Uptake of Research-Based Instructional Strategies in Undergraduate Chemistry, Mathematics, & Physics**, an NSF-funded study.
- Approximately 1300 post-secondary math instructors were surveyed
- Respondents asked how events of 2020 affected views and actions with respect to diversity, equity, and inclusion.
- Apkarian et al., 2022 focused on changes reported by those surveyed.

Framing of Current Study

- Now focused on those who were not previously invested in DEI efforts and indicated no change following 2020.
- Goal was to characterize those who might present resistance to DEI efforts and progress.

Data Reduction

- 305 respondents completed follow-up survey.
- 199 of these provided free responses
- 21 self-reported as having no prior investment in DEI efforts and no changes following 2020



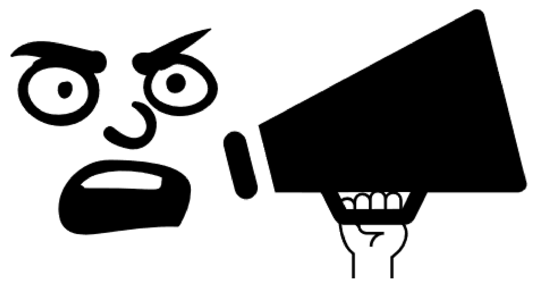
- Demographic information and free responses gathered for this subset of 21 respondents.

Data Analysis

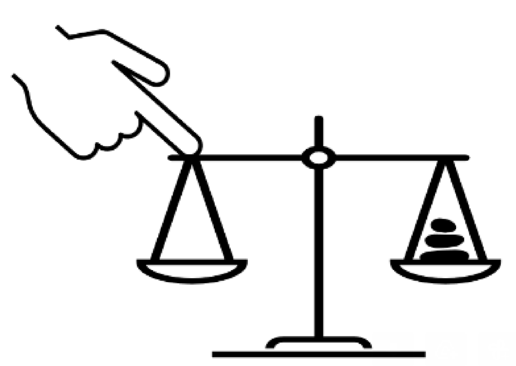
- Open coding (Corbin & Strauss, 1990) performed on free responses to identify reasons given for lack of DEI engagement
- Axial coding revealed five categories with common themes or motivations.
- Categories reframed as character archetypes.

Archetype Detail and Example Responses

Opposition (n = 2)



- Both respondents are white men.
- Neither believes they are personally responsible for DEI.
- Example Responses
  - *"It is actually annoying to see how this agenda gets pushed down people's throats."*
  - *"Affirmative action has gone too far and should be eliminated."*



Meritocrats (n = 6)

- All men (5 white, 1 Hispanic)
- 4/6 believe that DEI is beneficial to STEM
- Example Responses
  - *"Mathematics is inclusive for every race…This has nothing to do with equity issues."*
  - *"Personal equity issues are a bit like…disabilities such as autism or dyslexia or depression…Success is the best cure and so empowering."*

Good Apples (n = 6)

- All white (5 men, 1 woman)
- All agree that students from different groups have equal aptitudes
- Example Responses
  - *"I would just like to teach, treating each person as infinitely precious in the eyes of God."*
  - *"Both before and during 2020, I have tried to maintain a principled, fair, conservative position on diversity."*
  - *"I support diversity and opportunities for all."*

Wallflowers (n = 5)

- 3/5 believe they have a personal responsibility to DEI engagement
- Example Responses
  - *"We are teaching online right now. That is the focus of my teaching."*
  - *"I am not on campus and do not have opportunities to participate in diversity events."*
  - *"My views continue to be the same: less focused on equity and more on the overall unfair treatment of adjunct teachers."*

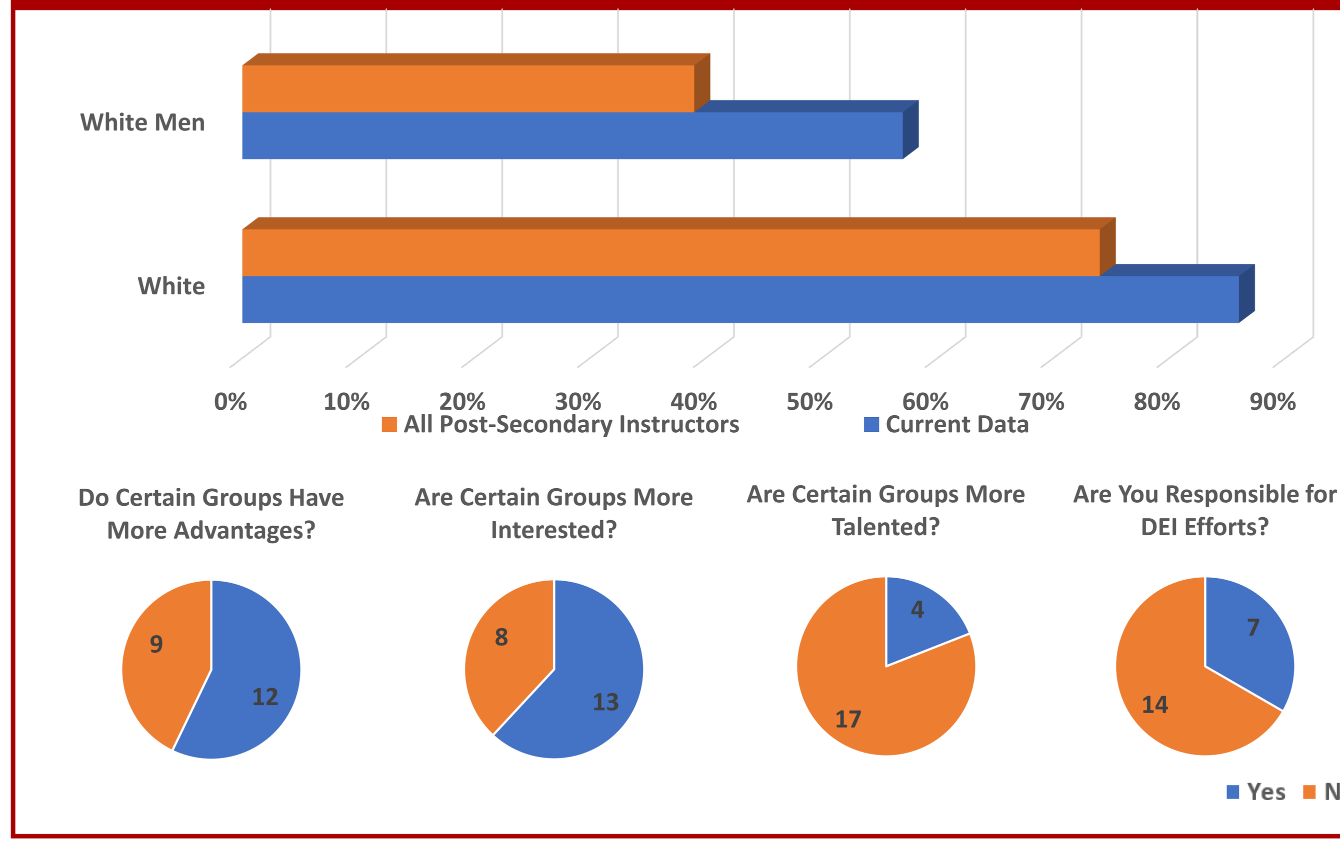
Exceptionalists (n = 7)

- 6 men, 1 woman
- 6 white, 1 declined to identify their race
- Example Responses
  - *"While the return of overt personal racism in recent years is dismaying, I just don't see it in math and science."*
  - *"There isn't an issue with [DEI] in any of the department I've worked in. I've never witnessed such issues in the workplace."*

Overview of Archetypes

- Opposition
  - *DEI efforts are inherently wrong.*
- Meritocrats
  - *STEM fields are inherently neutral.*
- Good Apples
  - *I'm not a part of the problem.*
- Wallflowers
  - *Higher priorities exist elsewhere*
- Exceptionalists
  - *The problem may exist, but it doesn't exist **here**.*
- **Note**: Some respondents classified as multiple archetypes.

Summary of Reduced Data Set



Discussion and Key Takeaways

- Majority of data set is white, perhaps suggesting that privilege conceals the need for DEI advancements.
- In this study, most obstacles to DEI are moderate, as opposed to vehemently opposed to DEI efforts.
- This study corroborates prior research on belief in meritocracy (e.g., Alvarado, 2010; Au, 2013; Liu, 2011).
- Good Ones archetype are consistent with "for all" rhetoric (Martin, 2003).
- Understanding the motivations behind people's reticence to embrace DEI efforts may facilitate engagement with them.

Research on Mathematical Proof: A Review of RUME Conference Proceedings 2020-2022

Rosina Andrews
Middle Tennessee State University

Amanda Lake Heath
Middle Tennessee State University

Keywords: Proof, literature review, methodology

Mathematical proof is one of the major topics of research in the RUME community. In recent years, we have anecdotally noticed a trend in RUME that proof research is often conducted in laboratory settings rather than within authentic classrooms. Further, we, along with our collaborators, have special interest in researching proof as a collaborative activity (Bleiler-Baxter et al., 2021, 2023; Heath, 2022; Heath & Bleiler-Baxter, under review; Heath et al., 2022) because of our conviction that proof is a "communal, negotiated, and sense-making process" (Ko et al., 2016, p. 618). Yet, research on collaborative proving is still considered a new direction for proof research (Heath & Bleiler-Baxter, under review). In this project, we seek to review recent literature produced in the RUME conference proceedings to identify trends in up-and-coming research on proof and proving at the undergraduate level. We seek to answer the question: What kinds of research are being conducted on proof and proving in the RUME community?

Methods

In a methodical search of RUME conference proceedings (Karunakaran & Higgins, 2021, 2022; Karunakaran et al., 2020) during the period 2020-2022, we included contributed, preliminary, and theoretical reports containing the words "proof" or "proving" in their title. Two researchers developed and revised categories of interest for the reports, separately coded all reports according to these categories, and resolved any disagreements. The coding categories included: research conducted in real classrooms, survey research, interview research (non-task-based), task-based interview research, artifact analysis, assessment/inventory measures, text/document analysis, collaborative proof research, and early-career scholar first authorship.

Findings

A total of 30 reports qualified for inclusion in the review: 11 out of 148 reports (7.4%) in 2020, 4 out of 49 reports (8.1%) in 2021, and 15 out of 145 reports (10.3%) in 2022. Notable findings include the strong presence of interview research on proof (17/30 reports, 56.7%). Moreover, an overwhelming majority of interview-based research involved task-based interviews (13/17 reports, 76.5%). Our suspicions of a lack of research in authentic classroom contexts were confirmed, as only 6 reports (20%) used data collected from a real classroom. The number of reports concerning collaborative proving has slowly grown, with 2 reports in 2020, 3 reports in 2021, and 4 reports in 2022 concerning collaborative proving. Although this is still a minority of proof research at RUME in the last three years (9/30 reports, 30%), we noticed an overwhelming majority of RUME reports on collaborative proving had early-career first authorship (8/9 reports, 88.9%) compared to the presence of early-career scholarship in the reports included (22/30 reports, 73.3%). We will include a complete summary of the findings in our poster presentation, including trends in proof research in RUME over the past three years.

This review of literature can help the RUME community identify trends in proof research and identify ways in which the research base can grow. During the poster session, we will solicit feedback for how to continue this investigation and questions about trends in proof research the RUME community would like to see answered.

Research on Mathematical Proof: A Review of RUME Conference Proceedings 2020-2022

Rosina Andrews and Amanda Lake Heath
Middle Tennessee State University

Mathematics and Science Education Doctor of Philosophy Program

Focus of Review

Mathematical proof is one of the major topics of research in the community of Research in Undergraduate Mathematics Education (RUME). We aimed to review literature produced in the RUME conference proceedings from the past three years to identify trends in up-and-coming research on proof and proving at the undergraduate level.

Research Question: What kinds of research are being conducted on proof and proving in the RUME community?

Method and Procedure

In a methodical search of RUME conference proceedings during the period 2020-2022, we included contributed, preliminary, and theoretical reports related to proof research containing the keywords "**proof**" or "**proving**" in their title. A total of 30 reports qualified for inclusion in the review: 11 out of 148 reports (7.4%) in 2020, 4 out of 49 reports (8.1%) in 2021*, and 15 out of 145 reports (10.3%) in 2022.

Two researchers developed and revised categories of interest for the proceedings papers and separately coded all reports according to these categories.

*There was no RUME Conference in 2021 due to COVID-19. In lieu of a face-to-face conference, the organization published a set of research reports open only to early-career scholars as lead authors.

Authorship of RUME Proof Reports 2020-2022 (All Authors)

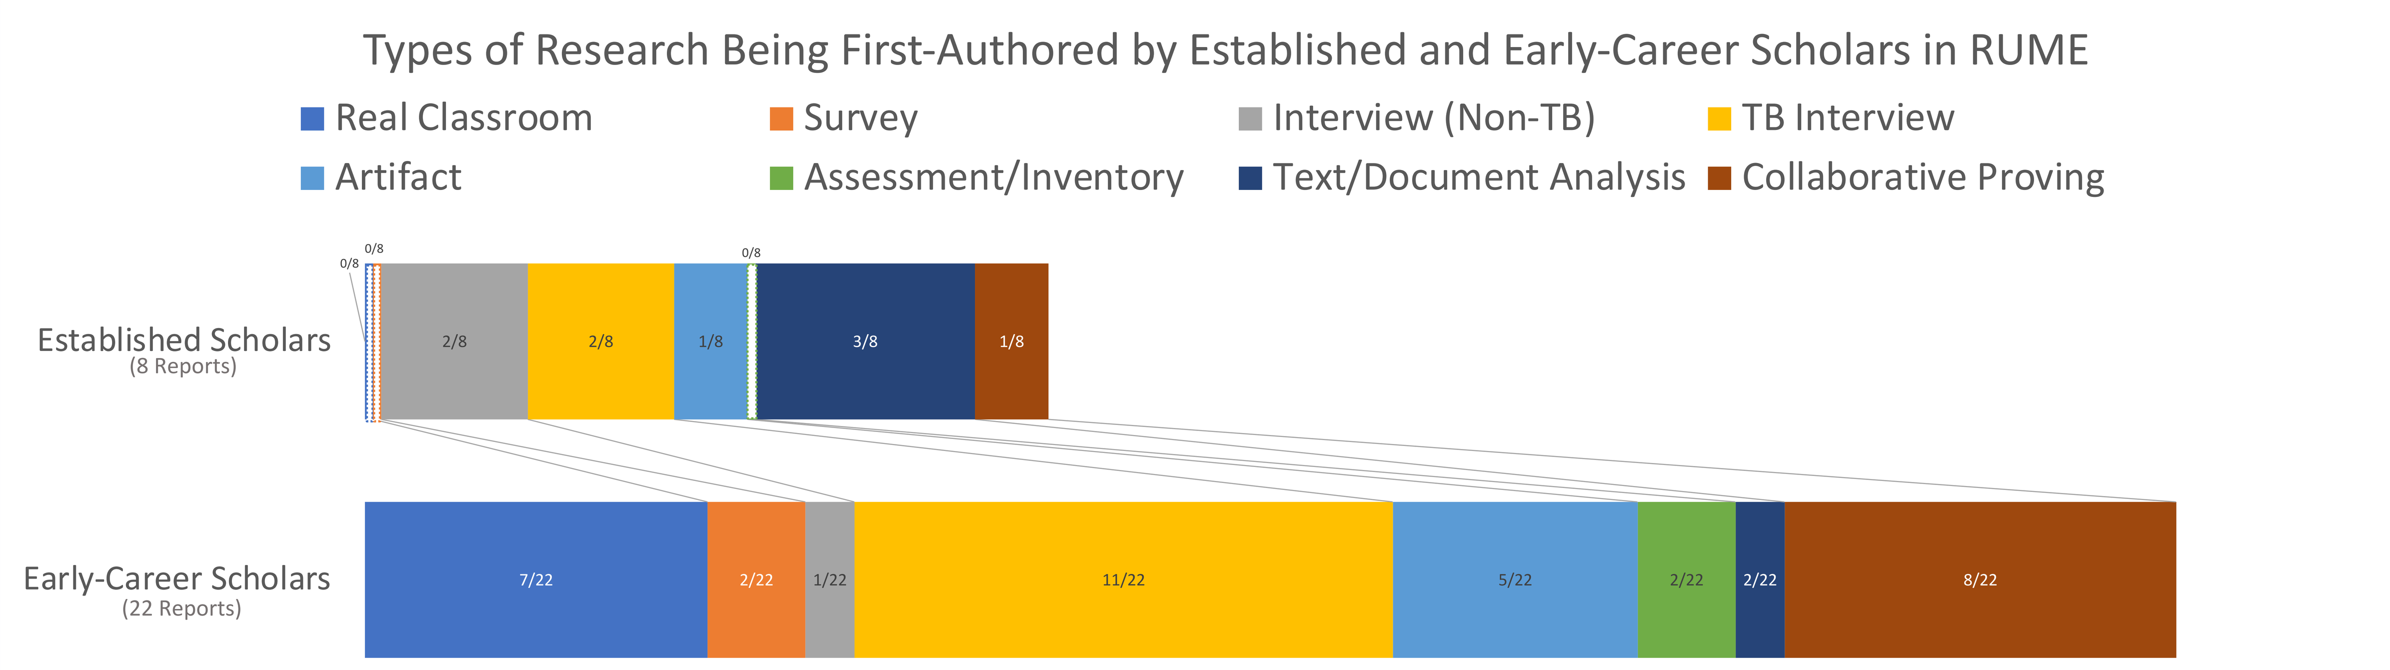
Amanda Lake Heath: alh2ei@mtmail.mtsu.edu

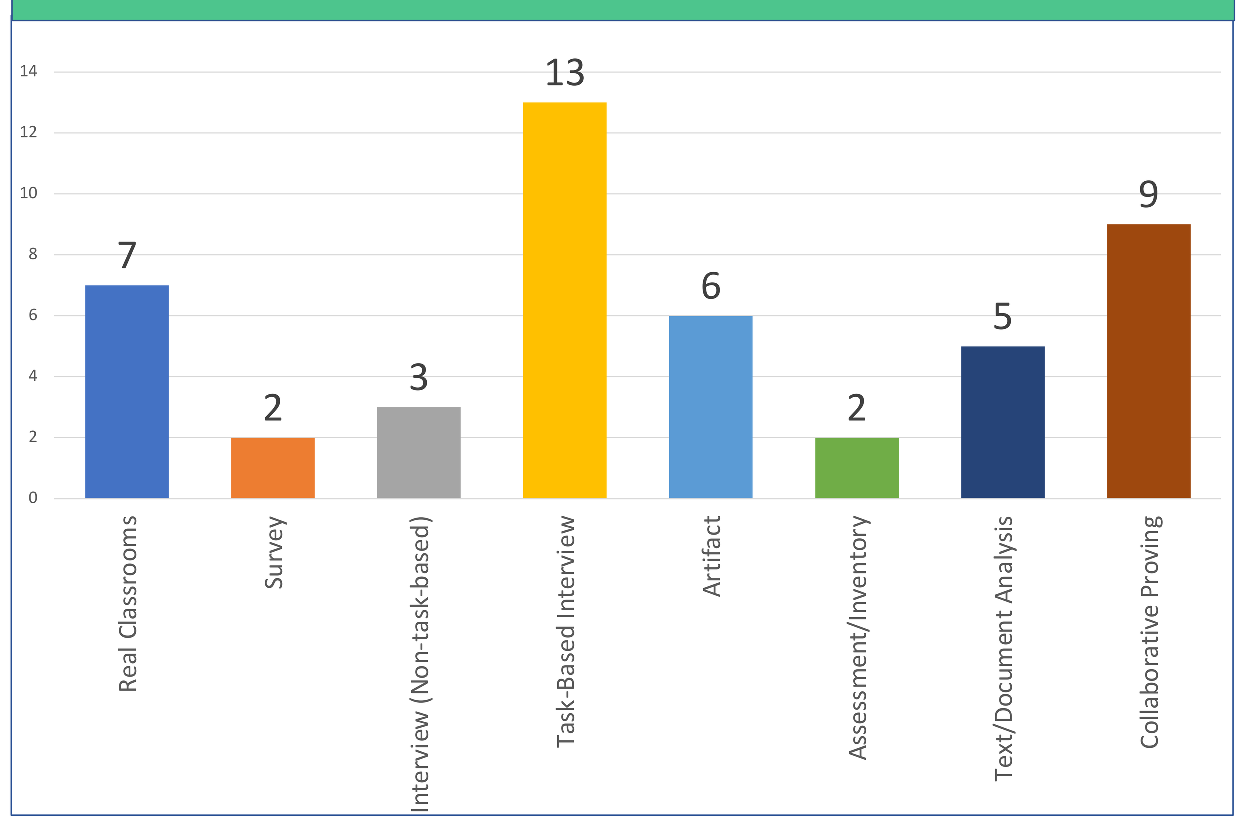
Trends Among Early-Career Scholars in Proof Research



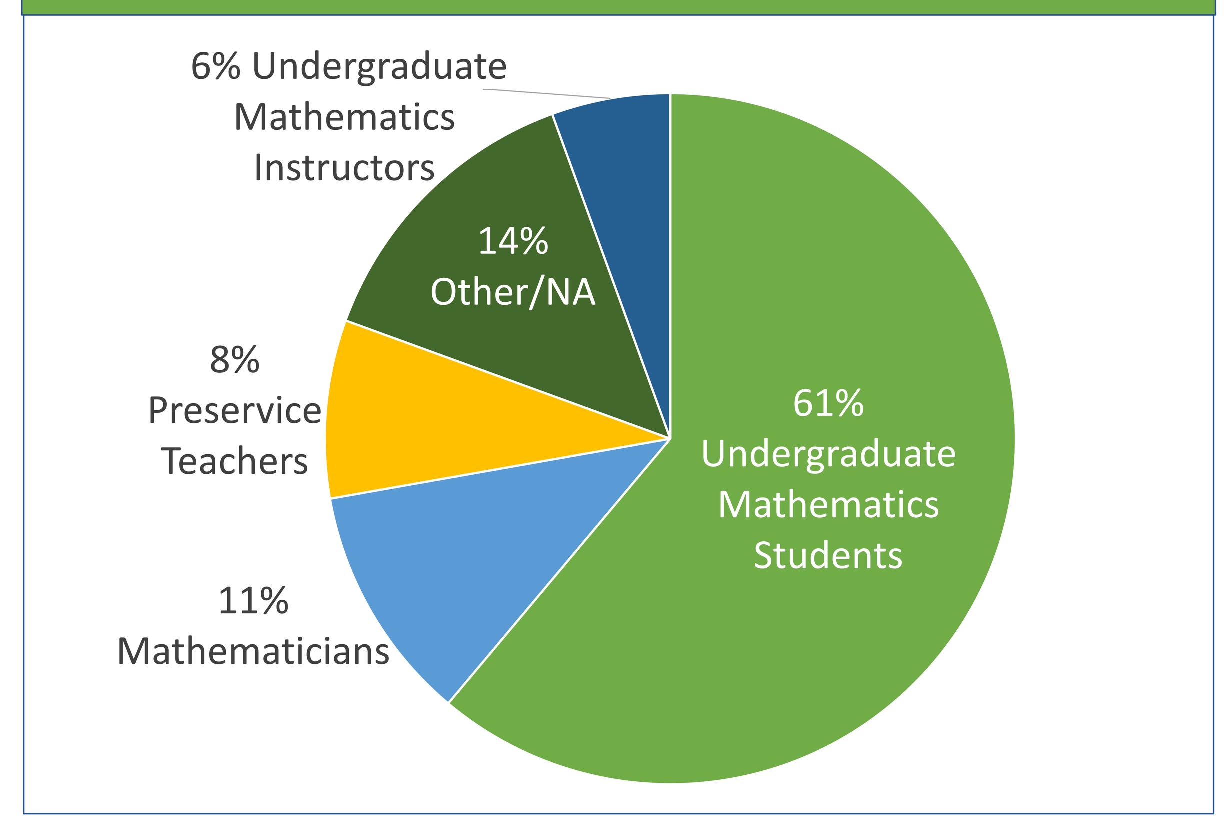
Adopting the definition of "early-career scholar" from the 2021 RUME Reports request for proposals:

- Current graduate or undergraduate student
- Post-doctoral scholar
- Pre-tenure faculty members
- Faculty who are not in a tenure-track position, but are at most 6 years removed from their graduate degree

Data in Current Proof Research



Populations of Interest



Code Definitions

Code	Description
Real Classroom Research	The study employed data collected from an instructional space, either physical or virtual, shared by instructor(s) and students, which mimics as closely as possible the naturalistic setting of their class meetings on any given day. This does not include classroom lessons of pre-service teachers delivering lessons as a course assignment.
Survey Research	The study employed data collected through a survey of opinions or experiences of participants.
Assessment/Inventory Measure(s) Research	The study employed data collected through an assessment or inventory, which assigned a score of some kind (e.g., pre-test/post-test, self-efficacy inventory).
Interview Research (Non-Task-Based)	The study employed data collected through a general interview not rooted in a think-aloud mathematical task.
Task-Based Interview Research	The study employed data collected through an interview rooted in having participants narrate their thoughts and actions while completing a mathematical task.
Artifact Analysis	The study employed data from classroom or course artifacts such as homework, classwork, or written reflections.
Text/Document Analysis	The study analyzed written resources (textbooks, exams, research publications, etc.) in order to answer a research question about the state of available resources.
Collaborative Proving Research	The study employed data from the context of collaborative proving (whether in a classroom or in an interview setting) or the study aimed to investigate collaborative proving as a primary goal. It is not enough for the course context to involve collaborative proving or collaboration without it being an element of the research.
Research Subject	A categorical variable describing the population of interest in the report. Pre-Service Teacher, In-Service Teacher, Undergraduate Mathematics Instructor, Mathematician, Multiple of these, or Other/NA.

Results

This review discovered three trends in undergraduate proof research in recent RUME conference proceedings:

01
The RUME Proceedings Reports concerning proof are dominated by early-career scholars, but there may be a new wave of interest in research on collaborative proving from and conducting research in real classrooms among early-career scholars in RUME.

02
Research was most often conducted in laboratory settings, with frequent use of task-based interviews

03
Research was most often focused on undergraduate math students.

Discussion

Why Conference Proceedings?

We chose to first look at the RUME conference proceedings because these best reflect the current research happening in undergraduate mathematics education research, as the process of publishing in a peer-reviewed journal may take an extended period of time and not best reflect current endeavors.

Future Directions

As we recognize some proof research may have been overlooked due to our search methods, we intend to expand this search in the future to more systematically identify research related to proof. This may occur either within the RUME proceedings by attending to the primary and secondary categories listed in accepted RUME submissions, or by expanding our keyword search in reputable research journals.

Questions

- When we expand the search to journal publications, what journals should we consider in order to get a broad representation of the field?
- What kinds of questions do you have about the proof research being conducted in RUME?

How one GTA used Data to Promote Student Engagement

Katie Taylor
University of Alabama

Derek Williams
Montana State University

Keywords: student engagement; social engagement; GTA development; group work

Student engagement is essential for rich learning (Middleton et al., 2017). Research shows that student engagement consists of emotional, social, cognitive, and behavioral components (Middleton et al., 2017); tends to decline in mathematics classrooms over any time interval (e.g., Martin et al., 2015), in-the-moment states fluctuate (e.g., Williams, 2022); and that classroom environments can be designed to promote engagement (Fredricks et al., 2004). Given research on college instructors attending to engagement is rare, the purpose of this study is to investigate how one GTA reflected on student self-reports of engagement during a precalculus course to promote engagement. We also discuss whether and how students responded to the GTA's strategies.

Theoretical Framework

Classrooms are dynamic environments influenced by a myriad of factors. We draw on dynamic systems theory (Vauras et al., 2013) to attend to the interpersonal back-and-forth between instructors' pedagogical strategies and students' reactions.

Methods

We address the questions: (1) How did a GTA use student engagement data to make pedagogical decisions?, and (2) How did students respond to the GTA's implementation?.

We collected self-reported information about student engagement using the experience sampling method (Nakamura & Csikszentmihalyi, 2009). The survey instrument was informed by flow theory, and has been used in college mathematics classrooms (e.g., Williams, 2022). These data were then aggregated and visualizations were shared with the GTA during virtually conducted and recorded meetings. We also recorded classroom observations. We used qualitative analysis methods and state space grids (e.g., Turner et al., 2014) to produce results.

Results and Conclusions

The GTA's primary strategy to promote engagement was group work, and the students' self-reported engagement, on aggregate, improved when group work was implemented. However, the GTA could rationalize when and why group work would either not be appropriate or would potentially not influence student engagement with hypotheses that included activity length and problem difficulty. Classroom observations also revealed patterns in student-teacher conversations and group work activity. The GTA's location in the classroom was related to whether students asked the GTA questions versus asking their peers. The amount of visible interaction between group members was based on the details and instructions provided by the GTA's when introducing activities. Our results show a link between the GTA's expected student involvement in groups with the self-reported levels of engagement and data to offer potential explanations for these relationships. Thus, we propose GTAs can attend to student engagement in ways that support students' growth and instructors' pedagogical goals during a single semester in a mathematics course.

Derek Williams, Montana State University

PURPOSE & MOTIVATION

- Research shows that student engagement
  - is a complex meta-construct consisting of behavioral, social, emotional/affective, and cognitive components (Fredricks, Blumenfeld, & Paris, 2004; Middleton, Jansen, & Goldin, 2017)
  - tends to decline in mathematics classrooms over any time interval (e.g., Martin et al., 2015)
  - in-the-moment states fluctuate (e.g., Williams, 2022)
  - and that classroom environments can be designed to promote engagement (Fredricks et al., 2004).
- Given research on college instructors attending to engagement is rare, the purpose of this study is to investigate how one GTA reflected on student self-reports of engagement during a precalculus course to promote engagement.
- We also discuss whether and how students responded to the GTA's strategies.

RESEARCH QUESTIONS

1. How did a GTA use student engagement data to make pedagogical decisions?
2. How did students respond to the GTA's implementation?

THEORETICAL FRAMEWORKS

Classrooms are dynamic environments influenced by a myriad of factors. We draw on dynamic systems theory (Vauras et al., 2013) to attend to the interpersonal back-and-forth between instructors' pedagogical strategies and students' reactions.

RESULTS

GTA Statements During Discussions/Reflections

"On Friday, it is supposed to be all group work…I think that will be good. Maybe even more so than on Monday…or maybe group work goes too far sometimes."

"Admittedly, today was more of a lecture format because I wanted to get a lot of stuff out of the way, so I expected those on the right to be way lower."

"I had them working together on the end but through the whole like first part it was like I had some questions where it was supposed to just be like alright them themselves think about it."

CONCLUSION

- The GTA's primary strategy to promote engagement was group work
  - The students' self-reported engagement, on aggregate, improved when group work was implemented
  - However, the GTA could rationalize when and why group work would either not be appropriate or would potentially not influence student engagement with hypotheses that included activity length and problem difficulty.
- Classroom observations also revealed patterns in student-teacher conversations and group work activity.
  - The GTA's location in the classroom was related to whether students asked the GTA questions versus asking their peers.
  - The amount of visible interaction between group members was based on the details and instructions provided by the GTA when introducing activities.
- Our results show a link between the GTA's expected student involvement in groups with the self-reported levels of engagement and data to offer potential explanations for these relationships.
- Thus, we propose GTAs can attend to student engagement in ways that support students' growth and instructors' pedagogical goals during a single semester in a mathematics course.

Network-Based Trajectory Analysis and Framework Development of Precalculus Curricula

Cristina Flores Vlad Nita John O'Meara Ashwin Vaidya

Montclair State University

Keywords: network theory, curriculum, identity, complexity science, connectivity, precalculus

This synthesis of previous work and ongoing research efforts calls for a network theory mediated analysis to investigate the affordances of curriculum and, in particular, its alignment with student learning processes. The three factors that are identified and considered in this study are the student, curricular materials, and the respective environments from which these members arise and how these act as determinants of curriculum development and design. There are three primary research questions addressed here: **(1)** How does the development of connections between topics within a specific precalculus course's curricular materials (textbook and online learning platform) over the course of a semester influence and/or align with the development of students' connections? **(2)** How does the development of connections between precalculus topics as perceived by students with respect to average path length (APL), clustering coefficient (CC), and the distribution of highly connected topics (Hubs) correlate with their performance in the course? **(3)** To what extent do equitable and identity-based curricular supplements (having students provide specific personal connections to the material, as well as draft problem sessions based on student interests) have an impact on student performance and/or perceived connectivity of precalculus topics?

A network theoretic perspective of various precalculus curricula (O'Meara & Vaidya, 2021) proves helpful in identifying and motivating key features of the subject as they appear in course texts. Based on this framework, an undirected network representation of a specific precalculus course's materials is constructed in which nodes represent topics introduced throughout the materials, and edges represent explicit connections formed between topics. Edges are weighted based on frequency of relation between two given topics, and nodes are weighted based on overall degree distribution. Students are administered an IRB-approved survey on a biweekly basis in which they are provided with sets of topics covered in the course up to a given point. They are then asked to form any connections they see fit, and these self-reported connections are stored as undirected networks whose properties and relevant metrics are analyzed upon each submission period through the end of the semester to gain insight into student learning trajectories. The corresponding poster will display the dynamic nature of the evolution of students' networks, as well as insights into how course performance can be correlated with both features of the students' networks and the course's 'ideal' network structure. This project aims to lay the foundation for meaningful intervention and predictive analytical tools that instructors can make use of in order to identify which students are likely to struggle in the course, and with what particular topics they are failing to fully comprehend. Such an extension is mitigated by a qualitative analysis of identity-based surveys and collaboratively constructed problem sets where the presence of personal connections in this medium are compared and correlated to the students' connected network structures and their overall performance in the course.

The implications of this work seek to assist in the optimization of the complex system synthesizing various feedback-based designs within educator roles, student response, and the interactions between the two as they pertain to various stages of the curriculum development process. The results of this study aim to provide a deeper understanding of the extent to which the components of an andragogical system can be refined via regulated and personalized learning methods.

Mathematical Modeling of Student Learning Network

MONTCLAIR STATE UNIVERSITY

John O'Meara, Cristina Flores, and Vlad Nita
Advisor: Ashwin Vaidya

Department of Mathematics
Montclair State University
1 Normal Avenue, Montclair, NJ 07043

Introduction

This synthesis employs a network theory mediated analysis to investigate the affordances of curriculum and, in particular, its alignment with student learning processes. Via the utilization of various lenses of network theory, 'connected curriculum' design (Fung, 2017), and modern learning curve theory (Thurstone, 1918; MacLellan et al, 2015), we collectively postulate that education is inherently a complex system at various scales and stages of the learning and teaching process. A network perspective of precalculus curricula (O'Meara and Vaidya, 2021) proves helpful in identifying and motivating key features of the subject as they appear in course texts. Of these, hubs and time-series developments of relevant computed metrics have been particularly useful in mapping the alignment between the preset goals of the precalculus course, as identified in previous literature, and its execution. At the same time, this analysis has also been valuable in identifying the trajectory of the textbook curricula in adequately preparing precalculus students for success in calculus and beyond.

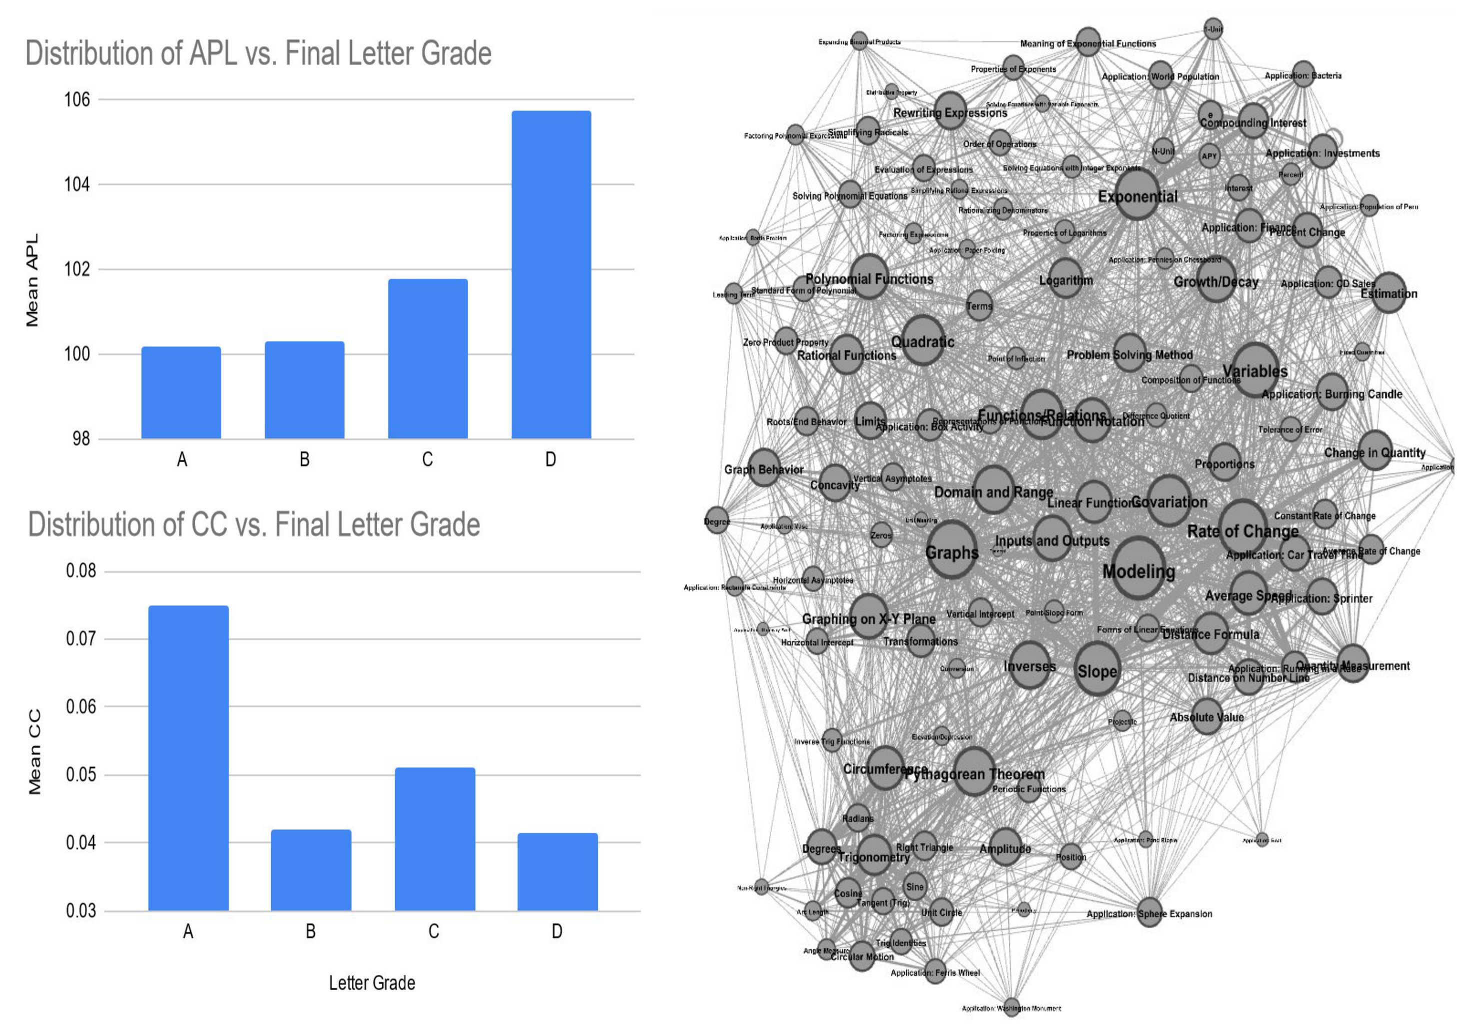

Figure 1: Aggregate results of student concept maps / self-reported networks in which individual perceived connections are formed amongst course topics. Pictured above are histograms displaying relevant network metrics with respect to final grade distribution (left), and the union of all student networks with node size adjusted for degree/span of connectivity (right).

Research Questions

(1) How does the development of connections between topics within a specific precalculus course's curricular materials (textbook and online learning platform) over the course of a semester influence and/or align with the development of students' connections?

(2) How does the development of connections between precalculus topics as perceived by students with respect to average path length (APL), clustering coefficient (CC), and the distribution of highly connected topics (Hubs) correlate with their performance in the course?

(3) What affordances do the alignment between research-based curricular taxonomy and course materials provide? How do observations in precalculus influence the transition for students into calculus and beyond?

(4) To what extent do equitable and identity-based curricular supplements (having students provide specific personal connections to the material, as well as draft problem sessions based on student interests) have an impact on student performance and/or perceived connectivity of precalculus topics?

Research Design

Students are administered an IRB-approved survey (FY21-22-2488) on a biweekly basis in which they are provided with sets of topics covered in the course up to a given point. They are then asked to form any connections they see fit, and these self-reported connections are stored as undirected networks whose properties and relevant metrics are analyzed upon each submission period through the end of the semester to gain insight into student learning trajectories. This acts as an intervention and predictive analytical tools that instructors can make use of in order to identify which students are likely to struggle in the course, and with what particular topics they are failing to fully comprehend. Such an extension is mitigated by a qualitative analysis of identity-based surveys and collaboratively constructed problem sets where the presence of personal connections in this medium are compared and correlated to the students' connected network structures and their overall performance in the course.

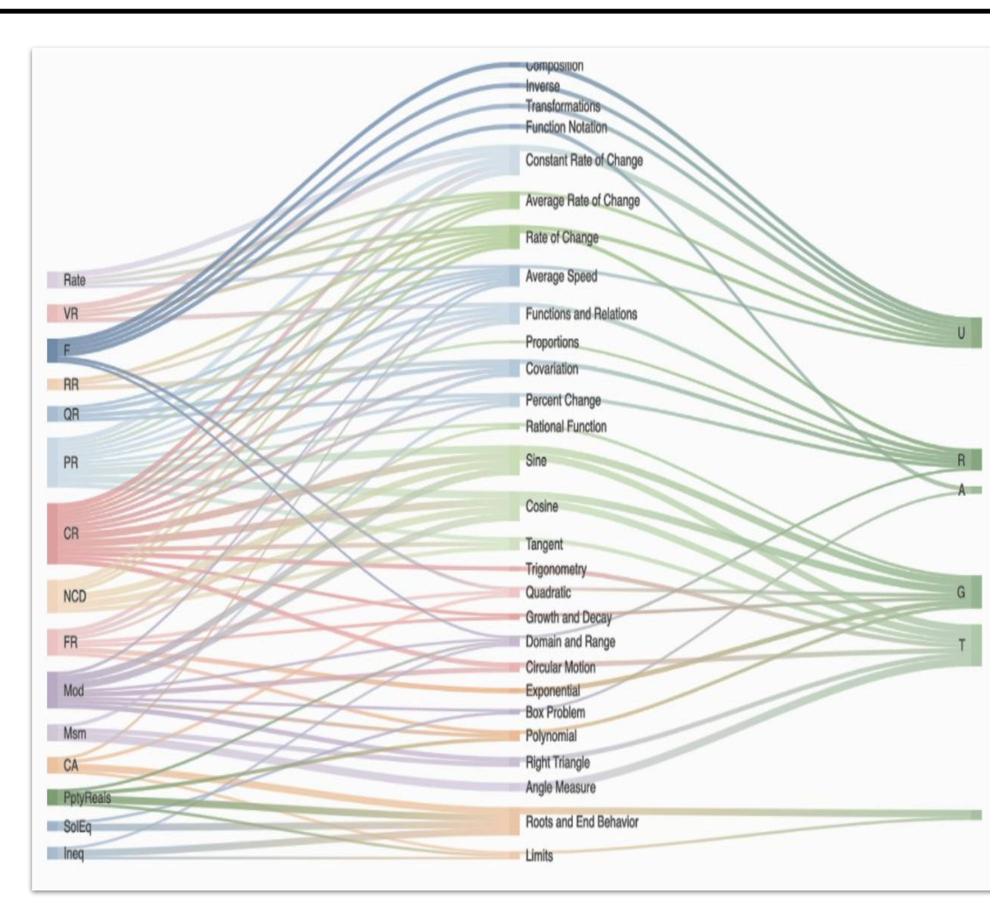

Figure 2: Representation of prominent precalculus topics as an informational exchange between precalculus taxonomy, course textbook, and calculus taxonomy principles.

Findings

Highly successful texts have been found to display a power law with respect to frequency distribution of connected topic inclusion ($\alpha = 0.05$), among consideration of other theoretical distributions, to assess whether or not meaningful learning patterns retain consistent underlying patterns and/or distributions. The most well-connected topics (Hubs) are regarded as necessary markers of classroom discourse, and the extent to which they are considered in taxonomical goals was measured with respect to the empirical distributions of both the intended curriculum and enacted curriculum.

The results of this study aim to not only provide a deeper understanding of how intended and enacted curriculums interact with each other, but also considers to what extent the components of an andragogical system can be refined via the magnitude of their presence in both course materials and feedback provided directly by active participants in the learning environment.

Keywords: Professional Development, Practitioners, Emerging Researchers

Faculty involved in education research have highly varied backgrounds. Some have received formal training through graduate programs in discipline-based education research (DBER),others may begin as a postdoctoral researcher, still others may not have begun until they were established faculty at an institution. Some are hired because of their education specialities (Bush et al., 2017), while others grow into this role as part of their engagement with the pedagogical mission of their unit.

Researchers who complete graduate programs or post-doctoral programs in education research are prepared for research. Those who become involved with education research as faculty have limited options for formal learning and guidance. The Professional development for Emerging Education Researchers (PEER) program was established to support these emerging DBER practitioners (Franklin et al., 2018). PEER offers workshops and mentoring to support emerging DBER practitioners in developing their education research skills.

PEER is strongly grounded in two theoretical perspectives: responsive teaching, and communities of practice. Responsive teaching is a model of teaching in STEM education that places high importance on centering and responding to the ideas of students and the connections they are making (Robertson et al., 2015). PEER workshops also seek to develop a local community of practice among participants (Wenger, 1999). Many emerging practitioners are still developing their identity as education researchers, and a community of fellow practitioners is critical to supporting that development.

The challenges posed by the COVID-19 pandemic led to changes to PEER's structure as we pivoted to an online format. PEER has returned to offering in person workshops, but lessons learned during the pandemic have had lasting effects on how we assess and respond to the needs and interests of participants. Notably the existence of new hybrid and online formats, and the addition of an online "kickoff" meeting which is now held before most PEER workshops.

In this poster we present lessons learned during the pandemic, and the impacts on PEER. We discuss implications for professional development initiatives, focusing on integrating online sessions for community building and pre-workshop preparation. Pre-workshop online meetings can serve as tools for informing both participants and facilitators about the structure of the workshop, and identifying adjustments that may need to be made to the program.

Pandemic Changes

Online Field Schools

- Keep sessions short: reduce burnout
- Lots of small group discussions
- Facilitator panels: divide facilitators across different online rooms

Virtual Kickoffs

- Pre-fieldschool introductions!
- We are doing these even for in person field schools now
- Establish expectations for program ahead of time
- Get early participant feedback

Gateway Workshops

- Lightning fast, often online, 1.5-3 hours
- Quick introduction to fundamental topics
- Inexpensive, can be run at professional meetings/conferences
- Provide exposure

PEER

- Professional development for Emerging Education Researchers
- Est. 2014
- 22 in person field schools
- 4 online workshops
- Hundreds of participants
- Across 3 continents

Responsive

Collaborative

Research is...

Communicative

Playful

Our Research Model

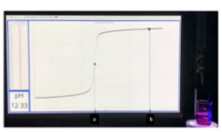
Using Multiple Disciplinary Lenses to Explore Students' Graphical Interpretation: A Case Study

Nigar Altindis Kathleen A. Bowe Brock Couch Melissa Aikens
University of New Hampshire

Key Words: Graphical Reasoning, Knowledge in Pieces, Shape Thinking, Multidisciplinary

We present a case study of how one student, Aubrey, utilized ideas from biology, mathematics, and chemistry to make sense of a graph common to introductory chemistry: a titration curve. Via multidisciplinary analysis, we found that Aubrey exhibited shape thinking activated by biology resources. However, while she also activated math resources, her interpretation was bound by treating the graph as a static object. Furthermore, Aubrey activated chemistry resources to 'read beyond the data,' but her inferences appeared to be influenced by biology resources. With the current findings, we argue that students may memorize graph features without understanding what is happening conceptually or mathematically and then transfer these learned facts to other disciplinary contexts. Therefore, instructors should be aware of the knowledge and reasoning skills a student may bring from other introductory STEM courses when interpreting graphs.

While previous literature has explored graphical interpretation generally and from specific disciplinary perspectives (e.g., Roth et al., 1999; Rodriguez et al., 2019), there is limited multidisciplinary work. This poster fills that gap by presenting a unique case study of a graphical interpretation task from chemical, biological, and mathematical points of view. Participants (n=15) were recruited from introductory biology and chemistry courses. Data include semi-structured, hour-long interviews involving three tasks. We present only the results of one task: Aubrey's graphical interpretation of a titration curve (Figure 1). A multidisciplinary analysis was conducted using Corbin and Strauss's (2008) constant comparison method.



Task 1: In a titration experiment, a base is added to an acidic solution at a constant rate. The graph (Figure 1) shows how the pH of the solution changes with the amount of base added. Using the graph, explain the relationship between the pH of the solution and the amount of base added to the solution.

Figure 1. The Titration Curve Task.

Aubrey employed resources from each discipline to interpret the titration curve, but her sense-making was bound to her understanding of a biology graph with a similar S-shape. This suggests students may memorize and transfer learned facts about graph features to other disciplinary contexts. However, to engage in authentic interpretation across disciplines, students need to be able to make sense of all curvature and critical points on a graph and understand how they emerge from simultaneous changes in quantities. Therefore, it may be valuable to prompt science students to think through mathematically meaningful critical points or graph features in the context of the physical phenomenon they represent. In conducting a multidisciplinary analysis, we discovered tensions between each discipline's interpretation and expectations. Thus, while this poster presents data and conclusions from a unique case study, it also provides pedagogical insights from adopting a multidisciplinary approach.

Background

Problem Statement

How do students reason about quantities and quantitative relationships as part of interpreting and making inferences about graphs commonly discussed in introductory biology and chemistry courses?

Theoretical Orientation

Quantitative Reasoning ⟷ Covariational Reasoning

Representations ⟷ Graphical Reasoning

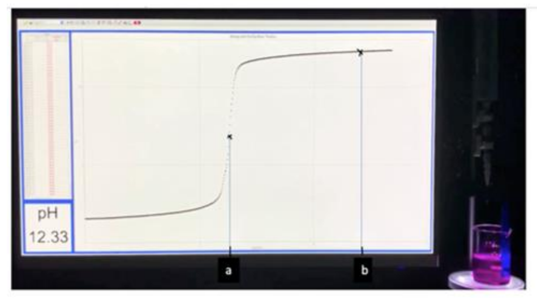
Data Collection

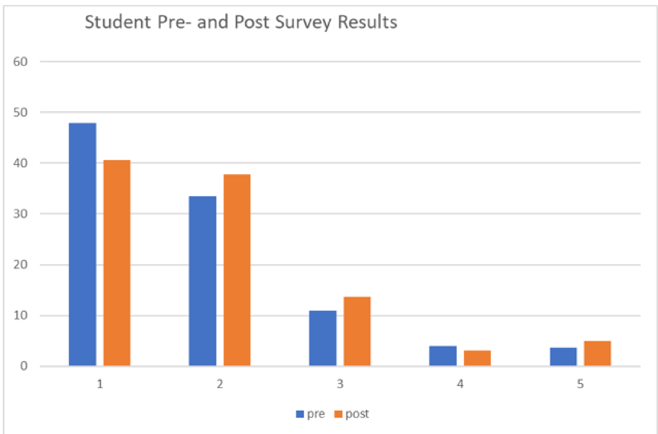
- Method
  - Surveys
    - Pre-survey (n=660)
    - Post-survey (n=492)
  - Interviews
    - Pre-interview (n=16)
    - Post-interview (n=15)

Titration Task

In a titration experiment, a base is added to an acidic solution at a constant rate. The graph below shows how pH of the solution changes with amount of base added. Using simulation video and the graph below, explain the behavior of function f that represents pH on the interval from $x = a\ , and\ x = b$.

1. pH is increasing at an increasing rate.
2. **pH is increasing at a decreasing rate.**
3. pH is increasing at a constant rate.
4. pH is decreasing at a decreasing rate.
5. pH is decreasing at an increasing rate.





Analytical Method

- Three disciplinary-based education experts (mathematics, biology, and chemistry) analyzed Aubrey's response from their disciplinary perspective
- Knowledge-in-pieces
- Open Coding
- Constant comparison

Findings

Biology

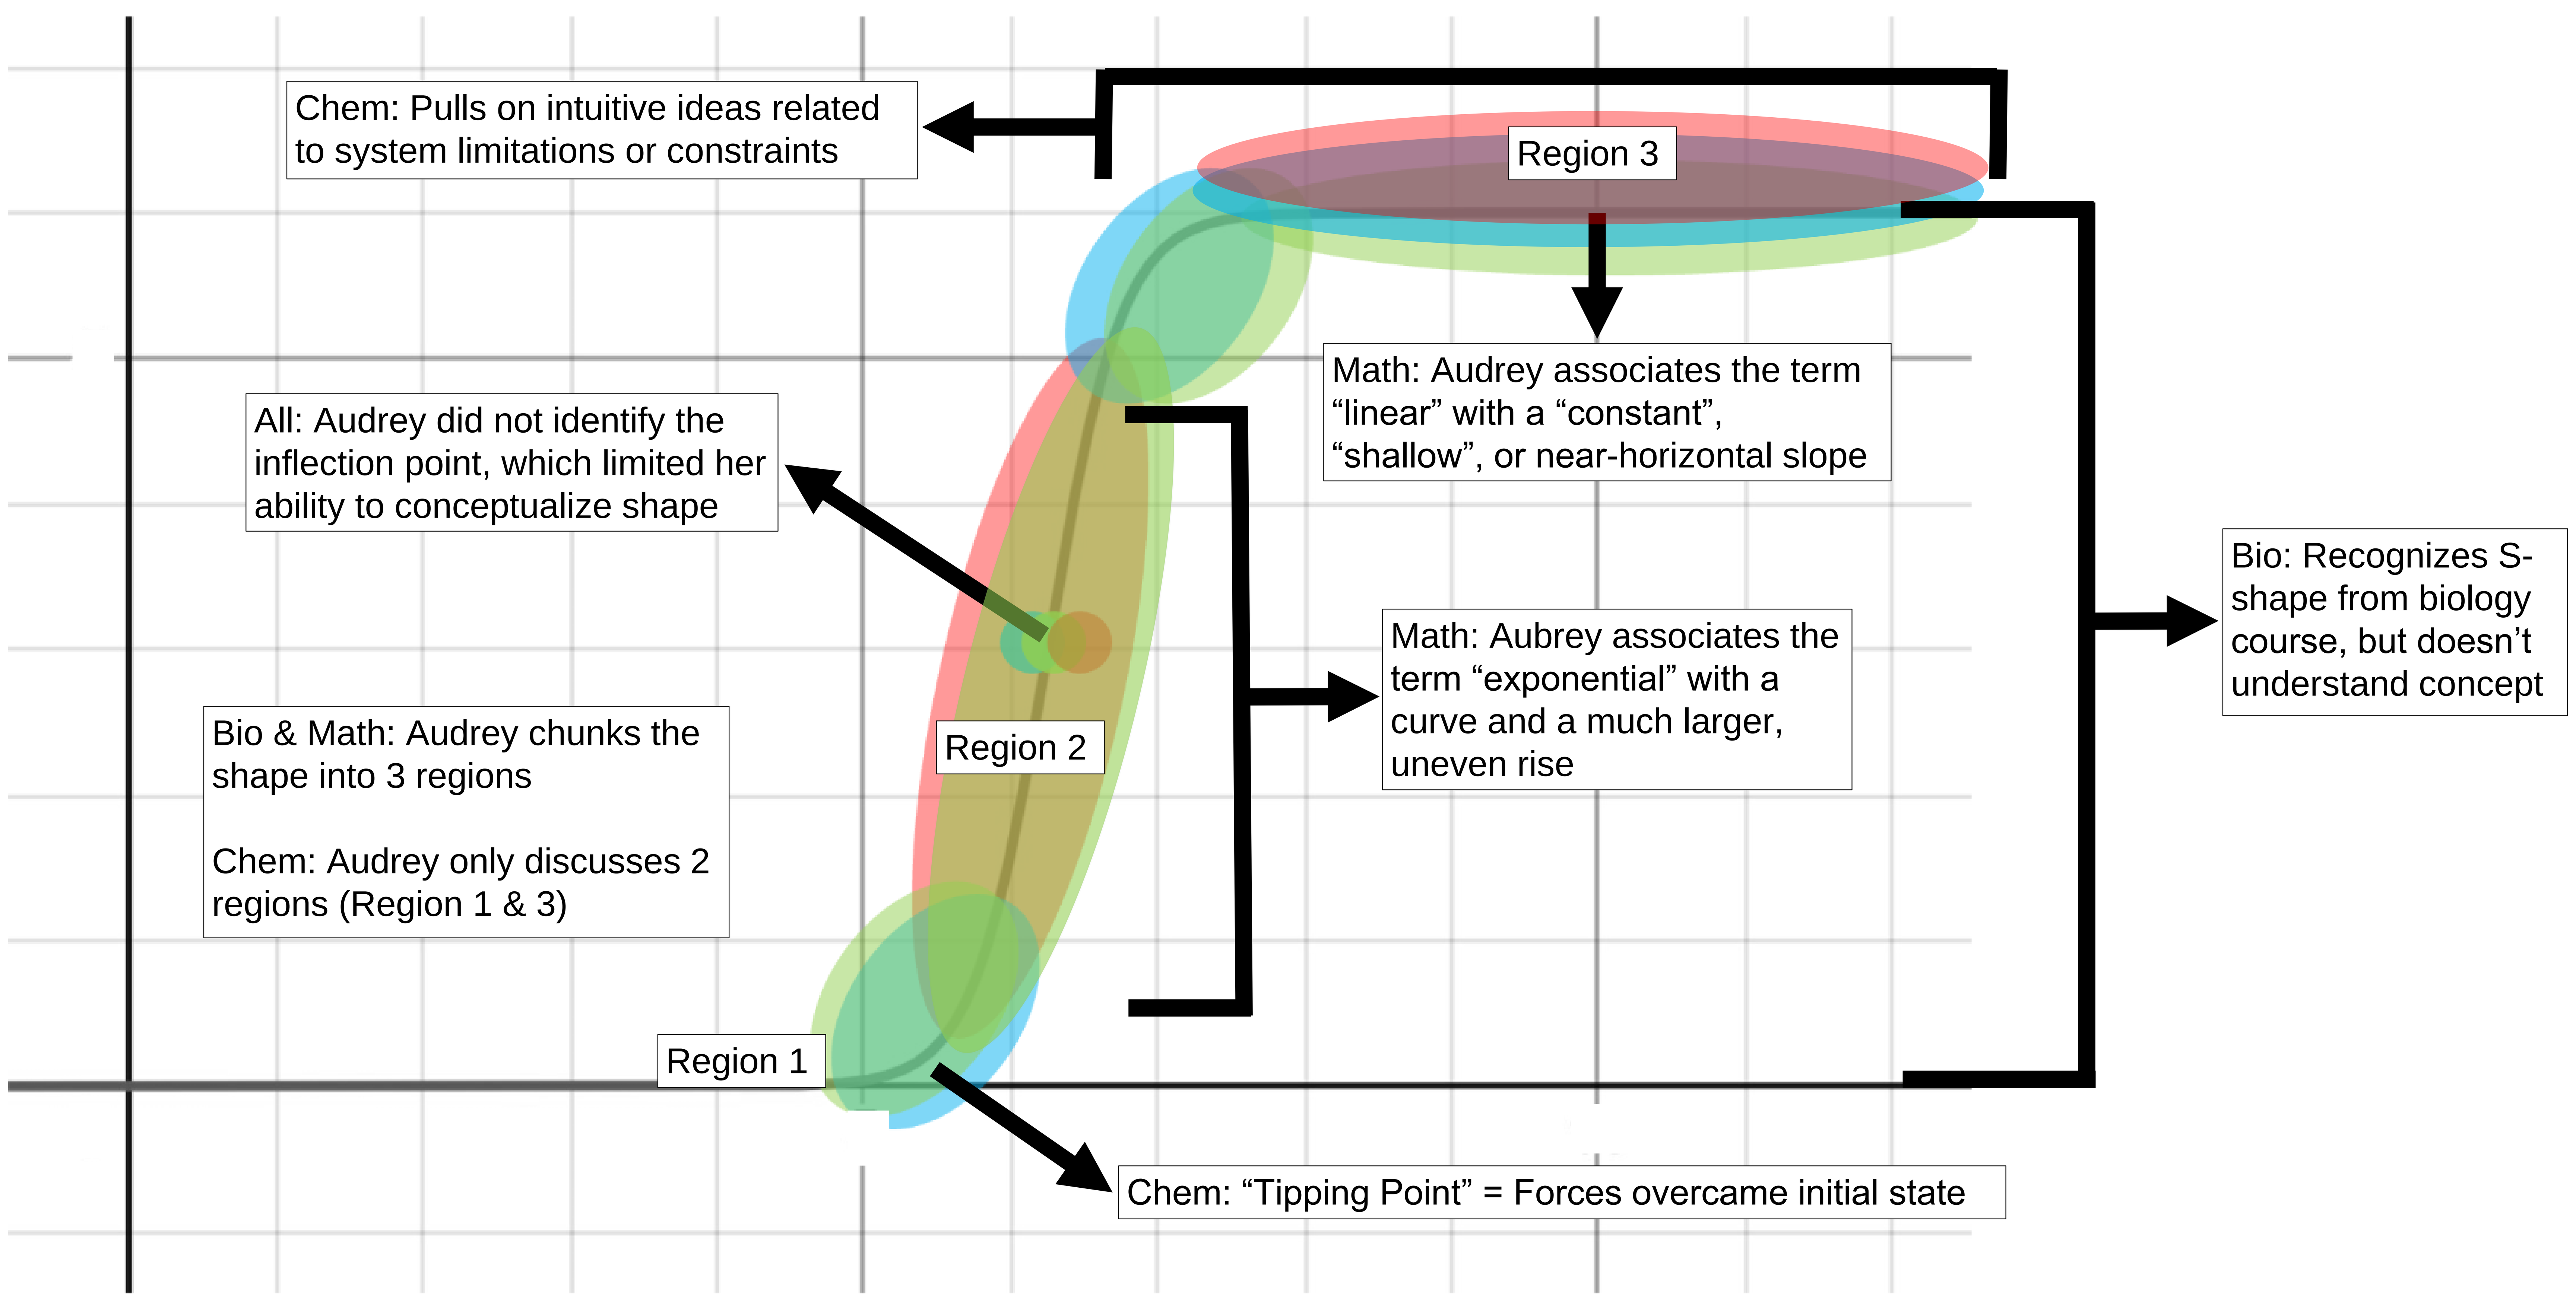
Overall: Aubrey activates biology resources that are rooted in viewing the graph as a static object

Chemistry

Overall: Aubrey activates chemistry resources to 'read beyond the data,' but her inferences appear influenced by biology resources

Mathematics

Overall: Aubrey activates math resources, but her interpretation is bound by treating the graph as a static object



Key Takeaways

- Instructors should be aware of the knowledge and reasoning skills a student may bring from other introductory STEM courses when interpreting graphs
  - Students may be viewing graphs as disconnected chunks, instead of a continuous set of data
  - Students may also be missing important mathematical features of the graph, such as the inflection point
- Graph features matter differently across disciplines, which may impact the type and sophistication of reasoning used
  - In science, it may be sufficient to associate concepts with chunks or shapes as part of focusing on interpretation and "reading beyond the data"
  - However, this may promote students to think of graphs as objects composed of shapes, rather than as emerging through covariation
  - Therefore, it may be valuable for science instructors to prompt students to engage with graphs from a more mathematical perspective

Preliminary Findings Regarding Student Learning from Lecture and Homework

Hadlee Shields
Oklahoma State University

Allison Dorko
Oklahoma State University

Keywords: homework, lecture, relearning

Lectures and homework both provide opportunities for students to learn mathematics. Researchers have focused on learning from lectures (e.g.,Krupnik et al., 2018; Lew et al., 2016; Lew & Zazkis, 2019) and learning from homework (e.g., Dorko, 2021; 2020a, 2020b; 2019; Ellis et al., 2015; Glass & Sue, 2008; Kanwal, 2020; Krause & Putnam, 2016; Lithner, 2003; Rupnow et al., 2021). Dorko and Cook (under review; 2022) propose attending to learning across the two settings is crucial to improving student learning in both settings. To that end, our study addresses the questions (1) *What did two developmental mathematics students learn in lecture and what did they learn from homework?* and (2) *How can we explain why they learn particular things in a particular context?*

The data collected spanned eight 75-minute lectures, three written homework assignments, six online homework assignments, and one exam from a developmental math class at a large US university. This constituted the material from the class period following the first exam to the class period directly prior to the second exam, and the exam itself. The content included creating graphs on a graphing calculator, using the graphs to solve inequality and optimization problems, solving linear equations by hand, and using slope to find horizontal or vertical changes in right triangle problems. The data corpus includes videos of the lectures, videos of each student doing the homework, and an interview with each student about their graded exam. In the homework sessions, the interviewer asked students to “think aloud”, asked where they had learned particular ideas, and showed students clips from the lecture video and asked what sense they had made of that portion of the lecture. In the post-exam interview, the interviewer and student discussed where the student felt they had learned the material tested in each question.

Because the course is a developmental math class, our theoretical perspective is that of *relearning*, which Amman and Mejia Ramos (2022) define as “learning about content that one has tried to learn before in a previous math course” (p. 752). Relearning is a suitable perspective for our work because it allows us to look at student learning in the context of homework and lecture in terms of the outcomes that are occurring and how the circumstances of the contexts support or limit those outcomes (Amman & Mejia Ramos, 2022). Data analysis is ongoing, following a thematic analysis method (Braun & Clark, 2020). Preliminary findings indicate students learned (a) how to identify independent and dependent quantities; how to use the calculator to make graphs, (b) how to interpret graphs, (c) how solving an inequality is different from solving an equation and how to do both on the calculator; (d) how to optimize functions on the calculator. Students commented that getting answers wrong in the online homework helped them understand how to solve inequalities and optimization problems.

For most of the items above, the students said they learned the ideas both in lecture and homework. Their comments indicated lecture exposed them to ideas and homework afforded an opportunity to “have to like remember and go back over how to do it” (Student 3) and have ideas “cemented in my brain” (Student 3).

Allison Dorko
Oklahoma State University

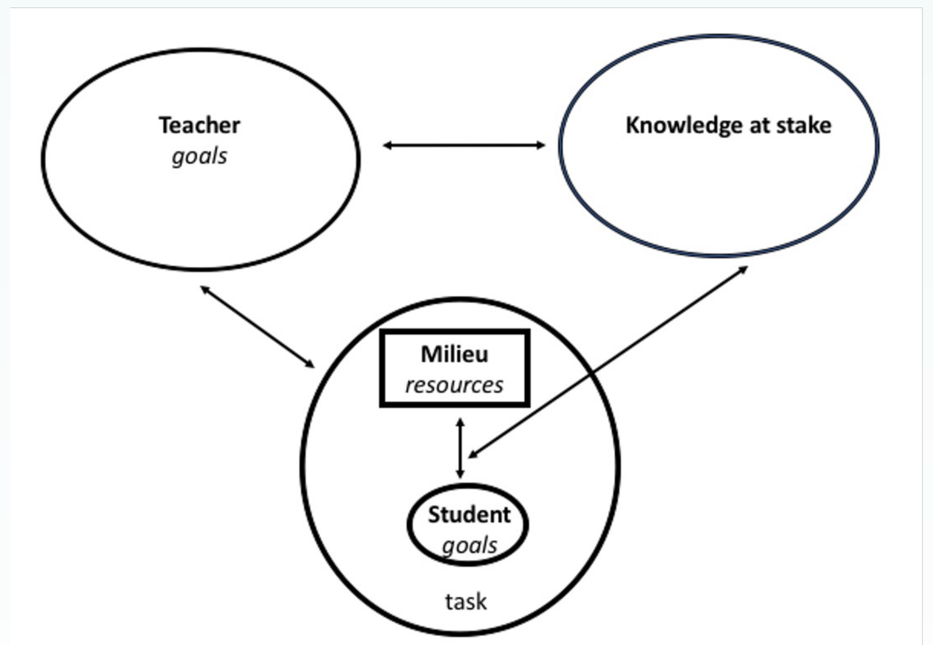
Abstract

Lectures and homework both provide opportunities for students to learn mathematics. Researchers have focused on learning from lectures (e.g., Krupnik et al., 2018; Lew et al., 2016; Lew & Zazkis, 2019) and from homework (e.g., Dorko, 2021; 2020a, 2020b; 2019; Ellis et al., 2015; Glass & Sue, 2008; Kanwal, 2020; Krause & Putnam, 2016; Lithner, 2003; Rupnow et al., 2021). However, these studies have focused on each milieu individually. Dorko and Cook (R&R, 2022) propose attending to learning across the two settings is critical for improving student learning in both settings. To that end, our study addresses the questions (1) *What did two developmental mathematics students learn in lecture and what did they learn from homework?* and (2) *How can we explain why they learn particular things in a particular context?*

Theoretical Perspective

Our work is broadly framed with the instructional triangle, and we make sense of an individual's learning through Piagetian learning theory.

- Instructional triangle (Cohen et al., 2005; Dorko, 2021; Herbst & Chazan, 2012): instruction is the interactions among teachers and students around content, in environments
  - Milieu: a space in which interactions around mathematical tasks occur
    - Lecture is one milieu; HW is another



- Piagetian learning theory (von Glasersfeld, 1995)
  - Students' schemes entail (among other things) an expected result of applying the scheme.
  - Perturbation occurs when an outcome differs from the expected result.
  - Perturbation may or may not result in accommodation to achieve equilibration.
    - We define learning as accommodation to a scheme.

Literature

Though student learning from online homework is a relatively new focus for undergraduate mathematics education researchers, studies have shown:

- Online homework is as effective as paper-and-pencil homework (Dorko, 2020).
- Most successful US college calculus programs have an online homework component (Ellis et al., 2015).
- Students commonly rely on example problems to complete homework.
  - In one study, 84.7% of students reported using worked examples while doing homework.

When completing online homework students used reasoning that included (Dorko 2021, 2020)

- Mathematical thinking
- Guessing
- Copying answers from various sources
- Mimicking the steps of a similar problem
- Reasoning based on expectations from experience

Students learn the procedures from online homework problems, but rarely develop the conceptual insights professors hope some problems might promote (Dorko, 2020, 2021, 2019)

Issues that professors face

- Students worry more about the procedure than the concept itself (Lew et al., 2016; Thompson, 2013; Thompson et al., 1994)
- Students only write what the professor writes (Lew et al., 2016)
- Students may miss verbal-only comments (Lew et al., 2016)

Data Collection Methods

Course context

We collected data from a developmental math class at a large US university. The content was from the class period following the first exam to the class period directly prior to the second exam, and the exam itself. The content included creating graphs on a graphing calculator, using the graphs to solve inequality and optimization problems, solving linear equations by hand, and using slope to find horizontal or vertical changes in right triangle problems.

The data collected include

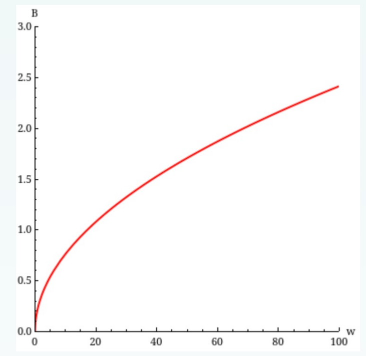
- Videos of eight 75-minute lectures,
- Videos of interviews with students as they completed
  - three written homework assignments
  - six online homework assignments
- The students' exam responses
- An interview with the students about their exams

Data Analysis Methods

Data analysis is ongoing, following a thematic analysis method (Braun & Clark, 2020).

1. Read lecture transcript, make list of the knowledge at stake (e.g. when/how/why to use CALC, INTERSECT on graphing calculator)
2. .Read transcript of HW that covered that content
   - Looked for influences of lecture on HW activity (e.g. doing something that was done in lecture, like using the TI-83 to find an intersection on a graph; using a word/phrase the instructor used, like "isolate" the variable)
3. In HW, identified instances student had to attempt problem multiple times, and sought to unpack how they worked their way to a correct answer
4. Repeat 1-3 for all lecture/HW pairs
5. For exam work and interview, looked at HW problems that covered same content as exam problem and what the student's activity looked like on that problem (e.g. multiple attempts, influences from lecture - see (1))

Example: Student 4 learned...



Online homework task: $B(w) = \frac{\sqrt{210w}}{60}$ gives the body surface area, B, in m^2, for a 210 cm tall man who weighs w pounds. Would weight gain have a greater effect on surface area for a lighter man or for a heavier man? (multiple choice)

Theoretical tenet	Data excerpt	Notes / explanation
Scheme	"I think that it's as someone gets heavier, their surface area increases, so would the weight gain have a greater effect on surface area for a lighter man or a heavier man, I think that means it's going to be heavier."	In S4's scheme for interpreting graphs, the only thing that matters is whether the graph is increasing or decreasing.
Expectation of scheme's outcome	That 'heavier' is correct	
Outcome	'Lighter' is correct	
Evidence of perturbation	[expresses surprise that actual outcome did not match expected outcome	
Evidence of equilibration via accommodation (evidence of learning)	"From 0 to 20 there's a sharper increase than up here…. Because it'll kind of level off somewhere… I think that it's asking more about like the slope and not, not just about the surface area. So I think that's why I got that wrong."	Getting the answer wrong resulted in S4 attending to the graph's rate of change. He modified his scheme to include rate of change as relevant to interpreting graphs.

Results

Preliminary findings indicate students learned (a) how to identify independent and dependent quantities; how to use the calculator to make graphs, (b) how to interpret graphs, (c) how solving an inequality is different from solving an equation, and how to do both on the calculator; (d) how to optimize functions on the calculator. Students commented that getting answers wrong in the online homework helped them understand how to solve inequalities and optimization problems.

- Influence of lecture on HW activity
  - **Taking time to make sense of given information:** Like the instructor, S1 took time to make sense of and employ given information
    - Identifying independent/dependent variables
    - Units
    - Labeling graph
  - **Using words the instructor used** (e.g. "isolate" a variable, "assign a variable")
  - **Problem contexts**
    - Remembered similar problem contexts from lecture and used this similarity to solve HW problems
    - Connected different problem contexts that both had concave up, decreasing graphs
  - **Use of skills:** table to set graphing window, table to select correct graph, CALC menu features, using graph instead of table to solve problems
  - **Ways of looking at graphs** (steepness for concavity, identifying increasing/decreasing as ways to justify use of procedures)
  - **Applying definitions** (recognized an equation as linear based on class definition)
- Learning from HW activity
  - **"Trial and error", "mastery," "putting stuff into practice":** student's description of what and how she learned from homework
    - She primarily went through CALC menu features via trial and error, taking several problems to sort out what to use when
  - **Solution to one problem influencing solution method to next problem** (e.g., generalizing the practical meaning of an increasing, concave up function)
  - **Quantitative meaning for concavity:** computing AROC over different intervals helped her see the changing rate of change and how it influences the shape of the graph

Discussion & Conclusion

- We think students' learning from mistakes can be explained by Piagetian learning theory: seeing an "incorrect" mark perturbs them
- Lecture appears to give students tools, (e.g. features of the calc menu) but they often go through a trial-and-error process in homework figuring out when to use each tool
- Students notice similar problem contexts, as well as abstracting underlying similarities in mathematical structure (e.g. concavity) .

Analyzing Student Understanding of Derivatives Through Tasks Presented Online

Enes Akbuga, Ph.D.[1], Annika Hurd[2], Zachary Benton Hurdle[3]
[1]enes.akbuga@drake.edu, Drake University, [2]Drake University, [3]Utah Valley University

Introduction

Calculus plays a crucial role in STEM (Bressoud 2021) and studies have indicated that **derivate** is a complex concept to learn (Park, 2015; Zandieh, 2000). Researchers have unpacked student cognitive processes and existing mental structures when doing mathematical tasks involving derivatives (Baker, 2000; Asiala, et al., 1997). The COVID-19 pandemic caused disruptions in mathematics courses and more instructors are using online tools like Desmos or WebAssign. We investigate research questions:

(1) To what extent are derivative tasks facilitated with prompting in an online environment helpful for student learning?

(2) What mental structures and connections exist in the student process of doing online derivative tasks?

Framework & Research Questions

APOS theory (Arnon et al., 2014; Dubinsky & McDonald, 2001) is utilized to study student understanding of derivatives. Examinations through APOS theory generally begins with the development of a **genetic decomposition** (GD) and following the GD for derivatives (Asiala et al., 1997), we explored student interpretation of derivatives. To unpack students' mental structures and processes involved, we focused on a Baker et al. (2000)'s **graphing schema** for derivatives which includes the **interval schema** and the **property schema**. Aligned with that, **the triad** (intra-, inter-, and trans) for schema development is used in the context of APOS theory.

Methodology

We conducted semi-structured clinical interviews with **five students** who had taken Calculus I at a college level. Sergio (white male) and Maxine (female of color) are incoming freshmen at state midwestern universities who had completed AP Calculus AB. Amber (white female) and Trisha (white female) completed while Vilma (female of color) was enrolled in Calculus I at a liberal arts midwestern university in the United States. All the interviews were **conducted via Zoom** while the students interacted with **Desmos**. Students described their thought processes as they worked on the two tasks related to derivatives. **The first task** pushes students to think critically about the conceptual understanding of the derivative as the instantaneous slope or slope of the tangent line while **the second task** requires creating a graph of f(x) solely based on given conditions and no equations. During the interviews, the researchers used prompts including "what is a derivative?" or asking students to evaluate f'(x) where x is an arbitrary point.

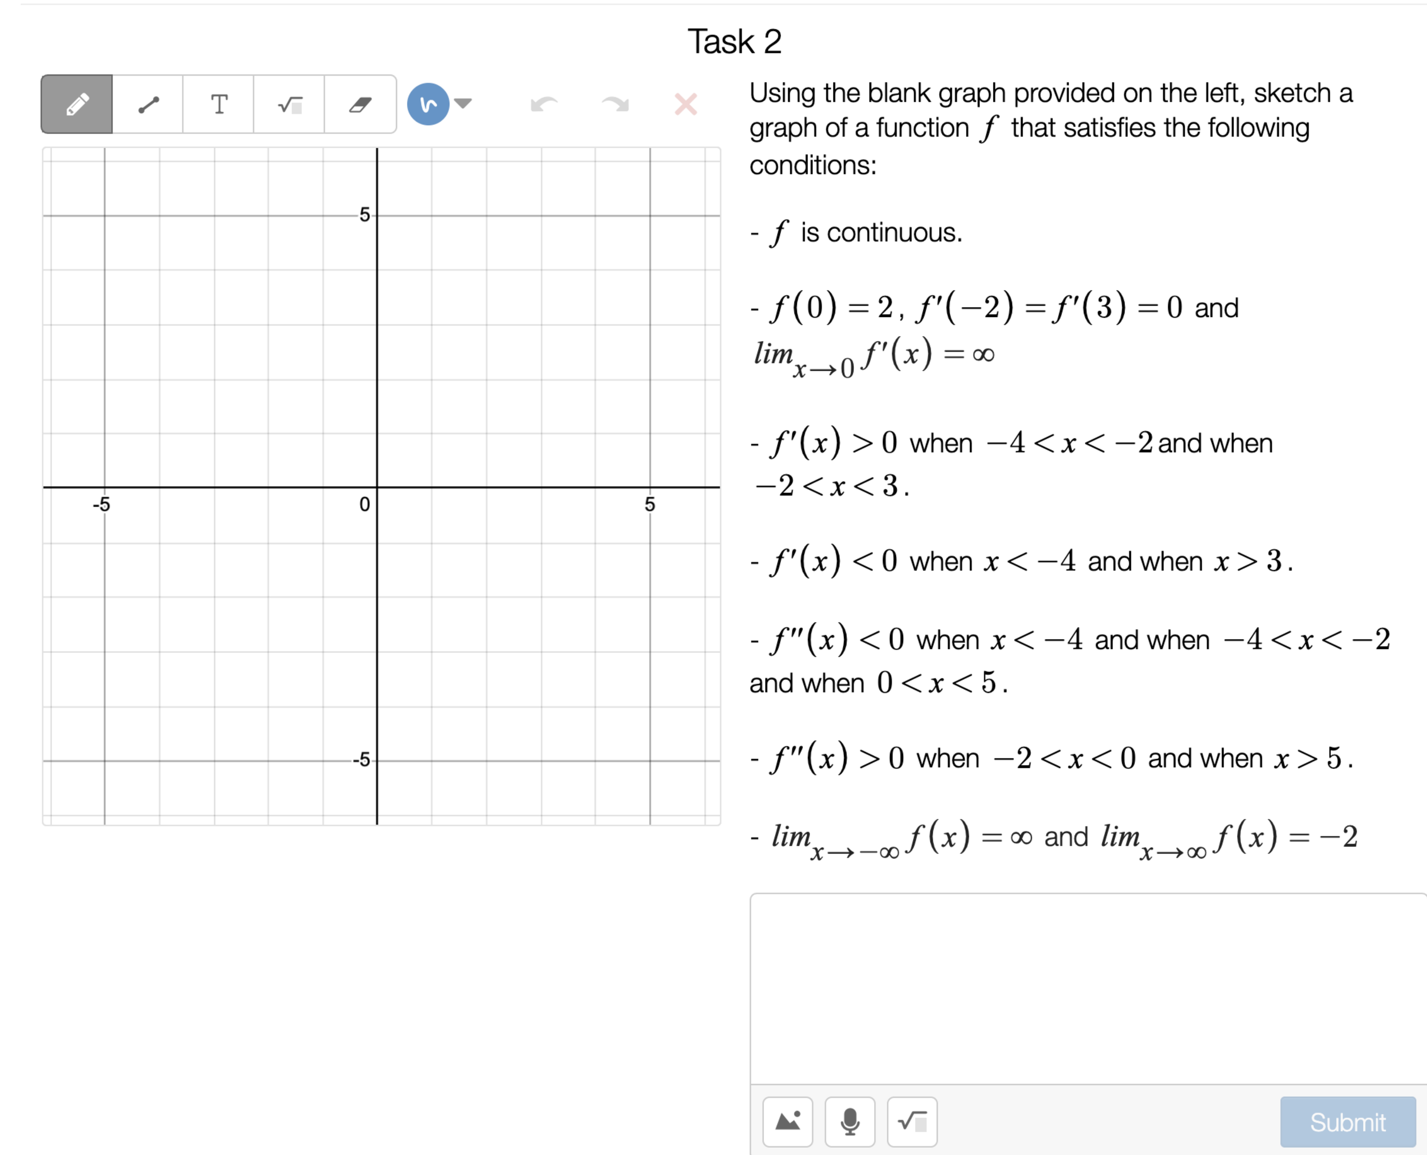
   ii. Coordinate with A to see f'(a) as the slope of a tangent line
   iii. Coordinate several interpretations of f'(a)
D. Graphical interpretation of the derivative as a function
   i. Seeing the derivative as the function, x → slope at (x, f(x))
   ii. Identifying f' with the line tangent at a point
E. Several coordinations to get the graph of f
   i. Graphical interpretation of f(x), for a single x
   ii. Interpretation of f'(x) for a single x as the slope
   iii. Process of x moving through an interval
      a. monotonicity of the function and sign of the derivative
      b. infinite slope (vertical tangent) and infinite derivative
      c. concavity of the function and sign of the second derivative
   iv. Drawing a complete or fully representative graph



The nine dimensions of the Derivative Schema.		Intervals ((-4, -2, (0, 3), etc.)		
		Intra-	*Inter-*	*Trans-*
Properties (monotonicity, concavity, differentiability, etc.)	*Intra-*	Intra-intra	Intra-inter	Intra-trans
	Inter-	Inter-intra	Inter-inter	Inter-trans
	Trans-	Trans-intra	Trans-inter	Trans-trans

Above we present the first task and GD used to analyze (Asiala et. al., (1997) on the left side and second above and the triad model used to analyze that data on the table above.

Results & Discussion

All participants remarked that the tasks looked very different from the type of problems that they had done in-class or for homework in Calculus I. None of the participants had difficulty with using the online tools and Maxine appreciated constructing graphs online. Sergio notes that "...on the [usual] homework you can just find a pattern and knock'em out pretty quick…" but explains that for the novel tasks " … you can't cheat it if it's a conceptual problem, you have to actually think about it." Results suggest that students continue to have difficulties in **going from just "taking derivatives" to conceptual understanding.**

We identified components of the genetic decomposition and their critical role in student understanding of derivatives. We also found evidence of Baker's (2000) two dimensions of student understanding of derivatives (property & interval). Vilma was the only student at trans-trans dimension. We found that using certain prompts like "What is a derivative" or "what's slope elsewhere?" via online environments could also be helpful, but there is a need to investigate this further.

Connecting Modern Algebra with Secondary Math Content

Violeta Vasilevska
Utah Valley University

Keywords: modern algebra, in-service teachers, connections with secondary curricula.

The 2010 report of the Conference Board of the Mathematical Sciences states that among four-year institutions with secondary pre-service teaching certification programs, 89% of the math departments require students to take abstract/modern algebra (Blair, Kirkman, & Maxwell, 2013). In addition, this requirement is advocated by many mathematical societies. However, there is a continued interest in and need for research on how knowledge of mathematical content is employed in teaching practice, as well as how secondary teachers view the relevance of their post-secondary courses in teaching (Zazkis & Leikin, 2010). In May 2019, the presenter attended *Connecting Advanced and Secondary Mathematics* conference, that brought together researchers, mathematicians, and teacher educators to explore these connections and develop plans for further research and/or professional development on these topics (Murray et al., 2017).

In fall 2019, the presenter taught a modern algebra class (covering topics of ring and field theory) for the Graduate Certificate in Mathematics for secondary level math in-service teachers. They implemented ideas from the conference by making intentional connections between the material taught and the secondary math curriculum. The presenter was interested in researching how these intentional teaching interjections changed the in-service teacher's opinion about the relevance of the advanced material covered with respect to the secondary math content the in-service teacher taught as well as the connections they see between the two curricula.

The students in the class (10 in-service teachers) were given pre- and post-surveys, that contained quantitative opinion questions about the relevance and connections between the advanced and secondary content in the curricula. The feedback obtained confirmed the advanced algebra material could be meaningful to teachers by connecting the material with the secondary mathematics and could also support teachers to re-conceptualize, re-structure, and re-understand their knowledge of secondary mathematics (Wasserman, 2016). The pre- and post-survey results showed the students' opinions changed significantly about the relevance and connections of the advanced algebra to secondary math content and about recognizing connections in their own classes.

In addition, students were asked to provide reflective feedback on the exam and the class projects about advanced topics they learned in the class that were the most useful/meaningful for them as well as sharing their opinions and suggestions on these topics. Almost all the advanced topics chosen by students as their favorites/most meaningful/useful, were the ones that were the most applicable in their high school classroom settings. In their comments, students expressed confidence that the advanced class material and connections made in class helped them understand the majority of topics that were covered in the course. As a result, they were now familiar to them on a deeper level. The in-service teachers expressed confidence in better understanding and being able to explain many seemingly true statements (taken for granted) they had been using in their own classes and making their students see relevance in mathematics.

Moreover, the presenter will discuss the questions of the pre- and post-survey results, which show a small increase in change of the students' opinions and brainstorm further (follow up) research questions.

Motivation / Literature Review

- Every five years, the Conference Board of the Mathematical Sciences(CBMS) executes a national survey of undergraduate mathematical and statistical sciences in two- and four-year colleges and universities.
- The 2010 report states that among four-year institutions with secondary pre-service teaching certification programs, 89% of mathematics departments require students to take abstract/modern algebra (Blair, Kirkman, & Maxwell, 2013).
  - ❖ Blair, R., Kirkman, E. E., & Maxwell, J. W. (2013). *Statistical abstract of undergraduate programs in the mathematical sciences in the United States: Fall 2010 CBMS survey*. American Mathematical Society.
- The Mathematics Association of America along with other professional mathematics societies also advocate for advanced courses such as these to be taken by future secondary mathematics teachers.
- Despite this requirement and advocacy, there continues to be a need for research on how knowledge of mathematical content is employed in teaching practice, as well as how secondary teachers view the relevance of their post-secondary courses to teaching (Zazkis & Leikin, 2010).
  - ❖ Zazkis, R., & Leikin, R. (2010). *Advanced mathematical knowledge in teaching practice: Perceptions of secondary mathematics teachers*. Mathematical Thinking and Learning, 12(4), 263–281.

Connecting Advanced and Secondary Mathematics (CASM) Conference (http://casmconference.org/)

Held in Minneapolis, MN, May 20-22, 2019
NSF Funded (53 participants)

- "The conference will bring together researchers, mathematicians, and teacher educators interested in exploring connections between advanced and secondary mathematics. The CASM Conference has three main objectives:
  - I. To develop plans for research and/or professional development to expand current knowledge on connections between advanced and school mathematics, so that attendees can take concrete steps to move projects forward.
  - II. To provide a space for mathematicians, mathematics educators, and other stakeholders to discuss their work and develop a common vision for future directions.
  - III. To share current research on mathematical connections between advanced and secondary mathematics, focusing specifically on abstract algebra."

❖ Murray, Eileen; Baldinger, Erin; Wasserman, Nicholas; Broderick, Shawn; White, Diana. *Connecting Advanced and Secondary Mathematics*. Issues in the Undergraduate Mathematics Preparation of School Teachers, v1 Aug 2017 (https://files.eric.ed.gov/fulltext/EJ1151024.pdf)

CASM Conference

- Five theme groups formed
  - ❖ Curriculum
  - ❖ Educator Knowledge
  - ❖ Item Development
  - ❖ **Professional Development for Teachers** (I was part of this group)
  - ❖ Project Design

Implementation

- Fall 2019:
  - ❖ Class: Modern Algebra (Ring and Field Theory)
  - ❖ Program: Graduate Certificate in Mathematics
  - ❖ 10 Students: Secondary-level math in-service teachers
- Proof-based class - hence very demanding and hard for students
  To address:
  - ❖ Why taking this class?
  - ❖ How to make the class relevant for students?
  - ❖ What is the connection to the material they teach at the high schools?

Research Project

- Collecting data from the in-service teachers (pre- and post-surveys) about the material/topics covered;
  - ❖ **What is the relevance of this material with respect to the secondary math content they teach**?
  - ❖ How to better equip them in teaching secondary math topics?
  - ❖ Which topics will prepare math education students better for understanding secondary mathematics?
  - ❖ What are in-service teachers' opinions and suggestions on the topics?

Survey Questions IRB Protocol #s 349; 350	Pre Survey	Post Survey
# of surveys	10	10
The *Abstract Algebra* material is relevant to secondary math content.	2.6	3.9
The *Abstract Algebra* provide connections to secondary math content.	2.5	4.3
The *Abstract Algebra* material equips the pre-service teachers to better teach secondary math content.	2.9	3.4
I have used *Abstract Algebra* material/concepts when teaching my secondary math classes.	2.3	3.9
I believe that *Abstract Algebra* material/concepts should be taught to pre-service teachers.	3.1	3.6

5 – strongly agree 4- agree 3 – neither agree nor disagree
2 – disagree 1 – strongly disagree

Student Feedback – Reflections

I. *Exam question – reflection*:
Describe your favorite part (or topic) of *Modern Algebra* class this semester. Explain why that part (or topic) was your favorite.

II. *Project question* – **Reflections on the course material**
- ❑ **address the topics covered;**
- ❑ **which topic(s)/concept(s) was/were most meaningful and useful for you;**
- ❑ **which topic(s)/concept(s) was/were the most exciting and new to you;**
- ❑ **which connections you see with this material and the high school curriculum;**
- ❑ **what would you change or leave the same in terms of the course content; etc.**

- Almost all the topics chosen by students as their favorites/most meaningful/useful, were the ones that
  - ✓ were most applicable in their high school classroom settings
  - ✓ provided connections to the secondary math content
  - ✓ were familiar to the students
- In their comments, teachers expressed confidence that the class material and connections made helped:
  - ✓ them understand the majority of topics that were covered in the course and were familiar to them on a deeper level;
  - ✓ them to understand and explain many seemingly true statements (taken for granted) they use in their classes;
  - ✓ them communicate mathematics to their students by connecting concepts;
  - ✓ their students see relevance in mathematics.

Conclusion

- The feedback above confirms that the *Abstract Algebra* material
  - ❖ can be meaningful to teachers by connecting it with the secondary mathematics;
  - ❖ can support teachers to re-conceptualize, re-structure, and re-understand their knowledge of secondary mathematics.

  (Wasserman, N. (2016). Abstract algebra for algebra teaching: Influencing school mathematics instruction. *Canadian Journal of Science Mathematics and Technology Education, 16*(1), 28-47).
- The pre- and post-survey results show that students' opinions changed significantly about
  - ✓ the relevance of the *Abstract Algebra* to the secondary math content;
  - ✓ connections of the *Abstract Algebra* to the secondary math content;
  - ✓ recognizing these connections in their own classes.
- Why the small increase in change of the opinion of the students about the last question on the survey? Few conjectures:
  - ✓ the proof-based classes are difficult, demanding, and time consuming;
  - ✓ most of the in-service teachers have taken the needed prerequisite (*Abstract Algebra* course (Graph Theory)) long time ago;
  - ✓ lucking of good proof writing skills.
- **Further research questions:**
  - ❖ What connections of *Abstract Algebra* can impact teacher instructions?
  - ❖ How can Variation Theory be implemented in *Abstract Algebra* classes with goal to impact teacher instructions?

Prospective Secondary Mathematics Teachers Integrating Reasoning and Proving in their Teaching

Rebecca Butler
University of New Hampshire

Sophia Brisard
University of New Hampshire

Merav Weingarden
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Keywords: Reasoning and Proof, Secondary Teachers, Beginning Teachers, Teacher Education

Transitioning from teacher preparation programs to teaching in school is fraught with challenges (Smagorinsky et al., 2004; Thompson et al., 2013). Specifically, beginning teachers struggle to implement reasoning and proving in real classrooms and recontextualize what they learned in their teacher preparation programs (Gomez Marchant et al., 2021; Stylianides et al., 2013). In this study, we investigate how prospective secondary mathematics teachers (PSTs) who participated in a capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020), envision and enact what they learned in the course in their student teaching experience and first year of teaching their own class.

We followed two PSTs, Olive and Diane, through the course, student teaching, and first year of teaching. Data included, for each teacher, six video-recorded lessons and six post-lesson interviews, which invited reflection on integrating reasoning and proof in the lesson. Data were analyzed through open coding (Patton, 2002) inspired by activity theory (Ellis et al., 2019; Engeström, 1987) with attention toward aspects that enable or inhibit enactment of reasoning and proof, such as their cooperating teacher, the school and classroom norms, and set curriculum.

As PSTs, Olive and Diane developed knowledge and skills for teaching reasoning and proof in secondary classrooms. As student teachers, they expressed a deep desire to integrate reasoning and proof into their teaching but encountered challenges which hindered their enactment of this vision. They felt obliged to conform to the norms of teaching established by their cooperating teachers; mostly notetaking and computational practice. Nevertheless, as student teachers working with a cooperating teacher, they still found ways to engage students with reasoning and proof by pushing for student explanations and designing short proof-related activities. As time progressed, they stepped into teaching their own classrooms. They embraced their independence and carved out unique paths to engage students with reasoning and proof. They devoted class time to group work, exploration-based activities, and invited reasoning and justifying.

This inquiry aims to provide an increased understanding of prospective teacher education with respect to mathematical reasoning and proof and how PSTs' knowledge and practices continue to develop during their cooperative and independent early-career teaching experiences. Notably, the proof-related practices learned in the course reemerged as the PSTs taught their own classes, despite facing pressures to teach in more traditional ways during student teaching. Our study contributes to a better understanding of the PSTs' development as mathematics teachers in their university programs and beyond.

Students' Voice in an Active Calculus Learning Environment: How Do Students Perceive Purposeful Design Learning Environments

Nigar Altindis Orly Buchbinder Karen Graham
University of New Hampshire

Keywords: Active Learning, Calculus, Collaborative Small Groups

Previous studies emphasized the advantages of student-centered over instructor-centered teaching and learning of Calculus (Ely, 2021). In addition, collaborative group work in calculus classrooms has been shown beneficial to meaningful student engagement with calculus problems (Hitt & Dufour, 2021) and greater students' success compared to traditional classrooms (Code et al., 2014). Yet, some studies observed students' resistance to active learning (Tharayil et al., (2018). Thus, it is important to continue investigating students' perceptions of active learning environments in Calculus courses.

This study was conducted at a four-year R1 university in the northeastern United States. Participants were students in a Calculus course, which runs in a large lecture (3 times a week) and recitation (twice a week) format. In Spring 2022, we introduced active learning into recitations and activities that focus on Scientific, Mathematical, and Metacognitive Processes (SMMPs). The students worked on SMMP activities in groups and presented their solutions in class. The recitation sections were facilitated by graduate teaching assistants and undergraduate learning assistants. At the end of the semester, we collected survey data on students' perceptions of their learning experiences in Calculus recitations. Data include surveys (n=150) with 7 Likert-scale questions and 3 open questions. We also collected students' classroom work, related home assignments and test items on the topics of SMMPs. The current analysis focuses on Students' perceptions of the active learning environment structure of the recitations and how it affected their learning experiences.

We found that 73% of the students indicated that communicating with their peers in the recitations helped them to clarify their mathematical thinking, 71% of the students stated that Calculus concepts became clearer after they heard explanations from other students in their group, 80% of the students stated that they would recommend group work for Calculus recitations to other students, and 72% of the students stated that they would like other courses to offer opportunities of group work. Student-written comments supported these results. One typical comment was: "I think that being in a group where we all have different levels of understanding or ways of understanding the class concept is helpful because it allows me to think through my thought process and explain it to my other group members."

Our results show that most students perceive small collaborative group works to provide meaningful learning experiences for them. These results echo previous studies (e.g., Hitt & Dufour, 2021) and extend them by identifying students' justifications underlying their views of the benefits of group work in Calculus recitations to their learning. These results, along with the analysis of students' achievement contribute to the growing body of knowledge on reforming the teaching of Calculus.

Students' Voice in an Active Calculus Learning Environment: How Do Students Perceive Purposeful Design Learning Environments

Nigar Altindis, Orly Buchbinder, & Karen Graham

University of New Hampshire

University of New Hampshire

NSF Transforming Undergraduate STEM Gateway Teaching and Learning by Emphasizing Core, Interdisciplinary STEM Practices (DUE # 2013427)

Background

Previous studies emphasized the advantages of student-centered over instructor-centered teaching and learning of Calculus (Hitt & Dufour, 2021). In addition, collaborative group work in calculus classrooms has been shown to be beneficial to meaningful student engagement with calculus and lead to greater students' success compared to traditional classrooms (Code et al., 2014). Yet, some studies observed students' resistance to active learning (Tharayil et al., 2018). Thus, it is important to continue investigating students' perceptions of active learning environments in Calculus courses.

Aim of the Project

We aim to support students meaningful learning experiences in Calculus via designing active learning environments. This study is focused on exploring students' perceptions of active learning environments in Calculus courses.

Research Question

How do students perceive purposefully designed active learning environments?

Method

Research Site: This research is conducted at a four-year R1 university in the northeastern United States. Participants were students in a Calculus course, which runs in a large lecture (3 times a week) and recitation (twice a week) format.

Data Collection and Participants: Data include surveys (n=150) with 7 Likert-scale questions and 3 open questions. Participants were undergraduate students enrolled first Calculus course at the university.

Design of the Study: We introduced active learning into recitations and activities that focus on Scientific, Mathematical, and Metacognitive Processes (SMMPs). The students worked on SMMP activities in groups and presented their solutions in class. The recitation sections were facilitated by graduate teaching assistants and undergraduate learning assistants. At the end of the semester, we collected survey data on students' perceptions of their learning experiences in Calculus recitations.

Design of Active Learning Environment

SMMP Activities Topics
Continuity
Implicit Differentiation
Derivative of Logarithmic Functions
Optimization Problems
Graphing
Antiderivatives

Instructional Routines
Launch the Activity
Small Group Exploration
Whole Class Discussion
Wrap-up/Closure

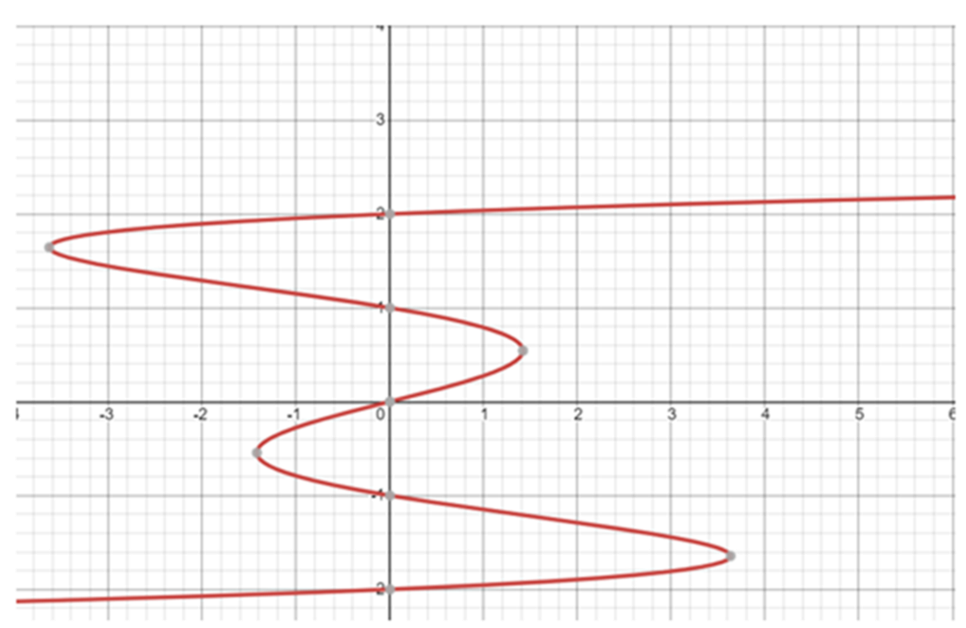
Small Group Exploration

Whole Class Discussion

An Example of SMMP Activity

Directions: Working with the peers in your group, solve the following problems. Make sure to show and justify all your work. Next, make sure everyone in the group understands the solution and participates. Finally, be prepared to report your answers to the whole class.

Task 1: In your small group, consider the curve on the graph and the equation of the curve: $x = y^5 - 5y^3 + 4y$. With your small group, explain how you would answer the following questions using both the symbolic equation and the curve graph.

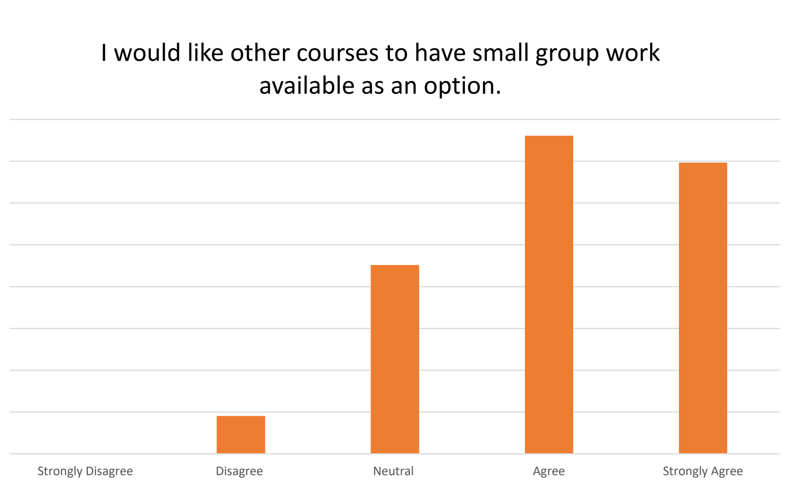


1) Is it possible to express y as an explicit function of x?

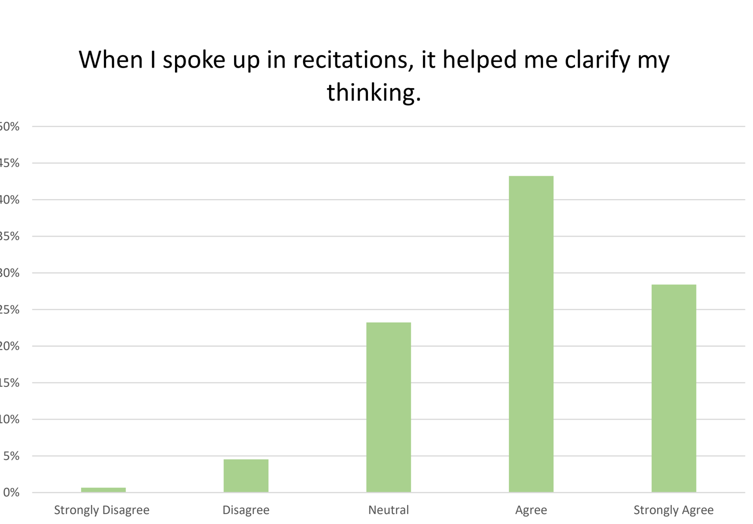
a) Explain your response using the graph.

b) Explain using the symbolic equation for the curve: $x = y^5 - 5y^3 + 4y$.

Survey Results

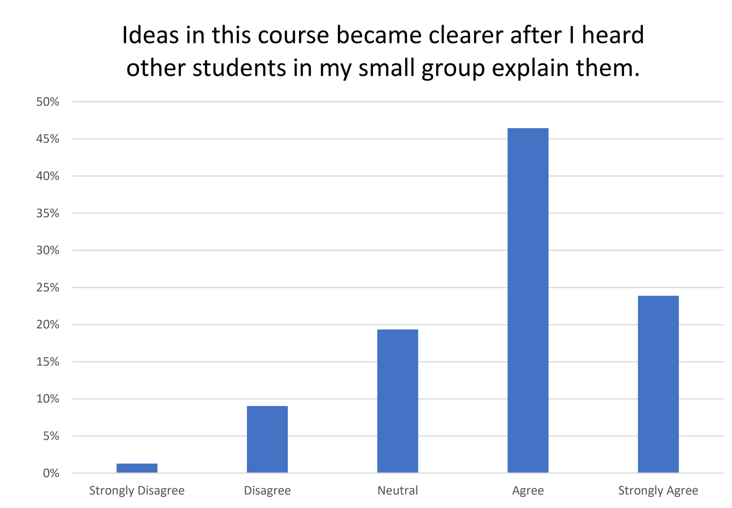


72% of students stated that they would agree or strongly agree with the statement: "I would recommend group work at Calculus recitation to other students."

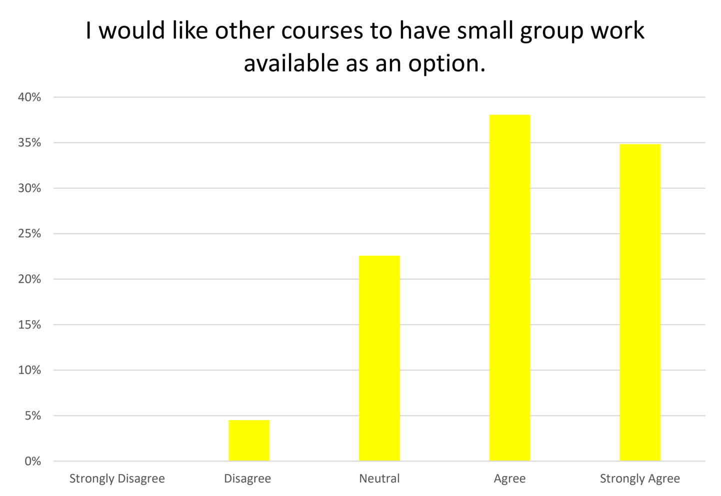


71% of students stated that they would agree or strongly agree with the statement: " When I spoke up in the recitation, it helped me to clarify my thinking."

Survey Results



70% of students stated that they would agree or strongly agree with the statement: "Ideas in this course become clear after I heard other students in my small group explain them."



73% of students stated that they would agree or strongly agree with the statement: "I would like other courses to have small group work available as an option."

Open-ended Questions and Samples from Students' Answers

Please comment on the aspects of the recitations that you think were most helpful for your learning

- Direct help from the TA and LA was super helpful. I learn better by working through things with other people. **Also teaching what I knew to my classmates helped me understand the content on a deeper level**
- I think that being in a group where we all have different levels of understanding or ways of understanding the class concept is helpful because **it allows to me to think through my thought process and explain it my other group members.**

Please comment on the aspects of the recitations that you think were least helpful for your learning

- I think sometimes the **worksheets are very long**
- I learn significantly more from Recitation than lecture, and don't have many complaints. Only thing I can think of would maybe **letting students design their groups at the beginning of the class**, but this also could be a downfall.
- Group work. Sometimes it can be helpful but **most of the time group members would rather work through their own work quickly versus helping other members.** Most of the help I receive in this class is from the TA or the LA.

If you were a TA designing recitation: What are at least two things, you would keep? Explain why these are strengths

- I would keep **group work** because it helps students collaborate and work through problems together.
- I would also keep **the end of class where we put problems on the board to help other groups that are still struggling with an explanation on how we did it.**
- I would **keep the LA** because having two people to help explain things is much better than one. Especially if they have different ways of explaining things.

Summary of Justifications

- Groupwork improved students' articulation of their thoughts.
- Groupwork helped students understanding of the content on a deeper level.

Discussion

- Our results show that most students perceive that small group work provides them with meaningful learning experiences.
- These results echo previous studies (e.g., Hitt & Dufour, 2021) and extend them by identifying students' justifications underlying their views of the benefits of group work to their learning in Calculus recitations.
- These results, along with the analysis of students' achievement, contribute to the growing body of knowledge on reforming the teaching of Calculus.

Novice Calculus Learning Assistants' Learning to Notice

Rebecca Butler
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Keywords: Learning Assistants, Teacher Education, Near-Peer Tutoring, Calculus

Learning Assistants (LAs) are undergraduate near-peer tutors who aid in the instruction of large lecture STEM courses (Otero et al., 2010). While many LAs do not pursue a career in teaching, they assume a para-professional role in classrooms. This experience has been shown to be transformative for students in these courses and for LAs themselves (Schick, 2018); however, the precise mode of LAs' development is not well understood. This study extends prior research on LAs as potential future teachers (Fineus & Fernandez, 2012; Gray et al., 2012; Vandegrift et al., 2020) by asking how the professional noticing of novice LAs develops over their first semester in a calculus classroom. Noticing refers to what teachers attend to and interpret in their instruction. Noticing is widely recognized as an important element of mathematics teacher development (van Ess & Sherin, 2008).

This study is a part of a multi-disciplinary project for reforming introductory STEM courses at a large, public, northeastern university. The four LAs participating in this study were in their first semester of teaching in a calculus course. The course follows a format of a large lecture (approx. 160 students) and recitations (approx. 20 students) led by a graduate teaching assistant. LAs were only present in recitations, helping small groups work through conceptually rich activities. The LAs also attended a weekly meeting on pedagogical topics, e.g., metacognition, types of questions, student ideas and content preparation. Data includes beginning and end of semester interviews, four written reflections throughout the semester, and video of recitations. In the interviews, LAs were asked to analyze samples of student work, reflect on clips of their teaching, and share their thoughts on the social dynamics in class. Interviews were coded on Stockero's (2008) five dimensions of noticing: actor, topic, stance, specificity, and artifact focus.

In their first interviews, LAs' comments were fairly general – discussing mathematics without relation to teaching or learning, and often evaluative in nature – LAs judged their pedagogical ability to provide students with clear, correct mathematical explanations. Comments about student thinking the classroom environment lacked detail, using the labels "good" or "not as good". This changed in their final interviews as LAs discussed specifics of student thinking and offered conjectures and explanations on classroom events. The focus of their comments shifted toward how the mathematics of a task created space for student learning. LAs also talked at length about specific students' ideas in relation to social dynamics of their classroom. LAs largely dropped their evaluative stance for making more assertions about teaching and learning.

Undergraduate peer tutoring is a growing phenomenon in introductory STEM courses, which provides unique teaching and learning experience. By characterizing how LAs professional noticing evolves, our study will advance understanding of LAs' growth as mathematics teachers and of their interactions with students. This will also provide greater insight into how LAs function within and contribute to undergraduate mathematics classrooms.

Prematriculation Interventions using ALEKS: Common Lessons-learned in two Programs

Caroline Junkins
McMaster University

Emily Braley
Johns Hopkins University

Keywords: Math Intervention, Precalculus through Calc II (P2C2), Student Success.

Students who enter university level calculus without a strong mathematical foundation in algebra and functions often struggle to succeed: repeating courses, leaving STEM, or dropping out entirely (Chen, 2013). Students from traditionally underrepresented groups are at particularly high risk of STEM attrition (Alexander et al., 2009). Here we describe student behavior in two interventions designed to provide a prematriculation experience for first-year university students. Each summer intervention paired content preparation with evidence-based learning strategies in an effort to reduce STEM attrition and increase success in gateway mathematics courses.

In Canada and the United States, the COVID-19 pandemic has had a large impact on K-12 students, with a major concern being mathematical preparation. Evidence indicates that current and future incoming university students are less prepared than their pre-pandemic counterparts (NEAP, 2022; EQAO, 2022). We know that high school teachers were forced to make curricular decisions that did not have in mind calculus preparation; for example, omitting logarithmic functions from the curriculum (Sacka, 2021). To shore up the mathematical skills of incoming students in an efficient way, the programs described here make use of a popular online intelligent tutoring system called Assessment and Learning in Knowledge Spaces (ALEKS). Within ALEKS, the curriculum for each program was shaped to be closely aligned with the local context and curricula, ensuring that student engagement with the material will be served in their upcoming courses. This alignment was directly communicated to students, instructors, advisors and administrators in each program.

Despite differences in local context and format of the "non-mathematical" components of each program, we found common experiences with respect to student engagement with ALEKS:

1. ALEKS can be offered as a stand-alone product, but ALEKS alone was not sufficient to motivate student engagement or open lines of communication with faculty or peers.
2. Synchronous support for ALEKS (e.g. office hours) were underutilized, with the majority of participants in one program reporting that they were able to find answers to their questions within ALEKS. Students in both programs instead used office hours to ask questions related to placement and course selection.
3. While students in both programs retained access to ALEKS into the start of the Fall semester, very few students remained active in the platform once classes started. This result could be attributed to lack of time during this busy transitional period, and/or decrease in motivation as seen in previous applications of ALEKS (Fang et al., 2019)

In addition to these shared insights, we will also report on differences between ALEKS use across the two programs, including learning gains, time spent on ALEKS and the distribution of topics mastered. Through this poster presentation, we aim to:

- learn more about experiences with ALEKS at other institutions,
- hone in on strategies for better student engagement with the tool, and
- gauge community interest for support in analyzing the local data needed to establish and evaluate similar interventions.

Prematriculation interventions using ALEKS: Common lessons-learned in two programs

Caroline Junkins, McMaster University

Emily Braley, Johns Hopkins University

Keywords: Math Intervention, Precalculus through Calc II (P2C2), Student success

Why provide early support for STEM students?

Students are much more likely to succeed in university-level calculus when equipped with a strong foundation in algebra and pre-calculus. Success in Calculus is crucial for students who intend to pursue a degree in STEM. Literature suggests that without early success in college STEM courses, students may struggle to succeed: repeating courses, leaving STEM, or dropping out entirely (Chen, 2013). Students from traditionally underrepresented groups are at particularly high risk of STEM attrition (Alexander et al., 2009).

Here we describe student behavior in two summer interventions designed to provide a prematriculation experience for first-year university students.

Each summer intervention paired mathematical content with evidence-based learning strategies in an effort increase success in calculus.

Has the pandemic affected STEM-preparedness?

In Canada and the United States, attempts to measure impact of the COVID-19 pandemic indicate that current and future incoming university students may be less prepared than their pre-pandemic counterparts, with a major concern being mathematical preparation. (NEAP, 2022; EQAO, 2022).

Not all students were able to interact with the full high school curriculum; for example, some classes omitted exponential and/or logarithmic functions from the pre-calculus curriculum (Sacka, 2021).

As a result, we may see a higher degree of heterogeneity in terms of preparedness of incoming students.

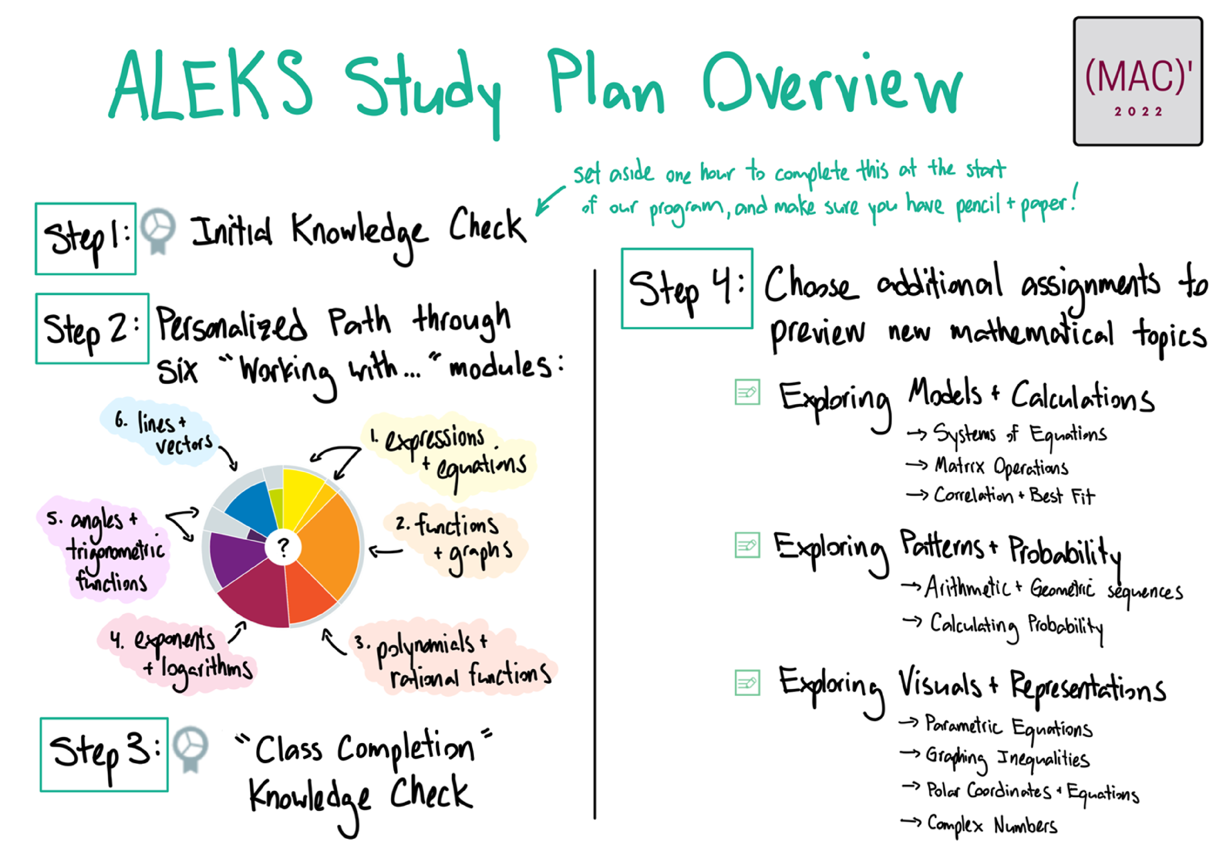
How can the intervention be customized?

To target relevant mathematical skills in an efficient way, the programs described here make use of an online intelligent tutoring system called Assessment and Learning in Knowledge Spaces (ALEKS).

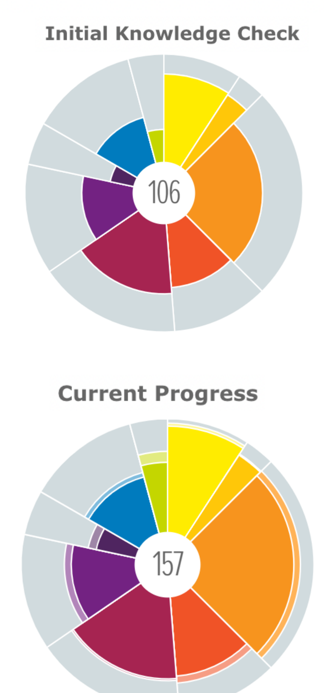
Within ALEKS, the curriculum for each program was shaped to be closely aligned with the local context and curricula, ensuring that student engagement with the material will be served in their upcoming courses.

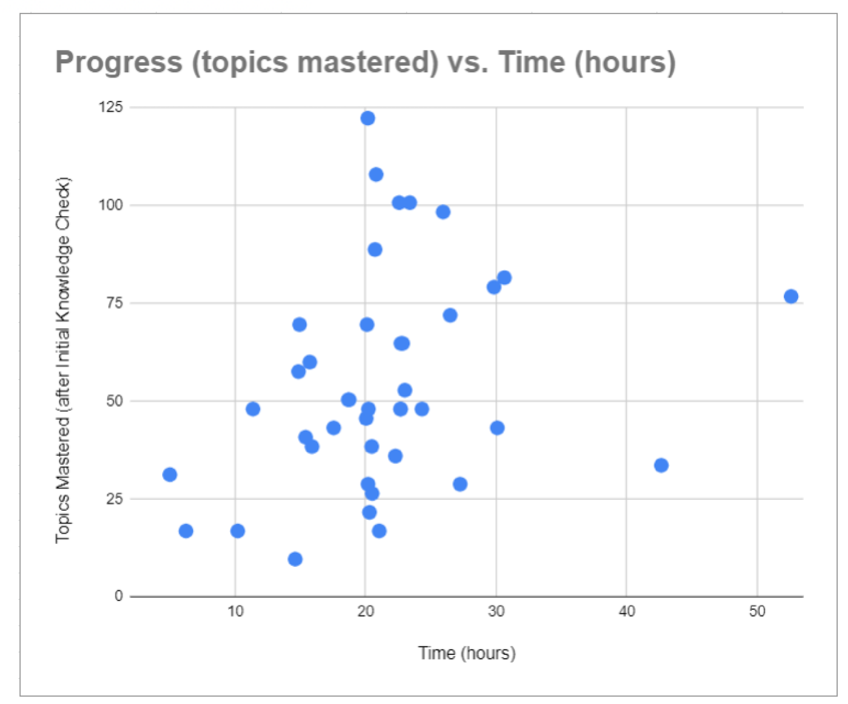
This alignment was directly communicated to students, instructors, advisors and administrators in each program.

McMaster's Peer-Run Inclusive Math Experience (MacPrime)

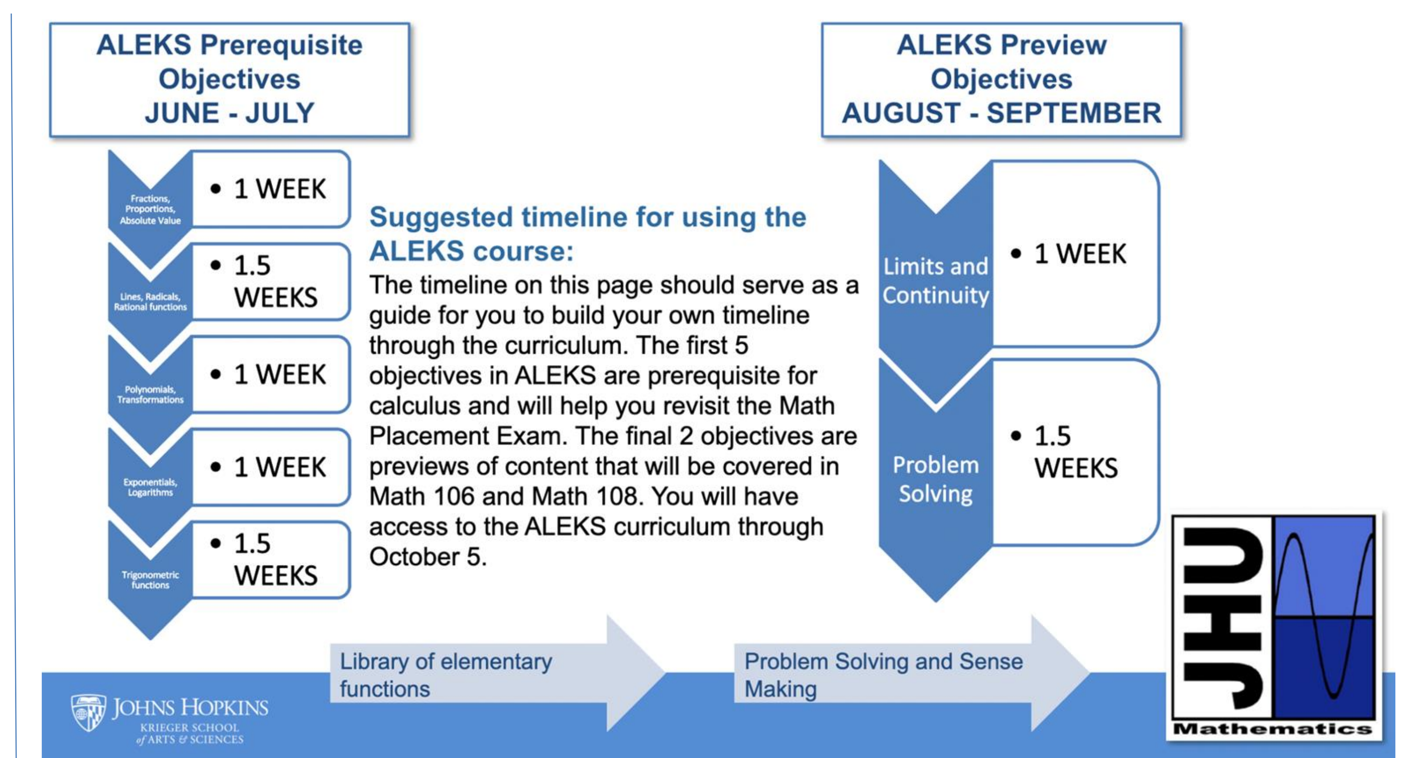


Summer 2022 - ALEKS Pie

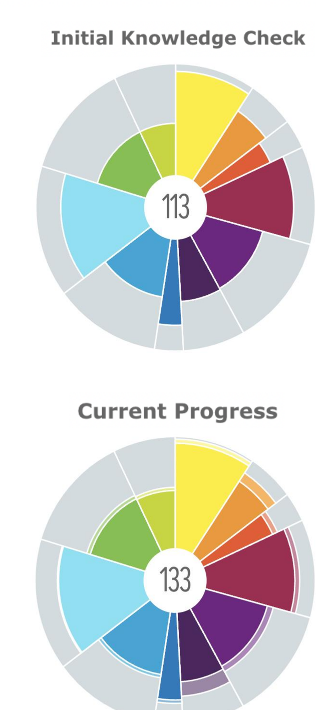


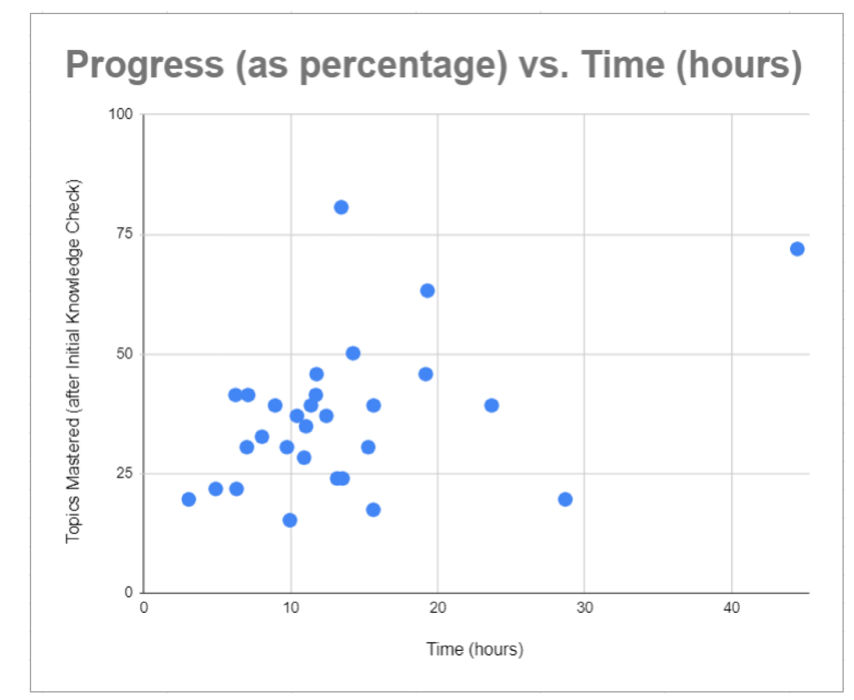


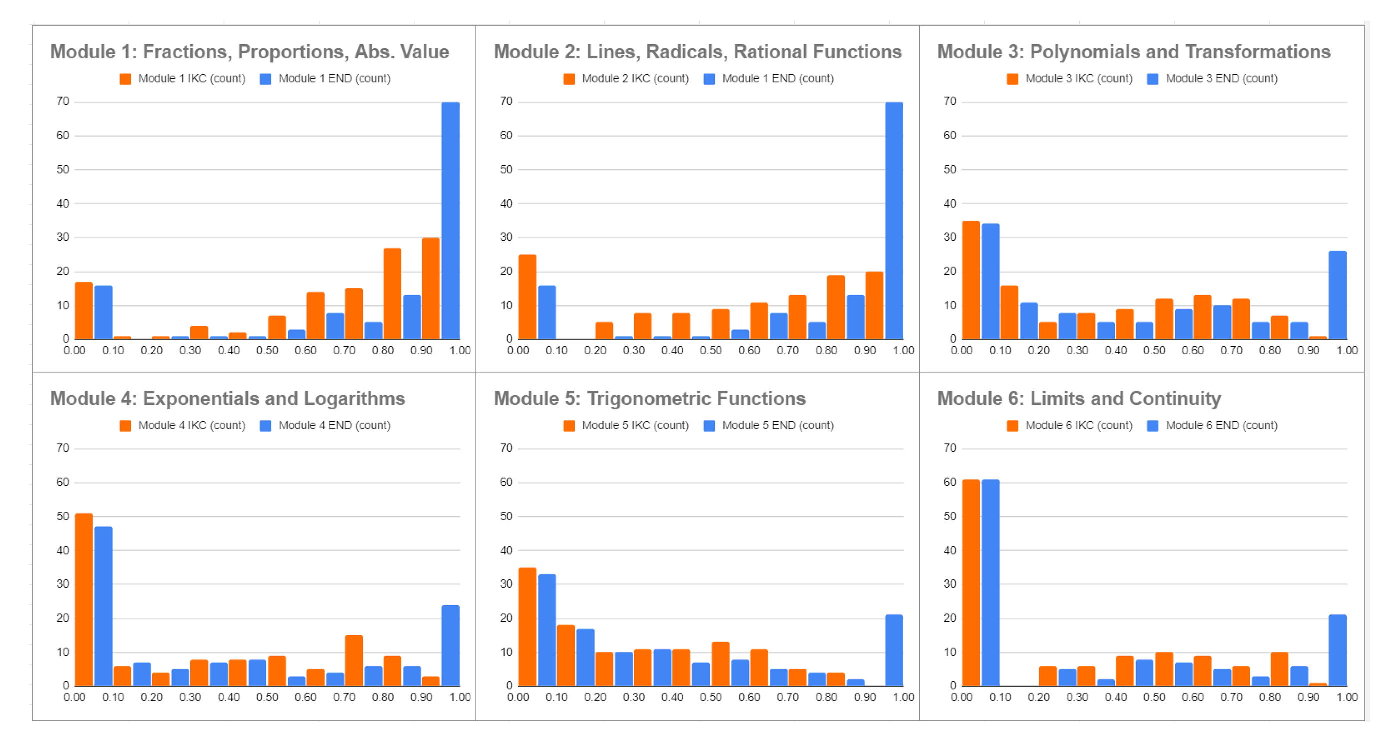
Johns Hopkins' Student Success Programs



Summer 2022 - ALEKS Pie







Student Engagement with ALEKS

- ALEKS alone was not sufficient to motivate student engagement or open lines of communication with faculty or peers.
- Synchronous support for ALEKS (e.g., office hours) were underutilized, participants at McMaster reporting that they were able to find answers to their questions within ALEKS. Students in both programs instead used office hours to ask questions related to placement and course selection.
- Time spent in ALEKS (time active in the system) was weakly to moderately correlated with progress through either program's curriculum (number of topics mastered after Initial Knowledge Check): Pearson $r = 0.30$ (McMaster) and $r = 0.43$ (Johns Hopkins),
- Very few students remained active in the platform once classes started. This result could be attributed to lack of time during this busy transitional period, and/or decrease in motivation as seen in previous applications of ALEKS (Fang et al., 2019)

Can we use program data to better "Mind the Gaps"?

Kornelson, Moore-Russo and Reeder (2020) identified six categories of algebraic errors commonly exhibited by calculus students, found in Modules 1-3 of each program:

- Simplifying
- Distributive property
- Variable isolation
- Operations with rational expressions
- Operations with radicals
- Composition of functions

The authors suggest that even when mastery of these skills is demonstrated in ALEKS, instructors should consider a just-in-time approach, as well as mitigating factors that could be causing mistakes. Data collected from these programs could provide guidance for aligning additional interventions for a given cohort of students.

We hope to learn more about:

- **Experiences with ALEKS products at other institutions (courses/programs, placement, etc.)**
- **Strategies for better student engagement with ALEKS**
- **Community interest for support in analyzing data needed to evaluate programs using ALEKS**

Take our survey:

Longitudinal Study of Women's Sense of Belonging in Undergraduate Calculus

Casey Griffin
University of Delaware

Keywords: sense of belonging, gender, undergraduate calculus

Undergraduate women leave STEM majors at a higher rate than men – especially after taking Calculus I (Chen et al., 2013; Seymour & Hunter, 2019). Research identifies low sense of belonging as a major reason why women leave STEM majors (Seymour & Hunter, 2019; Shapiro & Sax, 2011). One feels a *sense of belonging* (SB) when they feel valued or accepted in an academic community, and that their contributions are valued (Good et al., 2012). Studies have shown that students' SB can be attributed to their social connectedness (SC) with the people in their class and their perceived competence (PC) in the course material (Rainey et al., 2018). Further, Rainey et al. (2019) found that students who experienced active learning reported a stronger SB. However, few quantitative studies have investigated students' SB in relation to its influencing factors. This study examines undergraduate women's SB over the course of one semester in an active learning Calculus course. I address the research questions: For undergraduate women enrolled in an active learning Calculus course, (1) How do SC and PC contribute to their SB?, (2) In what ways do their SB, SC, and PC change over the course of the semester?

This study takes place at a Mid-Atlantic research university during the Fall 2022 semester. Two sections of the active learning Calculus course were offered, with a total enrollment of 127 students. These students are typically freshmen intending to major in STEM and do not know upon enrolling that the course provides substantial active learning opportunities (primarily small-group work and whole-class discussions). To measure students' SB, SC, and PC, a survey was designed and administered to all students during Weeks 1, 7, and 14 of the semester. The survey consisted of Good et al.'s (2012) Mathematical Sense of Belonging scale, items from several scales measuring SC (Frisby & Martin, 2010; Hoffman et al., 2003; Maloney & Matthews, 2000; Wanders et al., 2019), and items from Wigfield and Eccles' (2000) Expectancy-Value scale and Cribbs et al.'s (2015) FICSMath scale to measure PC. The data set was reduced to only include participants who self-identified as women (e.g., women and trans women).

Findings indicate that both SC and PC have a significant effect on women's SB. A regression of SB on SC and PC accounted for 47% of the variance in SB at Week 1 ($F[2,46]=20.684$, MSE=.374, $p< .001$), 67% at Week 7 ($F[2,43]=44.145$, MSE=.235, $p<.001$), and 69% at Week 14 ($F[2,40]=44.522$, MSE=.259, $p<.001$). Interestingly, PC held greater influence at Week 1 ($\beta_{SC}=.379$, $p_{SC}=.001$; $\beta_{PC}=.492$, $p_{PC}<.001$), while SC held greater influence at Week 7 ($\beta_{SC}=.641$, $p_{SC}<.001$; $\beta_{PC}=.305$, $p_{PC}=.003$) and Week 14 ($\beta_{SC}=.655$, $p_{SC}<.001$; $\beta_{PC}=.328$, $p_{PC}=.001$). Additionally, students' SB, SC, and PC each increased significantly between Week 1 and Week 7 and plateaued from Week 7 to Week 14 (Table 1). Results from this study confirm that SC and PC hold a significant influence over women's SB. Further, women in an active learning Calculus class can experience positive changes in their SB that align with changes in their SC and PC.

Table 1. Women's Sense of Belonging, Social Connectedness, and Perceived Competence Means.

	Week 1	Week 7	Week 14	p_1	p_2
Sense of Belonging	3.9312	4.5488	4.6159	<.001	.517
Social Connectedness	4.3676	4.7735	4.8537	.001	.444
Perceived Competence	3.7591	4.0335	4.0518	.008	.855

Longitudinal Study of Women's Sense of Belonging in Undergraduate Calculus

Casey Griffin

University of Delaware

Research Questions & Definitions

For undergraduate women enrolled in a year-long active learning Calculus course,

1. In what ways, if any, do their **sense of belonging**, **social connectedness**, and **perceived competence** change over the course of the first semester?
2. How do **social connectedness** and **perceived competence** contribute to their **sense of belonging** at the beginning, middle, and end of the first semester?

Sense of Belonging: feeling accepted in an academic community, and that your presence and contributions are valued

Social Connectedness: feeling socially connected or similar to those around them

Perceived Competence: feeling like they understand the material or received good grades

Context

- **Setting:** Undergraduate Calculus course with frequent opportunities for students to engage in active learning via group work and whole-class discussion; 2 sections offered with 127 students total
- **Participants:** Women enrolled in active learning Calculus; mostly first-year students intending to major in STEM

Data Collection & Analysis

Data were collected during Fall 2022 from women enrolled in active learning Calculus using online surveys.

Regression was used to analyze data at each time point.

Repeated Measures ANOVA was used to analyze data across time.

Major Findings

1. Sense of belonging, social connectedness, and perceived competence…

a) All **increased** between Week 1 and Week 7

b) All **plateaued** between Week 7 and Week 14.

Table 1.
Women's Sense of Belonging, Social Connectedness, and Perceived Competence Means.

	Week 1	Week 7	Week 14
Sense of Belonging	3.9312	4.5488***	4.6159
Social Connectedness	4.3676	4.7735***	4.8537
Perceived Competence	3.7591	4.0335***	4.0518

Note. These results are based on students who completed all three surveys, so N=41. Asterisks are used to denote the *p*-values (* for $p<.05$, ** for $p<.01$, *** for $p<.001$ significance levels) corresponding to the significance of the difference between that time-point and the previous time-point.

2. Social connectedness and perceived competence **significantly contributed to** students' sense of belonging throughout the semester.

a) **Perceived competence** held greater influence at Week 1

b) **Social connectedness** held greater influence at Weeks 7 & 14

Take a picture to download the full paper.

Related Tables

Table 2.
Regression of Sense of Belonging on Social Connectedness and Perceived Competence.

		Sum of Squares	df	Mean Square	F	Sig.
Week 1 N=49	Regression	15.472	2	7.736	20.684	<.001
	Residual	17.204	46	.374		
	Total	32.676	48			
Week 7 N=46	Regression	20.788	2	10.394	44.145	<.001
	Residual	10.125	43	.235		
	Total	30.913	45			
Week 14 N=43	Regression	23.037	2	11.518	44.522	<.001
	Residual	10.349	40	.259		
	Total	33.385	42			

Note. Sample sizes at each week differ here because each regression was run without regard for how many participants completed multiple surveys.

Table 3.
Regression coefficients.

		Unstandardized coefficients		Standardized coefficients		
		B	Std. error	Beta	t	Sig.
Week 1 N=49	Constant	-.214	.685		-.312	.756
	Social Connectedness	.510	.148	.379	3.438	.001
	Perceived Competence	.514	.115	.492	4.467	<.001
Week 7 N=46	Constant	-.086	.500		-.172	.864
	Social Connectedness	.702	.106	.641	6.632	<.001
	Perceived Competence	.326	.104	.305	.3152	.003
Week 14 N=43	Constant	-.304	.525		-.580	.565
	Social Connectedness	.759	.109	.655	6.955	<.001
	Perceived Competence	.302	.087	.328	3.480	.001

Conclusions

- **Social connectedness** and **perceived competence** do in fact significantly influence women's **sense of belonging** in mathematics.
- The amount of influence each contributor had on **sense of belonging** was different at different time points.
- Women in an active learning Calculus class can experience positive changes in their **sense of belonging** over time.

Instructor Perceptions of Student Example-Use

Jordan E. Kirby
Middle Tennessee State University

Keywords: Proof, Example-Use, Mathematical Knowledge for Teaching

Researchers have commonly found students from K-16 struggle to understand the purpose of a proof and how to construct proofs (e.g., Harel & Sowder, 2007; Healy & Hoyles, 2000; Stylianides, 2007). One component leading to this struggle is the difficulty in understanding the purpose of examples in a proof context (Aricha-Metzer & Zaslavsky, 2019; Ellis et al., 2019; Epp, 2003). Few studies in the field of example-use in proof investigate the mathematical knowledge for teaching (MKT) that would support instructors of these proof classes to effectively build upon and communicate strategies of using examples to their students (Zaslavsky & Knuth, 2019). In particular, mathematical knowledge for teaching proof (MKT-P) is a promising framework to investigate instructors' knowledge of the example-use subdomain of proof. I will use MKT-P to further describe the sub-domains of knowledge for content and students (KCS) and knowledge for content and teaching (KCT). This study applies the MKT-P framework to answer the following research question:

1. How do instructors of introductory proof classes perceive students' understanding and use of examples?

This study is part of the author's dissertation. Instructors of introductory proof courses across the southeastern United States were interviewed from September 2022 to November 2022. During the interviews, participants were asked to respond to six sample student responses to two questions adapted from Balacheff (1987) regarding example-use in proofs. Later in the interview, the participants sorted and ranked the six responses. Interviews were coded according to the MKT framework outlined by Ball and colleagues (2008) and further coded with a lens of MKT-P outlined by Stylianides and Ball (2008), Steele and Rogers (2012), and Lesseig (2016).

One of the main findings of this study includes the variety in ways instructors value the role of example use in their students. Some instructors held a strong stance that any example used to aid understanding by the student should be fully excluded in the written product. Other instructors instead said they wanted to see more reasoning in the written product by their students and to include more examples. For instance, Steven noted when reflecting on a student submission from Gina, "I mean, it's reasoning by example, which is always rough." This starkly contrasts with Mark who responded to the same instance from Gina with, "She is arguing from the picture, which I appreciate." The field of example use in proof would benefit from more explanation as to the roles of examples for practicing instructors of introduction to proof classes. Aricha-Metzer and Zaslavsky (2019) argued productive instances of example-use aided student understanding and proof production. There is a potential disconnect between the state of the literature of example-use in proof and the practice of practitioners of proof courses. Presenting this in a poster format will allow me to share quotes from my interviews and detailed information about my participants. I hope to gather insight from attendees for future directions with this work and how to disseminate information to practitioners hesitant to include examples in their proving.

Instructor Perceptions of Student Example-Use

Jordan E. Kirby

Middle Tennessee State University

jek3b@mtmail.mtsu.edu

Introduction

- Understanding the purpose of examples in a proof context can help students develop proving skills (e.g., Harel & Sowder, 2007; Healy & Hoyles, 2000).
- Although work has been done understanding the student side of examples, far less work has been done on understanding how to aid instructors to help their students use examples more efficiently (Zaslavsky & Knuth, 2019).

Research Question

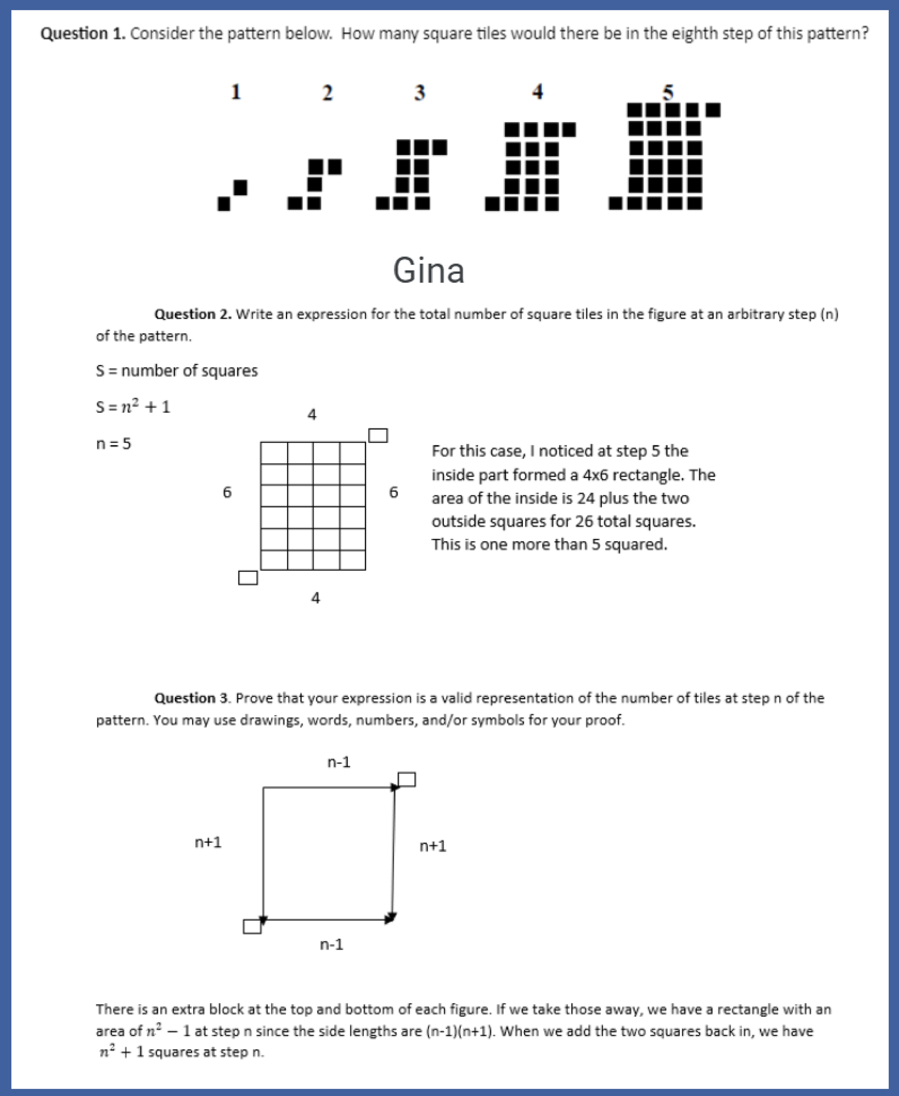
- How do instructors of Introduction to Proof courses perceive students' understanding and use of examples?

Methods

- 1-hour semi-structured interviews with 11 professors of Introduction to proof classes across the SE US.
- Instructors were presented with sample student answers to basic proof tasks.
- Instructors responded to these tasks and gave feedback about their understanding of the student and how they would respond to the student in their class.
- Then, instructors were asked to organize the responses in whatever manner they deemed necessary.
- Finally, the 6 student work samples were ranked from "best progress toward a proof to least progress toward a proof."

	R1/R2	Masters	Baccalaureate
Math	2	2	2
Math Ed	2	1	2

Do it, but don't show me



Question 1. Consider the pattern below. How many square tiles would there be in the eighth step of this pattern?

Gina

Question 2. Write an expression for the total number of square tiles in the figure at an arbitrary step (n) of the pattern.

S = number of squares

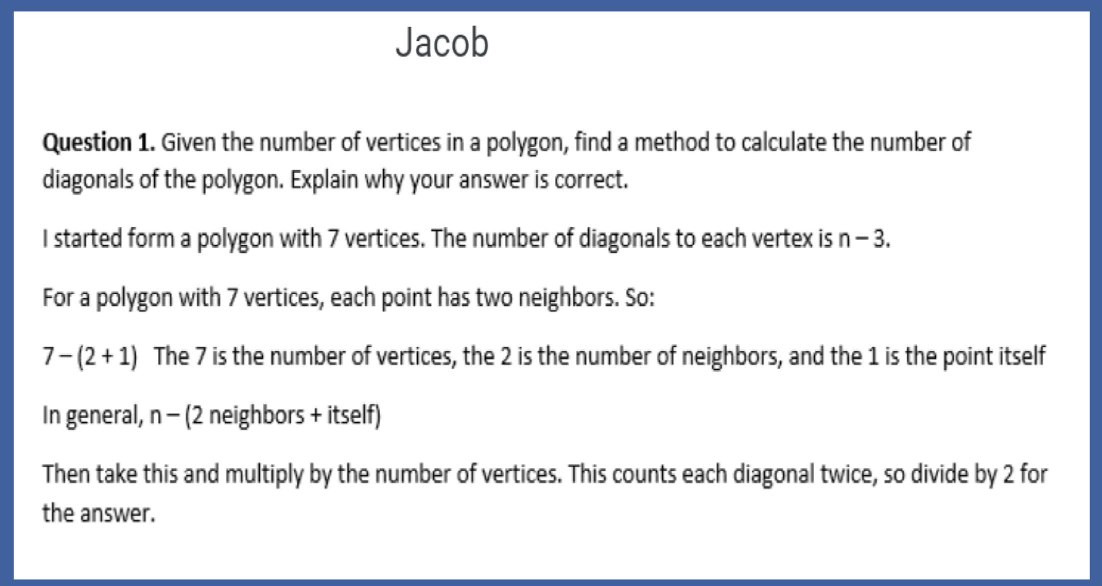
S = $n^2 + 1$

n = 5

For this case, I noticed at step 5 the inside part formed a 4x6 rectangle. The area of the inside is 24 plus the two outside squares for 26 total squares. This is one more than 5 squared.

Question 3. Prove that your expression is a valid representation of the number of tiles at step n of the pattern. You may use drawings, words, numbers, and/or symbols for your proof.

There is an extra block at the top and bottom of each figure. If we take those away, we have a rectangle with an area of $n^2 - 1$ at step n since the side lengths are (n-1)(n+1). When we add the two squares back in, we have $n^2 + 1$ squares at step n.



Jacob

Question 1. Given the number of vertices in a polygon, find a method to calculate the number of diagonals of the polygon. Explain why your answer is correct.

I started form a polygon with 7 vertices. The number of diagonals to each vertex is n – 3.

For a polygon with 7 vertices, each point has two neighbors. So:

7 – (2 + 1) The 7 is the number of vertices, the 2 is the number of neighbors, and the 1 is the point itself

In general, n – (2 neighbors + itself)

Then take this and multiply by the number of vertices. This counts each diagonal twice, so divide by 2 for the answer.

Evan (Assistant Professor at Private Baccalaureate/ Math Ed/ 4 years experience/Lecture):
"So she has a nice little example here, of when if n is equal to five, so for this case, you notice the step five, the inside part formed a four by six rectangle, the area inside is 24, plus the two outside squares for 26 Total squares. This is one more than five squared. Okay, that's great for that particular example. So it kind of shows me how she came up with that formula."

Steven (Professor at Public R1/ Math/ 22 years experience/Lecture):
"I mean, it's, it's reasoning by example, which is, which is always rough."
"I would say that the n minus one n plus one could have helped me early on."

Barry (Associate Professor at Public M1, Math, 7 years experience/ Lecture):
"So, I do like the, I guess, kind of started out with, you know, thinking of a fixed number, just to kind of get an idea of what to do with it."

Lisa (Assistant Professor at Public R1, Math Ed, 4 years experience/ IBL):
"Okay, so it's interesting, because like, I think Jacob is thinking about seven-sided figure, right? And he's taking it as like a generic example. But then the seven is actually never important. Like in his work. Like, he could have, you know, thought about seven and then gone through and replaced all the seven with an M, and now think would have been enough."

Howard (Professor at Public M1, Math Ed, 17 years experience, lecture)
"But as an educator in a first course, I want to see the example, right? And if you're leaving the example out, you're actually leaving out a step in the learning."

Data Analysis

- Data was first coded by episode looking for instances of knowledge of content and teaching (KCT) or knowledge of content and students (KCS) using the mathematical knowledge for teaching framework (Ball et al. 2008).
- Then, a thematic analysis was conducted across episodes looking for themes within KCS and KCT.

Results

- Almost even split of instructors who wanted to see the students written example in their final product (HW).
- No difference based on PhD, time at university, self-identified teaching style.
- Slight difference on if the instructor was at an R1/R2 institution versus anything else.
- Almost all participants asked students to show their thinking through examples when asked how to respond to students.

Discussion

- As a field, researchers have argued that examples, when used productively, aid student understanding and production of proofs (Aricha-Metzer & Zaslavsky, 2019).
- There seems to be a disconnect between what researchers believe, and what we believe in practice.
- Should students be expected to write textbook proofs in introduction to proof classes for all assignments?

Online Undergraduate Mathematics Classes Impact on Student Perceptions

Mikayla Dokos
Indiana University of PA

Dr. Valerie Long
Indiana University of PA

Dr. Yuliya Melnikova
Western Governors University

Keywords: online learning, student perceptions, undergraduate mathematics, challenges

Background

Online learning has been present in universities and other post-secondary institutions since the introduction of internet access in the 1990s (Johnson & Seaman, 2022). The COVID-19 pandemic has since caused higher demand for online learning and remote instruction to assist with mitigation efforts of the global pandemic (Barlow et al., 2020; Ramadhani et al., 2021). Specifically in mathematics courses, online platforms such as Desmos, GeoGebra, MyMathLab, and WeBWorK are used to supplement learning and teaching (Hauk & Segalla, 2005; Oates et al., 2014). A research study by Serhan and Almeqdadi (2020) on student perceptions of MyMathLab and WebAssign found advantages of using online platforms to be immediate feedback and flexibility of access. Another study by Valdez and Maderal (2021) indicated students preferred online homework over pen-and-paper traditional methods due to the accessibility of lecture notes and math software. Despite the possibilities that online learning offers, there are possible challenges for students in undergraduate math classes. Issues with technology, internet difficulties, and ease of forgetting assignments were challenges students faced in undergraduate online math classes (Serhan & Almeqdadi, 2020). Furthermore, if students were not trained on given technology, they faced difficulty with using online tools and technology effectively. Other challenges are how time-consuming and non-user friendly various online tools can be (Hauk & Segalla, 2005; Naidoo, 2020). With these challenges in mind, the aim of this research is to explore student perceptions in online undergraduate math classes.

Methodology and Results

This study was conducted at a public university in the northeast region of the United States. In spring 2021, 19 online sections of Probability and Statistics were included in the study with 39 out of 464 students consenting to participate. Face-to-face courses were not an option due to the worldwide pandemic. The study participants completed a 17-item survey measuring their perceptions of learning mathematics online. Data was analyzed quantitatively using descriptive statistics.

Despite the small response rate, this study yielded some interesting preliminary findings. Some results included 41% of the students stated they were motivated to complete assignments, 39% were not confident in succeeding, and 59% believed they would perform better had the course been offered in person. These findings mirror those from Serhan and Almeqdadi (2020). When students were asked about the challenges they were facing, motivation was selected with the highest frequency (64%), and 51% of students stated they struggled with understanding course material. The pandemic forced universities to move courses online, and students had no choice in their course delivery. Many participants shared common suggestions and concerns to make online learning better. They requested live meetings (face-to-face or video conference), more accessible content, and the inclusion of clear explanations. Further results and areas for future research will be presented in the poster.

Impact of Online Undergraduate Mathematics Courses on Student Perceptions

Mikayla Dokos, Valerie Long, Yuliya Melnikova
IUP Department of Mathematical and Computer Sciences

Abstract

The mode of instruction, online versus face-to-face classes, may be a positive or a negative experience. During the spring 2021 semester, data was collected from three online statistics courses to measure student perceptions. This poster presentation will discuss the impact of online undergraduate mathematics classes on student perceptions.

Background

While online learning has played an important part of curriculum and teaching in universities, it has become more prominent due to the need for distance education to help mitigate the spread of COVID-19 (Ramadhani, 2021). Online platforms like Zoom, OER (open educational resources), and Blackboard allow for learning to be flexible, adaptable, and accessible to students. However, with online learning comes unforeseen challenges. Researchers have found difficulties in communication (Ramadhani, 2020), issues with technology, and ease of forgetting assignments (Serhan & Almeqdadi, 2020). Other researchers found that online platforms such as WeBWorK were not user-friendly (Hauk & Segalla, 2005). Research is needed to understand the influence of online classes on student perceptions.

Research Question

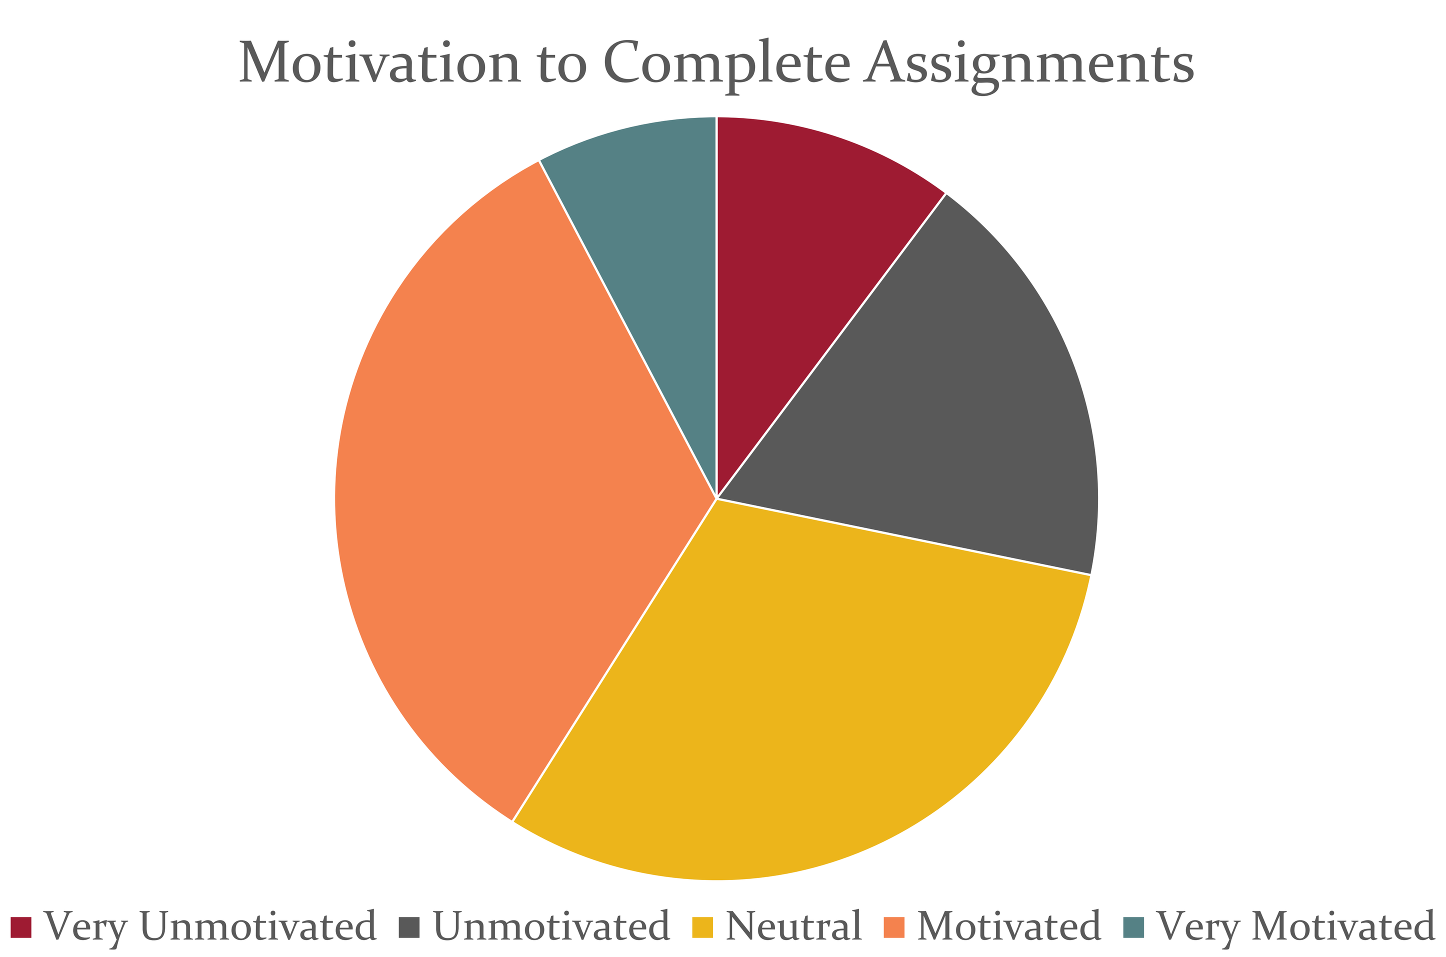
What are the impacts of an online undergraduate mathematics class on student perceptions?

Methodology and Procedures

Due to the variety of majors represented amongst statistics classes, the perceptions of students from three undergraduate statistics courses were examined in this study; Probability and Statistics, Probability and Statistics for Business Majors, and Probability and Statistics for Natural Science.

A 17-question online survey was distributed among 464 students across 19 sections of these courses, of which 39 responded yielding a response rate of 8.41%. Data was analyzed using descriptive statistics.

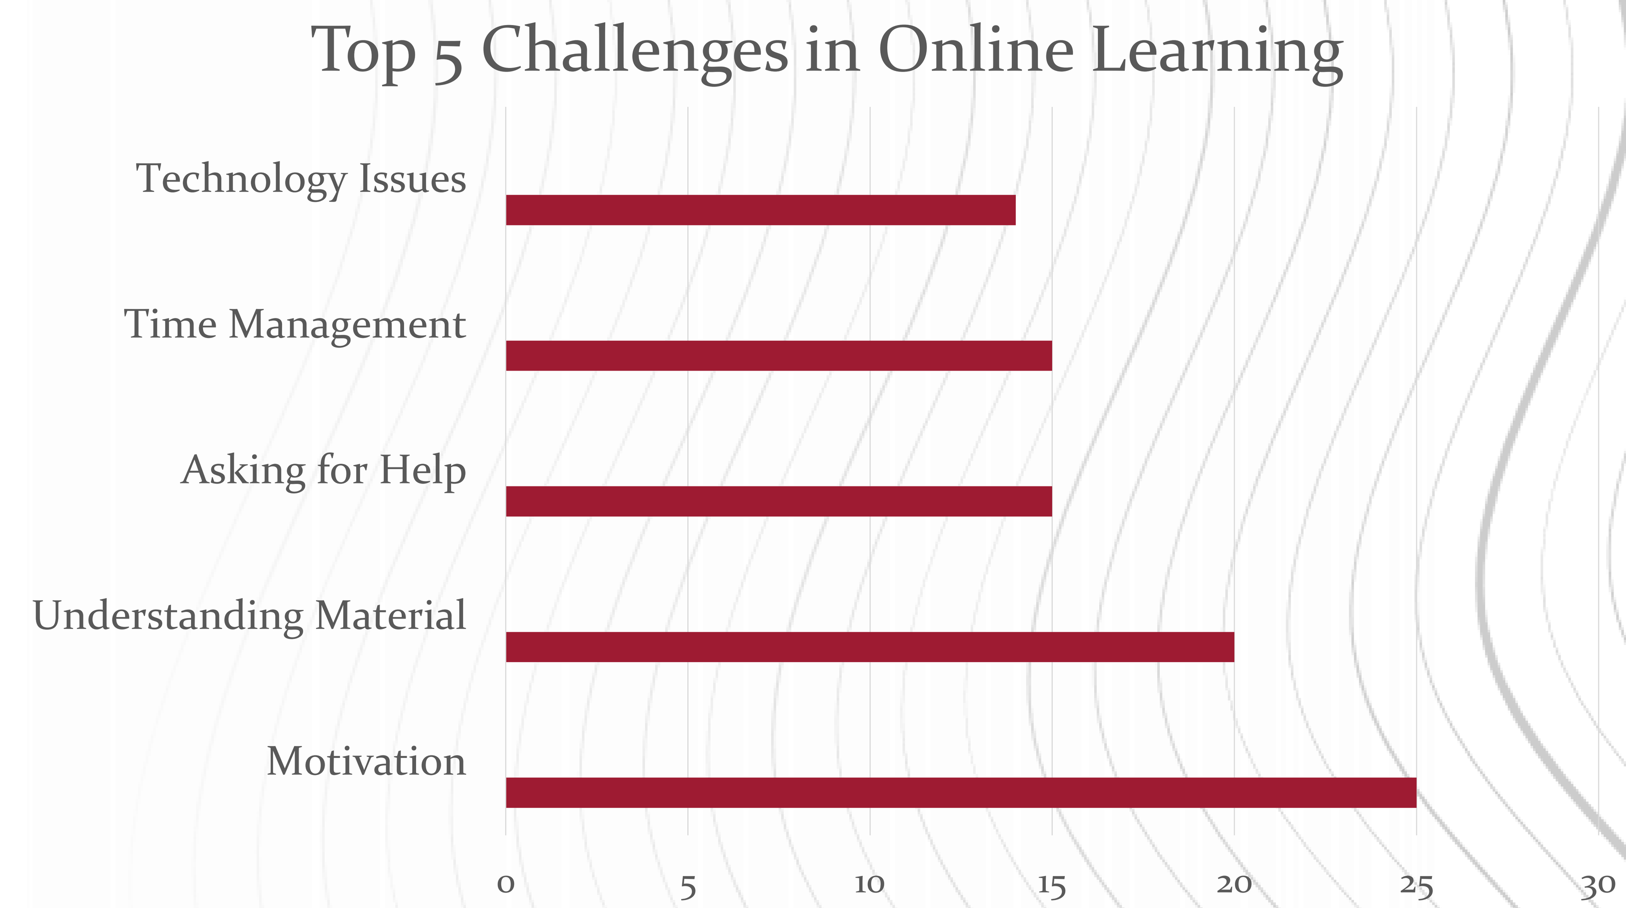
Results and Discussion



41% of the students from this sample stated they were motivated to complete assignments. Approximately 39% of students were not confident in succeeding in their statistics course. However, about 59% stated they would perform better had the course been offered in person.

Results and Discussion Cont'd

Students shared their opinions about challenges they faced while learning statistics online. The top 5 challenges were staying motivated, understanding the material, asking for help when struggling, time management, and technology difficulties.



Some general themes emerged when students were asked "what could make this course better?". The themes were

- the request to have live meetings (face-to-face or video conference)
- need more access to the content, and
- include more clear explanations/instructions.

Student statements specifically addressed technology, such as WeBWorK not being user-friendly, asking for lectures to be posted online, and having specific instructions and training for how to use course software (R Studio).

The Teaching and Learning of Geometric Proof: Role of the Teacher

Mara P. Markinson
Queens College of the City University of New York

Keywords: geometry; proof; teacher content knowledge; beliefs; attitudes; pre-service; novice

The purpose of this study was to explore preservice and novice secondary mathematics teachers' proof-writing abilities and beliefs about geometry (particularly proofs), in order to propose ideas about how to improve the teaching and learning of geometric proofs. This study contributed to the pre-existing research on Shulman's (1986) categories of teachers' knowledge. Although many studies distinctly examined subject matter content knowledge, pedagogical content knowledge, or curricular knowledge, the present study began to examine these factors in conjunction. Moreover, the researcher did not find pre-existing studies focusing solely on the beliefs, attitudes, and content knowledge of pre-service and novice secondary mathematics teachers with regard to geometric proof.

I created a five-item content assessment (eMATHinstruction, 2017, 2018a, 2018b; The University of the State of New York, 2015, 2016) to administer to preservice and novice secondary mathematics teachers. Each content assessment item was taken from end-of-year assessments for high school students. I met with 29 participants to administer the assessment while asking questions regarding their feelings, beliefs, and confidence in regard to teaching proof in high school geometry. The administrations of these content assessments and simultaneous interviews were audio-recorded and transcribed, and subsequently analyzed for trends in the participants' responses using five qualitative codes: Beliefs and Attitudes (BAA), Issues of Correspondence Between Substance and Notation (ICSN), Expressing Understanding and Self-Doubt (EUSD), Mathematical Language (ML), and Pure Mathematical Issues (PMI).

The results of the study showed that the majority of the preservice and novice secondary mathematics teacher participants do not currently feel prepared to teach proof in high school geometry, from standpoints of both mathematical content knowledge and confidence. The participants with no geometry teaching experience mainly drew on their own experiences from high school, and tried to remember specific rules and standards that their particular teachers tried to instill. This finding supports the ideas of Schoenfeld (1985) and Battista (2009), who also found that most secondary school students see proof-writing as nothing more than following a set of prescribed rules. This study, however, also illuminated issues within participants' Mathematical Knowledge for Teaching (MKT). Specifically, participants did not connect the ideas of rigid motions and equality of measures to congruence, used circular reasoning, and made incorrect visual assumptions when considering diagrams. In response to the interview questions that addressed participants' beliefs and feelings about proof and proving, the participants overall voiced preferences to teach other courses over geometry. Many participants gave up without attempting one or more content assessment items, displaying the need for stronger beliefs in their own abilities. Although participants were not told that the assessment items were high-school level problems, many of them expressed that they knew that from previous exposure via tutoring or student teaching.

Since teachers' attitudes are so easily transferrable to the students in their charge, it is important to continue to conduct research in this area so that the state of the teaching and learning of geometric proof can be improved.

On the Evolution of Graduate Student Mentees' and Mentors' Conceptualizations of Peer Teaching Mentorship

Scotty Houston
University of Memphis

Melinda Lanius
Auburn University

Josias Gomez
University of Memphis

Leigh Harrell-Williams
University of Memphis

RaKissa Manzanares
University of Colorado Denver

Gary Olson
University of Colorado Denver

Kathleen Gatliffe
University of Colorado Denver

Mike Jacobson
University of Colorado Denver

Keywords: Graduate Teaching Assistant (GTA), Professional Development, Peer Mentoring

Peer mentoring programs can provide instructional support for graduate teaching assistants (GTAs) (Rogers & Yee, 2018; Yee & Rogers, 2017) through more specialized and detailed discussions than just working with faculty (Speer et al., 2015; Yee & Rogers, 2016). Lanius et al. (2022) explored how mentees and mentors participating in a comprehensive multi-component GTA pedagogical training program, *Promoting Success in Undergraduate Mathematics Through Graduate Teacher Training* (Harrell-Williams et al., 2020), at three universities at the start of an academic year conceptualized the role of an effective mentor. In this poster, we explore whether this conceptualization of the mentor role changed over the course of the academic year after participation in components of the training program: a GTA Teaching Seminar, Critical Issues Seminar, and peer mentoring (including mentor training).

Forty GTAs across three universities completed online surveys in August 2020 and May 2021, answering the same items both times. Two Likert-type items asked about their view of the mentor role in a mentor-mentee relationship. For the first item, a score of "1" indicated viewing the role of mentor as an authority figure whereas a score of "5" indicated more of a collaborative relationship. For the second item, a score of "1" indicated the mentor is a problem-solver and "5" indicated being an empowerer. Mentors also answered two items rating themselves on these continuums. All GTAs were asked to describe the characteristics of an effective mentor.

The related samples Wilcoxon signed-rank tests indicated that there were no statistically significant changes for mentees or mentors for the Likert-type items from August to May. Specifically, six mentees of 23 mentees and five of 17 mentors did not "change" on either of the role conceptualization items. Five of 11 mentors did not "change" on the self-as-mentor items. However, Spearman correlations across timepoints only ranged from .20 to .56, indicating some individual change which was also supported by the qualitative data. The poster will also report results from a psycholinguistic analysis of the responses to the open-ended items. Future work will explore changes in role conceptualization as mentees become mentors.

On the Evolution of Graduate Student Mentees' and Mentors' Conceptualizations of Peer Teaching Mentorship

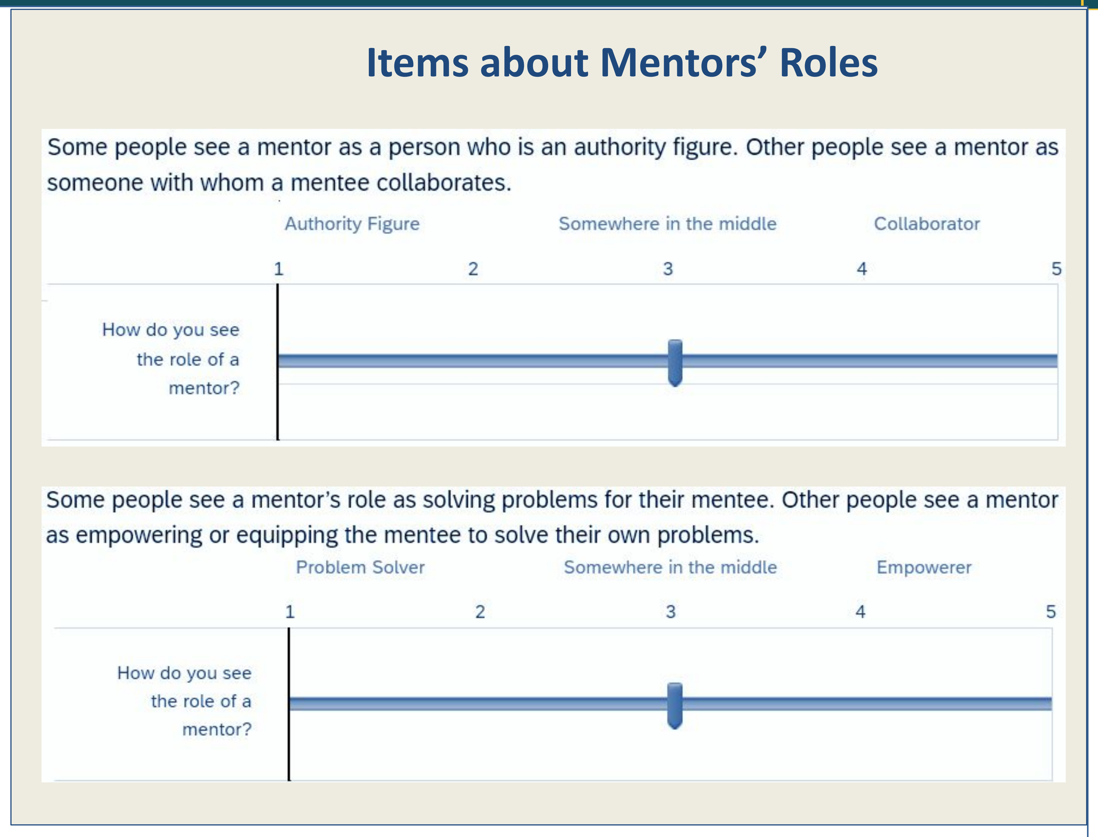
Scotty Houston[3], Melinda Lanius[2], Josias Gomez[3], Leigh Harrell-Williams[3], RaKissa Manzanares[1], Gary Olson[1] , Kathleen Gatliffe[1],Mike Jacobson[1]
[1]University of Colorado Denver, [2]Auburn University, [3]University of Memphis

Background

There is ample evidence that peer mentorship among graduate students benefits their academic, professional, psychological, and social learning (Lorenzetti et al., 2019). Specifically, peer teaching mentorship supports graduate teaching assistants' (GTAs) instructional effectiveness, leadership, and confidence (Belnap, 2005; Lorenzetti et al., 2019; Funkhouser et al.,2021; Yee & Rogers, 2017). Views on what makes an "effective" mentor vary throughout literature (NASEM, 2019). Based on the social theory of learning, mentors and mentees tend to conceptualize the mentor role as an authority figure or collaborator, and a problem solver or empowerer (Lanius et al., 2022). In this poster, we examine how GTAs' conceptualization of a peer-mentor's role changes over time as they engage in the peer-mentoring component of the PSUM-GTT program.

Methods

- Research Question: How did mentees and mentors' conceptualizations of peer teaching mentorship change?
- Sample: Start-of-year survey completed in August 2020 and May 2021 by 23 mentees and 17 mentors.
- Survey items:
  - 2 Likert-type items about mentors' roles (see box to the right)
  - 1 open-ended question:
    "What do you believe are the characteristics of an effective mentor?"
- Analysis:
  - Related samples Wilcoxon signed-rank tests & Spearman's correlation to assess change over time
  - Qualitative coding analysis to organize and group descriptive terms for characterizing an effective mentor obtained from the open-ended survey question.



Take-aways

- Neither the repeated samples tests nor the "problem solver/empowerer" correlations were significant.
- The four Transition Diagrams provide insight into interesting cases for further qualitative analysis.
- Both mentees and mentors increased their mentioning of "good listener" as important for effective mentors.
- Mentors increased their mentions of effective mentors as "knowledgeable" while mentees were unchanged.
- Mentees prioritized the "availability" of mentors more in May whereas mentors were unchanged.
- "Constructive feedback" mentions increased over time for mentees but decreased significantly for mentors.
- "Relevant experience" of mentors decreased in mentions for both mentees and mentors over time.

Data Context: About PSUM-GTT

The Promoting Success in Undergraduate Mathematics through Graduate Teaching Assistant Training (PSUM-GTT) program employs a multi-component approach to training.

- Seminar on teaching with a focus on equity and inclusion
- Critical Issues in STEM Education seminar series
- One-to-one peer mentoring
- Support from a peer TA coach
- Visits to K-12 mathematics classrooms and enrichment experiences

Students' Justifications and Their Proofs by Mathematical Induction

Mario A. Gonzalez
Texas State University

Valentina Postelnicu
Governors State University

Keywords: mathematical induction, justification, proof

Mathematical induction has proven to be difficult for students to understand (Ernest, 1984) and, more broadly, the purpose of proof; often remaining unfulfilled as to the certainty of $P(n)$ for values of n for which the statement is proven (Avital & Libeskind, 1978; Harel, 2002). The research perspective in this paper is the proving-as-convincing research paradigm (Stylianides et al., 2017).

Some studies have focused on students' convictions with how they develop or shift (Brown, 2014) and how students convictions may be understood (Weber & Mejia-Ramos, 2015). Others have studied how mathematical arguments may be convincing (Stylianides & Stylianides, 2009). Generally, students may show evidence of this with their justifications regarding proofs.

As part of a larger study, we had students complete a task asking to produce a proof by mathematical induction and provide justifications for the truth value of $P(n)$ for certain values of n. The purpose of this study is to examine the relationship between students' abilities to construct a proof by mathematical induction and their types of justifications based on their written responses to the task. In this study, 59 undergraduate STEM majors across two semesters were given the following task:

a) Prove the statement $P(n)$ by mathematical induction for $n \in \mathbb{N}$, $n \geq 6$,
$P(n)$: $17 + 20 + 23 + \ldots + (3n - 1) = n(3n + 1)/2 - 40$.
b) Is the statement true for $n = 10$? Justify your answer.
c) Is the statement true for $n = 5$? Justify your answer.
d) Comment on your difficulties, if any.

For a preliminary analysis, a framework has been developed loosely based on work by Harel and Sowder (1998) who described the act of justifying as "how students ascertain for themselves or persuade others of the truth of a mathematical observation" (p. 243). We have incorporated the domain of discourse (Stylianides et al., 2007) and domain of validity (Healy & Hoyles, 2000) into a framework to help define these terms.

For proof justification, a student provides justification using his or her proof of the statement. For $P(10)$, it is inferred that the student understands the associated domain of validity for his or her proof. For $P(5)$, it is inferred that the student is convinced that for any value not within the domain of validity (but in the domain of discourse), the statement is false. For empirical justification, the student does not use his or her proof for justification. However, a student may feel the need to provide an additional verification, such as a calculation, that is different from his or her proof after having already proven the statement.

We found that students often relied on empirical justifications (53%), as reported in the literature. However, we also found interesting results. Some students (17%) relied on the proof for both cases, and a few (7%) used proof justification for $P(5)$ and empirical justification for $P(10)$, a result found only to be reported once in the literature (Stylianides et al., 2007). These findings contribute to the field by showing that students may use different sources for justifying statements depending on where the value in question lies. Educators may use these results to attend to how students may operate in the domain of validity and domain of discourse when understanding the purpose of proof.

Students’ Justifications and Their Proofs by Mathematical Induction

Mario A. Gonzalez and Valentina Postelnicu

Department of Mathematics in the College of Science and Engineering at Texas State University

Rationale

Mathematical induction has proven to be difficult for students to understand (Ernest, 1984) and, more broadly, the purpose of proof; often remaining unfulfilled as to the certainty of $P(n)$ for values of n for which the statement is proven (Avital & Libeskind, 1978; Harel, 2002).

The research perspective in this paper is the proving as convincing research paradigm (Stylianides et al., 2017). Stylianides et al. (2017) stated that this research paradigm on proof revolves around studying students’ convictions with evidence (i.e., mathematical arguments and proofs) and how it is related to the mathematics community’s accepted forms of proof.

In this proving as convincing research paradigm, deductive arguments, such as proofs by mathematical induction, convince mathematicians while arguments relying on specific calculations or having the appearance of proof remain unconvincing (Stylianides et al., 2017).

Theoretical Background

Ernest (1984) described the necessary steps to prove a statement by mathematical induction which grounds itself in *modus ponens*, a deductive argument, and the Principle of Mathematical Induction (PMI).

For mathematical statements, the domain for finding whether a statement is true is called the domain of discourse (Stylianides et al., 2007). The domain of discourse for proofs by mathematical induction is any natural number, n, greater than the basis step, n_0 ($n \geq n_0$). In Healy and Hoyles (2000), they called the domain for which a statement is known to be true the domain of validity. The domain of discourse for $P(n)$ in the task for this study is $n \geq 5$ where n is a natural number, however, the domain of validity is $n \geq 6$.

For this study, the term justification describes how a student determines the validity of a mathematical statement for a value (Harel & Sowder, 1998). Students provide these justifications with written responses to the task. Note that the proofs with which students interact are their own proofs by mathematical induction.

We have incorporated the domain of discourse (Stylianides et al., 2007) and domain of validity (Healy & Hoyles, 2000) into a framework to help define these terms.

Categories

For proof justification, a student provides justification using his or her proof of the statement. For $P(10)$, it is inferred that the student understands the associated domain of validity for his or her proof. For $P(5)$, it is inferred that the student is convinced that for any value not within the domain of validity (but in the domain of discourse), the statement is false.

For empirical justification, the student does not use his or her proof for justification. However, a student may feel the need to provide an additional verification, such as a calculation, that is different from his or her proof after having already proven the statement.

Purpose

As part of a larger study, we had students complete a task asking to produce a proof by mathematical induction and provide justifications for the truth value of $P(n)$ for certain values of n. For these values, we investigated students’ responses for which source, either their proofs or non-proof related reason(s), was used to determine the truth of the statement.

The purpose of this study is to examine the relationship between students’ abilities to construct a proof by mathematical induction and their types of justifications based on their responses to the task.

The Task

In this study, 59 undergraduate STEM majors were given the task below. With the students’ responses, we performed preliminary analyses of the justifications, and we discuss these students’ justifications.

a) Prove the statement $P(n)$ by mathematical induction for $n \in N, n \geq 6$,

$$P(n)\text{: } 17 + 20 + 23 + \ldots + (3n - 1) = \frac{n(3n+1)}{2} - 40.$$

b) Is the statement true for $n = 10$? Justify your answer.

c) Is the statement true for $n = 5$? Justify your answer.

d) Comment on your difficulties, if any.

Table 1. The interactions between the responses of whether P(10) and P(5) are true.

		$P(10)$ result	
	Evidence of Source	Proof Justification	Empirical Justification
$P(5)$ result	Proof Justification	17 (29%)	4 (7%)
	Empirical Justification	7 (12%)	31 (53%)

(Top Left) Proof Justification for P(10) and Proof Justification for P(5).

b) Is the statement true for n=10? Justify your answer.

Yes, the statement is true for n values greater than or equal to 6. Since 10 is greater than 6, the statement holds true.

c) Is the statement true for n=5? Justify your answer.

No, the statement is not true for n = 5. The statement is only true when n = 6 or greater than 6. Since 5 is a lower number than 6, the statement is not true for when n = 5.

(Top Right) Empirical Justification for P(10) and Proof Justification for P(5).

b) Is the statement true for n=10? Justify your answer.

$\frac{10(3(10)+1)}{2} - 40$

b) is false

$3(10)-1=29$ $\quad$ $155 - 40 = 115$ $\quad$ $29 \neq 115$

n=10 is false

c) Is the statement true for n=5? Justify your answer.

no because $n \geq 6$

$5 \leq 6$ which makes this false

(Bottom Left) Proof Justification for P(10) and Empirical Justification for P(5).

b) Is the statement true for n=10? Justify your answer.

Yes because we checked ~~it~~ and the statement is true for any $n \geq 6$ by the PMI, and $10 \geq 6$

c) Is the statement true for n=5? Justify your answer.

It is not true for n=5.

$P(5)\text{: } 3(5)-1 = \frac{5(3(5)+1)}{2} - 40$

$14 \neq 0$

(Bottom Right) Empirical Justification for both P(5) and P(10).

b) Is the statement true for n=10? Justify your answer.

$\frac{10(31)}{2} - 40 =$ $\quad$ $17+20+23+26+29$

$155 - 40 = 115$ $\quad$ $37 + 49 + 29$

$86 + 29 = 115$

$n = 10$ ✓

I was thinking too fast and I forgot the -40

c) Is the statement true for n=5? Justify your answer.

$(3(5)-1) = 14$ $\quad$ $\frac{5(16)}{2} - 40$

$\frac{80}{2} = 40 - 40 = 0$

$14 \neq 0$ $\quad$ n=5 not true

Findings

Note that students’ written comments on part d) of the task are included in the figures. Some students declined to respond to part d).

We found that students often relied on empirical justifications (53%), as reported in the literature. However, we also found interesting results. Some students (17%) relied on the proof for both cases, and a few (7%) used proof justification for $P(5)$ and empirical justification for $P(10)$, a result found only to be reported once in the literature (Stylianides et al., 2007).

Some students responded to part d) by writing that they did not experience difficulties. This is interpreted that students may not perceive the relationship between a proof and the domains of discourse and validity.

These findings contribute to the field by showing that students may use different sources for justifying statements depending on where the value in question lies. Educators may use these results to attend to how students may operate in the domains of discourse and validity when understanding the purpose(s) of proof.

Next Steps

We plan to use these findings to help develop tasks to better understand how students’ justifications change based on the domains of discourse and validity.

Future research investigations may include these constructs and the relationship with students’ convictions with mathematical statements and arguments.

Exploration of Students' Experiences Transitioning from Secondary to Tertiary Mathematics

Samuel Waters
University of Northern Colorado

Keywords: Transition, University Mathematics, College Algebra, Phenomenology

Early experiences in undergraduate mathematics contribute to student persistence STEM majors (Courturier & Cullinane, 2015). The transition from high school to undergraduate mathematics remains problematic for both students and instructors despite increased attention on the issue (O'Shea & Breen, 2021). Motivated by the need to understand STEM-specific issues related to student transitions to college, this study investigated two research questions: (a) What is the essence of the lived-experiences of first-year undergraduate students transitioning to their first post-secondary mathematics course? and (b) How do students view their transition after their first undergraduate mathematics course?

Previous research on transition to college found when students do not feel like they belong at their institution or in a classroom, there is less academic engagement and lower achievement (Bowman et al., 2019). While many researchers have investigated the transition to collegiate mathematics, most are focused on specific aspects of the mathematics courses such as content, instruction, or classroom environment (Blackmore, 2021; Chuene, 2011; O'Shea & Breen, 2021). This study enhanced existing research by taking a more holistic view of transitions including factors in and out of the mathematics classroom.

Through a constructivist lens, this study focused on the meaning that students construct while experiencing their transition to undergraduate mathematics and their reflections on these experiences. As the qualitative approach of the study, an interpretative phenomenological analysis (IPA) centered the study on individual experiences and the meaning-making of both participant and the researcher (Smith & Shinebourne, 2012). Goodman et al.'s (2006) transition theory served as an analytical framework. Participants were three first-year students who were enrolled in College Algebra during their first semester at a mid-sized university. The first interview occurred at week ten of the first mathematics course. One participant was selected for a follow-up interview at the start of their second semester. Each interview was transcribed and coded using In Vivo coding followed by pattern coding to identify themes.

Three overarching themes were: (a) adjusting to new course expectations, (b) navigating challenges outside the classroom, and (c) changes in mindset and motivation. All participants shared experiences adjusting to new expectations for participation and working with others, which two participants noted helped them learn and made them more comfortable in the classroom. Participants described an emerging independence which contributed to changing mindsets in the mathematics classroom. One participant shared that since he was in college now, "I had to think differently… I had to change the mindset of what I needed to do." Another spoke about how her experiences in College Algebra provided an outlet to explore a new sense of self, stating "I felt more in my own skin." Findings from this study point to several implications for instructors including setting and communicating clear expectations to assist students in understanding their new environment. Encouraging group work early in courses can help students build connections and develop a sense of belonging both socially and academically within the classroom. Further research can explore how students' mathematical identities change during the transition to college mathematics.

Exploration of Students' Experiences Transitioning from Secondary to Tertiary Mathematics

UNIVERSITY OF NORTHERN COLORADO
Mathematical Sciences

Samuel Waters, Graduate Student, Educational Mathematics Ph.D. and Advisor Dr. Gulden Karakok

Motivation, Purpose, Research Questions

Motivation

- High dropout rates at universities linked to failure in mathematics point to a remarkable **subject-specific challenges** for students transitioning from secondary to tertiary educational environments (Rach & Heinze, 2017).
- Understanding student experiences provides institutions and faculty with needed information to set up supports and interventions to promote student success in mathematics (Blackmore et al., 2021).

Purpose

The purpose of this longitudinal phenomenological study was to describe first-year undergraduate students' experiences transitioning from high school to undergraduate mathematics classrooms.

Research Questions

- Q1 What is the essence of the lived-experiences of first-year undergraduate students transitioning to their first post-secondary mathematics course?
- Q2 How do students view their transition after their first undergraduate mathematics course?

Research Design and Methods

Research Paradigm: Constructivism

The central tenant of constructivism is that meaning is constructed by human beings as they interact with the world; reality cannot exist separate from the knower's experiences (Crotty, 1998).

Methodology: Interpretive Phenomenological Analysis (IPA)

Phenomenological studies attempt to describe a phenomenon by focusing on the common meanings that individuals have towards a shared experience (Creswell & Poth, 2018).

Setting: mid-sized, regional university in the Rocky Mountain Region

Participants: Participants were three undergraduate student volunteers enrolled in College Algebra during Fall 2021, their first semester of college after graduating high school in Spring 2022.

Dan (he/him)	Caucasian; majoring in English Education; enjoys fantasy and board games
Sela (she/her)	Hispanic; majoring in Psychology; oldest of five; first-generation college student; "quiet and chill"
Solus (he/him)	Hispanic; majoring in Business Marketing; out-of-state student; "shy"

Note: Pseudonyms, pronouns, and all personal descriptors were selected and provided by the participants

Data Collection: Each participant partook in an interview ten to twelve weeks into their first semester. One participant, Sela, was selected for follow-up and was interviewed two additional times during Spring 2022.

Data Analysis: Interview transcripts were reviewed and coded using in vivo and descriptive codes. Codes were also initially categorized based on Schlossberg's 4S components. Pattern coding was then used to identify main themes.

Students' Voices

"when I walked into college my first day, **I didn't really see myself [how I do] now**." - Sela

"I feel like it [College Algebra] just made the semester a bit more better, I guess. **I felt more in my own skin** than I did…a class that I actually felt motivated doing, felt pretty good in." - Sela

"I guess the thing that changed was **having a new mindset since it was college now.** I had to think differently… I had to change the mindset of what I needed to do and what I needed to change about myself." – Solus

"During the year I'd been really good about sticking to a sleep schedule and just overall I was doing a lot better with mental health and physical health and a lot of that stuff. **So a lot of the reasons I really loved that math class weren't exactly about the math class. There was other contributing things.**" - Dan

Results

Adjusting to New Course Expectations

Description	Example
Differences in perceived instructor support	"A lot of professors aren't really there to teach." – Dan
Greater focus on process and conceptual understanding.	In high school math class, "I didn't have to explain a lot of it and you just had to get the answer." - Solus
Access to peer supports and multiple solution strategies	"I got to learn more about how the other peers did math, like how they solved their problems. They would explain it and it taught me a new way than the original way I learned and so it's a new strategy to put in the books." –Sela

Navigating Challenges Outside the Classroom

Description	Example
Other responsibilities	"I started working this semester my first job because I never really worked before, so it's something new that I've been trying to get used to and then also [getting] used to making time around it. I get less time to complete it [homework] and so I think I'm rushed to do it [homework]." - Sela
Difficulty in making friends	"I've been really slow to meet new people and make friends." – Dan
Outside stress interacting with mathematics	"it's getting to the point where I'm just like, I need to ask for an extension time because there's too many things to do. And so, when I do have time, it's usually for more work." - Solus

Changes in Mindset and Motivation

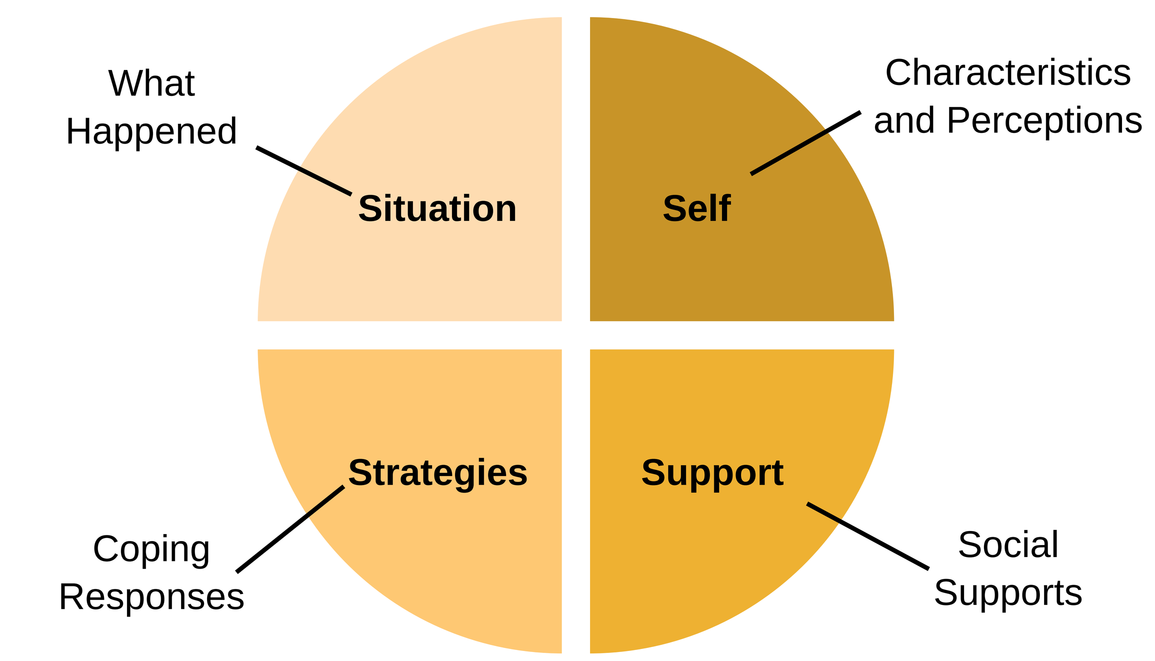
Description	Example
Growing sense of independence	"It's just adjusting to living on my own." – Dan
Independence related to mindset	Solus made a conscious decision to adopt a new mindset when entering college (quoted above). "Not having to rely too much on others." – Solus
Independence related to motivation	Dan took ownership of his own learning and did not rely on others for motivation in mathematics.

Reflections on the Transition

Description	Example
Assessing support and strategies	"teaching them was teaching myself" – Sela
Developing independent identity	Sela was able to see herself as an individual instead of just as a member of her family. The interactions Sela had in her mathematics course provided an outlet to explore this new sense of self (quoted above).
Applying lessons learned moving forward	"Because of that previous group work I had in College Algebra… I didn't feel pressure…I felt easily able to really speak with them and share my opinion as well…I know that if it were younger me, I wouldn't have been able to do that." - Sela

Analytical Framework

Schlossberg et al.'s (1995) Transition Theory



Trustworthiness and Limitations

Trustworthiness

- Research journal, reflexivity, and bracketing
- External checks from peers and other researchers
- Member checks during and after interviews

Limitations

- Sample: size; same course at same institution; enrolled in mathematics in first semester right after high school
- Dan and Solus were only interviewed once

Implications and Future Research

Implications for Practice

- Undergraduate instructors can reflect on how they communicate course expectations to help students assess their new situations.
- Consider how to incorporate group work early in the course to assist students with their academic and social transitions.
- Be understanding of factors outside of class that might be contributing to academic challenges.
- Build structured peer supports to take advantage of lessons learned by students who have gone through the transition.

Recommendations for Future Research

- Examine secondary-to-tertiary mathematics transitions in other settings (e.g., institutions, courses, etc.)
- Investigate how transitions are impacted by recent and ongoing educational experiences related to COVID-19
- Further explore the potential of group work to facilitate student transitions in mathematics.
- Research how students' mathematical identities change during transition.

Embodiment as Evidence for Student Engagement in an Inquiry-Based Mathematics Classroom

Kaylee Fantin-Hardesty
Colorado State University

Rachel Tremaine
Colorado State University

Jocelyn Rios
Colorado State University

Hortensia Soto
Colorado State University

Keywords: Embodiment, inquiry, engagement

The multi-dimensional construct of student engagement is an important aspect of students' experiences with mathematics, and increased levels of engagement support students' academic achievement (Carini et. al, 2006; Pilotti et al., 2017) and positive mathematics identity (Voigt et al., 2022). We propose that embodiment is a useful lens for exploring evidence of such engagement. Embodiment is the notion that "thinking does not occur solely in the head but also in and through a sophisticated semiotic coordination of speech, body, gestures, symbols and tools" (Radford, 2009, p. 111). While scholars have studied student engagement in the context of specific embodied tasks through self-reporting instruments (Georgiou & Iannou, 2020; Lindgren et. al, 2016), there is a gap in the literature regarding how embodiment might provide evidence of students' engagement. As student engagement with meaningful mathematical tasks is one of four pillars of Inquiry-Based Mathematics Education (IBME) (Laursen & Rasmussen, 2019), the IBME classroom is an ideal setting to study observable, embodied student engagement. In this poster, we present a microanalysis of three episodes of embodied engagement between two students (Rebecca and Lauren) in an IBME Discrete Mathematics classroom.

We draw on Fredericks et al.'s (2004) summaries of *behavioral* (on-task, participatory classroom actions), *affective* (emotional response or investment to the task at hand and its associated discoveries), and *cognitive* (students' self-regulation of learning) engagement to assess whether embodiment captures classroom engagement. These categories of engagement are not disparate, and thus we consider them as "dynamically interrelated" (Fredericks et al., 2004, p. 61). We also leverage definitions of embodiment that draw from Nemirovsky et. al (2012) in which mathematics is framed as a perception-action cycle and is evidenced by bodily activities including gesture, gaze, and body position to address our research question: *In what ways can embodiment provide evidence for students' engagement with meaningful mathematical tasks?*

Our three selected episodes support the notion that all three categories of student engagement are observable, embodied phenomena in the IBME mathematics classroom. For example, in one episode Rebecca's body positioning, gesture, and use of materials, without verbiage, illustrates her behavioral and cognitive engagement as the professor and Lauren converse. An embodied lens enabled attention to Rebecca's rich engagement that otherwise may have gone unnoticed. Thus, we assert that leveraging embodiment to study student engagement provides new insights into how students engage with meaningful tasks in an IBME classroom. This perspective can be utilized by both researchers and instructors in constructing a more nuanced understanding of how students engage with mathematics tasks.

Motivation

Engagement in the math classroom is an important component of student experience and achievement. (Carini et al., 2006; Pilotti et al., 2017; Voigt et al., 2022)

"Developing valid and reliable measures [for student engagement] is especially important in math and science because **engagement** in these subjects **is so critical to academic achievement and career choices** related to STEM." (Fredericks et al., 2016)

Measuring student engagement is often limited to self-reporting or observation scales which privilege verbal participation. (Fredericks & McColskey, 2012; Hodgson et al., 2010)

We propose embodiment as a lens through which to observe student engagement in the classroom,

Research Question: In what ways can embodiment provide evidence for students' engagement with meaningful mathematical tasks?

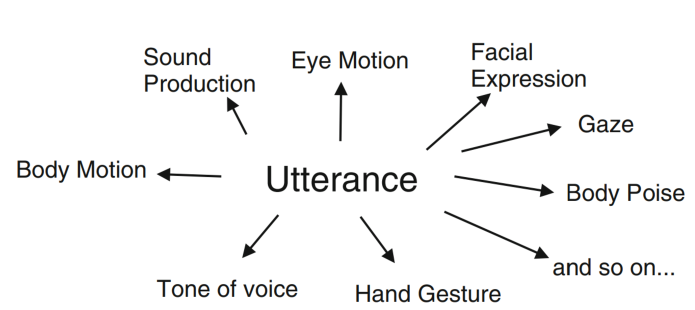
Embodied Cognition

Embodied cognition asserts that "…thinking does not occur solely in the head but also in and through a sophisticated semiotic coordination of speech, body, gestures, symbols and tools." (Radford, 2009, p. 111)

Embodiment can *enhance* student engagement with tasks. (Georgiou & Iannou, 2020; Lindgren et al., 2016)

We categorized the embodiment of our participants using Nemirovsky and Ferrara's (2009) notion of **multimodal utterances.**

Nemirovsky & Ferrara (2009)
Figure 2: The multimodality of an utterance



Student Engagement

Fredericks et al. (2004) provide three categories of student engagement:

- **Behavioral Engagement:** on-task, participatory classroom actions
- **Affective Engagement:** emotional response and investment in the task
- **Cognitive Engagement:** students' self-regulation of learning, thoughts, and perseverance

Student engagement with meaningful mathematics tasks is one of four pillars of Inquiry-Based Mathematics Education (IBME). (Laursen & Rasmussen, 2019)

Methodology

Participants:

- Students of an undergraduate Discrete Mathematics course
- An experienced instructor (Dr. A) who follows an Inquiry-Based Mathematics Education (IBME) teaching paradigm

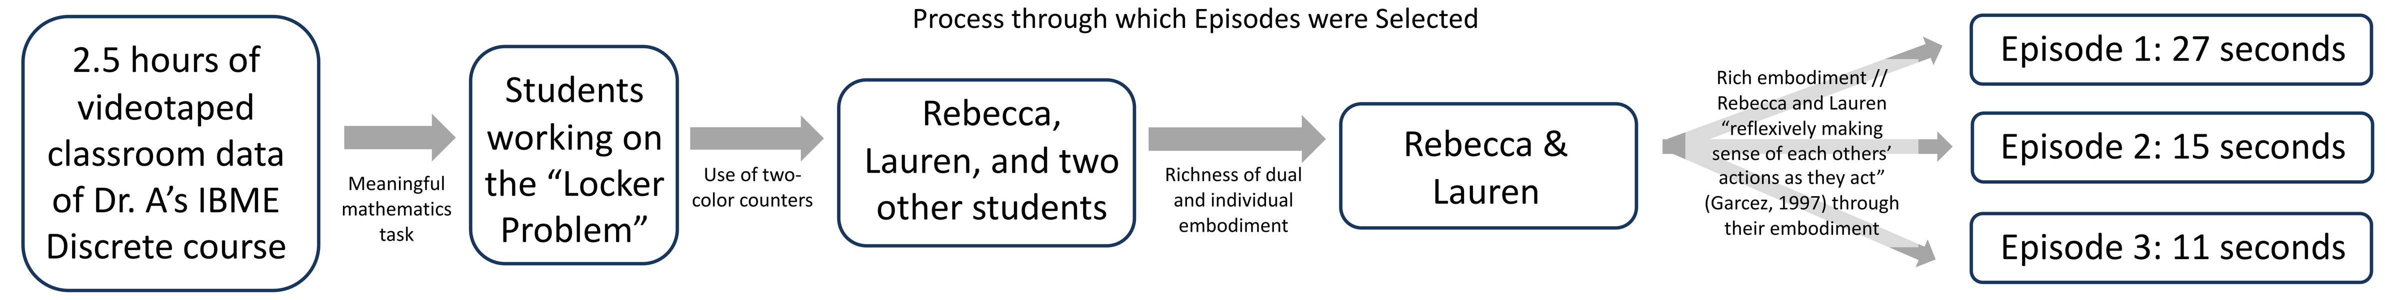
Data Collection and Selection:

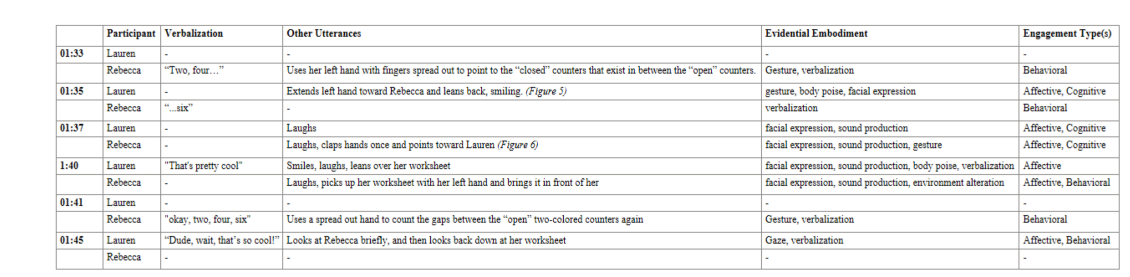
- Videotaped a total of 2.5 hours of classroom footage
- Narrowed our focus to a *meaningful mathematical task* that the students worked on the "Locker Problem" *(physical copy of worksheet available for viewing)*
- Analyzed the engagement of two students, Rebecca and Lauren, who utilized two-colored counters and worked both individually and together to solve the Locker Problem

Analysis:

- Microanalysis (Garcez, 1997): second-by-second transcription and description
- 2x Thematic Analysis (Braun & Clarke, 2006) – *a priori* coding according to Nemirovsky & Ferrara's (2009) multimodality of utterances and Fredericks et al.'s (2004) three domains of engagement.

Process through which Episodes were Selected





Screenshot of Full Microanalysis and Coding for Episode 2

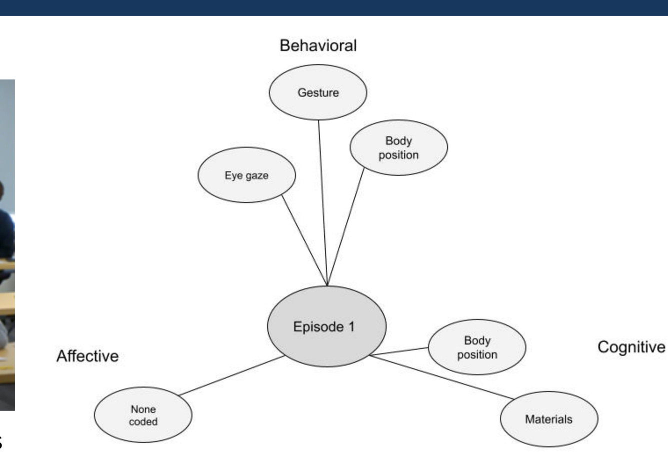
Results

Episode 1: Responsive Resetting

Rebecca interacted with her two-colored counters in direct response to the conversation she heard Lauren and Dr. A having.

Rebecca (right) leaned towards her counters and began resetting them to their original "closed" position when Dr. A (center) prompted Lauren to reconsider the problem.

Rebecca pushed additional counters towards her original line of counters, while Dr. A and Lauren continued discussing Lauren's worksheet.

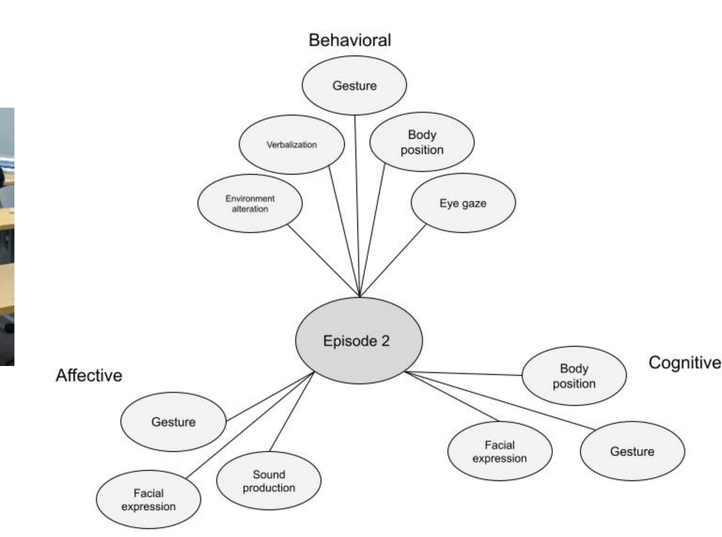


Episode 2: Collaborative Conjecturing

Lauren and Rebecca discovered a pattern in their counters, and expressed excitement when the pattern continued.

Lauren and Rebecca nonverbally and excitedly acknowledged each other, demonstrating a shared understanding of the pattern they both noticed, without ever verbalizing the pattern itself.

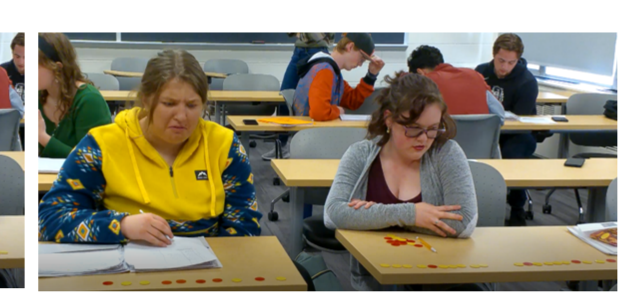
Rebecca laughed, clapped, and pointed to Lauren in a continued display of excitement. This exchange was demonstrative of affect, cognitive, and behavioral engagement by both students.



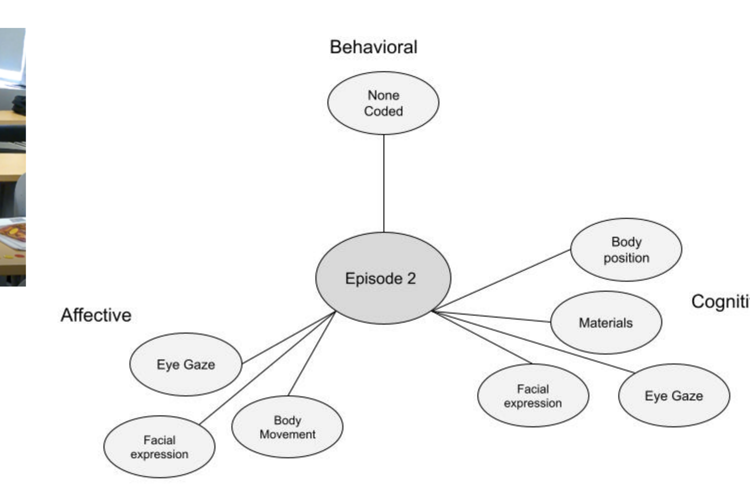
Episode 3: Second-guessing Squares

Lauren and Rebecca both expressed deep confusion when they overheard Dr. A validate a classmate's conjecture, which did not match their materials.

Both students looked towards Dr. A and a fellow classmate, while listening to their discussion. Lauren adopted a confused expression in response to a statement made by Dr. A that seemed contradictory to the pattern discovered in Episode 2.



Lauren shook her head in a continued state of confusion. Rebecca stared intently at the counters in front of her. Both students remained silent, seemingly attempting to reconcile Dr. A's statements with their own discovered pattern.



Findings & Discussion

Embodiment **can** and **does** provide evidence of student engagement in all three domains!

Embodiment provides evidence for students' engagement in ways which…

1. …illuminate engagement which may have gone unnoticed under observational scales which privilege verbalization
   - Episode 1 - Rebecca responds non-verbally to Dr. A's guidance
2. …account for the multimodal nature of both utterances and engagement as constructs (Fredericks et al., 2004; Nemirovsky & Ferrara, 2009)
   - Episode 2 - Rebecca laughs, claps her hands, and points to Lauren, indicating emotional and cognitive engagement
3. …consider the broader classroom context in which the students are engaging with the task (Hodgson et al., 2017; Kahn, 2014; Keith, 2016)
   - Episode 3 - Rebecca and Lauren's cognitive engagement is largely impacted by Anthony's conjecture in the classroom environment

Using embodiment to learn about students' classroom engagement **broadens the definition** of what it means to be a **classroom participator**, and captures engagement that might otherwise go unnoticed. Embodiment has strong potential to help educators notice, understand, and empower non-verbal participation. Further, embodiment offers an additional lens through which researchers may assess engagement.

Future Work

- Triangulating observations with self-assessment data (particularly with relevance to the students' cognitive engagement)
- Examining what a microanalysis of engagement would look like under different teaching paradigms

How Calculus Students Describe and Use Volume in Calculus and Non-Calculus Tasks

Ian West
University of Maine

Existing research indicates that some learning challenges Calculus students face may not be related to the Calculus-specific content, but rather from issues related to prerequisite knowledge. Several Calculus topics such as volume by slicing and volumes of revolution have a prerequisite topic of volume. These Calculus topics tend to be challenging for students in various ways. Better understanding how these students describe and use volume may help inform instructors as well as potential reforms to practices to better support student learning of these Calculus topics.

Keywords: calculus, volume, integration, student description

Existing literature documents the influence of prerequisite knowledge on the learning of limits and differentiation (e.g., Dorko, 2012; Ferrini-Mundy & Graham, 1994; Orton, 1983). It is possible that these issues could also extend to other Calculus topics. In particular, could student understanding of volume influence thinking on volume by slicing or volumes of revolution problems? A 2012 study indicated that, on tasks prompting Calculus students to find the volume of prisms, issues arose with conceptions and calculations, including some students making calculations more suggestive of surface area than volume (Dorko, 2012). Building on findings about understanding of integration (e.g., Jones, 2015; Sealey, 2014), we replicated Dorko's study's design with a focus on volume-related topics found in second-semester Calculus.

Approached from a cognitive perspective, data were collected via written response to surveys distributed to second-semester Calculus students from a large public university. Three questions were prompts to find the volume of a rectangular, a circular, and a triangular prism. Data was also collected in the form of follow up interviews to the survey task. During the interviews, students were asked to solve two volume of revolution tasks, similar to those typically presented in their Calculus class. Students were asked to describe their solutions, as well as why they think their solutions are or are not accurate. Data included what was recorded on paper, as well as video and audio interview recordings. We collected 97 responses to the survey task and have conducted 7 interviews. Of the students who completed the survey, 20% of students used an incorrect formula to calculate the volume of the cylinder and 11% for the triangular prism. These findings are similar to those of Dorko (2012). Analysis of interview data indicates some issues with volume in Calculus tasks as well as uncertainty about the volume ideas. One student stated, "it's the basic geometry that's gonna get me." While this student ultimately correctly completed each task, the student was consistently unsure of the volume formula they were using for both the disk and shell method when setting up each problem. The student was also unable to sufficiently justify the volume formula.

These findings suggest that volume-related ideas are influencing thinking about calculations done in second-semester Calculus. The poster will display student-generated volume sketches and will expand on these findings as well as others from the larger study. This will include findings from additional interviews and discussion of implications.

How Calculus Students Describe and Use Volume in Calculus and Non-Calculus Tasks

Ian West

Center for Research in STEM Education, The University of Maine

Background and Purpose

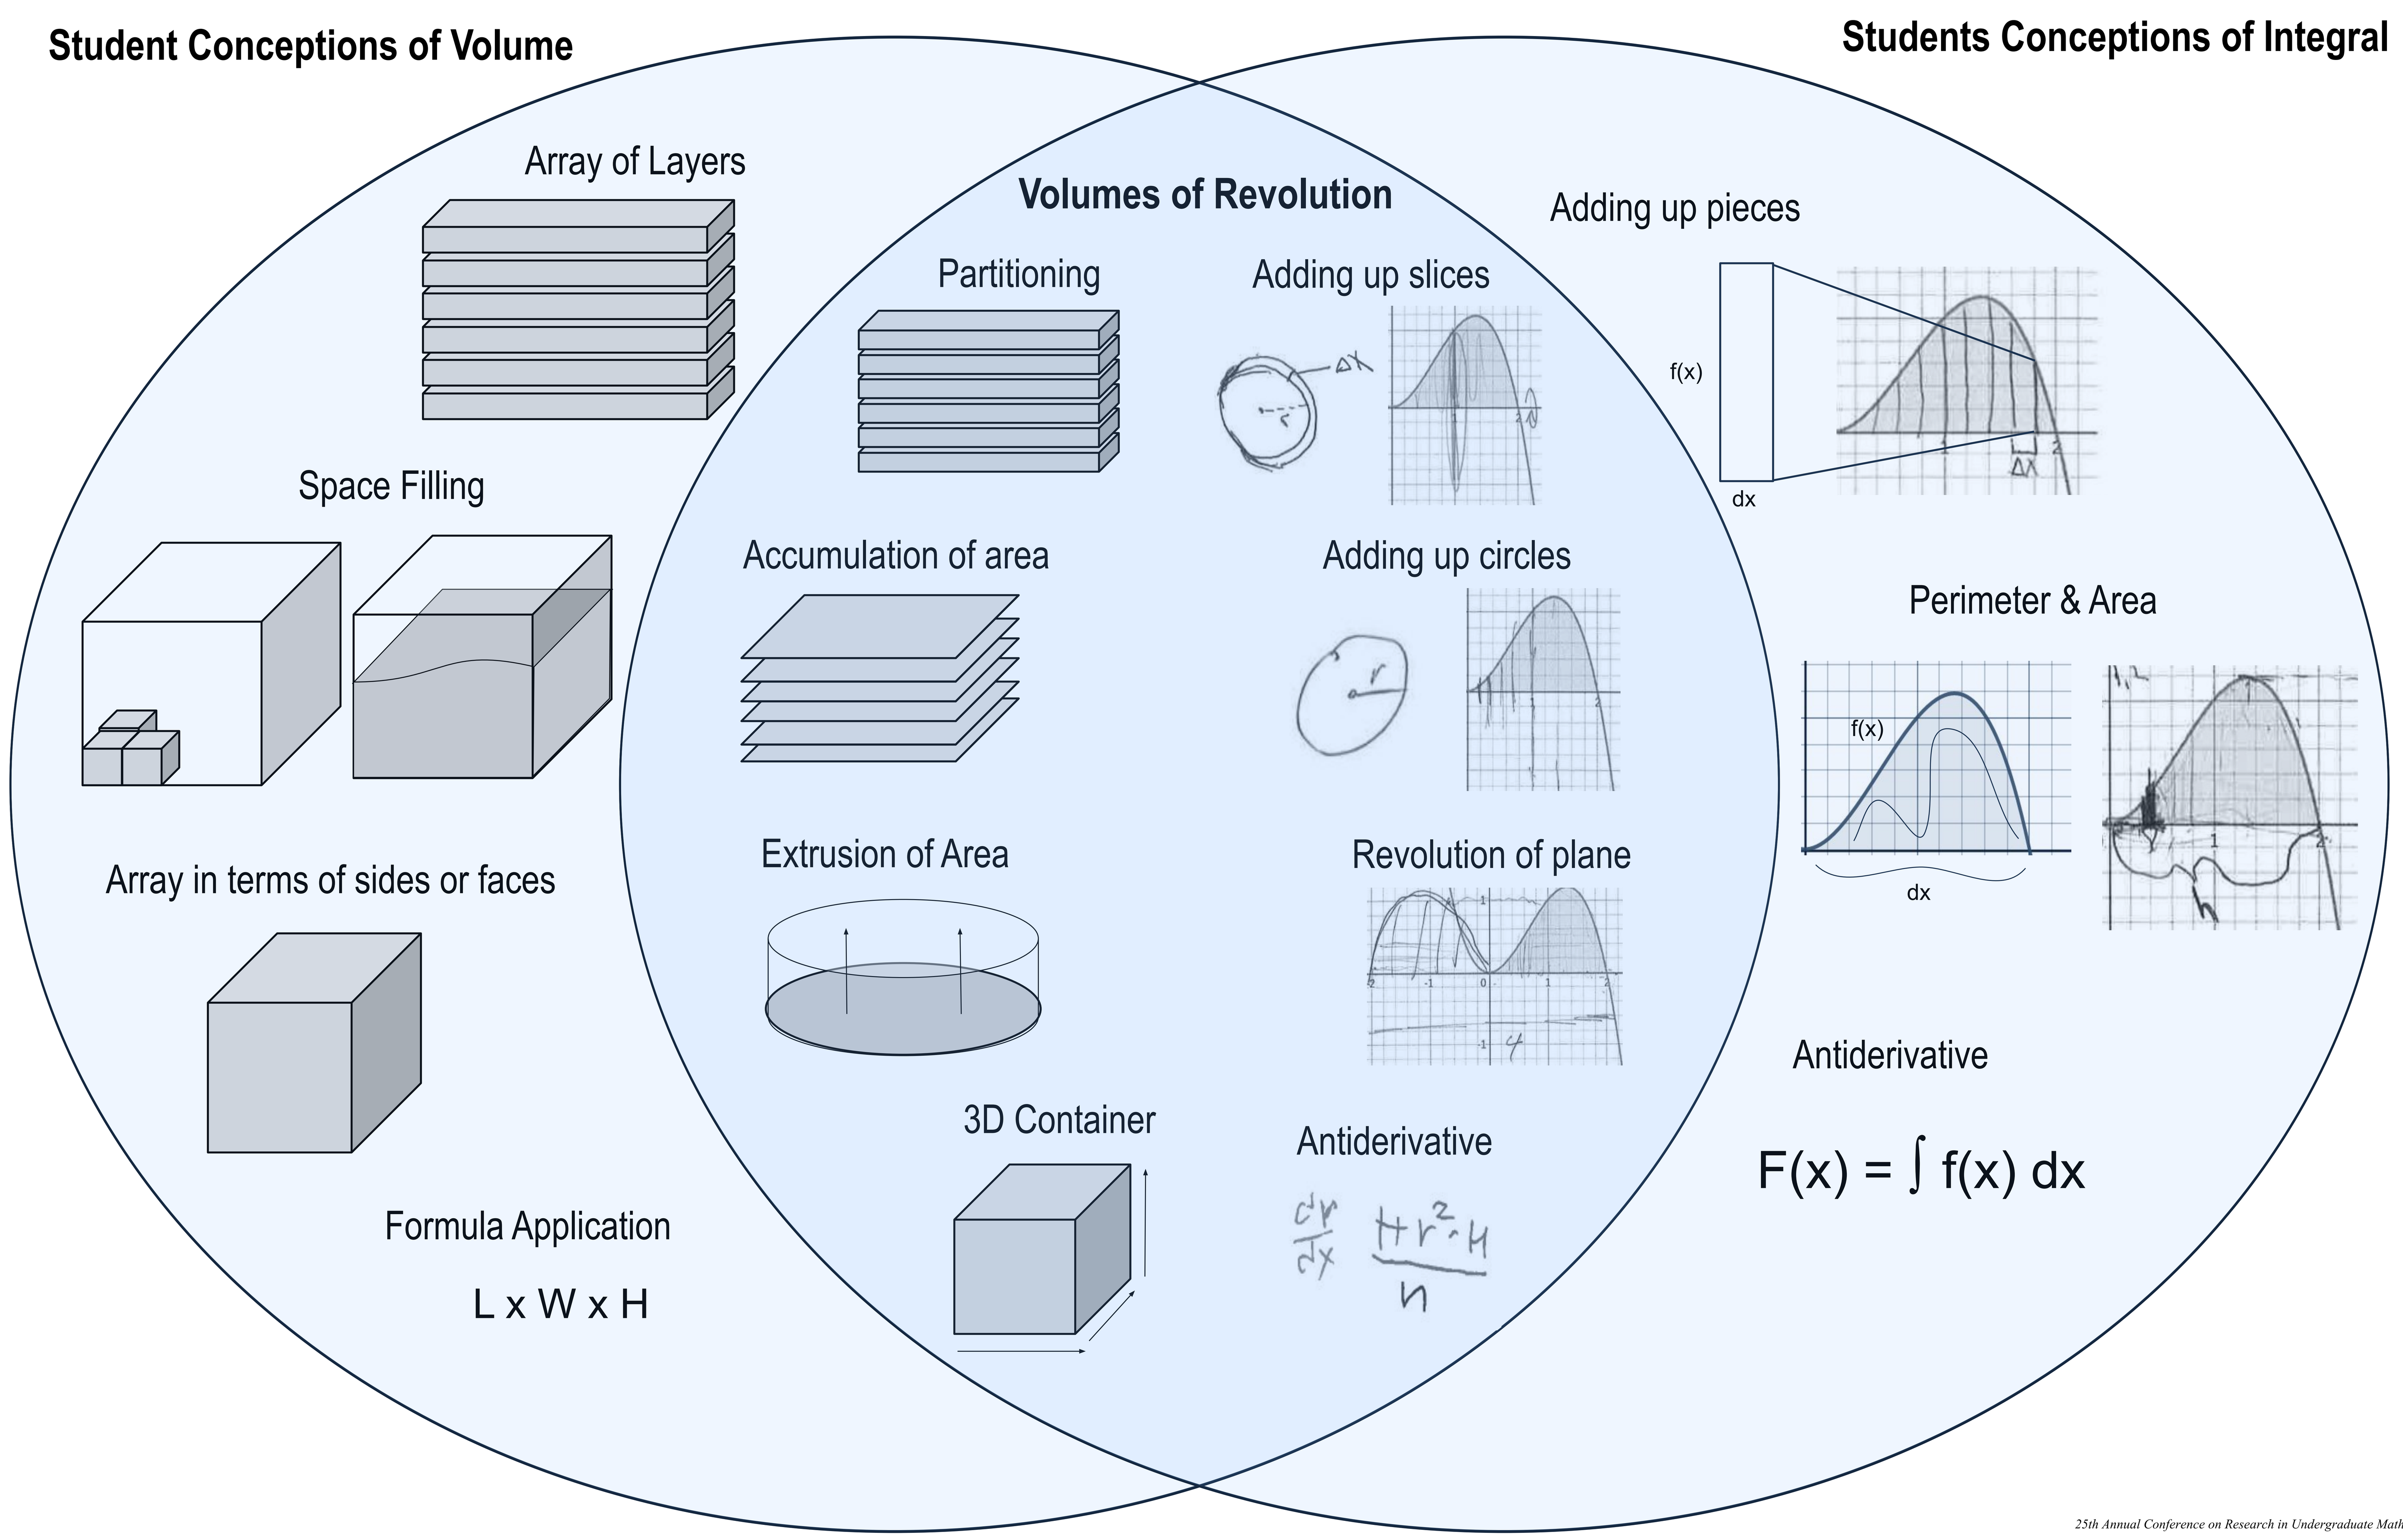
Existing literature documents the influence of prerequisite knowledge on the learning of limits and differentiation (e.g., Dorko, 2012; Ferrini-Mundy & Graham, 1994; Orton, 1983; Stewart & Reeder, 2019). It is possible that this is the case for other Calculus topics. In particular, could students' conceptions of volume influence their thinking on volume by slicing or volumes of revolution problems? Based on the interview data, we contend that Calculus students draw on both their conceptions of the integral and their conceptions of volume when solving these types of problems.

Jones (2013, 2015) investigated how Calculus students conceptualize the integral. Three of the student conceptions of the integral are highlighted in this study.

- **Adding up pieces**
The integral as the area under a curve partitioned into infinitely many rectangular pieces that are summed up. A representative rectangle indicates the multiplication of the function and the differential and applies to all other rectangular pieces. The bounds of integration indicate where the pieces start and stop.
- **Perimeter and Area**
The integral is the area under a curve, but as a singular unit rather than partitioned into pieces. The multiplication inside the integrand is given by the perimeter of the region bounded, with the function being the top curve, the differential being the bottom base, and the bounds of integration being the left and right sides.
- **Antiderivative**
The integral is the inverse process of differentiation. Students use "function matching," where the function inside of the integral must have some original function for which it is the derivative of.

Battista and Clements (1998) investigated how Elementary students conceptualized volume through three-dimensional cube arrays. The categories presented in this study are supported by Dorko (2012) and survey data gathered as part of the larger study of this research.

- **Array of Layers**
Volume is the summation of finitely many three-dimensional unit slices.
- **Space Filling**
Volume is the amount something can hold. This conception can take the form of three-dimensional unit cubes or as the filling of a whole unit.
- **Array in terms of sides or faces**
Volume is bounded by the perimeter or surface area. In this conception, the student measures volume only using the exterior of the shape.
- **Formula Application**
Volume as simply a formula, such as length times width times height, to be plugged in and evaluated.



Integral Conceptions

- **Adding up slices**
The integral represents the volume of the solid formed by revolving the region around the axis of rotation, with the solid partitioned into infinitely many slices, where the function represents the radius of the disk and the differential represents the thickness of the slice.

"Alright, so you could imagine that, if you wanted to revolve it around the axis, you could imagine a bunch of little circles, going around the x-axis. You could like slice it up into a bunch of little circles . . . and if you sum them up using an integral, that will give you a volume. . . . but it's technically gonna be little disks."

- **Adding up circles**
The integral represents the volume of the solid formed by revolving the region around the axis of rotation, with the solid partitioned into infinitely many two-dimensional slices, where the function represents the radius of the circle and the differential represents the infinitesimal difference between each slice.

"We're finding the areas between zero to two, so that's the integral you have. You are forming a bunch of circles with rotating it around the x-axis. . . . they're like slices. . . . it wouldn't be any width."

- **Revolution of plane**
The integral represents the volume of the solid formed by revolving the region around the axis of rotation. The area under the curve is a singular unit of area and the integral "does the work" of revolving it around the axis.

"So we can find the circumference of the circle, which would be the value four, cause you have negative two to two . . . so you have four pi and then we multiply that by, um, the area under a curve."

- **Antiderivative**
The integral is the inverse process of differentiation.

"It would just be, you know, looking at the problem and then applying the differentiation rules, you know, in reverse."

Volume Conceptions

- **Partitioning**
Volume is the summation of infinitely many infinitesimally thin three-dimensional slices.

"You can think about volume of something as first smaller volumes. . . . So if you have a big rectangle, you can first think about it as maybe not like a rectangle, but maybe like a few boxes on top of each other."

- **Accumulation of area**
Volume is the summation of infinitely many two-dimensional regions of area.

"What you could imagine it's volume as turns into it's area as you keep making it's height much much thinner, and if you stack a ton of these essential areas- what are essentially areas- on top of each other, you can effectively get a volume."

- **Extrusion of area**
Volume is a region of area multiplied by some depth.

"A disk being a circle that's kind of raised up."

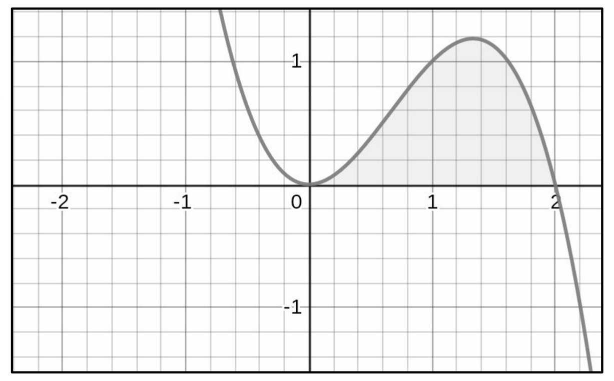
- **3D Container**
Volume is the space inside of a container, bounded by planes.

"to describe volume, I'd say it's like the amount of water a closed container could hold."

Methods

- **Survey tasks (n=97)**
  - distributed to second and third semester Calculus students
  - prompted students to find the volume of three prisms
  - supports literature on student conceptions of volume
- **Follow-up interviews (n=7)**
  - conducted after students completed summative assessment on volumes of revolution
  - included two volumes of revolution tasks
    - revolving a region around the x-axis (disks)
    - revolving a region around the y-axis (shells)
  - students were asked to explain their process

Using a grounded theory inspired approach, segments of the transcribed interviews were coded into emerging categories for both conceptions of the integral and conceptions of volume.



Findings and Implications

- **For instruction**

Our data suggests that students recall their prior conceptions related to volume when solving volumes of revolution or volume by slicing tasks. We contend that **students use both their conceptions of the integral and of volume when solving these tasks.** We suggest that instructors of Calculus should care about their students' understanding of volume. Presenting Calculus students with integration by slicing of simple prism tasks may help reveal students' conceptions of volume and how their conceptions do or do not align with their conceptions of integration.

- **For further research**

The research presented in this poster is part of a larger study investigating student conceptions of the integral and volume. Jones (2015) quantitatively analyzed the productivity of the integral concepts they identified in both the mathematics and applied contexts. It is beyond the scope of this research to quantitatively analyze the conceptions identified in this poster. We suggest further research **to investigate these conceptions of integral and volume to help determine if the productivity of some concepts over others remains the case in the context of applied Calculus problems.**

Student Engagement in Online Calculus 1: Cognitive and Social Dimensions

Emmanuel Barton Odro
University of Nebraska Lincoln

Derek Williams
Montana State University

Keywords: affect and cognition; argumentation model; online calculus; student engagement

At the university level and in STEM fields students' drop out in part due to not being able to pass mathematics courses, particularly Calculus I. According to the Mathematical Association of America (MAA), Calculus I occupies a unique position as a gateway course to STEM degrees. Almost all STEM majors need to take at least the first course in Calculus. Hence, there is the need to understand how to create successful Calculus courses, particularly in online settings. This study examines the ways students engage with the mathematical content, each other and the course while learning about the concept of derivative in an asynchronous online Calculus I course. The purpose of this research is to investigate the nature of students' cognitive and social engagement in an asynchronous online Calculus I course.

Methods

In this qualitative study, we investigate the question, What is the nature of students' (a) cognitive, and (b) social engagement as they learn about limits and derivatives in an interactive asynchronous online calculus 1 course?

We analyzed weekly discussion posts from 23 participants for evidence of argumentation (Toulmin, 1958) and social presence (Swan & Shih, 2005) to learn about students' cognitive investment with mathematical content and ways of interacting with each other, respectively. We also drew on features of the learning management system used to facilitate the course to understand students' behaviors. Additionally, transcripts from interviews with six students were analyzed to further understand student engagement during the course.

Results & Conclusion

In general, students' initial posts to discussion boards almost always contained evidence of cognitive engagement in the form of components of mathematical arguments; however, dramatic differences in whether replies to initial posts contained components of mathematical arguments occurred. We found that the cognitive demand (Smith & Stein, 1998) of the prompt influenced whether reply posts contained evidence of cognitive engagement. Specifically, high-demand tasks tended to yield replies with components of mathematical argumentation more often than low-demand tasks. Regarding social engagement, students tended to participate in more back-and-forth interactions when they were assigned to small discussion groups. We also noted that the composition of initial posts could influence whether other students replied. Specifically, when initial posts involved a level of uncertainty from the original author, classmates tended to reply more often. Results from this study demonstrate the importance of conceptualizing student engagement as a multidimensional construct, and indicate that pedagogical practices such as using high-cognitive demand tasks, promoting rough draft thinking (Jansen, 2020), and grouping students for online discussions will promote student engagement and learning in asynchronous online courses.

Comparing Student and Instructor Perspectives of Teaching Actions to Foster Creativity

Cory Wilson
University of Oklahoma

Miloš Savić
University of Oklahoma

Keywords: Creativity, Student-Teacher Perception, Teacher Actions

Research Question/Background Literature/Methods

Do students and instructors perceive teacher actions to foster creativity in the same way? Zepke et al. (2013) found that tertiary students and teachers similarly valued particular teacher classroom behaviors such as providing feedback, enthusiasm, and encouraging critical thinking, while Fitzgerald et al. (2020) noted that teachers' perceptions of teaching tend to be more positive than students' perceptions of teaching or teaching actions. We define teacher actions to foster creativity to include acknowledged actions (in or out of class) from the teacher that made a student feel creative (Satyam et al., 2022; Tang et al., 2022). These actions may be intended by the instructor, but may not be perceived as such - this is the impetus of our study.

Structured interviews were conducted via Zoom with two groups of Calculus 1 instructors: those who participated in a professional development series focusing on fostering creativity in the classroom (PD) and a group who received no such direction (Non-PD). Instructors were asked questions regarding their approach to teaching through the lens of fostering creativity, reflections on specific classroom interactions, and the effectiveness of their approaches. Interviews were also conducted with students from the instructors' classes. Students were asked about creativity in the classroom and the instructor's actions in fostering creativity. Transcripts were coded for instances of teacher actions reported to foster creativity identified in Satyam et. al (2022). Transcripts received multiple coding passes in order to reach agreement. Once coding was complete, counts were aggregated and organized by individual instructor for analysis.

Results/Discussion/Acknowledgments

Instructors from PD and Non-PD cohorts reported a similar number of creativity-fostering teaching actions (an average of 20.29 for PD instructors and 19 for Non-PD instructors), but students of PD instructors reported higher actions (8.83) than their Non-PD counterparts (5.92). Standard deviation in responses from PD students was higher (7.08) than the standard deviation from the Non-PD students (5.31).

We believe the findings suggest two pertinent things: that instructors and students do perceive creativity-fostering teacher actions differently; and that when instructors are intentional about creativity practices, students acknowledge and recognize the attempts through the higher total actions. However, the difference in standard deviations suggests that students who experience intentionally creative practices from the PD instructors perceive a larger range of creativity-fostering actions than those students who see similar but unintentionally creativity-fostering practices from Non-PD instructors. This is consistent with the findings of Lew et al. (2016) - without cues, students have trouble identifying the key elements that teachers intend to convey. Future research might focus on persistence of students' perceptions of creativity in future math classes.

Comparing Student and Instructor Perspectives of Teaching Actions to Foster Creativity

Research Question

Do students and instructors perceive teacher actions to foster creativity in the same way?

Introduction

Zepke et al. (2013) found that tertiary students and teachers similarly valued specific teacher classroom behaviors such as providing feedback, enthusiasm, and encouraging critical thinking, while Fitzgerald et al. (2020) noted that teachers' perceptions of teaching tend to be more positive than students' perceptions of teaching or teaching actions.

We define **teacher actions to foster creativity** to include acknowledged actions (in or out of class) from the teacher that made a student feel creative (Satyam et al., 2022; Tang et al., 2022). These actions may be intended by the instructor, but may not be perceived as such.

What is Mathematical Creativity?

We situate creativity following Satyam et al. (2022): "if any item (process or product) is new to the student then that is an act of creativity." We believe creativity to be relative to the student rather than oriented toward the mathematical community and that creativity can be developed and fostered.

Data Collection/Methods

Structured interviews were conducted via Zoom with two groups of Calculus 1 instructors: those who participated in a professional development series focusing on fostering creativity in the classroom (PD) and a group who received no such direction (Non-PD). Instructors were asked questions regarding their approach to teaching through the lens of fostering creativity, reflections on specific classroom interactions, and the effectiveness of their approaches.

Interviews were also conducted with students from the instructors' classes. Students were asked about creativity in the classroom and the instructor's actions in fostering creativity. Transcripts were coded for instances of teacher actions reported to foster creativity identified in Satyam et. al (2022). Transcripts received multiple coding passes in order to reach agreement. Once coding was complete, counts were aggregated and organized by individual instructor for analysis.

Teacher Actions

Satyam et al. (2022) grouped teaching actions which foster creativity into four themes. An action is coded as:

Task-Related
Properties of a mathematical content task that were (re)designed, evaluated, or assessed by the instructor

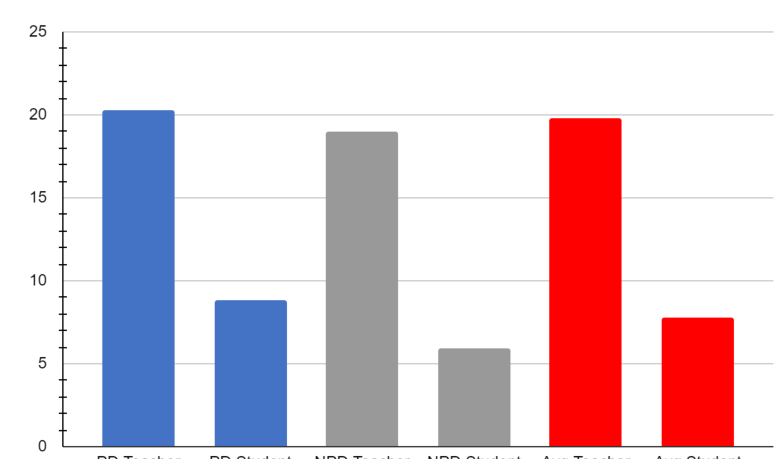
Active Learning
action that is student-centered, including inquiry-oriented (or -based) instruction (Kuster et al., 2018; Shultz & Herbst, 2020)

Holistic Teaching
actions that do not require a response from students, yet psychologically build an environment for fostering creativity

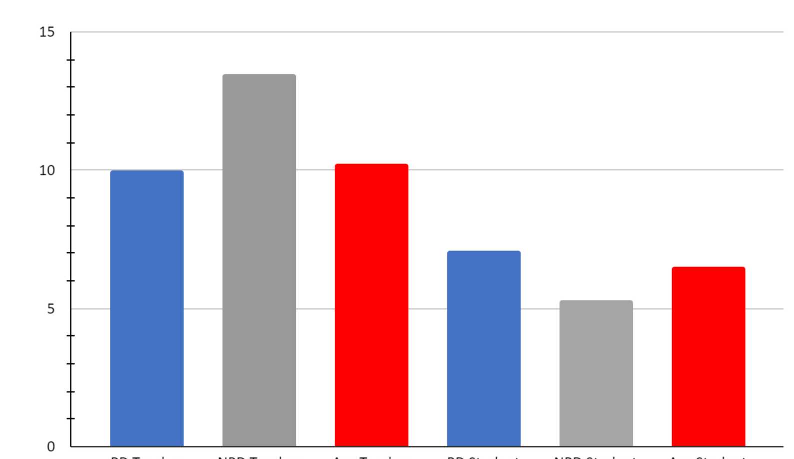
Teacher-Centered
action that involves instructor input with little to no student feedback, whether it be verifying correctness or connecting topics

Results

Average Code Counts for Teachers and Students



Standard Deviation of Code Counts for Teachers and Students



PD Teacher Codes (by Action Type)				
	Task-Related (n=52)	Teacher-Centered (n=12)	Inquiry Teaching (n=35)	Holistic Teaching (n=43)
Average	7.43	1.71	5	6.14

PD Student Codes (by Action Type)				
	Task-Related (n=74)	Teacher-Centered (n=12)	Inquiry Teaching (n=59)	Holistic Teaching (n=65)
Average	3.08	0.5	2.46	2.71

Non-PD Teacher Codes (by Action Type)				
	Task-Related (n=20)	Teacher-Centered (n=9)	Inquiry Teaching (n=22)	Holistic Teaching (n=25)
Average	5	2.25	5.5	6.25

Non-PD Student Codes (by Action Type)				
	Task-Related (n=17)	Teacher-Centered (n=9)	Inquiry Teaching (n=21)	Holistic Teaching (n=31)
Average	1.31	0.69	1.62	2.38

Discussion and Future Work

We conclude that **students and instructors do perceive teacher actions to foster creativity differently**, and the difference is independent of participation in PD.

- When instructors are intentional about creativity practices, students acknowledge and recognize the instructor's attempts.
- PD students perceive a larger range of creativity-fostering actions than Non-PD students. This is consistent with the findings of Lew et al. (2016) - without cues, students have trouble identifying the key elements that teachers intend to convey.

Future work might investigate:

- Persistence of student perceptions of creativity in future classes
- Differences in perceptions of teaching actions between instructors at different stages of their careers or between contingent/non-contingent faculty
- Longitudinal data on math attitude beliefs for students whose mathematical creativity is encouraged and fostered

Opportunities to Learn Provided by a Commonly Used Business Calculus Textbook

Thembinkosi P. Mkhatshwa
Miami University

Contributing to the growing body of research on opportunities to learn provided by undergraduate mathematics textbooks, this study reports on the analysis of optimization examples given in a commonly used business calculus textbook in the United States. Findings of this analysis indicate that the textbook consistently encourages students to interpret critical numbers and extrema, in addition to encouraging students to verify whether or not critical numbers produced minimum/maximum values of the objective functions from which they were determined. The analysis further revealed that the textbook rarely encourages students to include units of extrema, provides limited opportunities for students to reason about objective functions that have more than one critical number, and provides minimal opportunities for students to reason about absolute extrema problems, respectively. Recommendations for different stakeholders, including business calculus textbook authors and business calculus instructors, are included.

Key words: Opportunity to learn, optimization problems, business calculus, textbook analysis

Textbooks play an important role in students' learning of mathematics at all levels. In fact, according to Reys et al. (2004), "… the choice of textbooks often determines what teachers will teach, how they will teach it, and how their students will learn" (p. 61), a sentiment that is shared by several other researchers (cf. Alajmi, 2012; Begle, 1973; Kolovou et al., 2009). Although much research as reported on opportunities to learn about various mathematical topics at the K-12 level (cf. Alajmi, 2012; Charalambous et al., 2010; Dole & Shield, 2008; Jones & Tarr, 2007; Pickle, 2012; Stacey & Vincent, 2009; Stylianides, 2009; Thompson et al., 2012), there is a paucity of similar research at the undergraduate level, which is the motivation for the present study.

The study reported in this paper is part of a larger study (Mkhatshwa, 2016b) that examined: (1) students' reasoning about optimization problems, (2) opportunities to learn about optimization problems via two course lectures each of which was attended by approximately 300 students, and (3) opportunities to learn about optimization problems provided by a course textbook. The current study reports on opportunities to learn about optimization problems via examples provided by the course textbook (Haeussler et al., 2011), a widely used textbook in the teaching of business calculus in the United States (Mkhatshwa & Doerr, 2016a).

Consistent with findings reported by other researchers (cf. Reys et al., 2004), one major finding of the larger study is that the presentation of optimization problems during course lectures closely followed the presentation of optimization problems in the textbook. Findings of the present study suggests that the textbook encourages students to interpret critical numbers and extrema, and to verify extrema using various methods such as the first or second derivative test, respectively. In addition, the textbook rarely encourages students to include units of extrema, provides limited opportunities for students to reason about objective functions that have more than one critical number, and provides minimal opportunities for students to reason about absolute extrema problems. In light of the findings of the present study, we recommend, among other things, that business calculus textbook authors provide more opportunities for students to reason about units of extrema, objective functions that have at least two positive critical numbers, and absolute extrema problems (Mkhatshwa, 2019) in economic contexts.

Foregrounding Inversely Proportional Relationships in Integration by Substitution

Andrew Izsák, Tufts University

Background

Foci of Past Calculus Research[1]

- Co-variation
- Functions
- Limits
- Derivatives
- Integrals

Significant Omission

- Students' understandings of multiplication and division *with quantities* in the context of calculus topics

Why it Matters

- College students often have limited understandings of multiplication and division *with quantities*
- Multiplication and division *with quantities* foundational for derivatives, integrals, families of functions central to calculus
- Studying formulae alone unlikely to help students understand quantitative foundations for calculus

The Study

Developed Novel, Semester-Long Course

- Introduced an explicit meaning for multiplication based in measurement

N	$\bullet$	M	$=$	P
# of units in 1 group		*# of groups in 1 product amount*		*# of units in 1 product amount*

- Emphasized drawings of lengths and areas
- Worked only with piecewise linear functions and step functions. (No discussion of limits)
- **Strand 1**:Division, prop. relationships, slopes of lines, function composition, chain rule
- **Strand 2**: Multiplication, areas, inversely prop. relationships, integration by substitution

Data Collection

- 18 undergrad. students, Fall 2021
  - 15 completed at least 1 calculus course
  - No STEM majors
- In-class group work on sets of word problems
- Whole-class discussion focused on how the $N \bullet M = P$ structure fit problem situations
- Collected written homework and exams

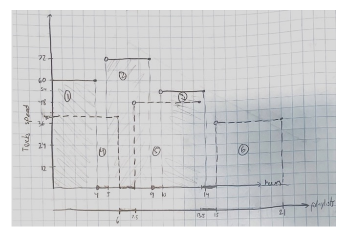
Larsen, S., Marrongelle, K., Bressoud, D., & Graham, K. (2017). Understanding the concepts of calculus: Frameworks and roadmaps emerging from educational research. In J. Cai (Ed.), *Compendium of research in mathematics education* (pp. 526–550). National Council of Teachers of Mathematics.

Results

Strand 2

- Students debated whether rectangular areas could represent products other than areas. For instance, can areas represent distances (e.g., rate • time = distance) or volumes (e.g., area • height = volume)? This is NOT obvious to all students.
- Students were able to reason appropriately about situations in which P was fixed.
- One final exam 13 students gave appropriate solutions to the following problem:
  - Three friends on a road trip. **Steve** drives 60 mph for 4 hrs. They rest 1 hr. **Chara** drives 72 mph for 4 hrs. They rest 1 hr. **Zawadi** drives 54 mph for 4 hrs.
  - Graph speed vs. time. Explain how the graph shows distance each friend drives.
  - Consider same situation but time is measured in playlists; 1 playlist is 40-min.

One Student's Solution



"Area 1 correlates to the distance driven by Steve…. N • M = P ….

60 miles in a column • 4 column = 240 miles

….The new function is drawn with a dotted line….the distance traveled is still represented by the area underneath the function….Area 1 = Area 4….

40 miles in a column • 6 column = 240 miles"

Comments

- A special case of integration by substitution, stated as

$$\int_{g(a)}^{g(b)} f'(u)du = \int_{a}^{b} f'(g(x)) \bullet g'(x)dx$$

- This formulation treats integrand as rate-of-change, consistent with the FTC.
- Justifies equation by explaining that each rectangle in a Riemann sum for the left-hand side has the same area as the corresponding rectangle in a Riemann sum for the right-hand side

Math Placement and Academic Achievement: An Internal Analysis

Sean Gruber, Johns Hopkins University
Emily Braley, Johns Hopkins University
Richard Brown, Johns Hopkins University

The results presented here offer preliminary insights into the course patterns and academic achievement of students taking entry-level math courses at Johns Hopkins University (JHU) from Fall 2017 through Fall 2021. First, we used students' math placement exam results and end-of-semester grades in their first math course to predict academic achievement when considering whether students followed their placement recommendation. Second, we compared trends in placement data and academic achievement of students taking math courses at JHU before and during the COVID-19 pandemic.

Keywords: Math Placement, Contradictory Recommendations, Entry-Level Courses

Empirical evidence suggests undergraduates' persistence and interest in majoring in STEM fields are associated with their achievement (Chen, 2013) and experiences in entry-level and first-year STEM courses (Bressoud et al., 2013; Crisp et al., 2009; Gainen, 1995, Seymour & Hewitt, 1997). Considering many students must take the recommendations of a math department (Apkarian et al., 2017), it is important that departments review their math placement processes and recommendations to students on a regular basis, a common practice of successful calculus programs (Bressoud & Rasmussen, 2015).

The Math Placement Exam (MPE) at Johns Hopkins University (JHU) is broken into two parts, MPE1 and MPE2, which provide unique course recommendations. Aggregating data from Fall 2017 through Fall 2021, we conducted a binary logistic regression using students' first-semester course grades as the outcome variable. The placement recommendation and the course a student took served as the independent, nominal variables. Our study focused on students who were recommended to take precalculus, calculus I, or calculus II.

Many students at JHU taking calculus courses are on a pre-medical track and, thus, aim to earn a relatively high GPA in preparation for applying to medical school. As a result, it was important for us to choose a grade threshold for our binary outcome variable that reflected our Department's efforts to "prepare students to be numerate citizens and productive employees" while conducting this internal review of the MPE (American Mathematical Association of Two-Year Colleges, p. 14). In turn, we chose a grade of B- or above as the grade threshold.

Preliminary results suggested that students who were recommended to take precalculus or calculus I on MPE2 were statistically significantly less likely to earn a grade of a B- or better if they took the course they were recommended for when compared to students who 'jumped' one course above their recommendation (e.g., were recommended for precalculus and took calculus I). Students recommended to take calculus I by MPE1 or MPE2 who took precalculus were less likely to earn a B- or better when compared to those recommended for calculus I who took calculus I. A similar pattern held for students recommended to take calculus II on MPE2 but who took calculus I. Finally, only for the 2020 and 2021 cohorts did students receive contradictory recommendations to take calculus I (on MPE1) and precalculus (on MPE2). The preliminary findings presented here may be used to inform other institutions in their review of how students are placed into calculus-sequence courses while considering how to measure the mathematical preparedness of students affected by the pandemic who are now entering college.

Math Placement and Academic Achievement: An Internal Analysis

Sean Gruber, Emily Braley, and Richard Brown - Johns Hopkins University (JHU)

Background and Motivation

Undergraduates' persistence and interest in majoring in STEM fields are associated with their achievement (Chen, 2013) and experiences in entry-level and first-year STEM courses (Bressoud et al., 2013; Crisp et al., 2009; Gainen, 1995, Seymour & Hewitt, 1997).

Considering many students must take the recommendations of a math department (Apkarian et al., 2017), departments should review their math placement processes and recommendations to grow successful calculus programs (Bressoud & Rasmussen, 2015).

Research Questions

1. Aggregating data between Fall 2017 and Fall 2022, where are students ending up after their placement recommendation results?
2. Are placement recommendations indicative of performance in the math class they first take?

Context

Many students at JHU taking calculus courses are on a pre-medical track.

- Only 9 (2%) did not make the grade satisfaction of a C- or better.
- 1,746 of 5,534 (31.6%) students between 2017 and 2021 did not meet the grade satisfaction cutoff of a B- or better.

Math Placement Exam

The Math Placement Exam (MPE) at Johns Hopkins University (JHU) is broken into two parts, MPE1 and MPE2, which provide unique course recommendations:

- Students with no prior calculus experience take MPE1 (makes recommendations for precalculus or calculus I).
- Students with some calculus experience, then take MPE2 (makes recommendations for precalculus, calculus I, calculus II, or one of calculus III, linear algebra or differential equations).
- If MPE2 recommends precalculus, then students go back and take MPE1.

Model

Binary Logistic Regression:

- Outcome variable: First-semester course grades categorized into two groups using a threshold of B- or better.
- Independent variables: Placement recommendation and the course a student took.

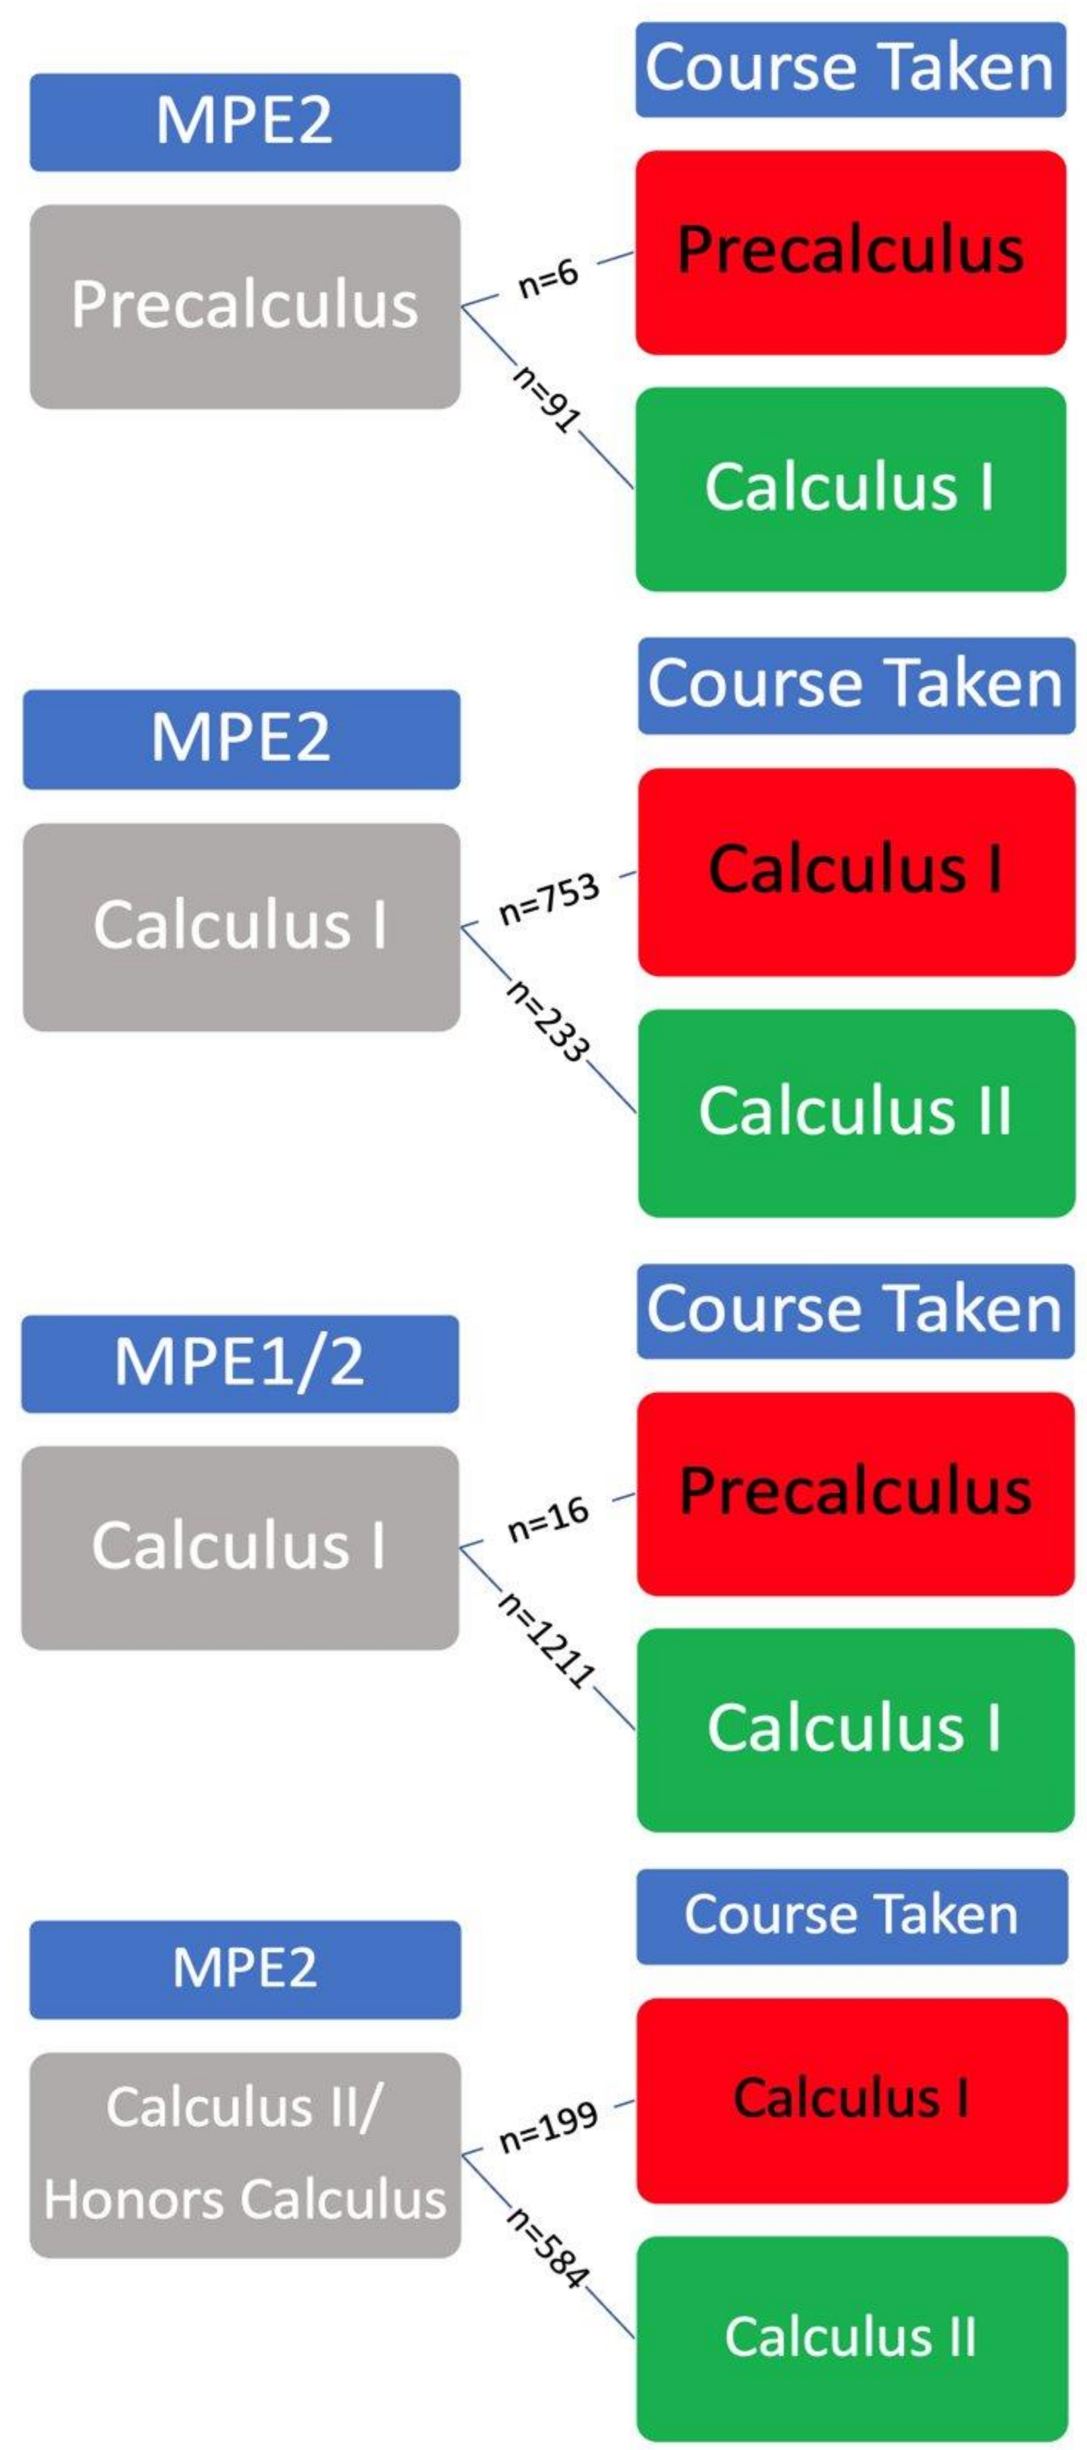
$$P(s_i) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 Rec_i + \beta_2 Take_i)}}$$

where $P(s_i)$ is the probability student i earns a B- or better considering they are recommended for course Rec_i and take course $Take_i$ (could be different from recommended course).

Results

We report on students who were recommended to take precalculus, calculus I, or calculus II.

Red - less likely to earn at least a B-
Green - more likely to earn at least a B-



Contradicting recommendations (MPE1 recommends calculus I, MPE2 recommends precalculus):

This impacts a small (n=69) group of students and only occurred in the 2020 (n=39) and 2021 (n=30) cohorts.

Conclusions and Next Steps

Strengths	Weaknesses
MPE2 is doing a reasonable job of recommending students for calculus II or above.	Neither MPE1 nor MPE2 are effectively sorting students into precalculus or calculus I.

1. Update the placement tests based on what we have learned and STEM-preparedness literature from ALEKS and "Minding the Gaps" (Kornelson et al., 2020).
2. Connect with advising (broadly) and admissions to inform changes and share outcomes.
3. Discuss a path for those who receive contradicting recommendations.
4. Continue to build peer-to-peer networks, mentoring relationships with faculty, and other outside-of-class supports found to help female and students of color remain and succeed in STEM fields of study (Ellington & Frederick, 2010; Griffin et al., 2010; Palmer et al., 2011; Seymour & Hewitt, 1997).
5. Track changes and continue tracking efficacy of recommendations from the tests.

Provider Motivation for Working with Novice College Mathematics Instructors

Jonathan Farley
San Francisco State University

Keywords: novice college instructor professional learning, Provider, TA

A *Provider* is a person who offers opportunities for professional learning to novice college instructors (e.g., new faculty, graduate student teaching assistants and associates [GTAs]) Motivation theory has been studied in a variety of work contexts, including higher education (Daumiller et al., 2020). However, there is no existing research specific to the motivation of Providers of professional development much less about those who work in college mathematics contexts. Knowledge of Provider motivation would be valuable for at least two reasons: (1) knowing the motivations of people who become providers has implications for employers to attract and retain Providers and (2) understanding Provider motivation can inform the identification and development of new Providers (i.e., moving the field to purposeful development and away from the accidental Provider, who "fell into" it).

The research question is the following: What do Providers report as motivating them to choose to be a Provider of professional learning for novice college mathematics instructors? The framework for answering this question relies on motivation theories, change theory about people, power, structures, symbols in departments (Reinholz & Apkarian, 2018), and research on Provider professional orientations (Martinez et al., 2021). These interact to shape Provider work. In particular, structures include the interrelationships of people and roles like Course Coordinator, instructor, GTA, seminar leader.

Data were from surveys and interviews among people who had participated in a Provider workshop. Of the ten people who did the survey five agreed to interviews. For data analysis, I transcribed the interviews and did open coding for each interview, then cross-interview thematic coding, then case story development that used existing frameworks for motivation, professional orientation, and change theory to structure each story. I wrote case stories for each interviewee and contacted them for feedback. The poster will present a cross-case analysis of similarities and differences among interviewees, including charts documenting sources and enactments of motivations.

Implications for research include the need for investigation of the relationship between Provider motivation and Provider effectiveness in supporting professional learning by novice instructors. Participants' reflections and stories also connect to the emerging need for research on what motivates Providers to do scholarly work related to being a Provider.

My goals in sharing the poster and having conversations with RUME attendees are for both feedback and thinking about future reporting. In particular, I wonder how attendees at the conference would talk about their own motivations for doing academic research, including RUME. Conversations about this would be useful for me to refine how I report on the motivation of Providers who do academic research about professional development of novice college instructors.

Reasoning Students Employed When Mathematizing During a Disease Transmission Modeling Task

Elizabeth Roan
Texas State University

Jennifer A. Czocher
Texas State University

Keywords: mathematical modeling, differential equations, student reasoning

Few studies explicitly focus on students' understanding of differential equations for representing real-world phenomena (Lozada et al., 2021). Rowland and Jovanoski (2004) studied the meanings students have for the terms of an already constructed differential equation and found that across contexts, students tend to conflate amount with rates of change of amounts. Our goal is to document students' reasoning while constructing differential equations that represent real-world phenomena (called mathematization) in a way that helps instructors connect their students' emergent models with normatively correct models. We frame students' reasoning while mathematizing using theories of quantitative, co-variational, and multi-variational reasoning (Carlson et al., 2002; Jones, 2018; Thompson, 2011). Using this lens builds on previous findings that the operations students use on quantities reflect the quantitative relationships perceived by the student, (Larson, 2013), and that the models that students could potentially make depend on (and are constrained by), the quantities the student imposes onto the situation (Czocher et al., 2022).

The purpose of this study was to (1) catalog the quantities students impute while modeling a disease transmission scenario from first principles and (2) document students' rationales when combining those quantities. We wanted to know: What are participants' existing ways of reasoning when writing equations to model of the spread of a disease throughout a community? To answer this question, we present work from STEM undergraduates who participated in a set of individual cognitive task-based interviews via Zoom. Data were analyzed by first identifying the quantities participants imposed onto the task scenario and then documenting the participants' (inferred) reason for using specific arithmetic operations($\mathrm{e.g.}, +, -, \div, \times$) on quantities.

Our results reveal the rationales for using arithmetic operations to depict specific aspects of the dynamics of spread of disease throughout a community. All three participants constructed models for the instantaneous rate of change of the sick and healthy populations, though at times using unconventional notation. All three participants constructed a model for the change in the healthy population by covarying healthy people and sick people. They did this by noting that the decrease in the healthy population is equal in magnitude to the increase in sick population. Two participants depicted this relationship using the arithmetic operation $-$, while one participant, Rua, chose not to use any notation to depict this relationship. We infer that Rua was covarying the number of sick people and the number of healthy people, but not multi-varying sick, healthy and time. Our contribution extends what is known about students understanding of differential equations by reporting on how covariational and multivariational reasoning played a role in students' construction of a differential equation that models disease transmission. We infer that covariational and multivariational reasoning were observable because our participants were working on differential equations modeling task focused on disease transmission.

Reasoning Students Employed When Mathematizing During a Disease Transmission Modeling Task

Elizabeth Roan, Dr. Jennifer A. Czocher

TEXAS STATE UNIVERSITY
The rising STAR of Texas

Introduction

- Few studies exist on students' understanding of differential equations for representing real-world phenomena (Lozada et al., 2021).
- Students tend to conflate amounts of change and rates of change of amounts in many different contexts that require differential equations (Rasmussen & King, 2000; Rasmussen & Marrongelle, 2006; Rowland & Jovanoski, 2004; Mkhatshwa, 2018).
- **Goal:** document students' reasoning while constructing differential equations that represent real-world phenomena (called mathematization) in a way that can inform instructors about how to connect their students' emergent models with normatively correct models.

Theoretical Perspective

Mathematical model - a conceptual system consisting of **elements, rules governing interactions**, the **relationships between elements**, and **operations**. Expressed into the world through different representations (Lesh & Doerr, 2003)

Elements are:

- **Quantitates** - triple of an object, attribute, quantification (Thompson, 2011).
  - Ex attributes: length, volume, cardinality, speed, and density (Ellis, 2007).
  - A quantity is cognitively distinct from (mathematical) variables.

Relationships between elements and operations are described by

- **Covariational reasoning** - cognitive activities for coordinating two varying quantities (Carlson et al., 2002)
- **Multivariational reasoning** - the cognitive activities for coordinating more than two varying quantities (Jones, 2018)

RQ: What are participants' existing ways of reasoning when writing equations to model the spread of a disease throughout a community?

Results

- 3 participants constructed a model for the change in the healthy population by covarying healthy people and sick people.
  - All noted that the decrease in the healthy population is equal in magnitude, and inversely related to, the increase in sick population.
  - 2 depicted this relationship as $\frac{dS}{dt} = -\frac{dh}{dt}$
  - 1 depicted this relationship as $\frac{dS}{dt} = \frac{dh}{dt}$
- We infer that the decision to use/not use the symbol– is rooted in the participants multivariation of sick, healthy and time.

Methods

Data collection

- Cognitive task-based interviews with 20 STEM majors who completed or were enrolled in differential equations
- Report 3 computer Science majors on a Disease Transmission (SI compartment model) task.

Analysis

- Identify quantities participant imposes onto task
- Note arithmetic operations used on quantities
- Document participants' reason for using that arithmetic operation
  - quantitative, covariational, and multivariational reasoning.

Rua

$$\Delta S(t) = (H(t) \cdot S(t) \cdot r) \qquad \Delta H(t) = (H(t) \cdot S(t) \cdot r)$$

Rua: It's (referring to $\frac{dW}{dt}$) the same (as $\frac{dI}{dt}$). Um, I think there was one of the equations that we were working through, where I believe the aspect of negativity or positivity was something I was kind of trying to internalize or view, probably, where I think this is a similar outlook just depending on how you're looking at it. Uh, it would either-- you know, if that rate is something that's representative of decay or growth with regards to sick, then it should be the opposite for healthy, and vice versa. If it was growth or decay for healthy, then it should be the opposite-- I guess that's because they're inversely related-- for the sick.

Winnow & Roion

Winnow:

$$\frac{ds}{dt} = \frac{m^{5}}{s(t) \cdot h(t)} \cdot h(t) \cdot r \qquad \frac{dh}{dt} = -\left(\frac{m}{s(t) \cdot h(t)} \cdot h(t) \cdot r\right)$$

Winnow: That would show the rate of change of healthy people, so I guess it would be a negative number because the healthy people would be-- the number of healthy people would be decreasing. Later says: We got was minus 5 healthy people because we had 5 new sick people

Roion:

$$\frac{\partial I}{\partial t} = 1.\left(a \cdot \left(c\, \underbrace{w(t)}_{\text{well}}\right) \underbrace{I(t)}_{\text{infected}}\right) \qquad \frac{\partial W}{\partial t} = -\left(a \cdot c\, I(t)\right) \cdot w(t)$$

Roion: OK. So for this one (referring to $\frac{dW}{dt}$), it'd pretty much be the same (as $\frac{dI}{dt}$) but in the negative direction, as the amount of well people would be decreasing as more infected…

ER: OK. So are you saying that $\frac{dW}{dt}$ is the same as $\frac{dI}{dt}$ but negative?

Roion: Yes.

ER: OK. And what tells you that that's the case?

Roion: It's because as more people are infected, that means less people in the community are actually well. So it's decreasing as time goes on, as more of the infected people interact with the well people.

Discussion

- We extend what is known about students' understanding of differential equations by reporting on how covariational and multivariational reasoning played a role in students' construction of a differential equation that models disease transmission.
- We infer that covariational and multivariational reasoning were observable because our participants were working on modeling disease transmission using differential equations.

Data Scientists' Use of Embodied Ideational Mathematics in Conveying Concepts Rooted in Linear Algebra

Ashley Armbruster
Colorado State University

Kelsey Brown
Colorado State University

Sarah Lutz
Colorado State University

Hortensia Soto
Colorado State University

Keywords: Embodiment, data science, ideational mathematics, linear algebra

Embodied cognition is the theory that learning is influenced by the body through a variety of modalities. Nathan (2022) summarizes literature indicating that forms of embodiment such as body form, gesture, simulation, and materialist epistemology can support student learning. Other studies in embodied cognition focus on ways in which people's perceptions and ways of thinking about a topic can impact teaching and learning and place a high level of emphasis on ideational mathematics. Ideational mathematics is defined as an individual's perception of formal ideas (Schiralli & Sinclair, 2003; Sinclair & Gol Tabaghi, 2010). While previous studies centered on mathematicians, our work centers specifically on the emerging field of data science. Despite the significant amount of literature on embodiment in mathematics (Alibali & Nathan, 2012; Hall & Nemirovsky, 2012; Sinclair & Gol Tabaghi, 2010), there exists a gap in the literature on the impact of embodiment as it relates to data science. Thus, we wish to better understand how instructors use ideational mathematics regarding concepts they present in their classrooms. In conducting this investigation, we leverage Nathan's (2022) summary of various forms of embodiment to address our research question: In what ways do mathematicians use embodiment to convey ideational mathematics when discussing data science concepts rooted in linear algebra?

We conducted one-hour audio and videotaped interviews with two data scientists (Hunter and Elizabeth) with varying backgrounds. Hunter's area of expertise is topology, and Elizabeth's expertise is in harmonic analysis. In this poster, we present an analysis of two episodes from these interviews. The selected episodes provide evidence of Nathan's (2022) summary of the four forms of embodiment. The two data scientists primarily discussed concepts ideationally, and used representational gestures, materials, and simulation that accompanied personified verbiage. For example, Elizabeth explained an activity that she uses with students in her capstone course to teach cosine similarity within natural language processing. Her activity, which she referenced as a "Bag of Ingredients" model, uses grounded, real world examples of recipes to clarify the broader, more complex "Bag of Words" model. She related comparing ingredients in recipes to comparing words in documents of various length to discuss the comparison of common words and synonyms. Hunter integrated various tools and materials such as drawings on a whiteboard and a model of a molecule to explain principal component analysis, a key concept in the field of data science. The concepts discussed in both episodes are rooted in linear algebra, a mathematics subject which both participants identified as an area of struggle for students. The implications of the insights offered through analysis of these episodes is particularly relevant as data science programs become increasingly predominant and institutions search for the best ways to convey material.

Data Scientists’ Use of Embodied Ideational Mathematics in Conveying Concepts Rooted in Linear Algebra

Ashley Armbruster, Kelsey Brown, Sarah Lutz, Hortensia Soto
Colorado State University

COLORADO STATE UNIVERSITY

COLORADO STATE UNIVERSITY

Motivation

- Existence of outlines of introductory data science courses (Baumer, 2015; Hicks & Irizarry, 2018)
- Studies exploring mathematicians’ ideational mathematics (Sinclair & Gol Tabaghi, 2010; Soto-Johnson et al., 2016) and embodiment (Marghetis et al., 2014).
- Linear algebra in the formal, symbolic, and embodied worlds of thinking (Stewart, 2018).
- Minimal research on the teaching and learning of data science.

Research Question: In what ways do data scientists use embodiment to convey their ideational mathematics when discussing concepts rooted in linear algebra?

Principles of Teaching Data Science

- Organize around Case Studies
- Integrate Computing
- Minimize Notation
- Mimic Experience
- Demonstrate Critical Thinking

Hicks and Irizarry (2018)

Theoretical Framing

Embodied cognition: The theory that learning is influenced by the body through a variety of modalities.

Type of Embodiment	Definition	Examples
Body Form	Use of body and the environment	Tracing a circle on hand
Gesture	Spontaneous Movements of hands, arms, and other body parts	Indexical (pointing), Representational (iconic and metaphoric), Beat
Simulation	Using imagination to extend ideas	Use of MATLAB or other technologies
Materialist Epistemology	Use of materials and manipulatives	Annulus, water wheel, blocks

(Nathan, 2022)

Conceptual Mathematics

- Formal, public representations
- Examples
  - Textbook definition of Principal Component Analysis (PCA) : dimensionality reduction method which transforms a large data set into a smaller one that still contains most of the information

Ideational Mathematics

- An individual’s perception of formal ideas
- Examples
  - PCA produces the best view in 2-D or 3-D space for physical, geometric intuition
  - Matrix multiplication as gobbling up a vector, throwing information away, and spitting out a vector

(Schiralli & Sinclair, 2003; Sinclair and Gol Tabaghi, 2010)

Methodology

Participants: Two **data scientists** working in a mathematics department at a research university in the Rocky Mountain area.

- Hunter - Topologist
- Elizabeth - Harmonic Analyst

Data Collection and Analysis:

- Videotaped approximately hour-long interview with each participant.
- Open coded entire interview for embodiment (Nathan, 2022).
- One episode was selected from each interview, approximately 10 to 15 minutes in length, after the first round of coding.

Results

(1) Mathematical areas of expertise influence ideational mathematics and forms of embodiment

Participant	Embodiment Type	Transcliptions
Hunter Focused on visual & geometric representations through **body form, gesture, & materials**	**Movement, Body Form, Perception** • Used body to represent data science and mathematics as vast fields, and topology’s role in each	➢ “Inside of data science, topology is a very small part, on the order of 1% of all data science” 
	Gesture - metaphoric • Topology a “pretty big area” (left) of the “vast landscape” of mathematics (right) • Described how to formalize geometric representation of data	 	Materialist Epistemology • Whiteboard inscriptions visually represented a high-dimensional data set as: ○ Chart of numbers ○ 5D and Cartesian planes ○ Points arranged in circular formation	 ➢ “We formalize blurring one’s vision by maybe growing a ball around each data point”
Elizabeth Represented physical & abstract objects through **body form, gesture & simulation**	**Movement, Body Form, Perception** • Utilized environment to fix “locations” of abstract mathematical objects	➢ Matrix multiplication “gobbles up vector” and “throws away” information” ➢ Measured by nullity 
	Gesture - metaphoric • Established “locations” of null space and column space on either side of her	
	Simulation • Described matrix multiplication as “gobbling up” and “spitting out” vectors, and “throwing away” information • Nullspace fixed to her right • Column space fixed to her left	 ➢ A vector is “spit out”, measured by rank

(2) Data science can be explained using relatable materials and simulations, reducing need to rely heavily on symbolism

Participant	Embodiment Type	Transcliptions
Hunter Use of relatable PCA example through **gesture, simulation, & materials**	**Gesture** - metaphoric • Uses hands to represent familiar shapes to describe data	 ➢ “Maybe the data set is arranged among a sphere, and maybe there’s a good reason why the data is well-modeled by a sphere
	Simulation • Relatable PCA example: data represents medical characteristics of a doctor’s patients	➢ “It can stretch and bend in fold in different ways. . .you have many different points in 24-D space” 	Materialist Epistemology • Molecule represents 24-dimensional data set • Annulus represents the 24D data “living” in two dimensions	 ➢ “Turns out, this molecule lives on a very lower-dimensional, 2D space inside of 24 dimensions”
Elizabeth Use of relatable and immersive **simulations & gesture**	**Gesture** - metaphoric • Returns to established “location” of nullspace for song decomposition • Collided hands together representing orthogonality	 ➢ In the outputs of the decomposed songs, the “stuff that was thrown away was all the low frequency things”
	Simulations *Rank-Nullity Theorem Demo* • Decomposition of various songs based on frequencies • Used songs familiar to students *Bag-of-Ingredients Model* • Modified Bag-of-Words model using recipes and ingredients instead of random words	➢ Bag-of-ingredients didn’t recognize that two different cookies were both sweet because they used different sugars, so “those two parts of the vectors were orthogonal” 

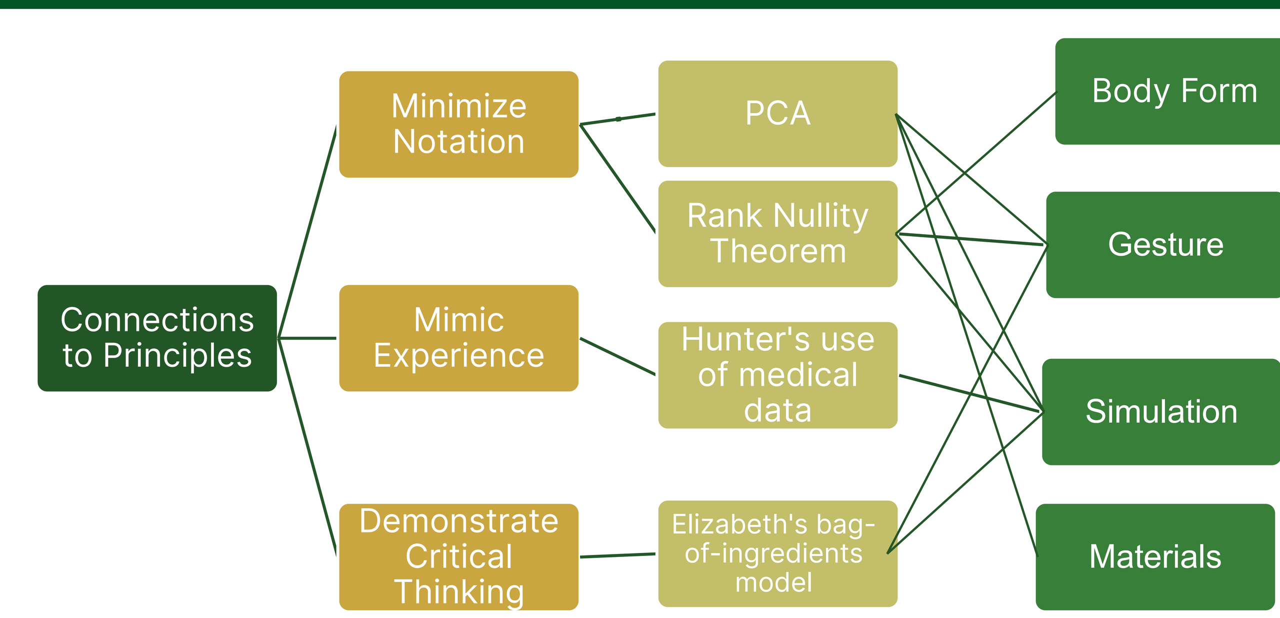
Discussion and Implications

Expertise Influence in Embodiment:

- Both participants utilized gesture,
- Hunter used **physical** materials and Elizabeth used **imagined** materials
- Need faculty with **varied expertise** to effectively **teach all students** while keeping the plethora of approaches to data science in mind (National Academies of Science, Engineering, and Medicine, 2018).

Relatable Explanations:

- Opens up “multiple pathways for students of different backgrounds to engage at levels ranging from basic to expert” (National Academies of Science, Engineering, and Medicine, 2018, p. 64)



While discussing the linear algebra concepts they thought were important in data science, the participants explained their ideational mathematics with varied embodiment reflective of their backgrounds.

ELITE PD

Engaged Learning, Inclusive Teaching, & Equity

professional development

Adapting the TRU Framework: Tracking Changes in MGTAs' Instructional Practices

Hayley Milbourne[1], Sloan Hill-Lindsay[2], Mary E. Pilgrim[2], Mary Beisiegel[3], Elite PD Research Group

[1]University of San Diego, [2]San Diego State University, [3]Oregon State University

Background

- Lecture-based teaching continues to dominate undergraduate mathematics, despite its negative impact on student success in STEM.
- Mathematics graduate teaching assistants (MGTAs) make up significant portion of the undergraduate teaching force.
- However, MGTAs are often not adequately prepared to teach in engaging, inclusive, and equitable ways.
- Without robust professional development (PD) for teaching that focuses on active, engaged teaching practices, MGTAs often replicate the lecture-based teaching practices that they have experienced.
- Consequently, the lecture-based teaching culture is perpetuated, and undergraduate students do not receive the benefits of evidence-based teaching.

Research Questions

***RQ1*. How does the ELITE PD program support MGTAs to transform their teaching practices to be more engaged, inclusive, and equitable?**

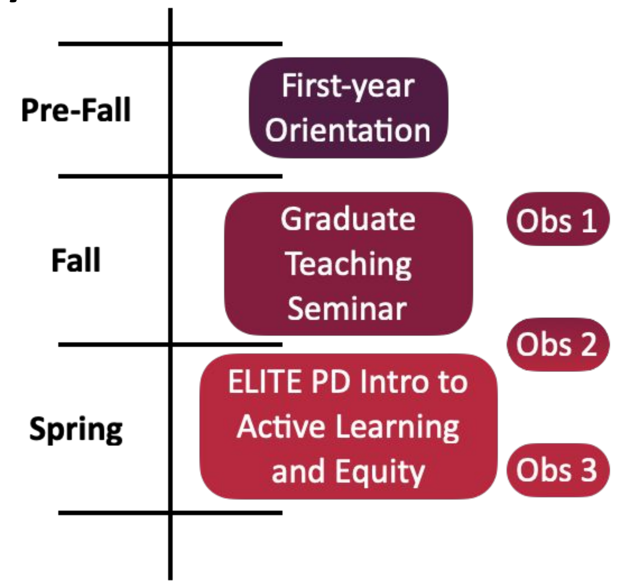
RQ2. What are undergraduate students' experiences and perceptions of MGTAs' teaching practices and how do these change over time?

RQ3. How do the teaching practices of MGTAs in the ELITE PD program compare to MGTAs who do not participate in the program, both within the same graduate program as well at different institutions?

RQ4. What identifiable aspects of individual, institutional, and departmental cultures inhibit or support sustainable change?

Data & Methods

Classroom observations of MGTAs' teaching in their first year:



Theoretical Framework: TRU

The Mathematics	Cognitive Demand	Access to Mathematical Content	Agency, Authority, and Identity	Uses of Assessment
The extent to which the mathematics discussed in the observed lesson is **focused** and **coherent**, and to which **connections between procedures, concepts and contexts** (when appropriate) are addressed and explained.	The extent to which classroom interactions **create and maintain an environment of productive intellectual challenge** that is conducive to students' mathematical development.	The extent to which classroom activity structures **invite and support the active engagement of all of the students** in the classroom with the core mathematics being addressed by the class.	The extent to which students have opportunities to **conjecture, explain, make mathematical arguments, and build on one another's ideas**, in ways that contribute to students' development of **agency, authority, and their identities** as doers of mathematics	The extent to which the teacher **solicits student thinking** and subsequent instruction response to those ideas, by **building on** productive beginnings or **addressing emerging misunderstandings**.

The Mathematics

Small Group Work

TRU	ELITE PD
The focus is on the grade level mathematics with the role of the teacher focused on supporting students exploring and justifying	The focus is on a particular mathematical idea or concept where the role of the GTA is to support students exploring and justifying, with a focus on conceptual understanding

Individual Work

TRU	ELITE PD
The focus is on the designed lesson and materials.	The focus is on the delivery of content rather than the structure of the designed lesson.

Cognitive Demand

TRU	ELITE PD
The focus is on the designed lesson and materials as well as the teacher interactions.	The focus is on the delivery of the lesson and materials as well as the GTA interactions.

TRU	ELITE PD
The focus is on the grade level mathematics and its development.	The focus is on helping students understand concepts introduced.

Original TRU Framework

Discussion

Why TRU?

- Captures aspects of equity and inclusivity not captured by other instruments, as well as identity and agency
- Other instruments did not capture the mathematics and the content element, nor did it capture the interactions between students.

What is different?

- TRU
  - Created for use in K-12 classrooms under Common Core
  - Focus is on the materials themselves in addition to the implementation of them
  - Teachers have more control over the materials they use in the classroom
  - Teachers are the ones introducing the topics and reinforcing them
- ELITE PD
  - Courses are focused on building on past material
  - Focus is on the facilitation of engagement with the prepared materials rather than the materials themselves
  - MGTAs often do not have control over the materials/activities used in their classrooms
  - Often, MGTAs are not introducing the topic to the students for the first time; rather they are reinforcing it

Observation 1

- The first observation of each MGTA indicates where they are in their teaching.
- Initial results indicate that there is room for growth for the MGTAs
  - One particular area for growth is in their understanding of group work versus individual work

Future Work

- How do undergraduate student perceptions align with what the framework helps to capture?
  - If they do align, this is an opportunity to use these reports as a way to gauge what is happening in the classroom, which is more sustainable

Effects of Representations in Complex Analysis on Student Understanding in Real Analysis

Aubrey Kemp
CSU, Bakersfield

Brian Ryals
CSU, Bakersfield

Jonathan Troup
CSU, Bakersfield

Research suggests that providing students opportunities to learn about concepts in a different context can deepen their understanding of these concepts (Kemp & Vidakovic, 2022; Troup et al, 2022; Baker et al. 2000, Dreiling, 2012; Hollebrands et al., 2010). Additionally, recent research has suggested that students reasoning about mappings from $\mathbb{R} \to \mathbb{R}$ rather than graphs in $\mathbb{R}^2$ may open new affordances for students in their reasoning about mappings from $\mathbb{C} \to \mathbb{C}$, as they attempt to generalize from graphs in $\mathbb{R}^2$ rather than mappings from $\mathbb{R} \to \mathbb{R}$ (e.g., Soto & Hancock, 2019; Troup et al., 2017). The proposed intervention investigated in this study represents a potential converse to Troup et al.'s observation in that learning about concepts in Complex Analysis may offer opportunities for student understanding of concepts in Real Analysis to deepen. This study was conceived due to students in one of the researcher's Complex Analysis class expressing that learning about sets and neighborhoods in the Complex plane made aspects of real analysis, such as the $\epsilon - \delta$ definition of a limit, more understandable. The researchers' intent for this pilot study was to determine more precisely the possible ways in which this realization can occur. We hoped to identify, (1) In what ways is student understanding of concepts (such as sets and neighborhoods) in Real Analysis affected by being introduced to these concepts in the Complex space?, and (2) What pedagogical implications emerge from obstacles students may face seeing different representations of these concepts?

In this poster, we outline an ongoing study intended to characterize, through the lens of APOS (Action, Process, Object, and Schema) Theory, ways in which learning concepts in Complex Analysis might render concepts in Real Analysis more approachable for a student. Baseline data was collected via a Real Analysis class assignment in Spring 2022 at a Western Hispanic Serving Institution. We then introduced the students to an 18-minute video mini-lecture covering geometric representations of ϵ and δ neighborhoods in the complex plane and a corresponding definition of limit. We collected data afterward with another class assignment and compared this to our baseline data to determine what, if anything, changed in students' reasoning and responses after watching the video. Our findings from this pilot study revealed some easily correctable limitations of the current methodology, including the format and timing of data collection. Despite these limitations, initial results suggest a common perspective the researchers named *range-axis entanglement* where the student had a strong tendency to believe the inputs and outputs of a function must be graphically represented on an xy-plane. We believe this may be a consequence of an early coordination of Processes within the Limit schema.

We hoped that exposure to these concepts in a different context could offer affordances for students to overcome obstacles and better reason abstractly. In future data collection, we plan to adjust the presentation of the relevant concepts in the context of Complex Analysis as an activity in class instead of a video. We also plan to collect data through interviews to target student understanding in both Complex and Real Analysis. Particularly, that as students become proficient with mappings $\mathbb{C} \to \mathbb{C}$, and in so doing disentangle the range and axis concepts, they might become more proficient with mappings $\mathbb{R} \to \mathbb{R}$ as a resultant side effect. For this poster, we present these preliminary findings, including examples of the range-axis entanglement, from the first stage of our study. We also provide future research plans, including ways we intend to refine the methodology for future stages of our larger project.

Effects of Representations in Complex Analysis on Student Understanding in Real Analysis

CALIFORNIA STATE UNIVERSITY BAKERSFIELD

Aubrey Kemp Brian Ryals Jonathan Troup

Abstract: Research suggests that providing students opportunities to learn about concepts in a in a different context can deepen their understanding of these concepts. Additionally, recent research has suggested that students reasoning about mappings from $\mathbb{R} \to \mathbb{R}$ rather than graphs in $\mathbb{R}^2$ may open new affordances for students in their reasoning about mappings from $\mathbb{C} \to \mathbb{C}$, as they attempt to generalize from graphs in $\mathbb{R}^2$ rather than mappings from $\mathbb{R} \to \mathbb{R}$. The proposed intervention investigated in this study represents a potential converse to this observation that the lack of opportunities for students to engage with $\mathbb{R} \to \mathbb{R}$ in comparison with $\mathbb{R}^2$ leads to difficulty with mappings $\mathbb{C} \to \mathbb{C}$. In this poster, we outline an ongoing study intended to characterize, through the lens of APOS (Action, Process, Object, and Schema) Theory, ways in which learning concepts in Complex Analysis might render concepts in Real Analysis more approachable for a student. We present preliminary findings from the first stage of our study. We also provide future research plans, including ways we intend to refine the methodology for future stages of our larger project.

Key words: Limits, $\varepsilon - \delta$ proofs, APOS Theory, Visualization, Complex Numbers

Research Questions

1. In what ways is student understanding of concepts (such as sets and neighborhoods) in Real Analysis affected by being introduced to these concepts in the Complex space?
2. What pedagogical implications emerge from obstacles students may face seeing different representations of these concepts?

Literature Review

Providing students opportunities to learn about concepts in a different context can deepen their understanding of these concepts (Kemp & Vidakovic, 2022; Troup et al., 2022; Baker et al. 2000, Dreiling, 2012; Hollebrands et al., 2010)

Limits:

- Students rely heavily upon graphs and formulas in understanding the limit concept (Williams, 1991)
- *Obstacle of formalism*: the tendency for students to view the formal representation of a mathematical object as if the representation was itself the object (Sierpinska, 2000)
- In addition to relying on a formal definition of limit, students can benefit from dynamic/geometric ideas and representations of limits (Tall & Vinner, 1981)
- Reasoning about mappings from $\mathbb{R} \to \mathbb{R}$ rather than graphs in $\mathbb{R}^2$ may open new affordances for students in their reasoning about mappings from $\mathbb{C} \to \mathbb{C}$, as they attempt to generalize from graphs in $\mathbb{R}^2$ rather than mappings from $\mathbb{R} \to \mathbb{R}$ (e.g., Soto & Hancock, 2019; Troup et al., 2017)

APOS (Action-Process-Object-Schema) Theory (Dubinsky, 2002; Arnon et al., 2014):

- *Action* – can transform objects with external stimuli or by performing steps

Ex: For $\lim_{x \to a} f(x) = L$ - may evaluate f at a single point x that is close to or equal to a.

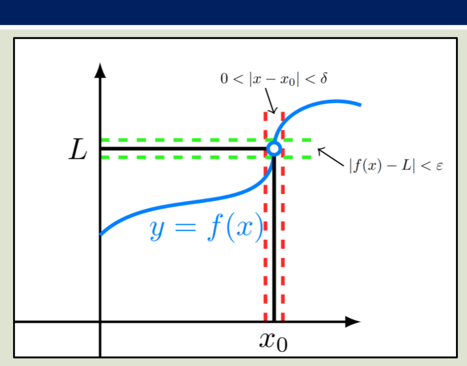
- *Process* – can imagine performing these Actions without necessarily doing so; can *coordinate* Processes with others to form connections between concepts

Ex: May evaluate the function at more than one point, each point getting nearer to a, interiorize this action, and construct a domain process in which x approaches a. They also may construct a range process in which $f(x)$ approaches L, and coordinate these processes by applying the function f to both processes

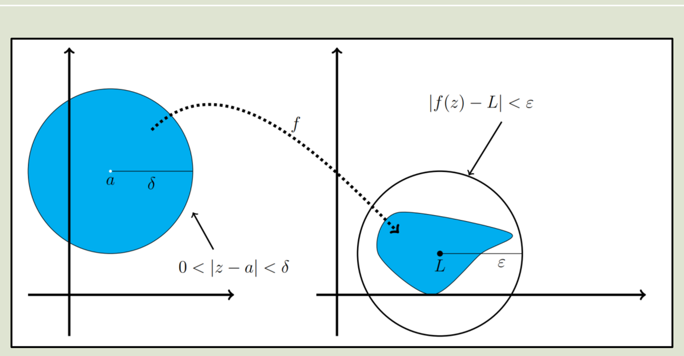
- *Object* – can think of a Process as a totality to which Actions or Processes may be applied

Ex: Considering limits at a point of combinations or compositions of functions

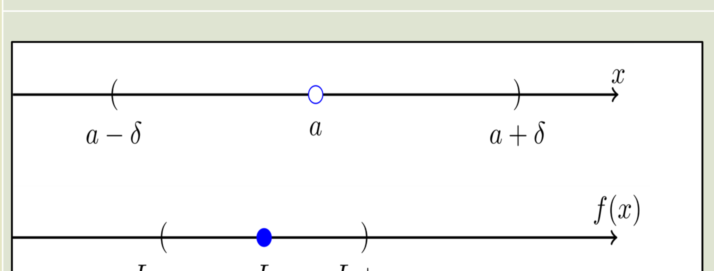
Visualizations



Typical geometric picture in $\mathbb{R}$ (focus on pre-image and image as one graph)



Typical geometric picture in $\mathbb{C}$ (focus on pre-image and image as two graphs)



Desired geometric picture in $\mathbb{R}$ (focus on pre-image and image as two graphs)

Methodology

- 13 volunteers from a Real Analysis course at a western university (out of 20 students enrolled)
- Coursework (homework, assessments) collected for analysis
- Participants:
  - Saw traditional classroom algebraic and geometric treatment of one dimensional $\varepsilon - \delta$ limits in $\mathbb{R}$
  - Watched short lecture on the algebraic and geometric treatment of one dimensional $\varepsilon - \delta$ limits in $\mathbb{C}$.
  - Were asked to draw "before" and "after" pictures that correspond to the pre-image and image and to elaborate on their thinking
- Using APOS Theory, analyzed whether there were then any changes in their geometric understanding in $\mathbb{R}$.

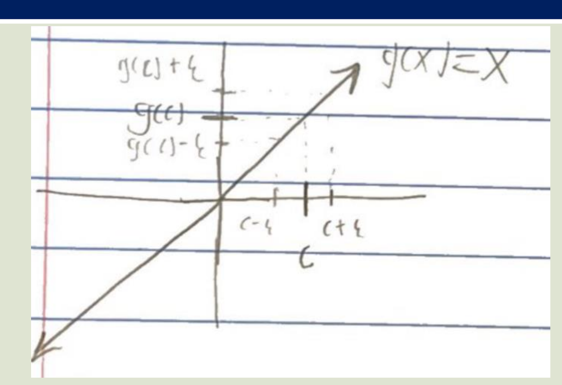
Definition Given in Class

4.1.4 Definition Let $A \subseteq \mathbb{R}$, and let c be a cluster point of A. For a function $f : A \to \mathbb{R}$, a real number L is said to be a **limit of** f **at** c if, given any $\varepsilon > 0$, there exists a $\delta > 0$ such that if $x \in A$ and $0 < |x - c| < \delta$, then $|f(x) - L| < \varepsilon$.

Before Exposure to $\mathbb{C}$ | After Exposure to $\mathbb{C}$ | Analysis Highlights

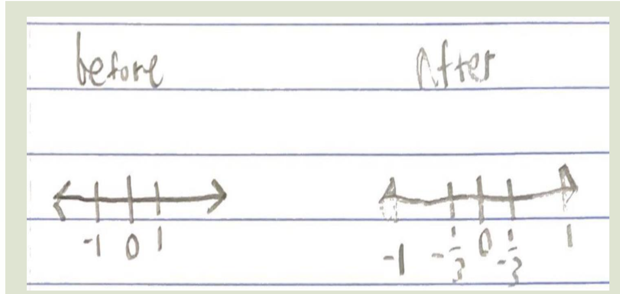
Student 1

Before Exposure to $\mathbb{C}$



"The limit of the polynomial $g(x) = x$ is precisely $g(c)$ for c in $\mathbb{R}$, since if $0 < |x - c| < \varepsilon \to |x - c| < \varepsilon$. In other words, **as we approach the c value, we also approach the $g(c)$ value.**"

After Exposure to $\mathbb{C}$



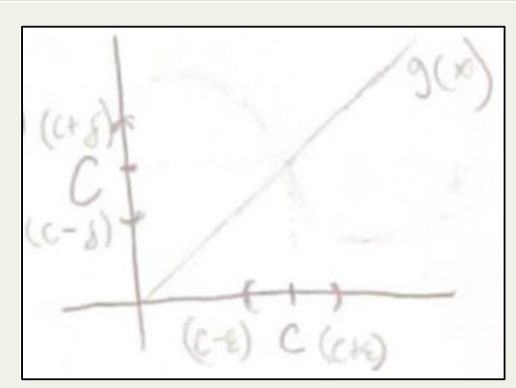
"The function $3x$ **stretches the real number line** by a factor of 3. Since $\dim(\mathbb{R}) = 1$, **our pictures only have one dimension**, whereas $\dim(\mathbb{C}) = 2$ as seen as $\mathbb{C} = \mathbb{R} \times \mathbb{R}$."

Analysis Highlights

- Before: Process conception ("approach")
- After: Process conception (if prompted may show evidence of Object)
- *Limit schema* – Evidence of successful coordination between image and pre-image processes
- No evidence of Range-axis entanglement

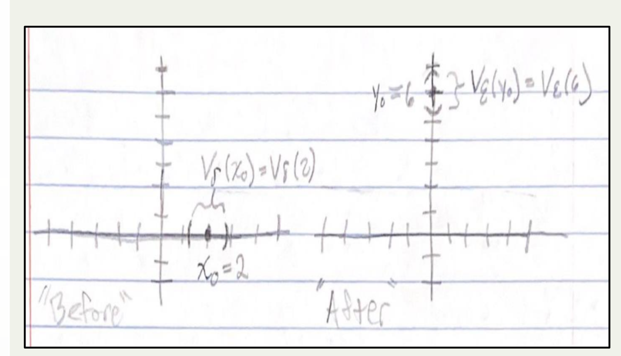
Student 2

Before Exposure to $\mathbb{C}$



"If an **infinite amount of points** is in the ε –neighborhood of c, then there also [is] **an infinite number** of points in the δ –neighborhood of c. So the **number $g(x)$ approaches as x approaches c is also c.**"

After Exposure to $\mathbb{C}$



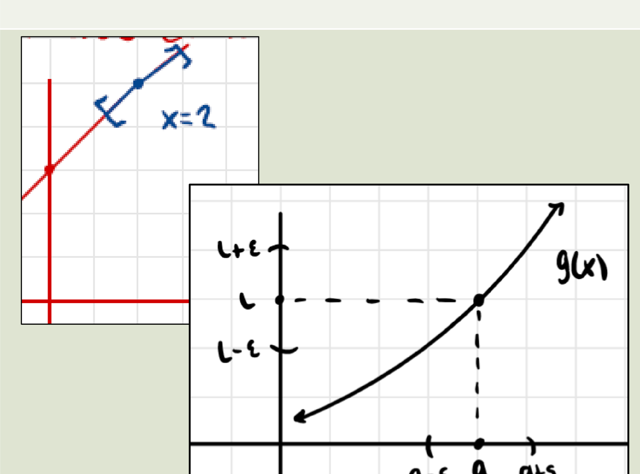
"In this function **$f(x)$ is our output and x is our input**. So we can have $f(x)$ be our after image and x be our before image. So if we have an ε-neighborhood around $y_0 = 6$ then we know **there must be a corresponding** δ-neighborhood around $x_0 = 2$."

Analysis Highlights

- Before: Process conception (relating neighborhoods as processes)
- After: Process conception (relating the neighborhoods as objects)
- *Limit schema* – Object conception of **Function**; May need to de-encapsulate **Function** object to strengthen the coordination of **Range** and **Graphing** processes
- Range-Axis Entanglement

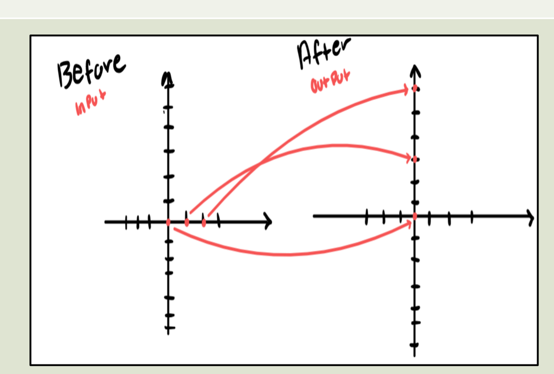
Student 3

Before Exposure to $\mathbb{C}$



"Could be that c is the same distance as epsilon, not sure. Cannot write a full explanation as I don't know where c is.

After Exposure to $\mathbb{C}$



"For the before graphs, I **choose the x values** with $x \in \mathbb{Z}$. I stopped at $x = 2$ because $c = 2$. All of these points remain on the x-axis. For the after graphs, **I used the points from the x-axis and plugged into $y = 3x$.** My **y values only stuck to the y-axis.**"

Analysis Highlights

- Before: Pre-Action conception (could refine understanding of cluster point)
- After: Action conception (picking specific points to relate)
- *Limit schema* – Action conception of **Function**; May need to work on coordination of **Pre-Image** and **Image** processes to interiorize

"Why Complex?"

- Symbolically, the definitions of a limit in the Real and Complex space are nearly identical, though the visual interpretation is different
- Promotes thinking of neighborhoods and their images as sets
- Detangles the function f from the y-axis
- Visual generalizes to more abstract setting (traditional visual doesn't!)
- Complex still uses same notation as $\mathbb{R}$ (unlike $\mathbb{R}^2$)
- Offer affordances for a better comprehension in $\mathbb{R}$?

Preliminary Results

- Did not clearly affect understanding
- Possibly allowed for coordination reversal for some students
- Illuminated schema development and obstacles within
- *Range-Axis Entanglement*: Strong tendency to believe the inputs and outputs of a function must be graphically represented on an xy-plane (face an obstacle in "separating" pre-image and image)
  - Consequence of early coordination of Processes within the Limit schema?
  - How can we effectively guide students?

Limitations of Present Study

- Format of data collection
  - No interviews to probe for understanding
  - Questions in prompts did not target understanding in both $\mathbb{R}$ and $\mathbb{C}$ as well as they could
  - Video was 18 minutes → In class activity next time
- Timing of data collection
  - Collect after semester or at least not during finals
  - Introduce concepts $\mathbb{C}$ in class before this video

Future Directions

- As students become proficient with mappings $\mathbb{C} \to \mathbb{C}$, and in so doing disentangle the range and axis concepts, do they become more proficient with mappings $\mathbb{R} \to \mathbb{R}$?
- Continuing investigating this idea and *range-axis entanglement*
- Student understanding of absolute value in relation to the limit definition
- How does replacing the notation $|x - y|$ with $d(x, y)$, where d stands for distance, affects student conceptions.

Designing Tasks to Teach Mathematical Induction

Valentina Postelnicu
Governors State University

Mario Gonzalez
Texas State University

We conducted a study on the teaching and learning of mathematical induction, based on the principles of didactical engineering, with undergraduate students enrolled in a Discrete Mathematics course at a four-year university. Students' performance on induction tasks improved. We focus here on designing tasks with the potential to foster inductive reasoning and give meaning to the Principle of Mathematical Induction.

Keywords: Mathematical Induction Tasks, Didactical Engineering, Undergraduate Students

The recent research on mathematical proofs is rich, but not many studies specifically address mathematical induction. A proof by mathematical induction may be used whenever we have a statement $P(n)$, where n is a natural number. According to Ernest's (1984) framework, the steps of a mathematical induction proof are:

- basis step, checking that $P(n_0)$ is true (n_0 is the smallest value for which $P(n)$ is true),
- inductive step (checking that $P(k) \rightarrow P(k+1)$, $k \geq n_0$), and
- invocation of the Principle of Mathematical Induction (PMI).

We report on a study on the teaching and learning of proofs by mathematical induction, with undergraduate students enrolled in a Discrete Mathematics course taught by the first author at a four-year university. We focus on the application of the principles of didactical engineering (Artigue, 1994) to design tasks with the potential to foster inductive reasoning and give meaning to the PMI. Figure 1 illustrates the phases of the didactical engineering process.

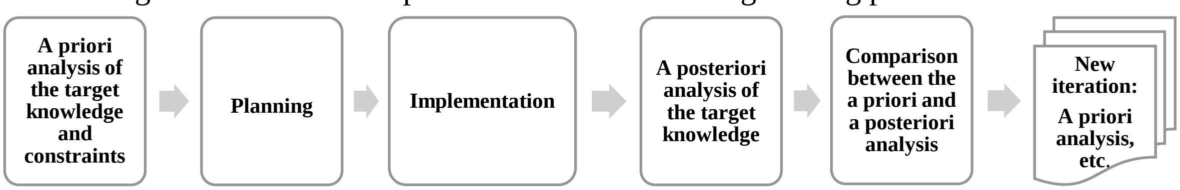

Figure 1. The didactical engineering process adapted after Artigue (1994)

At the beginning of the fourth iteration, the a priori analysis revealed that our students had difficulty giving meaning to mathematical induction as a method of proof. Although our students' performance improved with each iteration, the induction step remained procedural in nature. Ernest (1984) drew our attention to the usefulness of analogies to the PMI. Harel (2001) used tasks that defined sequences recursively and fostered inductive reasoning, thus giving meaning to the PMI. Other studies highlighted the importance of visual representations (Stylianou and Silver, 2004) and gestures used during the teaching and learning process (Kokushkin, 2020). Based on research and our own experience with the teaching and learning of mathematical induction, we designed, implemented, and refined tasks with the potential to foster inductive reasoning and give meaning to the PMI. One such task asked the students to create their own analogy to the PMI (Postelnicu and Gonzalez, 2020), while another task used visual representations. We discuss the use of visual representations, intended to help the students define a sequence recursively and find the general term of the sequence and the formula for the sum.

Keywords: Equity, Graduate Teaching Assistants, Professional Development

In response to national movements for social justice in education, there has been an increase in efforts to develop institutional structures to support diversity, equity, and inclusion (DEI) in the classroom. Teachers are tasked with supporting diverse groups of students from varied backgrounds (Ameny-Dixon, 2004). However, research indicates that there is a lack of support to empower practitioners to create equitable learning environments (Perez et al., 2020).

One significant portion of the teaching force in undergraduate mathematics is Mathematics Graduate Teaching Assistants (MGTAs). Iverson (2012) noted that current graduate education is insufficient for developing MGTAs’ skills and knowledge for fostering social change. While there is scant literature on teachers’ conceptions of DEI - the little that exists indicates that many practitioners have varied understandings of these concepts (Bell et al., 2007; Fifty et al., 2022; Garmon, 2005). Therefore, there is a need to explore how to support MGTAs in developing equitable and inclusive teaching practices.

In this study, we investigate MGTAs’ initial conceptions of equitable teaching practices. Additionally, we report our initial observations on how the MGTAs interacted with specific activities throughout a teaching seminar focused on active learning and DEI topics. This work is part of a larger project that aims to design and implement a multi-stage, MGTA professional development program centered on equity and inclusion in a range of academic institutions.

In our initial findings through semi-structured interviews and post-class surveys, we noticed that MGTAs’ conceptions of equity generally referred to a deficit in students’ content knowledge. For example, a significant portion of our subjects thought that equitable teaching involved providing extra office hours or spending more time with students in the classroom based on how well they understood the material. Few MGTAs demonstrated an awareness of differences in student backgrounds and identities that may have impacted their schooling.

We observed that directly discussing the diverse populations that take undergraduate mathematics courses supported the MGTAs in expanding their conception of equitable teaching practices. In particular, providing these MGTAs with descriptions and illustrations of students’ access needs, mathematical backgrounds, and classroom experiences aided the MGTAs in discussing ways in which they could create a more equitable teaching environment.

"What is Equitable Teaching?": Graduate Teaching Assistants' Perceptions of Equity

Franklin Yu[1], Blue Taylor[2], V. Rani Satyam[1], Rebecca Segal[1], Mary Beisiegel[3], Elite PD Research Group
[1]Virginia Commonwealth University, [2]San Diego State University, [3]Oregon State University

Context, Research Questions, & Methodology

Context:

- There has been an increase in efforts to develop institutional structures to support diversity, equity, and inclusion (DEI) in the classroom
- Current graduate education is insufficient for developing Mathematics Graduate Teaching Assistants' (MGTAs) skills and knowledge for fostering social change (Iverson, 2012)

Research Questions

- What are MGTAs' conceptions of *equitable teaching*?

Data Sources

- 31 Clinical Interviews with MGTAs at 3 institutions
- Clinical Interview consisted of questions asking about MGTAs teaching experience and ideas about equitable and inclusive teaching

Working Definition of "Equitable Teaching"

Equitable Teaching refers to focusing on the needs of every individual and ensuring the right conditions are in place for each person to achieve their full potential. An equitable classroom values the unique contributions that students of all backgrounds bring to the classroom and allows diverse groups to grow side by side, to the benefit of all.

Teaching practices include attending to:

- student identity, addressing stereotypes and bias
- intentional language use (e.g., Su, 2015)
- small-group structure and roles (e.g., Brown, 2018; Dasgupta et al., 2015; MAA, 2018; Reinholz, 2018)
- addressing needs of current-day students, including access and resources

What does "Equitable Teaching" mean to you?

MGTA Conceptions of Equitable Teaching

"How would you describe equitable teaching at the post-secondary level or college level?"

- Overall, the MGTAs had varying ideas on what "equitable teaching" entailed. Coding revealed overlapping themes.
- Besides "helping students", there was no one theme that appeared in more than 50% of MGTAs' responses.

Equitable Teaching as…

Using multiple/diverse teaching styles

"Equitable teaching is a way of designing **teaching methodologies** that allow for **multiple methods of learning** from students"

"I think having a **diverse set of ways that you present material.** Some students may be **more visual**. Some students really like to just **hear what you're saying**. So yeah, providing all the students with the best change to do well in your class I guess."

"So like **explaining things a different way**, playing a video, and doing something that's more quiet individual work"

"Split it up so there's a little of everything for **each type of student**… like for example if I'm speaking a lecture to you, I'm also trying to write down what I'm saying on the whiteboard so that students can get **both audio and visual** there"

Helping students who are behind

"Trying to figure out if there are students who are **falling behind** and figure out how to get them **back on pace**"

"To be equitable you want to make sure, like focus on students that **might not have the material down** and come back to them more often and engage with them more often"

"So students with different backgrounds like there's a lot of **students with gaps in their mathematical content** knowledge from prior courses and **so being able to help fill those**"

"So equity for me it's more like I give everybody what they need. So, for example, if I have office hours, and as they come in, if one student, I notice they have **more gaps**, they might need more time to spend with me vs. somebody who has just one or two questions that might be more of like a clarifying question."

Being accessible and available to students

"Equitable teaching would be providing all of the students with **equal access to a teacher or TA**. So **office hours that are accessible to everyone.** Maybe someone has a job on the side or is on a team or, you know, in the choir, something like that. And making sure you have office hours or **a way to reach you** even when everyone has all these different schedules."

"I want everyone to be **able to have that opportunity to come and study or ask questions,** or whatever they need to do. So I've definitely pushed myself to, **if someone can't make it to office hours, then I schedule other times"**

Equal access/provision to resources and learning

"Equity is every student has **equal access** to a laptop and reliable internet access or something like that"

"Equity, to me, probably implies a lot of **free available resources**. Things like that are kind of open door policies to allow students to try and **seek out as much support as they can**."

Involving Active Learning

"Of all of the class, like most of the time where it's **the most equitable is the active learning process**, because those are designed to be smaller **group work** activities, **working together**, and getting **questions answered**"

"Like **interactive with group work**, or you know, they're like creative and exploratory ways to engage with the material and those things are helpful for equity and inclusion. Having **students work together and talk to each other and collaborate**."

"It's most equitable when we're kind of in a **discussion mode**. When it's not me standing up there giving them information. More when it's **students asking questions or working on problems in smaller groups."**

Discussion

- Few MGTAs explicitly mentioned an awareness of how students' identities impact their classroom experience:

  *"Each student has **individual experiences** that they're bringing to the classroom and that, if we can **acknowledge those different identities** and those different backgrounds, that **we can help students have access** to the material in a better way."*

- While many MGTAs explained equitable teaching as "giving according to needs", most of these MGTAs associated this with different learning styles (Audio/Visual/Kinesthetic) or helping students who are behind on content knowledge.

The Elite PD Program

- We designed a professional development (PD) program for MGTAs focused on engaged learning, inclusive teaching, and equity (ELITE PD).
- The ELITE PD program spans 2-3 years and will be implemented at three collaborating institutions with differing contexts.
- MGTAs who participate in the program will be supported in making incremental changes to transform their teaching and broaden their understanding of equity and inclusion.
- Cohorts will be recruited from each institution and progress through a sequence of PD workshops, classes, and peer mentoring

Mathematics professors' goals through an integrated lens of guided reinvention and creation

Praveen Chhikara
University of Illinois at Urbana-Champaign

Rochelle Gutiérrez
University of Illinois at Urbana-Champaign

Keywords: Realistic mathematics education, Rehumanizing mathematics, alternative conceptions, conjecture, undergraduate mathematics, creation, guided reinvention

Guided reinvention or the guidance principle (Realistic Mathematics Education) examines how teachers can provide opportunities for students through "realistic" contexts to facilitate them to reinvent "higher" level formal concepts. (Gravemeijer, 2008; Van den Heuvel-Panhuizen, & Drijvers, 2020). Guided reinvention acknowledges collaborative students' work like whole group discussions. We assume that students can show or develop multiple understandings and even non-traditional knowledge in such discussions. Therefore, we consider the creation dimension (Rehumanizing Mathematics) which acknowledges students' conceptions and diverse forms of expressing mathematics (Gutiérrez, 2018) as a way of expanding guided reinvention. Being able to stray from traditional knowledge forms/representations can feel humanizing for students and help transform their relationship with mathematics as authors/creators of mathematics. By way of illustration of diverse forms, there can be sense-making alternative axiomatic models of a concept, which are different from the traditional ones. Moreover, students might show "proofs" that are non-deductive, non-symbolic, or visual. Creation privileges Nepantla moments of tensions within multiple perspectives (Gutiérrez, 2012); however, Gravemeijer's mathematization in guided reinvention process focuses on developing standard procedures, "limiting interpretations," and validations (Gravemeijer, 2000). This encourages us to identify how guided reinvention and creation can interact with and expand each other's use.

To obtain empirical evidence, we recruited five mathematics professors in India for our ongoing qualitative case study to explore how their views of their teaching roles might influence their interest/propensity to use guided reinvention and creation. One out of three interviews for each participant centers guided reinvention, another interview centers creation, and the final interview centers both concepts. "Member checking" is conducted in the last interviews by summarizing interpretations of the first two interviews to the participants. With a lens of guided reinvention and creation, we seek responses to our research questions on mathematics professors' perceptions of their role in facilitating students for abstract concepts, students' alternative conceptions (Fujii, 2020), students making conjectures, and students' participation. The findings can potentially exemplify and guide us on how guided reinvention and creation can be developed as an integrated framework, which can be used in later studies and support a more humanizing experience for students studying mathematics.

The poster presents the study's preliminary results, participants' quotes, future steps, and a Venn diagram depicting how guided reinvention and creation potentially interact. Among other results, we focused on one professor and noticed he finds it essential to provide realistic scenarios but thinks it becomes difficult to find such scenarios at "higher" abstraction levels. We identified that, for this professor, he finds it important to alert his students about informal writing so that they can avoid "errors," which might prevent guided reinvention or creation. We look forward to discussions with conference attendees about more results mentioned in the poster.

Enriching Assessment of Physics Quantitative Literacy: IRT with Multiple-Response Items

Trevor I. Smith

Suzanne White Brahmia
University of Washington

Keywords: Quantitative Literacy, Item Response Theory, Physics

Students in introductory physics courses are often asked to use familiar mathematics in novel ways. Improving students' quantitative literacy within physics contexts (i.e. physics quantitative literacy, or PQL) is a goal for many physics instructors. A challenge in assessing PQL is the blended relationship between students' general mathematical reasoning and conceptual understanding of physics. A recently developed multiple-choice instrument for measuring PQL includes several multiple-choice-multiple-response (MCMR) items for which students may select as many responses as they think are correct (White Brahmia, et al., 2021). The MCMR item format provides an opportunity to see the interaction between students' quantitative literacy and conceptual physics understanding.

Previous approaches to analyzing data from MCMR items fall into three categories: scoring response combinations as either completely correct or incorrect (Kubinger & Gottschall, 2007; Smith, et al., 2020; White Brahmia, et al., 2021), defining an *a priori* partial credit score for each response combination based on expert opinions (Wilcox & Pollock, 2014), or avoiding item scores by treating responses as categorical variables (Smith, et al., 2019; Vlach & Plašil, 2006).

In this poster we present a novel approach to defining a data-driven partial credit score for each combination of responses to MCMR items based on item response theory (IRT) analyses. We seek to address three research questions: 1) What score is assigned to each combination of responses based on IRT parameters? 2) How do correct and incorrect responses impact these scores? 3) How do scores based on IRT parameters relate to traditional dichotomous scores?

Data come from 3424 introductory physics students at a large research university. We apply IRT methods to MCMR data by treating each item as a combination of individual dichotomous response-items and grouped nominal response-items (Smith, et al., 2022). IRT parameters are used to define a score for each response combination (Smith & Bendjilali, 2022).

Our results show that the correct response combination for each item always has the highest IRT-defined score, even though the correct responses are not specified in the model. Correct individual responses have positive scores, and incorrect responses have negative scores. Total IRT-defined test scores strongly correlate with dichotomous test scores ($r = 0.8$). This supports the interpretation of IRT parameters as indicating levels of correctness and understanding.

Some analyses of grouped responses yielded counterintuitive results: we identified one item for which certain incorrect responses corresponded to positive parameters, and another item for which selecting two (out of three) correct responses was scored lower than selecting only one.

Our overall results indicate a strong potential for using IRT analyses to inform partial credit scores for MCMR items used to measure students' PQL; however, more consideration is needed to define the transformation from IRT parameters to partial credit scores.

Goal: Define partial credit for response combinations using both dichotomous and nominal IRT models to analyze data from MCMR items

Introduction

- Improving students' physics quantitative literacy (PQL) is a goal for many physics instructors.
- PQL is the blended relationship between students' general mathematical reasoning and conceptual understanding of physics.
- The **P**hysics **I**nventory of **Q**uantitative **L**iteracy (PIQL), includes multiple-choice-multiple-response (MCMR) items; students may select as many responses as they think are correct (White Brahmia et al., 2021).
- The MCMR items can show the interaction between students' quantitative literacy and conceptual physics understanding.
- Previous approaches to analyzing data from MCMR items fall into three categories:
  - scoring response combinations as either completely correct or incorrect (Kubinger and Gottschall, 2007; Smith et al., 2020; White Brahmia et al., 2021),
  - defining partial credit score based on expert opinions (Wilcox and Pollock, 2014),
  - treating responses as categorical variables without scores (Smith et al., 2019; Vlach and Plašil, 2006).

Methods

- PIQL response data analyzed using item response theory (IRT).
- Data come from 3424 introductory physics students.
- Each item is a combination of individual dichotomous response-items and grouped nominal response-items (Smith et al., 2022). See Table 1
- IRT parameters are used to define a score for each response combination (Smith and Bendjilali, 2022).

Item Response Theory

The probability of choosing a particular response k, given the student's overall physics quantitative literacy θ.

Dichotomous Two-parameter Logistic Model (2PL): A response option is either chosen or not chosen, e.g., response "A" to item 17.

$$P_{2pl}(k|\theta) = \frac{e^{a_k\theta+d_k}}{1+e^{a_k\theta+d_k}}$$

Nominal Response Model (NRM): A response option is a set of related responses or combinations of responses, e.g., responses "D", "E", "both D& E", or "neither D nor E" to item 18

$$P_{nrm}(k|\theta) = \frac{e^{a_k\theta+d_k}}{\sum_i e^{a_i\theta+d_i}}$$

Joint probability of selecting a particular combination of responses is the product of individual functions.

$$P_{16}(A,C,F|\theta) = P_{2pl}(C|\theta)P_{2pl}(D'|\theta)P_{nrm}(A\cap F|\theta)P_{nrm}(B'\cap E'|\theta)$$

$$= \left(\frac{e^{a_C\theta+d_C}}{1+e^{a_C\theta+d_C}}\right)\left(\frac{1}{1+e^{a_D\theta+d_D}}\right)\left(\frac{e^{a_{AF}\theta+d_{AF}}}{\sum_i e^{a_i\theta+d_i}}\right)\left(\frac{1}{\sum_j e^{a_j\theta+d_j}}\right)$$

$$= \frac{\exp\left[(a_C+a_{AF})\theta+d_C+d_{AF}\right]}{Z_{16}(\theta)}$$

where $i = \{0, A, F, AF\}$ and $j = \{0, B, E, BE\}$. $Z_{16}(\theta)$ is a summation including one term for every possible combination of responses.

The "a_k" parameters indicate level of PQL (Smith and Bendjilali, 2022), and a_0 = 0. We use these to define partial credit scores.

For the dichotomous 2PL model, a negative a_k value indicates that the probability of selecting response k is a monotonically decreasing function of θ. But for the nominal model, positive or negative a_k values indicate higher or lower PQL than not selecting any of the responses, respectively.

Important: The remainder of the questions on this survey may have more than one correct answer. Select ALL ANSWERS you believe are correct.

15. The internal energy of a system can be increased by doing positive work on the system or by heating it, and it can be decreased by cooling the system or if the system does work. Which if the following equations represent(s) this relationship (U is the internal energy of the system, Q is positive when energy flows into the system, and W is positive when work is done on the system)? ***Choose all that apply.***

   a. $\Delta U = Q - W$
   b. $\Delta U = -Q + W$
   c. $\Delta U = Q + W$
   d. $-\Delta U = Q + W$
   e. $-\Delta U = Q - W$
   f. $-\Delta U = -Q + W$

16. Consider the following statement about subatomic particles:

   "There are three times as many quarks as nucleons."

   Some students were asked to write an equation to represent this statement, using Q for the number of quarks and N for the number of nucleons. Which of the following are correct?
   Choose all that apply.

   a. $3Q/N$ b. $3Q = N$ c. $3Q + N$ d. $Q = 3N$ e. None of these are correct.

17. Shown at right is a picture of a small flag of the Kingdom of Bhutan, which has a dragon along its diagonal. A second version of the flag, not shown, is 1.5 times taller than the smaller flag and is also 1.5 time wider.
   Which of the quantities below are larger by a factor of 1.5 for the larger flag compared to the smaller flag? ***Choose all that apply.***

   a. The distance around the edge of the flag.
   b. The amount of cloth needed to make the flag.
   c. The length of the curve forming the dragon's backbone.
   d. The diagonal of the flag.
   e. None of these quantities are larger by a factor of 1.5.

18. The following problem is constrained to one dimension. A hand exerts a constant, horizontal force on a block as the block moves along a frictionless, horizontal surface. No other objects do work on the block. For a particular interval of the motion, the hand does $W = -2.7$ J of work on the block. Recall that for a constant force $\boldsymbol{F}$, and displacement $\Delta\boldsymbol{s}$, $W = \vec{F}\cdot\Delta\vec{s}$.

   Consider the following statements about this situation. Select the statement(s) that **must be true.** ***Choose all that apply.***

   a. The work done by the hand is in the negative direction.
   b. The force exerted by the hand is in the negative direction.
   c. The displacement of the block is in the negative direction.
   d. The force exerted by the hand is in the opposite direction as the block's displacement.
   e. The force exerted by the hand is in the same direction as the block's displacement.
   f. Energy was added to the block system.
   g. Energy was taken away from the block system.

19. Recall that the electric field is a vector quantity. At a location on the x-axis, the x-component of the electric field is measured to be $E_x = -10$ N/C, and the y and z-components of the field are measured to be zero.

   Consider the following statements about this situation. **Select the statement(s) that must be true.** ***Choose all that apply.***

   a. The source of the field is a negative charge.
   b. At that location of the x-axis, the field is in the negative x-direction.
   c. In this field, the motion of any charged particle is opposite to the direction of the field.
   d. The magnitude of the electric field is decreasing.
   e. The magnitude of the electric field at that location is 10 N/C less than it is at the origin.

20. Two objects can move in either direction along the x-axis. The two objects collide. As a result of the collision, object 1's velocity vector changes, $\Delta v_x = -10$ m/s.

   Consider the following statements about this situation. Select all statement(s) that **must be true.** ***Choose all that apply.***

   a. Object 1 is moving faster after the collision than it was before the collision.
   b. Object 1 is moving slower after the collision than it was before the collision.
   c. Whether object 1 is moving faster or slower after the collision than it was before the collision cannot be determined using only the information given.
   d. Object 1 moved in the positive direction before the collision, and in the negative direction after the collision.
   e. Object 1 moved in the negative direction before the collision and in the positive direction after the collision.
   f. Object 1 moved in the negative direction both before and after the collision.

Figure 1. MCMR items on the PIQL

Dichotomous and Nominal Response-items

Item	Independent Dichotomous Responses	Grouped Nominal Responses	Item	Independent Dichotomous Responses	Grouped Nominal Responses
15	C, D	A+F, B+E	18	A, B, C	D+E, F+D
16	A, C	B+D	19	A, B, C, D, E	–
17	A, B, C, D	–	20	D, E, F	A+B+C

Table 1. Strongly correlated response options are grouped and analyzed using the nominal response model (Smith et al., 2022).

IRT Parameter Results

	Expected Ranking	IRT Score		Expected Ranking	IRT Score
Item	C*	+0.67	Item	DG*	+1.39
15	AF	-0.20	18	D†	+0.04
	BE	-0.53		G†	+1.35
	D	-0.74		EF	+0.07
	A	-1.08		E; F	-0.46; +0.53
	F	-0.50		A; B; C	-0.20; -0.36; -0.57
	AC‡	-0.40		DE‡; FG‡	-0.48; -0.20
Item	D*	+2.27	Item	B*	+0.49
16	B	+1.54	19	A	0.00
	A	-0.41		C	-0.51

				ABC‡	-0.10
				E	-1.22

Table 2. Expected rankings of responses to MCMR items (higher on top), and associated partial credit "scores" defined from IRT parameters. Asterisks (*) indicate completely correct responses. Daggers (†) indicate partially correct responses. Double daggers (‡) indicate contradictory response combinations.

Takeaways

- Choosing mathematically equivalent responses indicates higher understanding than just choosing one of a pair. Example from item 15: $a_{AF} > a_A + a_F$ and $a_{BE} > a_B + a_E$.
- Incorrect independent (dichotomous) responses always have negative parameter values. Incorrect responses that are part of a nominal group may have positive or negative IRT parameter values. This suggests that any response from some groups indicates higher physics quantitative literacy (PQL) than not choosing any from the group.
- The order of the IRT parameter "scores" matches the expected ranking for most items, but there are some discrepancies. For example: choosing the two incorrect responses "E" and "F" on item 18 has a higher score than choosing the single correct response "D". More work is needed to reconcile these results.

Research Questions and Results

RQ1: What score is assigned to each combination of responses based on IRT parameters?

- See Table 2

RQ2: How do correct and incorrect responses impact these scores?

- All correct response scores are positive.
- All incorrect dichotomous response scores are negative.
- Incorrect nominal responses may be positive or negative, but all are lower than correct.

RQ3: How do scores based on IRT parameters relate to traditional dichotomous scores?

- IRT parameters used as scores give a range of total test scores from about 52 to 82 (compared with [0,20] for dichotomous scoring)
- When partial credit scores are scaled to have a range of [0,20], most (but not all) students have higher total scores when including partial credit.

Partial Credit vs. Dichotomous Scores

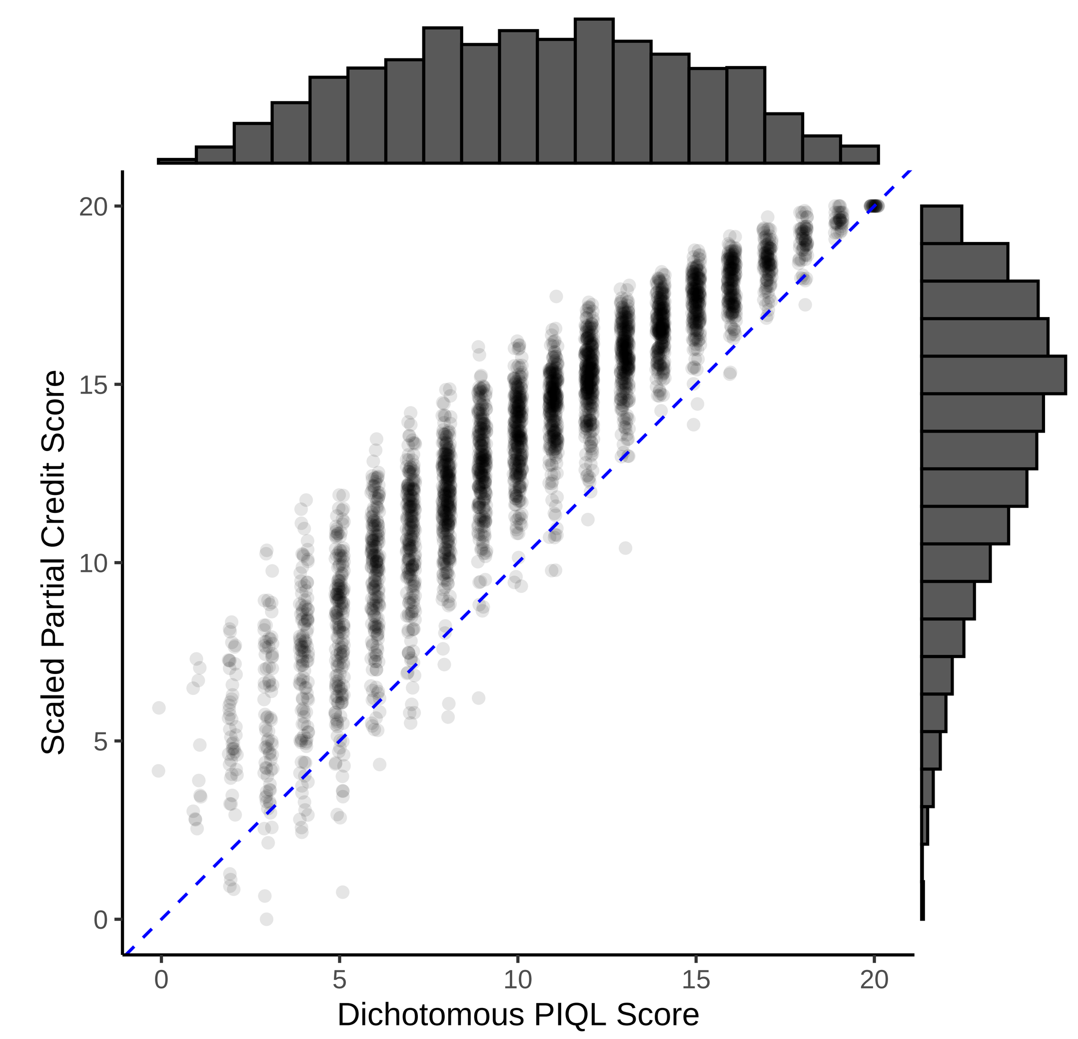

Figure 2. Partial credit scores have been scaled to have the same range as dichotomous scores: [0,20]. Points above the dashed blue line indicate higher partial credit scores, and vice versa. Histograms show the overall distribution for each score.

Conclusion

- The correct response combination for each item always has the highest IRT-defined score, even though the correct responses are not specified in the model.
- Correct individual responses have positive scores, and incorrect responses have negative scores.
- Total IRT-defined test scores strongly correlate with dichotomous test scores ($r \approx 0.8$). This supports the interpretation of IRT parameters as indicating levels of correctness and understanding.
- Some analyses of grouped responses yielded counterintuitive results: we identified one item for which certain incorrect responses corresponded to positive parameters.
- Our overall results indicate a strong potential for using IRT analyses to inform partial credit scores for MCMR items used to measure students' PQL; however, more consideration is needed to define the transformation from IRT parameters to partial credit scores.
- IRT parameters indicate how much knowledge or understanding is indicated by each response. Translating this into a partial credit score is not entirely straightforward.

Pre-Calculus Students' Mathematics and Art Cognitions in Making and Testing Conjectures About the Fibonacci Spiral and the Great Wave of Kanagawa

Tuto LopezGonzalez
San Francisco State University

Keywords: Cognition, Pirie-Kieren Model, Pre-Calculus

There are many forms of thinking and sense-making through artistic expression (e.g., painting, music, dance, and emotion). Similarly, there are many forms of thinking and sensemaking through mathematical expression (e.g., quantities, symbols, diagrams, logic). In mathematics, the Pirie-Kieren (P-K) framework has been useful for exploring the development of mathematical understanding (Pirie & Kieren, 1994). According to the P-K framework, a learner goes back and forth among eight cognitive layers when working on a mathematical task (primitive knowing, image making, image having, property noticing, formalizing, observing, structuring, inventizing). No similar framework exists for the development of artistic understanding. Research has suggested that bringing arts into a mathematics classroom can be viewed as a rich way of engaging learners (Baird, 2015). A growing interest in cognitive development at the intersection of mathematics and arts offers an opportunity to explore how it might be modeled as a non-linear dynamical recursive process as in the P-K framework.

Thinking about art can inform/shape thinking about mathematics and vice versa. The poster presents research exploring the nature of pre-calculus students' mathematics and art cognitions in making and testing conjectures about recursive relationships. The work examines the potential of using the P-K model for documenting students' mathematics and art understanding and how this understanding develops while including attention to responses such as gesturing and body language. I developed and conducted interviews with four pairs of college precalculus students. The interview task used the Fibonacci spiral and an Edo-period woodblock print, the Great Wave by Hokusai, as spurs for student thinking and interaction about mathematics and art. Qualitative inductive analysis examined the audio- and video-recorded interviews using the P-K framework to identify and describe the mathematical and art-centered/visual thinking by students as they made sense of and responded to aspects of the task.

This poster will illustrate the findings on how the Pirie-Kieren framework is useful in unpacking the math-rich and diagram/visual-rich aspects of cognition by pre-calculus students. This poster aims to provide a space for RUME participants to share and discuss how art (song, painting, poem, etc) can support thinking about an idea/concept in mathematics. Additionally, it is a goal of this poster's graduate student author to talk with visitors about existing research about or near to mathematics and arts cognition, both to learn what they suggest as related readings and what more or different they would hope to see in a long report about this research.

The implications of the research include the value of (1) revisiting existing research at the intersection of art and mathematics with multiple P-K diagrams in hand (one for art, one for mathematics, and one for both) to make better/different sense of cognition involving both mathematics and art and (2) designing new curriculum and related research on how to combine art and mathematics that is better informed by the ways the combining may influence mathematical understanding.

Pre-Calculus Students' Mathematics and Art Cognitions in Making and Testing Conjectures About the Fibonacci Spiral and the Great Wave of Kanagawa

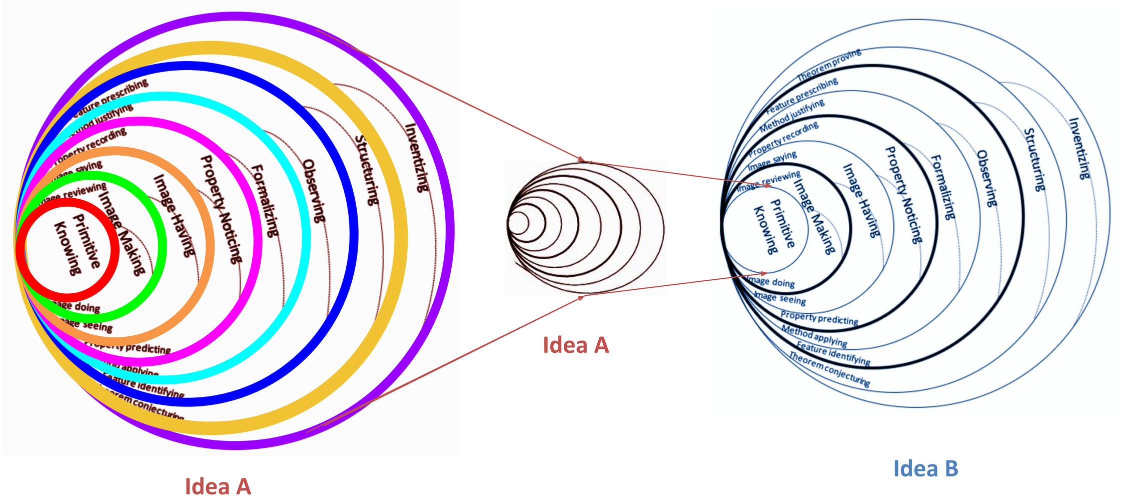
Tuto Lopez Gonzalez, San Francisco State University

Project Overview

The Pirie-Kieren (P&K) framework

The Pirie and Kieren (P&K) framework (Pirie & Kieren, 1989; 1994) provides a way to explore the development of mathematical understanding by suggesting that a learner move through eight cognitive levels of sophistication as they go through a learning situation.

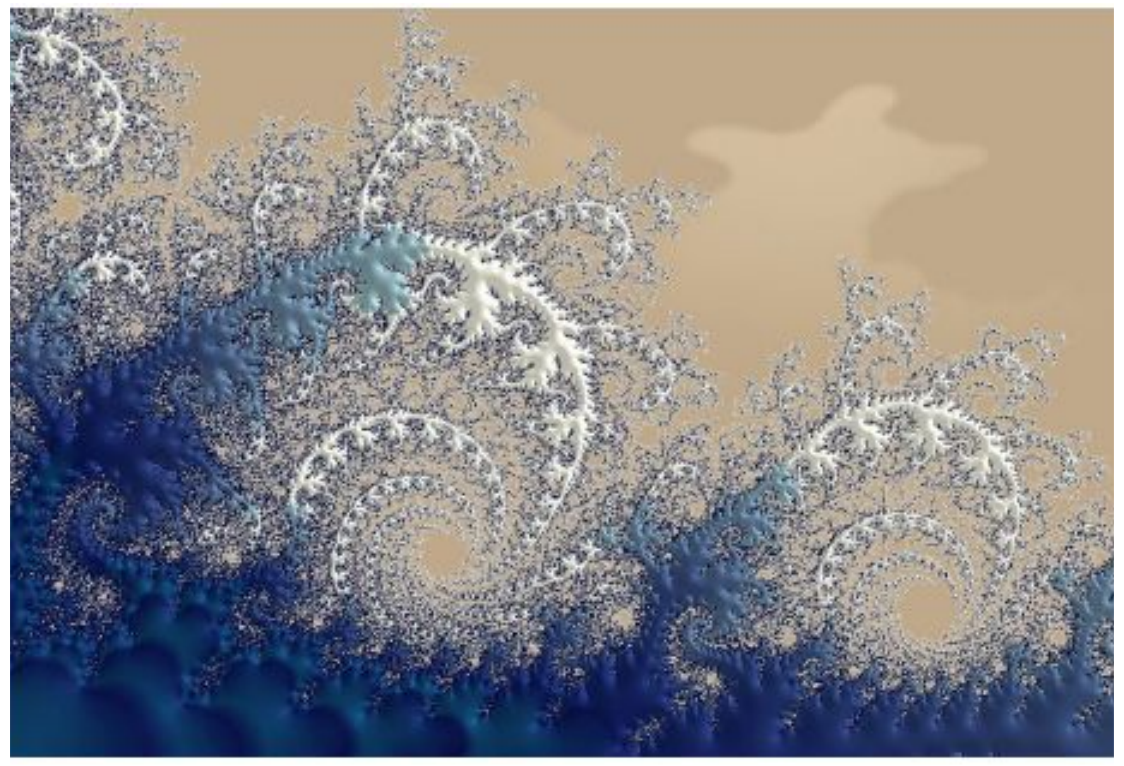
1. **Primitive knowing:** Learner's information brought to the learning situation.
2. **Image making:** The learner acts (mentally or physically) to gain an idea about a concept.
3. **Image having:** Single-activity associated images are replaced by a mental picture.
4. **Property noticing:** Notice properties and connections between mental pictures.
5. **Formalizing:** Description of class-like mental objects to produce full mathematical definitions.
6. **Observing:** Question formal statements verbalize cognitions about the formalized concept.
7. **Structuring:** Determine if formal observations are true by an axiomatic system (proof)
8. **Inventizing:** Complete understanding of a concept and pose questions that lead to new concepts



Self-similar nature - Encapsulated Idea A becomes Primitive Knowing for Idea B

Developing a framework for the development of artistic fulfillment/understanding

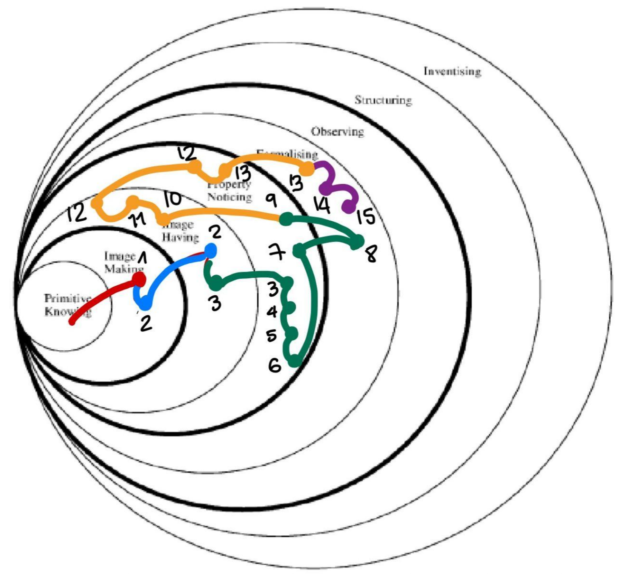
Research has suggested that bringing arts into a mathematics classroom can be viewed as a rich way of engaging learners (Baird, 2015). A growing interest in cognitive development at the intersection of mathematics and arts offers an opportunity to explore how it might be modeled as a non-linear dynamical recursive process as in the P&K framework.



I created an experience completed by 3 pairs of pre-calculus students. Each pair interacted with ***The Great Wave off Kanagawa (GWK)*** (1831) by artist Katsushika Hokusai. Participants were asked to analyze the GWK. Then, pairs completed a mathematical task with the **Fibonacci Spiral (FS)**. Finally they interacted with the GWK using the FS.

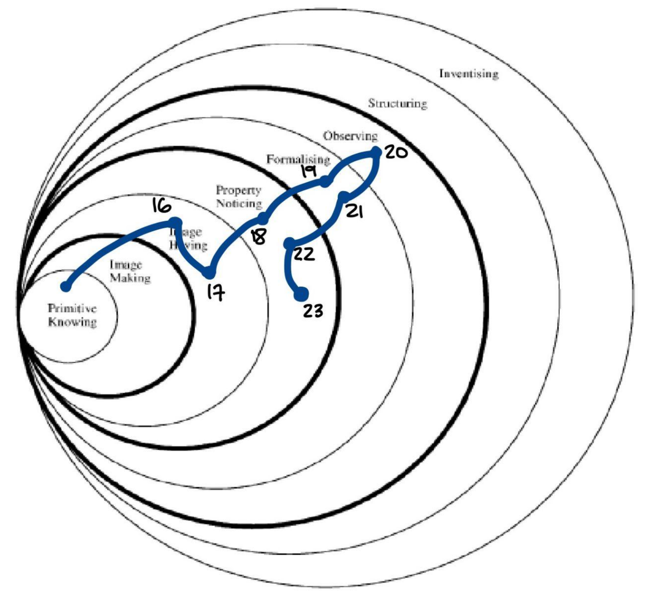
Maps of Development of Understanding

Part 1, Pair 1: Analyzing the GWK.



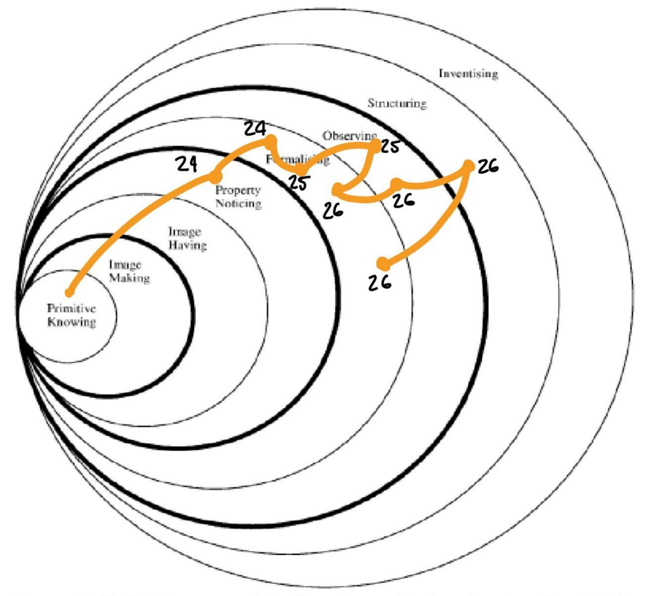
The P&K framework was extended to track the learner's development of fulfillment/understanding of the GWK.
(# indicates prompt of 27 questions total)

Part 2, Pair 1: Building the Fibonacci



The P&K framework for the development of mathematical understanding was used to draft the map on the second part of the experience
(# indicates prompt)

Part 3, Pair 1: Fitting the spiral



The P&K framework was extended to track the learner's development of fulfillment/understanding of both the GWK and the FS
(# indicates prompt)

Findings

In studying the nature of pre-calculus students' mathematics and art cognitions based on the experience, the following observations were done:

- P&K is useful for understanding mathematical cognition about the FS and documenting student's sense making.
- P&K is useful for exploring student's sense making and fulfillment of arts.
- A multi dimensional version of the P&K framework is proving useful in documenting how students use visual and mathematical information together to make sense of mathematical ideas related to the FS.
  - In analyzing art (Part 1) learners come up to the boundary (Meel, 2003) of formalizing.
  - When interacting with **both** the GWK and the FS (Part 3), learners crossed the boundary and entered mathematical formalizing.
- Preliminary analysis indicates gesturing when interacting with artwork is a form of embodied cognition that supports formalizing concepts beyond noticing.

Future Work

- Testing different Machine Learning algorithms such as decision trees, regressions and neural networks to help identify the cognitive level of sophistication a learner is in for a given mathematical task. Such algorithms can be useful for assessment, personalized learning, curriculum development, and future research.
- Extending the P&K map to a 3-dimensional map where the axis represent art fulfillment growing, mathematics understanding growing and time.

The Experience: Interacting with the Great Wave off Kanagawa

Engaging an Industrial Advisory Board for Curriculum Development

David Jacobson, Metropolitan State University
Rikki Wagstrom, Metropolitan State University
Wei Wei, Metropolitan State University

Keywords: Data Science, Industrial and Applied Mathematics, Curriculum Development, Industrial Advisory Board, Technical and Non-technical Skills

With rapid changes in STEM careers, gaps still exist between skills required by industry and learning objectives created by colleges and universities. Even well-designed curriculum must be constantly reevaluated and adjusted. Data Science and Industrial & Applied Mathematics are fast-evolving programs whose graduates are highly sought by industry. Prior research has provided valuable general insight into skills valued by industry and pedagogy effective for teaching these skills (Ferns et al., 2021; Jang, 2016; Lamancusa et al., 2008; Schwab-McCoy et al., 2021; SIAM and COMAP, 2016).

In this poster, we will describe how we engaged our Industrial Advisory Board to provide external input for our newly developed Data Science and Industrial & Applied Mathematics programs. We will then show how we have applied that feedback and made changes to our curriculum and pedagogies. Our Industrial Advisory Board consists of nine volunteer members representing multi-national companies with headquarters or having a large presence in the local metropolitan area. This includes several Fortune 500 companies. Specifically, Industrial Advisory Board members were queried for their open-ended responses on topics such as: What do you look for when you hire? What is the appropriate balance between developing technical and nontechnical skills, in terms of preparing students for careers in industry? What computer applications and programming languages are beneficial to integrate into an undergraduate mathematics and statistics curriculum? For which career paths?

There was strong agreement among our board members on the importance of the following technical skills: Multiple linear regression, logistic regression, machine learning techniques, model formulation and model building (choosing the appropriate model and communicating why a specific model is chosen) and being able to interpret and explain results. Familiarity with an object-oriented programming language is typically required for all industries represented by the board members. Most importantly, students need to have the ability and drive to learn different applications as they will likely have to learn multiple new programming languages, modeling techniques and business practices throughout their careers.

The primary focus of non-technical skills is on communication. Specifically, our board members stressed the importance of students learning to communicate technical details to both technical and non-technical audiences. Another essential non-technical skill is the ability to work in teams and have project experience.

We describe how the recommendations have been incorporated into the Data Science and Industrial & Applied Mathematics programs. Initial feedback from students and the Industrial Advisory Board members to both programs has been positive. In particular, the students like working on the open-ended problems and enjoy working on projects in teams. We identify areas we would like to further emphasize or add to our curricula. They include additional model formulation activities, more PowerPoint presentations (emphasis on summarization of results), code documentation, asking questions of clients and importance of continuous education and learning of new skills. The Advisory Board has also provided guidance on several career-readiness items such as resumes, networking and interviewing which we are expanding on.

Engaging an Industrial Advisory Board for Curriculum Development

David Jacobson, Rikki Wagstrom, Wei Wei

Metropolitan State University, St. Paul, MN

Introduction

- **About Metro State University:**
  - Mathematics and Statistics Department historically offered an Applied Mathematics BS degree
  - Students are frequently location-bound adult learners
  - Financial factors frequently require students to seek employment in the corporate sector after graduation
- **Key theme of 2017 survey of Applied Mathematics alumni working in the corporate sector:**
  - Mathematical skills are valuable, but
  - Increased background in statistics and computing would have improved marketability and preparation
- **Actions taken by Mathematics and Statistics Department:**
  - Creation of a Data Science BS and Industrial & Applied Mathematics BS
  - Creation of Industrial Advisory Board to provide curricular guidance and learning experiences for the two new programs

Industrial Advisory Board Members

- **Role of Industry Advisory Boards**
  - Assist university departments in ensuring that academic programs prepare students with the skills and capacities currently valued and expected by industry.
  - Provide external input on additional ways to enhance the student learning experience, such as providing data sets, guest lectures for courses, and real time experiences such as internships, capstone design projects, and mentoring opportunities
  - Serve as external reviewers to evaluate and adjust specific curriculum

- **Our industrial Advisory Board consists of nine volunteer members representing multi-national companies with headquarters or having a large presence in the Twin Cities metropolitan area.**

  - Best Buy
  - Target (2 members)
  - Traveler's Insurance
  - General Mills
  - US Bank
  - SPS Commerce
  - Cargill
  - CH Robinson

- **Board members were queried for their open-ended responses on several topics.**

Industrial Advisory Board Survey Questions and Summary of Responses

Question	Responses
What do you look for when you hire?	• Soft skills: Strong communication skills, effectively work in teams, time/project management skills • Programming experience: Python, R, Pearl, Java, SQL • Ability to learn; interest in learning; ambition • Experience working on projects: Want them to be able to effectively communicate their train of thought as they discuss prior work that they've done • Problem solving: Perseverance, willingness and ability to ask questions • Work with vendors effectively • Understanding of models: Being able to choose appropriate models and communicate rationale, understand advantages and disadvantages of different models
What is the appropriate balance between developing technical and nontechnical skills, in terms of preparing students for careers in industry?	• Individuals need both • Communicating technical details to technical and non-technical audiences is difficult but essential • Being able to make a clean, concise PowerPoint presentation is essential • Need to be interested in taking ownership for projects and have the drive to do it as well as possible • It's important to be able to ask (the right) questions • Problem solving strategies are important: (One board member asks the following of her employees: If a problem is not clearly stated, what could you do? What are some other strategies you can try?)
What computer applications and programming languages are beneficial to integrate into an undergraduate mathematics and statistics curriculum?	• Python and R: Most widely used; May or may not be a deal-breaker for hiring • SQL: Not a deal-breaker for hiring, but definitely helpful for database queries • Java: Helpful, but not essential • SAS and Excel VBA: Used at one company • Excel: Familiarity with spreadsheets is essential; VBA is helpful, but not essential • MATLAB: Not essential, used primarily in engineering applications • In general, familiarity with an object-oriented programming language is important • Data visualization software (Tableau, Power BI): Used at several of the companies represented, but not essential • Amazon Web Service (AWS): Helpful • If employees have the ability and drive to learn different applications, they can generally pick up what they need to know

Industrial Advisory Board Recommendations

- **Technical Skills**
  - Academic background must include multiple linear regression – what it is and when it works well
  - Knowledge of logistic regression and machine learning techniques are plusses
  - Model formulation is critical
  - Training versus validation versus test data
  - Be able to understand and translate business problems into a math / stat problem
  - Interpret and explain results
- **Non-technical Skills**
  - Communicating technical details to technical and non-technical audiences
  - Ability to work in teams and have project experience
  - Time/project management skills
  - Ability to lean new things (programming languages, modeling techniques, and business practices)
- **Overall**
  - Include project-based or inquiry-based classes
  - Open-ended problems which require practical skills, especially formulating and selecting models
  - Present results of projects in non-technical industry terms
  - Embed mini-projects into the curriculum
  - Emphasize code documentation

Implemented Recommendations

- **Industrial & Applied Mathematics**
  - Four-course sequence in modeling focused on formulating models and problem-solving
  - Incorporation of a team-based investigation of a large open-ended real-world problem
  - Instruction in technical communication
  - Communication of analyses, results, and recommendations to both technical and non-technical audiences
  - Completion of a statistics or mathematics internship, a Statistical Consulting course or a Mathematics Capstone
- **Data Science**
  - Project-based interdisciplinary focus with courses in Math/Stat, Computer Science, and Management Information Systems
  - Programming courses in R, Python, Java, SQL, and Tableau
  - Integrative experience through a statistics or data science internship, Statistical Consulting or a Data Science Capstone
- **Both Industrial & Applied Math and Data Science**
  - Regression Analysis course with a focus on model formulation
  - Career Center presentation on career opportunities
  - Courses with team- based projects with data analysis in R and presentations to both technical and non-technical audiences
  - Creation of student portfolios

Future Work

Initial feedback has been positive. Students like working on open-ended problems and team-based projects.

Areas of further curriculum emphasis:

- Model formulation activities
- More PowerPoint presentations with an emphasis on summarization of results
- Code documentation
- Asking pertinent questions of clients
- Importance of continuous education and learning of new skills

Work with the Industrial Advisory Board on expanding career-readiness guidance:

- Resume construction
- Importance of networking
- Job interviewing skills

Regular surveys of recent alumni for ongoing evaluation

Novice College Mathematics Instructor Communication About Cognitive Demand

Helena Almassy
San Francisco State University

Keywords: cognitive demand, scaffolding, novice instructors

Many incoming graduate students become novice instructors with little to no experience teaching at the college level. Such novices may take part in professional learning opportunities from general workshops on teaching to specific work to prepare for teaching with a particular curriculum (e.g., course coordination). One aspect of preparing to teach is developing skill in supporting students to "successfully engage with a mathematical task" (Stein et al., 2009). To do so, novice instructors must consider the context of the student learning experience as well as the level of cognitive demand for the mathematical task (Smith & Stein, 1998). A curriculum may have a wealth of mathematical tasks available to assign to students, requiring varying levels of cognitive demand (e.g., recalling and applying memorized facts, using procedures with and without connection to other knowledge, and the most cognitively demanding work of doing mathematics in a novel situation). Though research exists on cognitive demand and the preparation of teachers to attend to it for K-12 mathematics, little research has focused on the needs of novice college mathematics instructors. In this poster, the focus is on addressing the research question: How are novice instructors' instructional decisions informed and shaped by consideration of cognitive demand?

Previous research on cognitive demand in the preparation of novice instructors focused on how they interpreted and transformed the definitions of "cognitive demand" and "scaffolding" of student learning (Milbourne, 2018). The poster builds on this, focusing on how novice instructors make sense of and communicate with colleagues about cognitive demand in the context of a weekly teaching workshop. The data collected included nine novice instructors' responses within asynchronous online activities and live audio and video of three consecutive workshop discussions about cognitive demand in various college mathematics classroom examples (e.g., video case materials, Hauk et al., 2013). The inductive qualitative analysis uses van de Pol's (2010) framework for scaffolding, involving contingency, fading, and transfer of responsibility. Initial analysis indicates novice instructors described various "benefits" from lowering cognitive demand that expand on the collection reported by Milbourne. As in previous work, novices talked about "getting through more material". New "benefits" voiced by novices in this study included improving student confidence and self-efficacy. The new findings are related to consideration of the student's perspective.

The goal at the poster is to engage RUME conference participants in discussing novice instructor decisions on how to set cognitive demand goals and why they might set those goals. Poster-side conversation can inform the ultimate reporting of study findings. Results of the research can be used in (re)development of professional learning opportunities offered to novice college mathematics instructors and can shape future research on how novices improve their instructional skills in task-level decision-making.

Novice College Mathematics Instructor Communication About Cognitive Demand

Helena Almassy | San Francisco State University

Poster Purpose: To collect ideas while discussing novice instructor decisions on how to set cognitive demand goals and why they might set those goals.

Context

Project Objective:

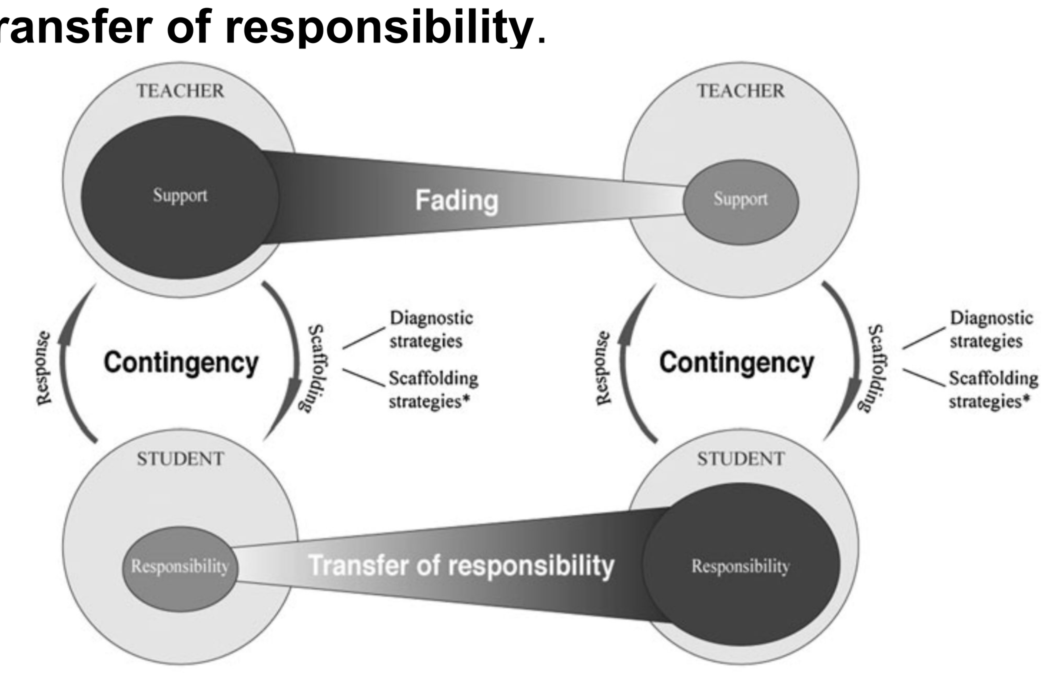
Understanding how are novice instructors' instructional decisions informed and shaped by consideration of cognitive demand.

Background:

Many incoming graduate students become novice instructors with little to no experience teaching at the college level. Such novices may take part in professional learning opportunities from general workshops on teaching to specific work to prepare for teaching with a particular curriculum (e.g., course coordination). One aspect of preparing to teach is developing skill in supporting students in successfully engaging with mathematical tasks. To do so, novice instructors must consider the context of the student learning experience as well as the level of cognitive demand for the mathematical task (Smith & Stein, 1998). Though research exists on cognitive demand and the preparation of teachers to attend to it for K-12 mathematics, little research has focused on the needs of novice college mathematics instructors.

Framework:

This project uses van de Pol's (2010) framework for scaffolding student learning. The characteristics of scaffolding included **contingency**, **fading** and **transfer of responsibility**.



Conceptual Model of Scaffolding from van de Pol (2010)

Research Questions

1) In the context of a particular classroom activity and associated assessment, what is the nature of GTA communication about and use of cognitive demand?

2) How are curriculum and assessment decisions for scaffolding student learning informed/shaped by GTA consideration of cognitive demand?

Mini-Course Embedded within a Teaching Workshop

Setting: Nine graduate students pursuing masters' in mathematics enrolled in a 3-credit Graduate Teaching Workshop. Each was a new graduate teaching associate (GTA) – instructor of record for undergraduate math courses for the first time. A 2-week section of the workshop was dedicated to noticing and responding to cognitive demand.

Asynchronous Activities:
GTAs did a mini-lesson that was organized as exploration, discussion boards, and self-quiz in classifying cognitive demand.

Synchronous Class:
Included small and whole group discussion of portions of the mini-course and readings related to student group work and classroom management techniques.

Levels of Cognitive Demand

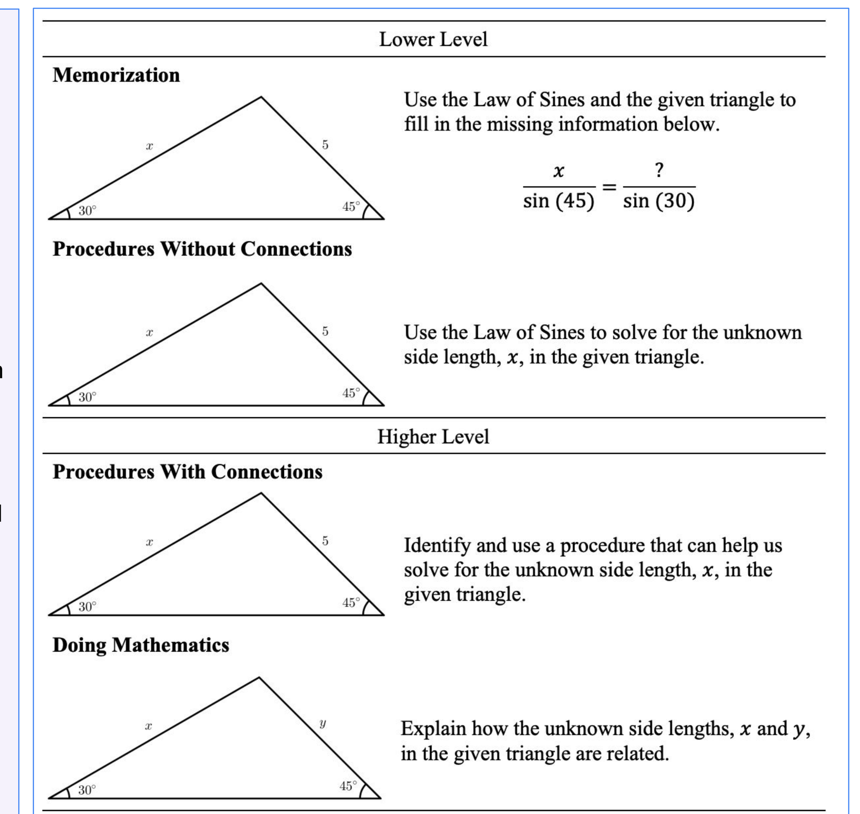
Lower-level demands *(memorization)*
- Involve either reproducing previously learned facts, rules, formulas, or definitions or committing facts, rules formulas or definitions to memory
- Cannot be solved using procedures because a procedure does not exist or because the time frame in which the task is being completed is too short to use a procedure
- Are not ambiguous. Such tasks involve the exact reproduction of previously seen material, and what is to be reproduced is clearly and directly stated

Lower-level demands *(procedures without connections)*
- Are algorithmic. Use of the procedure either is specifically called for or is evident from prior instruction, experience, or placement of the task.
- Little ambiguity exists about what needs to be done and how to do it.
- Have no connection to the concepts or meaning that underlie procedures being used
- Are focused on producing correct answers instead of developing understanding
- Require no explanations or explanations only describing the procedure that was used

Higher-level demands *(procedures with connections)*
- Focus student's attention on the use of procedures for the purpose of developing deeper levels of understanding of mathematical concepts and ideas
- Suggest explicitly or implicitly pathways to follow that are broad general procedures that have close connections to underlying conceptual ideas as opposed to narrow algorithms that are opaque with respect to underlying concepts
- Usually are represented in multiple ways, such as visual diagrams, manipulatives, symbols, and problem situations.
- Although general procedures may be followed, they cannot be followed mindlessly

Higher-level demands *(doing mathematics)*
- Require complex and nonalgorithmic thinking – no predictable, well-rehearsed approach or pathway is explicitly suggested by the task, task instructions, or a worked-out example.
- Require students to explore and understand the nature of mathematical concepts, processes, or relationships
- Demand self-monitoring or self-regulation of one's own cognitive processes
- Require students to access relevant knowledge and experiences and make appropriate use of them in working through the task
- Required students to analyze the task and actively examine task constraints that may limit possible solution strategies and solutions
- Require considerable cognitive effort and may involve some level of anxiety for the student because of the unpredictable nature of the solution process required

Based on Smith and Stein (1998)

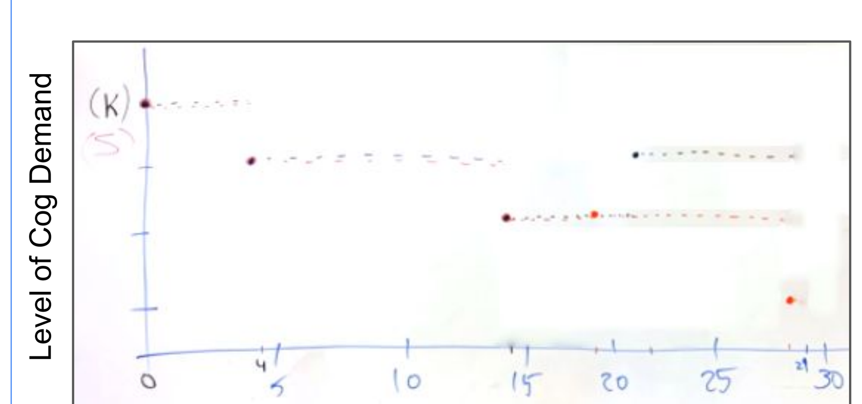


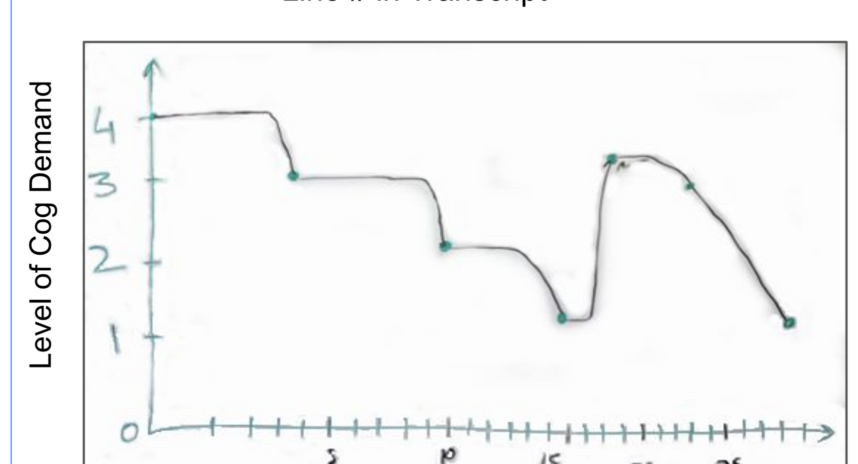
Data Collection:
Audio and video was recorded over three consecutive days during the synchronous workshop (~30 min recording each period). Participants completed portions of the asynchronous work in the previous week and some concurrently.

Results

Tracking Cognitive Demand

Given a conversation among Kristen, Brad, and Ted, (video & 29 lines of transcript), plot the cognitive demand across time/lines of transcript. GTAs agreed the interaction started at 4 (Doing Math) and ended at 1 (Memorization). But plots differed.





Later, individual GTAs described their decision-making. That communication highlighted their sense-making in trying to understand "level" of cognitive demand.

Changes in Cognitive Demand

I also think in the parts when the **cognitive demand __keeps constant__** it is because the question the instructor was proposing **gave the student the opportunity to continue thinking** and using their knowledge to try to solve the problem.

She does say "cancel" and it is **telling a student exactly what to do.** That is the exact point where the **__cognitive demand drops__**.

Brad answered by memory (he knows the rule). Then … the **__[cognitive demand] level increased__** because Ted found that it doesn't match up, they found a problem and **now they need to make some connections** to solve it.

Emerging Awareness of Cognitive Demand

"I was thinking that each of those is sort of mapped to one assignment like, one assignment is the level of doing math, or one assignment is the level of memorization. But then … **two students could look at the same problem** and be at **__different levels__** [of cognitive demand]. "

Personally, I believe that the learning shift should be continuous and that **there exist __sub-levels in between__ the 4 main cognitive demand levels** that were indicated because even in those 4 basic levels, there are already some **overlapping characteristics.**

Discussion

GTAs described various "benefits" from lowering cognitive demand that expand on the collection reported by Milbourne. New "benefits" voiced by novices in this study included **improving student confidence and self-efficacy**. The new findings are related to **consideration of the student's perspective**.

GTAs described practices that they thought would maintain cognitive demand of *Procedures With Connections.* Some would, some might not:

GTA suggestion	*# of GTAs*	*Likely Cognitive Demand Result*
__Ask the student:__ *What do we know about sides and angles?*	4	**Maintain** cognitive demand
__Direct the student:__ *Think about concepts related to trigonometry.*	2	**Reduce** cognitive demand
__Redirect the student:__ *Look at your notes and see what might be a useful procedure.*	1	**Maintain** cognitive demand

Posterside Conversation

- How might novice instructors set cognitive demand goals?
- Why would the particular cognitive demand goal be set by a novice instructor?
- How and why might the goals set by novice instructors about cognitive demand differ from experienced instructors?
- Other questions? Comments?

A Calculus Student's Relative Size Reasoning

Kayla Lock
Arizona State University

Keywords: relative size reasoning, relative size, precalculus, rational functions

The ideas of measurement and measurement comparisons (e.g., fractions, ratios, quotient) are introduced to students in elementary school and understanding these ideas as relative size comparisons (Faulkner, 2013, Joshua et al., 2022) are a part of the Common Core State Standards for Mathematics. Researchers have also reported how conceptual (Thompson et al.,1994) meanings for ideas in calculus such as the difference quotient (Byerley & Thompson, 2014), derivative (Byerley et al., 2012; Zandieh, 2000), and the fundamental theorem of calculus (Thompson,1994) involve a multiplicative comparison of two quantities.

Someone who engages in relative size reasoning would conceptualize comparing two quantities' values in a static or dynamic context as measuring one quantity's magnitude in units of the other quantity's magnitude (Lock, 2021). For instance, suppose a student engaged in relative size reasoning to compare two girls' heights. In this context, both quantities are of the same unit of measurement. Thus, the student, when comparing Lyndsey's height to Darien's height, would imagine Darien's height as the unit of measure used to determine how many times as tall Lyndsey's height is in relation to Darien's height. Therefore, she might say Lyndsey is 5/4 times as tall as Darien.

When the two quantities' values are not measured using the same unit, engaging in relative size reasoning will involve imagining the measure of one quantity's value in multiples of the other quantity's value. For example, speed is a multiplicative relationship between an amount of distance and an amount of time. If someone is traveling at a constant speed and travels 8 feet per 3 seconds, one would imagine that the number of feet one travels will always be 8/3rd times as large as the number of seconds it takes to travel that distance. Relative size reasoning is a way of thinking that a person has developed when conceptualizing the comparison of two quantities' values multiplicatively in static and dynamic contexts (Lock, 2021). The purpose of this poster investigates the questions:

What mental actions do beginning calculus students engage in when responding to tasks designed to assess students' relative size reasoning?

Radical constructivism (Glasersfeld, 1995) is the lens used in this study which takes on the perspective that every individual has their own reality and knowledge is constructed based on previous personal experiences. For this study I conducted 4 clinical interviews (Clements, 2000) where 5 calculus students from a large southwestern university worked on 22 tasks associated with different topics (fractions, rational functions, concavity, trigonometry, etc.) that were designed to elicit students' relative size reasoning. In this poster, I characterize a student's thinking by determining what meanings the student had in the moment while working through two tasks. Future research will aim refine my current framework that describes the mental operations involved in relative size reasoning as well as refine my current multiple-choice assessment based on my analysis of my data.

A Calculus Student’s Relative Size Reasoning

Kayla Lock

Under the advisement of Dr. Marilyn Carlson

Motivation and Research Question

- Common Core State Standards for Mathematics asks that students understand fractions as comparisons of relative size (Faulker, 2013, Joshua et al., 2022).
- This way of thinking supports students in understanding proportional relationships, rates, growth patterns, and derivatives (Byerley 2019; Joshua et al., 2022; Thompson and Thompson 1996, Zandieh 2000).
- Researchers have documented that students in university mathematics courses have difficulties comparing two *quantities* in terms of their *relative size* (e.g. Byerley, 2019; Tallman, 2015).

Research Questions:

- *What mental actions do beginning calculus students engage in when responding to tasks designed to assess students’ relative size reasoning?*

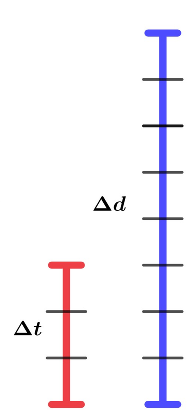
Relative Size Reasoning

- Someone who engages in ***relative size reasoning*** would conceptualize comparing two quantities’ values in a static or dynamic context as measuring one quantity’s magnitude in units of the other quantity’s magnitude.
- When the two quantities’ values are not of the same type of unit of measure (e.g., speed-relationship between an amount of distance and an amount of time), engaging in relative size reasoning will involve imagining the measure of one quantity’s value in multiples of the other quantity’s value (Lock, 2021).
- Relative size reasoning is a way of thinking (Thompson et al. 2014) that a person has Developed when conceptualizing the comparison of two quantities’ values multiplicatively.

Example: Constant speed of 8 feet per 3 seconds

the change in the number of feet one travels will *always* be $\frac{8}{3}$rd times as large as the number of seconds it takes to travel that distance.

$\frac{\Delta d}{\Delta t} = \frac{8}{3}$



constant speed of $\frac{8}{3}$ feet per second

Theoretical Perspective & Methodology

- **Radical constructivism** (Glasersfeld, 1995) is the lens used in this study which takes on the perspective that knowledge is constructed based on one’s previous personal experiences, and knowledge lies in the mind of the individual.
- ***Quantitative reasoning*** is the analysis of a situation into a network of quantities (measurable attributes of objects) and quantitative relationships (Thompson, 1994, 2012).
- ***Covariational reasoning*** refers to the mental actions involved in coordinating the value of two varying quantities and how the values vary in relation to each other (Carlson Jacobs, Coe, Larson, & Hsu, 2002; Saldanha & Thompson, 1998; Thompson & Carlson, 2017)
- This work draws on theories of students’ understanding in the moment and communicating mathematics:
  - Students explained their meanings in the moment for each response they had to the questions. Each question posed was used as a point to characterize the students’ meanings (Thompson, 2013).
- I report on 2 tasks from conducting five 1.5hr long clinical interviews (Clements, 2000) with 1 calculus student from a large southwestern university worked on 22 tasks from different topics (measurement, exponential growth, rational functions, and concavity) designed to elicit students’ relative size reasoning.

Results

Task 1: Paul is Skiing

Suppose Paul is skiing on a circular trail and he skied 27 miles. If one blip is 14 miles and the entire trail is 9 blips, what angle measure (in degrees) did Paul sweep out as he skied 27 miles on the circular trail?

After reading the problem Gabriel stated, **“we know there are 9 blips so that would be split into 9 pieces and each curvature would be 14 miles”** and then explained that since Paul skied 27 miles, **“that would be like almost two full blips.”** In this excerpt below, Gabriel’s statements and drawings suggest that he coordinated the 3 units of measure: blips, miles, and the circumference of the circular trail.

Excerpt 1

Gabriel: Since the, since the trail is circular and he is going through the, the trail, like in that circle, when you draw out the circle, you could kind of see that the, he is going to like traveling through or by the circumference of the circle.

Interviewer: So would you relate your idea of circumference in this question with what you said earlier about how he skied almost “2 full” <blips>.

Gabriel: Well the almost two full parts of like the split I did of the circle. Since we know **that the trail is made up of 9, equal blips, and each blip is 14 miles, we could kind of split the whole trail into 9 different equal pieces. And since we know that each blip is 14 miles, we know that each piece is also going to equal 14 miles. So when it comes to like something like 27, It's not quite two full pieces since two full pieces is 28**, but it's pretty close.

Interviewer: So how does that relate to what you talked about with circumference?

Gabriel: Since you can also split the circumference into 9 equal pieces and **since he is traveling, on the circumference, then the measure of the circumference is also equal to the 9 blips in total.**

Interviewer: So how would you compare the amount that Paul swept out in comparison to what you just talked about with circumference?

Gabriel: Oh, it was about it was about two ninths of the whole circumference.

Interviewer: How did you think about two and 9 and like, what is that two divided by 9 represent?

Gabriel: **The 9 represents the entirety of the circumference since it is split into 9 equal pieces. And the two is how much of those 9 pieces he was able to actually like get through.**

Gabriel then explains how Paul skiing 2/9 of the circumference is related to the angle measure in degrees that Paul swept out while skiing 27 miles (Excerpt 2)

Excerpt 2

Interviewer: What if we change this question to degrees (instead of measured in radians) how would you imagine going about that?

Gabriel: **We divide the 360 by 9 in order to get what the measurement of one of those slices is, and then we would be able to kind of find what the angle is of like the, the 27 or at least close to that.**

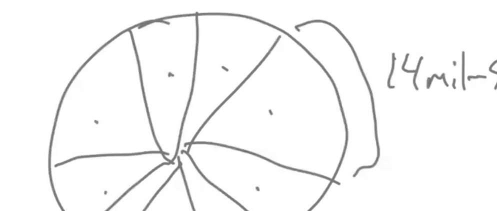
Interviewer: So would you be able to go through that process and kind of walk me through that?

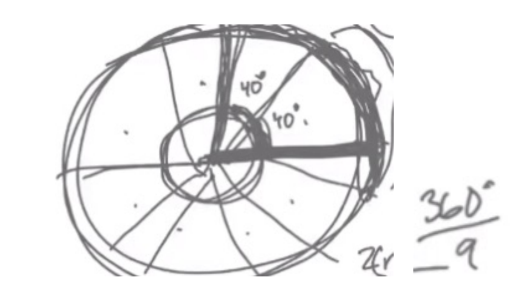
Gabriel: **So 360 divided by 9 is 40, which means that each angle is about 40 degrees. And since it takes up two of those, this angle right here, or 27 takes up about 80 degrees.**

Interviewer: How did you know it was about 80 degrees?

Gabriel: Oh, because of dividing the whole, uh, the whole circle. **Since the circle is going to be 360 degrees, no matter what if I divided that by 9, I got 40 degrees, which meant that every section of this would be also 40. Since 27 takes up about two of those sections, then I'd just add another 40 to that and it would be 80.**

This statement indicates that Gabriel leveraged his understanding of the length of the trail, which is 9 blips, and a full rotation in degree, which he stated is 360 degrees, in order to partition a full rotation into 9 parts and determine the angle measure swept out for each blip. Then he leveraged his thinking about skiing 2 chunks of the circumference to determine Paul swept out 80degrees as he skied 27 miles





Task 2: Gatorade Problem

5gallons of liquid flavoring are poured into a vat. Water will be added to the vat and mixed with the flavoring to produce a drink that will be bottled and sold. The ratio of flavoring to water in the mixture to the total volume of the mixture, x, can be defined as $f(x) = \frac{5}{x-5}$. As the total number of gallons of liquid increases, explain how the value of f varies.

Initially Gabriel read the problem aloud and substituted different values for x as he attempted to make sense of what the rational function conveyed about the context. As an example, Gabriel followed by explaining what the rational function represents when 5 is substituted for 3 (Excerpt 3).

Excerpt 3

Gabriel: So **the number of gallons has to be over 5 in order to produce anything because if it’s 5 or lower, it would just make either zero or a negative number for the denominator, which would mean that there is no like mixture at all.**

Interviewer: What do you mean by that?

Gabriel: There will be less, right? **Because the denominator is the thing that is increasing, and the numerator seems to be constant at a constant state of five.** Let's say we have 6 minus 5 down here. This is the variable. We would have 5 over 1, so that would be equal to 5. If we have like, let's say like 100 down here, minus 5, that would be like 95, which is a number that's a lot smaller.

Interviewer: So, in the first calculation you did where you did 6 minus 5, …what does that 5 represent and what does the 6 represent?

Gabriel: Oh, **The five represents five gallons of liquid flavoring are poured into a vat.** It doesn't really say how many units of the mixture there is. It just kinda says total volume of mixture. **I'm assuming it's gallons so I would assume that this (6) is like how many gallons of the mixture in total there are.** How many gallons of well, like ratio of mixture there is when six gallons of the liquid is put into the mixture.

This suggests Gabriel understood that the function represents the relationship between the total volume of the mixture and the liquid flavoring. In the next excerpt, Gabriel discussed the variation of the function f in the problem context.

Excerpt 4

Interviewer: So here as the number of gallons of liquid varies from 10 to 15, how does the comparison of flavoring to water vary?

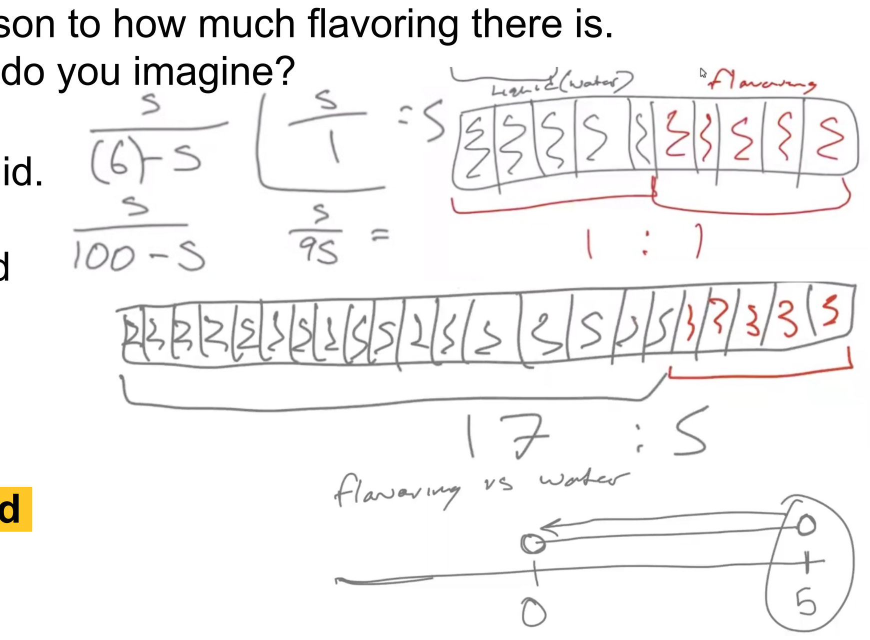
Gabriel: So it's kinda like the same thing like from over here where **the flavoring is overpowered by the amount of liquid that there is. Since the amount of flavoring isn't really changed, it remains at a constant five. If you keep on adding liquid without adding any more of the, the flavoring, then eventually there will be more liquid than the flavoring instead of having like a good, like equal ratio or a constant ratio between the two.**

Interviewer: So, what do you mean by a ratio?

Gabriel: So how much liquid(water) there is in comparison to how much flavoring there is.

Interviewer: When you say comparison and ratio what do you imagine?

Gabriel: So if there's five mixture or, or five parts of the mixture or of the flavoring, then there's five of the liquid. **So as the amount of liquid increases,** the flavoring doesn't also increase meaning that eventually instead of it being like a equal one to one, **the ratio isn't a one-to-one ratio. It's this, 17 to 5, which is what I meant earlier by the liquid overpowering the flavoring. The amount or the proper ratio of the liquid to flavoring decreases… like the more liquid that's added, the more of a smaller fraction the whole equation becomes.**



Conclusion

- This interview suggests that Gabriel’s fraction schemes include to partition a quantity into equal parts, and iterating it repeatedly based on the reference length he chooses.
  - This way of thinking appeared to support him in coordinating several units at the same time in task 1 in order to determine the angle measure Paul swept out as he skied 27miles.
- Gabriel’s language and drawings suggest he reasoned similarly while considering the ratio of flavoring to water as the number of gallons of water increased without bound. Gabriel coordinated the varying number of gallons of total volume, water, and a constant amount of liquid flavoring, while determining the relative size of flavoring to water.
- I argue that Gabriel was engaging in relative size reasoning in task 1 (static context) as well as a in task 2 (dynamic context).

Future Research

- If he continues to reason similarly in other tasks and if other students reason similarly.
- What is the role of relative size reasoning in understanding key ideas of precalculus and calculus.

How Groupwork Influences Students' Sense of Belonging in The Mathematics Classroom

Kristen Thompson, Tim Boester
University of Maine

Motivation and Background

Current STEM education research has shown that a low sense of belonging in STEM leads to lower academic achievement (Stachl & Baranger, 2020). There have been several studies that have explored how shifting to an inquiry-based learning model helps increase student understanding (Connors, 1990; Coopers et al., 2015; Studies et al., 2015), but few have gone into whether this change also leads to an increased sense of student belonging (De Corte et al., 2008).

> Belonging
> *the extent to which the undergraduate precalculus student believes that they are accepted and included as a valuable part of the of the learning community*
> adapted from (Stachl & Baranger, 2020)

The word to stress here is **value.** The idea of value is what belonging is framed as in this study; if someone can express that they add value, it gives insight into the fact that they feel they belong. Prior studies (Stachl & Baranger, 2020) have characterized belonging through perceived peer and faculty support, class comfort in sharing ideas, social connectedness, and empathy from instructors.

The goal of this study is to begin to explore the link between groupwork and a sense of belonging.

In what ways do students report an increased sense of belonging in a precalculus course with a groupwork-based learning norm?

Setting

The University of Maine Precalculus course utilizes the *Pathways to Calculus* curriculum from Arizona State University. This curriculum focuses on introducing function types through the lens of covariation: how one quantity varies with another quantity. Forgoing a traditional textbook, students complete a workbook of problems to learn key concepts in the course.

Precalculus meets five days a week for the whole semester. In Fall 2022, the three, 75-student student sections met three days per week in active learning classrooms on "lecture" days. These rooms (example at right) help to facilitate groupwork and establish it as a class norm. The other two days of class meet in smaller breakout groups (recitations) lead by teaching assistants. All class meetings also were aided by learning assistants, undergraduates who had previously taken the course.

On "lecture" days, the instructor does very little lecturing in the traditional sense. Students are tasked with working in their groups to solve the problems assigned that often allow them to produce the mathematical idea themselves. The whiteboards around the room provide a space for students to write out their work and solutions. When in the room, you can often see other groups checking their work with that produced by other groups. Most "lecture" days often have at least one cycle of the instructor introducing a problem context, students working in groups and displaying their solutions, and a subsequent whole-class discussion of the results.

Methods

Survey

A pre- and post-survey was administered to all three lectures. The survey was given to collect initial and final student opinions concerning belongingness and mathematics. It was also utilized to source students for further interviews (below). Because of low response rates in the post-survey, only pre-survey data is shown in the results (right).

Interview

Interviews (between 20 and 45 minutes) were conducted with four students to gain more insight concerning their experience in the class.

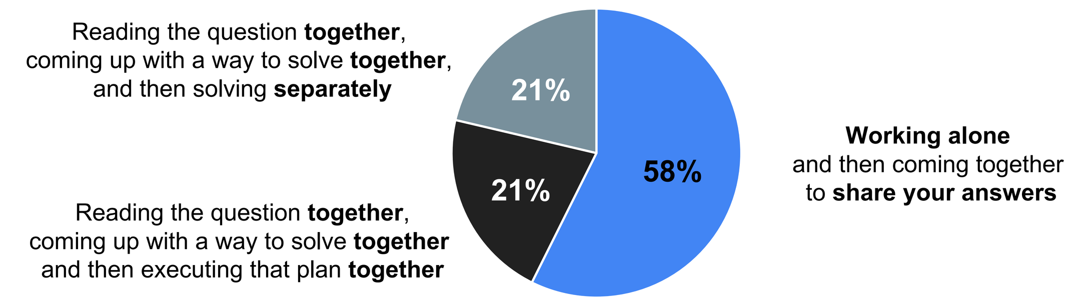
Example questions:
- What has your learning experience been in this class so far?
- What value do you feel you get out of groupwork?
- How comfortable do you feel sharing with your groupmates?
- How valuable is your input to the groupwork taking place?
- How do you feel about math and groupwork?

Demographics:
- 3 students solicited from survey responses, 1 volunteered
- 2 male, 2 female
- 1 student retaking the course
- 1 non-traditional student (outside 18–22-year-old demographic)

Results

Pre-survey results showed most students' conceptions of groupwork entailed only sharing answers. Less than a quarter of students believed groupwork meant working together during the entire problem solving process. (n = 136)

Which of the following best describes how you work on math in groups?



In the pre-survey, interviewed Students 2, 3, and 4 all expressed the view of working alone and only sharing answers. Student 1 expressed the view of preparing together and working separately. Thus the interviews showed growth in their belongingness, because all students reported working together to execute plans of action.

- All four students valued their participation in groupwork, increasing belonging.
- Students 1, 2, and 3 expressed evidence of emotional support (Student 1 example) as well as content support (Student 2 example) in increasing belonging.
- Only Student 3 expressed evidence of reinterpreting the social norms of groupwork through their own social norms as a sign of belonging.

Examples of Types of Belonging Evidence — Student Quotes and Analysis

"I like the like group dynamic and all. And it makes it a little bit **less scary** to like ask questions or give like an opinion, because you're not like sitting there in like a quiet room, with like all eyes on you. You just have the like five or six other people at your table"

"Just if someone gets it, they can explain it [to the group] in a way that the teacher hadn't. Um, so that's always **really valuable**. and then just like **emotional support in general**"

Student 1 – Evidence of Emotional Support

- Lessens the pressure of sharing out
  The norm of sharing with their individual group allows the student to feel less intimidated about discussing their own thinking.
- General emotional support
  The student can lean on their group members to get a new explanation and the moral support they need to get through the problem.

The presence of emotional support implies a sense of belonging.
Being able to emotionally lean on groupmates is evidence that they feel like they belong.

"I don't have to strain myself so hard on, what honestly is, a like simple aspect I am getting hung up on…. Uh, when I can discuss that with my group, and their like 'oh this.' I'm like 'ohhhh, okay' and then we continue on and if they hit a roadblock maybe I'm farther along then them and its that. So, its kinda like **distributed thinking**, but we are all still getting something out of it."

"Um, and there have been plenty of times where we have come to the wrong consensus and our group's…reasoning was wrong. **But we were wrong confidently together.**"

Student 2 – Evidence of Content Support, Distributed Thinking

- Remembering prior concepts and fixing errors
  Completing problems together allows the student to rely on their groupmates to help them remember the 'basic' math concepts they may have forgotten. They can utilize their group members to help them catch algebraic errors so the group can focus on new concepts.
- Distributed thinking
  Mixing of ideas allows everyone to get something out of group discussion, with each member brining something to the work.
  Talking through solutions is beneficial for everyone, no matter the math background they possess.
- Group confidence
  Groupwork gives them a sense of confidence when sharing, even if it is false confidence.

The presence of content support implies a sense of belonging.
Being able to be confident together about the mathematical content means one must feel a sense of belonging within the group.

"For like chem, where [teacher] has like the whole structured lecture set up, I think it is still slightly important, but its more important in a like, in like that detail moves the story along kind of."

"We made…a little **Snapchat group chat**. And if you are struggling with one of the questions on the homework… you can like… send a picture and its like, um, someone will usually get back to you and be like 'oh this is how I did it' [and] kinda explain it a little bit, or show what they did to do it or get it correct and stuff….. I have tried, I made group chats in like **other classes that haven't really gone as well**. Like everyone usually forgets about them and all. Like I tried making like a chem chat, like a chem group chat with some people and I think like no one has ever really used it"

"As a person with like, [mental heath issues], speaking in front of the whole class…. can make me pretty anxious… But like I'm just sitting with like 4, like really nice girls… like asking questions isn't as anxious, it takes some of the pressure and anxiety off."

Student 3 – Evidence of Reinterpreting Social Norms of Groupwork

- Comparison of groupwork norms to other courses
  This student contrasted their experience in precalculus with another course they were taking concurrently (chemistry). What they shared and how they shared impacted their learning of the material between the two courses.
- Transcending classroom social norms
  Continuing the groupwork-based norms outside of class time through the Snapchat group chat allowed the student to get or provide help anytime. This shows a reinterpretation of the classroom norms of groupwork through the students' own social norms. The student unsuccessfully attempted to carry this over to another class where there is not a groupwork-based learning norm.
- Reinterpreting social norms as emotional and content support
  The group chat provided both emotional support through the relief of anxiety, and content support through students helping each other with content.

The presence of reinterpreting classroom social norms through everyday social norms (establishing an active group chat) implies a sense of belonging.
Being able to take the class-based social norms around groupwork and reinterpret them through the students' own social norms is evidence that they feel like they belong.

"[I am] **still not very [comfortable sharing]**, I'm not the most open person most of the time, so I think like I said earlier the **layout of the room really helps** me to be a little bit more open about it"

"When I'm right, its really valuable, but I kinda said it again earlier, [only] **if I have something of value** I will share it"

Student 4 – Evidence of Value of Participation

- Importance of setting for groupwork
  Being placed at tables where students are forced to look at seatmates enabled this person to share when they felt comfortable. They embraced groupwork partly because of the room they were in. This student did not enjoy the course but was still able to get something out of it

This student did share, but only when they had something they felt was valuable.
If this student had an increased sense of belonging, they would feel comfortable sharing even when they weren't sure it was the correct answer.

Conclusions

Preliminary Results

The initial finding for the survey and four unique case studies show that, by the end of the course, they felt a sense of belonging. The students interviewed were able to talk about multiple ways they **added value to the class** or to the group they worked with. Majority of the interviewees also stressed how much groupwork was utilized to further their understanding of the course material.

Further Research

More data is currently being collected (Spring 2023), as the class is offered every semester. The initial results provide a strong case for continued data collection, as the preliminary data shows evidence of increased belongingness on the class and individual levels.
- Are there other impacts on belongingness from groupwork that have yet to be observed?
- What are the mechanisms that cause in-class groupwork norms to be reinterpreted by students into their own social norms of belongingness?
- What differentiates students for whom groupwork creates an increased sense of belongingness, and for those where groupwork doesn't increase belongingness?

Belongingness in mathematics has not been widely explored in undergraduate mathematics education, but its potential effects on success and retention deserve further study.

Challenges and Resources for Linguistically Diverse Students in Inquiry-Based Undergraduate Mathematics Curricula: The Case of Inquiry-Oriented Linear Algebra (IOLA) Tasks

Ernesto Daniel Calleros
San Diego State University & University of California San Diego

Keywords: Inquiry-Based Mathematics Education; Linear Algebra; Equity and Diversity

While there is consensus that inquiry-oriented (IO) instruction is a better alternative overall to lecturing (e.g., Laursen & Rasmussen, 2019), IO approaches may not be equitable for students from certain demographics (e.g., gender inequities in Reinholz et al., 2022). This analysis explores a question related to equity considering linguistic diversity: What linguistic challenges and resources do linguistically diverse undergraduate students experience in IOLA tasks?

Grounded in a sociocultural theory (e.g., Moschkovich, 2015), I constructed a framework that captures linguistic challenges and resources along three interrelated dimensions: (a) lexical – words and phrases in a task (e.g., Spanos et al., 1988), (b) situational – material, activity, semiotic, and sociocultural aspects of a task (e.g., Gee & Green, 1998), and (c) normative – social and sociomathematical norms engendered across tasks (e.g., Yackel et al., 2000).

The data analyzed were one-on-one semi-structured interviews (each lasting about 30-60 minutes) with 5 male linguistically diverse students from one IOLA course. The 5 students spanned a diverse range of cultural backgrounds (Korean, Vietnamese, Malaysian, Hispanic, and White) and comfort levels with English. In the interviews, each student was asked to arrange the first 12 mathematical tasks from their class from most to least challenging linguistically and to explain their ranking of each task. The tasks came from an expanded version of Wawro et al.'s (2013) IOLA curriculum. Each interview was analyzed task by task using the constant comparative method (Miles et al., 2020), allowing for both a priori codes and emergent codes.

Below are some of the main linguistic challenges and resources that students reported:

1. *Lexical:* Challenges included unfamiliar/unintended meanings of words in problem contexts, unfamiliar/unintended meanings of vector notation, and new mathematical terms; Resources included familiar words as well as translations and informal definitions of unfamiliar words and notation.
2. *Situational*: Challenges included high numbers of words and sub-questions, the exclusive use of English, the formality of definitions, symbolizing problem contexts, and algorithmatizing; Resources included low numbers of words and sub-questions, students' primary language(s), translation tools, visuals, and symbolic mathematical language that prompted specific procedures.
3. *Normative*: Challenges included violated expectations about the mathematical complexity level, a single "right" way to solve a task, and the prescription of generalized procedures.

In the presentation, further details will be provided about these findings, which suggest the need for pedagogical linguistic supports in task design and implementation that address and leverage the identified challenges and resources.

Linear Algebra Proof Constructions & Tall's Worlds of Mathematics

Kelsey Walters
Purdue University

Keywords: proofs, linear algebra, Tall's worlds of mathematics

Proof is central to mathematics, but proofs are notoriously difficult (Alcock & Weber, 2010; Britton & Henderson, 2009; Caglayan, 2018; Dorier et al., 2000; Epp, 2003; Moore, 1994; Stavrou, 2014; Weber, 2001). Generic example proofs are thought to be effective ways of developing and understanding proofs because they reveal the structure of a proof while providing the prover something concrete to focus on (Leron & Zaslavsky, 2013; Rowland, 2002). When linear algebra students need help writing a proof, they perform better on subsequent tasks if given a generic example proof rather than a formal proof (Malek & Movshovitz-Hadar, 2011). Researchers also recommend emphasizing geometry to develop students' understandings (Dogan, 2018; Ertekin et al., 2010; Hannah et al., 2013; Stewart & Thomas, 2010).

Through this study, I aim to add to the knowledge of linear algebra students' ways of thinking and working with proof constructions by examining the tools and strategies (e.g., generic examples) students use when encouraged to think about linear algebra concepts in different ways (e.g., geometrically). Tall (2013) describes mathematical thinking as occurring in three worlds. The embodied world consists of objects, graphs, diagrams, and their properties. The symbolic world contains symbols, operations, formulas, and calculations. The formal world consists of formal definitions, axioms, and proofs made up of logical deductions from axioms and definitions. My research question was: *What tools and strategies do students choose to use when working on proofs in the embodied, symbolic, or formal world of mathematics?*

To answer this, I conducted a multi-case study with four students enrolled in linear algebra: Rap, Advik, Jun, and Min (pseudonyms). In task-based interviews, I encouraged participants to use a given world of mathematics as they worked on proving or disproving a given statement. I used open coding (Corbin & Strauss, 1990; Strauss & Corbin, 1990) to detail the mathematical tools and strategies students used, and I coded the worlds of mathematics they used. To ensure that my coding was systematic and rigorous, I continually updated a master list of codes, keeping notes on the individual codes and how they were applied. I also performed member checks (Creswell & Miller, 2000; Merriam & Tisdell, 2016).

Comparing tools and strategies across constructions, some were used regardless of the world I encouraged participants to use. For example, Jun used cases and examples. Other strategies and tools were only used when I prompted participants to use a specific world. For example, Rap attempted to work directly from the hypotheses to the conclusion when creating symbolic proofs, but he worked backwards from the conclusion when using formal logic.

All participants used generic examples when asked to use the embodied world and chose other strategies when asked to use the symbolic or formal worlds (with a few exceptions). One interesting task was to prove or disprove the statement: *Let* $S = \{U_1, U_2, \ldots, U_p\}$ *be a set of two or more vectors. If* S *is linearly dependent, then there is a subset of* S *that is linearly independent and has the same span as* S*.* In their embodied generic examples, Rap and Advik began with linearly independent vectors and considered other vectors afterwards. However, their symbolic proofs began with a set of dependent vectors, and they removed vectors until they reached an independent set. This shows that one potential strength of the embodied world is to prompt students to create generic examples and to find different ways of structuring an argument.

Linear Algebra Proof Constructions & Tall's Worlds of Mathematics

Kelsey Walters

Purdue University

Introduction

Proof is central to mathematics, but proofs are notoriously difficult.[1-8] Generic example proofs are thought to be effective ways of developing and understanding proofs because they reveal the structure of a proof while providing the prover something concrete to focus on.[9-10] When linear algebra students need help writing a proof, they perform better on subsequent tasks if given a generic example proof rather than a formal proof.[11] Researchers also recommend emphasizing geometry to develop students' understandings.[12-15] Through this study, I aim to add to the knowledge of linear algebra students' ways of thinking and working with proof constructions by examining the tools and strategies (e.g., generic examples) students use when encouraged to think about linear algebra concepts in different ways (e.g., geometrically).

My research question was: **What tools and strategies do students choose to use when working on proofs in the embodied, symbolic, or formal world of mathematics?**

Methods

I conducted a multi-case study with four students enrolled in linear algebra: Rap, Advik, Jun, and Min. In task-based interviews, I asked participants to use a given world of mathematics as they worked on proving or disproving a given statement.

I used open coding[16-17] to detail the mathematical tools and strategies students used, and I coded the worlds of mathematics they used. To ensure that my coding was systematic and rigorous, I continually updated a master list of codes, keeping notes on the individual codes and how they were applied. I regularly discussed codes with a senior researcher. I also performed member checks.[18-19]

Acknowledgements

I would like to thank Rachael Kenney for her expert guidance and encouragement throughout this project.

This project would not have been possible without resources from Purdue University.

I would like to thank Rose-Hulman Institute of Technology for their financial support of my attending this conference.

Tall's Worlds

Tall describes mathematical thinking as occurring in three worlds.[20] The embodied world consists of objects, graphs, diagrams, and their properties. The symbolic world contains symbols, operations, formulas, and calculations. The formal world consists of formal definitions, axioms, and proofs made up of logical deductions from axioms and definitions. Table 1 gives examples of linear algebra concepts in the three worlds.

	Embodied World	Symbolic World	Formal World
Linear Independence		$a\begin{bmatrix}1\\0\\0\end{bmatrix}+b\begin{bmatrix}1\\1\\0\end{bmatrix}=0$ $a+b=0,\ b=0$ $a=0,\ b=0$	$c_1v_1+c_2v_2+\ldots+c_nv_n=0$ implies $c_1=c_2=\ldots=c_n=0$
Span		$c_1v_1+c_2v_2+\ldots+c_nv_n$ is in span$\{v_1,v_2,\ldots,v_n\}$	span$\{v_1,v_2,\ldots,v_n\}$ is the set of all linear combinations of $v_1,v_2,\ldots,v_n$

Table 1: Linear Algebra Concepts in the Three Worlds of Mathematics

Findings

Comparing tools and strategies across constructions, some were used regardless of the world I asked participants to use. For example, Jun used cases and examples. Other strategies and tools were only used when I prompted participants to use a specific world. For example, Rap attempted to work directly from the hypotheses to the conclusion when creating symbolic proofs, but he worked backwards from the conclusion when using formal logic.

All participants used generic examples when asked to use the embodied world and chose other strategies when asked to use the symbolic or formal worlds (with a few exceptions). In their work on the task in Table 2, Rap and Advik began with linearly independent vectors and considered other vectors afterwards when creating embodied generic examples. However, their symbolic proofs began with a set of dependent vectors, and they removed vectors until they reached an independent set. Table 2 shows parts of Rap's symbolic and embodied work.

Prove or disprove the following statement.
Let $S=\{U_1,\ U_2,\ldots,U_p\}$ be a set of two or more vectors. If S is linearly dependent, then there is a subset of S that is linearly independent and has the same span as S.

Rap's Symbolic Proof

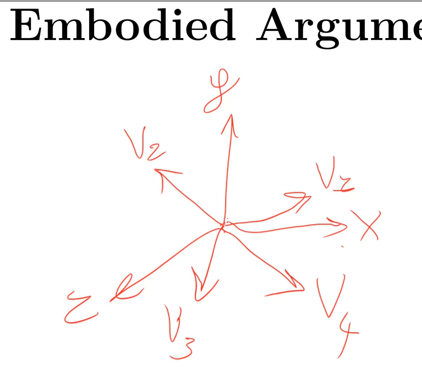
$$x_1U_1+x_2U_2\ldots x_pU_p=0$$

$$x_k\neq 0$$

$$U_k=\frac{x_1U_1\ldots+x_pU_p}{-x_k}$$

"which means that the other $n-1$ vectors is a subset of S, which may or may not be linearly independent. But it has the same span"

Rap's Embodied Argument



"you have V_1 and V_2. V_3 is, in this case, for now, it's linearly independent. Then V_1, V_2, V_3 span the entire space. $\ldots V_4$ is a part of that space."

Table 2: Portions of Rap's Symbolic and Embodied Work

Discussion & Further Research

Participants used generic examples when asked to use the embodied world, whereas other tools and strategies were used regardless of the world I asked participants to use. Further research could determine why students choose particular strategies and how educators can best support their use of various strategies across the mathematical worlds.

One potential strength of using the worlds of mathematics in the classroom is to aid students in thinking about different ways of structuring an argument. Participants also said the three-world framework was helpful for organizing their thoughts.

Through this study, I became interested in how students structure arguments when working in different worlds of mathematics. At times, Rap and Advik structured their arguments differently when reasoning in different worlds. I am interested in studying this further and, if this is a common phenomenon, finding ways to support students' use of various argument structures to develop student understanding of concepts and proofs.

Using Refutation to Address a Graphical Misconception in Calculus

Isabel A. White & Talia LaTona-Tequida
University of California, San Diego and San Diego State University

Background

Refutation

- Refutation texts have been shown to repair misconceptions held by students in science contexts.[6]
- Students have shown greater gains in multimedia learning environments when misconceptions are addressed.[5]
- Students prefer expository refutation over expository text and view refutation as more efficient.[3]
- There is less research reflecting the use of refutation in mathematics contexts and there is little, if any, research exploring refutation with the use of graphical representations.

Connecting *f* and *f'*

- Students have difficulty coordinating multiple graph features at once (e.g., how can a graph be decreasing and concave up?)[1]
- Students also struggle to interpret the derivative of a function when it is presented graphically.[4]
- Sketching the graph of *f* based on a graph of *f'* involves coordinating the properties of each and representing that graphically.

Research Questions

1. What is the effect of refutation videos and graphs on student performance?
2. Is there potential value in using refutation in a mathematics education setting?

Design & Procedure

Pilot Study

Pre-test → Expository Video n=96 → Post-test

Experiment

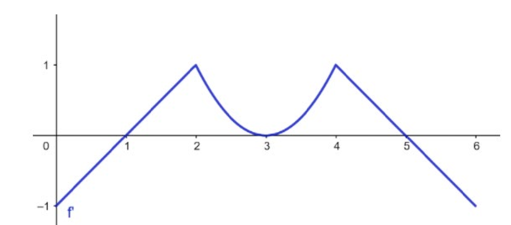
Pre-test → Refutation (Target n=50) / Expository (Target n=50) → Post-test → Spatial Reasoning Test

Materials

Pretest: 5 items
- 2 true/false
- 3 multiple choice

Example item:

The graph of f', the derivative of f, is shown to the right. Decide if the following statement is true or false:
The graph of f is increasing for 4 < x <5
a) True
b) False

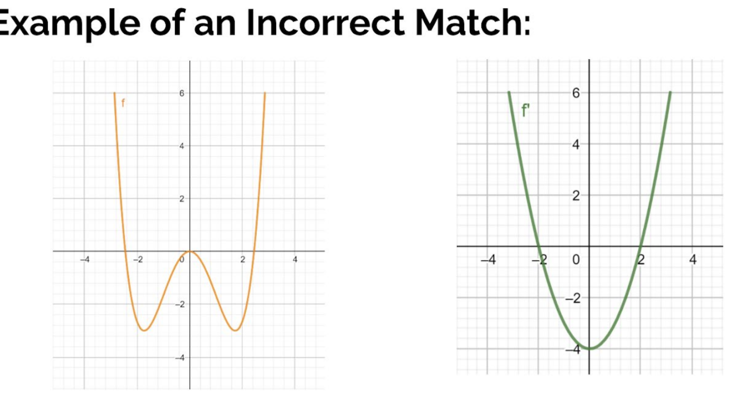


Refutation

Some students think that the behavior of ' matches the behavior of f. That is
- When f is positive, f' is positive
- When f is negative, f' is negative
- When f is 0, f' is 0

For example, students might match the following graphs of a function f and its derivative f'…

Example of an Incorrect Match:



Notice that the graph on the right matches the behavior of the graph on the left. However, the idea that the behavior f matches the behavior of f' is **not true!**

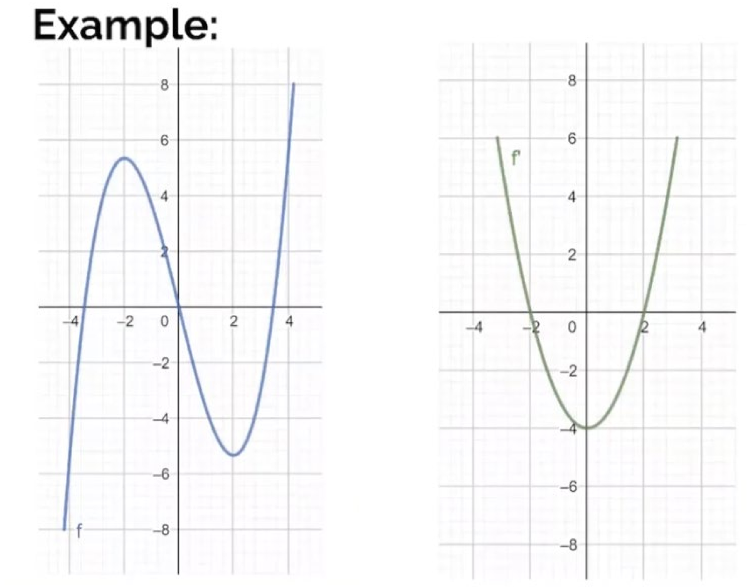
Exposition
(see right)

Exposition

Since the derivative value represents the slop of the tangent line the relationship is characterized as follows:
- When f is **increasing** the slope is positive, so f' is **positive**
- When f is **decreasing** the slope is negative, so f' is **negative**
- When f attains a maxima or minima, the slope is flat so f' is **0**

Behavior of f		Behavior of f'
$f(x)$	Is increasing	$f'(x) > 0$
$f(x)$	Is decreasing	$f'(x) < 0$
$f(x)$	Attains a local Maxima/minima	$f'(x) = 0$

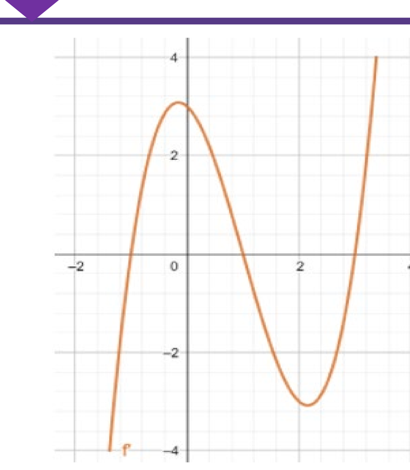
Example:



Post-test: 11 items
- 4 true/false
- 6 multiple choice
- 1 free response

Example item:

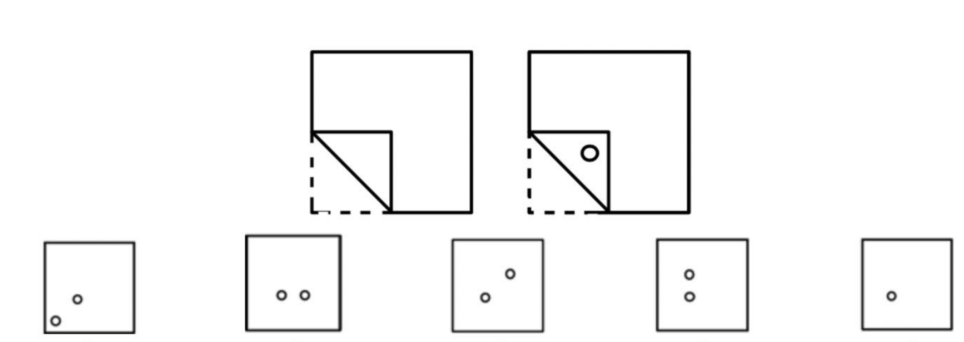
The graph of f', the derivative of f, is shown to the right. For -2<x<4 what are all the intervals in which the graph of f is increasing?
The graph of f is increasing for 4 < x <5
a) -1 < x < 1 and 3 < x ≤ 4
b) -2 < x < 0 only
c) -1 < x < 0 and 3 < x < 4
d) -2 < x < 0 and 2 < x ≤ 4
e) 3 < x ≤ 4 only



Spatial Reasoning Test:

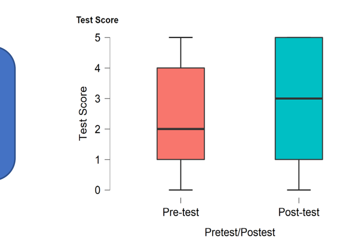
Spatial Reasoning has been shown to influence Calculus learning (Cromley et al., 2017).

Example item:



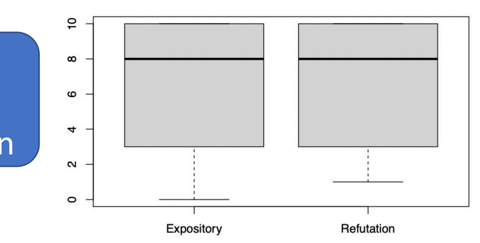
Results

Pre/Post Test Overall



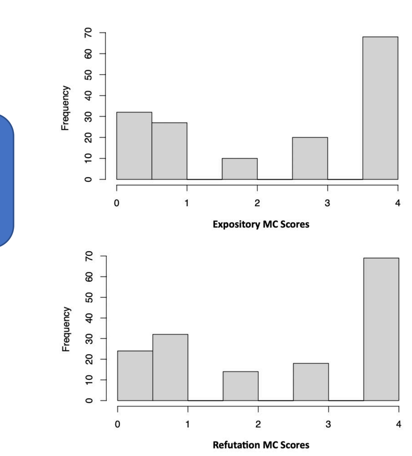
- Saw increases in learning overall

Post Test Score Comparison



- No significant differences in conditions were observed

Question Type Score Comparison



- Grouping by question type (T/F, Multiple Choice (MC)) yielded similar results

Analysis of FR Question

Expository	Refutation
39.3%	40.3%

- Same prevalence of misconception
- Differed in nature

Condition	Example
Expository	"I decided based on where the graph was decreasing"
Refutation	"From the video it stated that f and f' mirror each other"

Discussion

- Results suggest that our lessons improved learning overall
- Refutation failed to improve learning when compared to expository, and some cases reinforced the misconception
- The misconception was prevalent (40% of incorrect responses)

Implications

We interpret the results in several ways:
1) Acknowledging limitations of refutation (see Zengilowski et al., 2021)
2) Additional instructional supports are needed for building robust conceptions related to this topic
3) Using refutation in this way may reinforce existing prior conceptions about f and f'

Students' Solution Routines in a Nonstandard Problem on the Existence and Uniqueness Theorem for First Order Linear Differential Equations

Svitlana Rogovchenko
University of Agder, Norway

Yuriy Rogovchenko
University of Agder, Norway

Keywords: differential equation, existence and uniqueness theorems, conceptual understanding, commognition theory

University training of modern engineers should prepare them for the solution of applied problems, many of which are described by differential equations (DEs). Recent shift towards computer-led solution of engineering problems undermines the role of advanced mathematical thinking in the education of future engineers negatively affecting their conceptual understanding of mathematical subjects, including DEs. Teaching and learning of DEs at the university level is a relatively new area of education research. Recent empirical studies indicate that students tend to concentrate attention on specific solution techniques and "often fail to relate them to other concepts or ideas" (Camacho-Machín et al., 2012, p. 76).

We continue the research in (Rogovchenko & Rogovchenko, 2022; Rogovchenko et al., 2020; Treffert-Thomas et al., 2018) analyzing the work of students in mechatronics in their fourth year of studies on a set of non-routine problems on Existence and Uniqueness Theorems for linear DEs. For a graded assignment, we designed "tasks and projects that stimulate to ask questions, pose problems, and set goals" whereas students "must learn to inquire systematically" and "must actively construct their own knowledge" (Richards, 1991, p. 38). The data include students' written work (three scripts), answers to pre- and post-questionnaires, and transcribed audio recordings of small group discussions and class presentations.

We analyze the development of students' discourse in one of the assessment problems using the constructs of narrative and routine from the commognitive theory (Sfard, 2008). Mathematical narratives are endorsed with the help of routines. The routine is performed by a person P in a task-situation TS and consists of a pair task-procedure. The same procedure may become a basis for different types of routines, depending on the performer's vision of the task. Expert participants of mathematical discourse interpret most task-situations as requiring a (re)formulation and endorsement of a particular type of mathematical narrative. Such outcome-oriented routines can be called explorations (Lavie et al., 2018). Solution routines were coded, and students' scripts were classified. Based on the data analysis we conclude that the students were able to participate in an explorative routine and produce solution procedures depending on their vision of the task.

Students' Difficulties With the Understanding of the Concept of the General Solution to a Differential Equation: Can We Teach It Better?

Yuriy Rogovchenko
University of Agder, Norway

Svitlana Rogovchenko
University of Agder, Norway

Keywords: differential equation, general solution, conceptual understanding, textbook analysis

Differential equations find numerous real-life applications in natural and social sciences, economics. Teaching of differential equations to undergraduate students in mathematics, physics, engineering has a long history, and the content of the courses did not change much, paying attention primarily to the use of analytic techniques for finding closed form solutions. Recent advances in technology prompted changes to the syllabus of the courses in differential equations at many universities with a shift towards graphical and numerical approaches for the analysis of differential equations and understanding of the behavior of solutions, "the move away from a "cookbook" course to one that emphasizes modeling, qualitative, graphical and numerical methods of analysis" (Rasmussen & Wawro, 2017, p. 555). However, the research on teaching and learning of differential equations is scarce, "researchers are just beginning to form models of students' learning of differential equations" (Stephan & Rasmussen, 2002, p. 460).

Recent empirical research indicates that students face difficulties with the understanding of the concept of a differential equation itself and to the concepts of the general and particular solutions (Arslan, 2010; Camacho-Machín et al., 2012; Raychaudhuri, 2014). The authors analyzed tasks suggested in the literature for assessing conceptual understanding of solutions to differential equations, concluding that only one task out of five was stimulating students' reflections about the concept (Rogovchenko & Rogovchenko, 2022). Our analysis of students' work on non-routine problems that required understanding of several important theorems and notions including that of the general solution suggested that the explanation of the concept and its use in the course textbook could be one of the reasons for student difficulties.

The research question we address in the paper is: *How was the concept of the general solution introduced in the textbooks on differential equations during the last hundred and fifty years?*

What's OPDOC? A Rubric for Characterizing Online Professional Development

Kyra Gallion
University of Colorado Boulder

Tim Archie
UC Boulder

Sandra Laursen
UC Boulder

Keywords: professional development, online workshops, rubric, checklist

Professional development (PD) has the potential to improve teaching in STEM by helping educators gain knowledge and skills in research-based instructional strategies (RBIS). Instructor use of RBIS has been shown to improve student performance and support equity among students (Freeman et al., 2014; Laursen et al., 2014), and effective PD can help educators implement more RBIS in their classrooms. There has been a lot of research about what practices contribute to effective PD (e.g., Kennedy, 2016; Archie et al., 2022), but as more PD opportunities move online, new tools are needed to describe its characteristics. For instance, spontaneous group work may be quick to coordinate in person, but the same task would require a different set of tools and skills to be executed online. As a way to identify and describe some of these online characteristics, we have developed a rubric called the Online Professional Development Observation Checklist (OPDOC).

The OPDOC was created as an evaluative tool for a series of online PD workshops meant to improve the teaching of undergraduate mathematics instructors. The rubric is designed to be broad enough that it could be applied to a wide variety of online PD programs. It includes 19 items that are based on literature about effective PD practices, including strong logistics (Gaumer Erickson et al., 2017), interactivity among participants (Elliot, 2017; Gaumer Erickson et al., 2017), and support for implementation (Elliot, 2017; Ritzmann et al., 2013). The rubric also includes items that measure equity and inclusiveness, which were drawn from anti-racist rubrics (Blonder et al., 2022) to promote a supportive and collaborative PD environment.

The rubric was used in summer 2022 for both synchronous and asynchronous observation for over 156 hours of total observation of 8 different workshops on varied topics relevant to teaching college mathematics, each 24-30 hours long. There were two workshop models: an intensive model spanning 6 hours a day for 4 days, and a minicourse model spanning 3 meetings a week for 3 weeks. The content of the workshops, the facilitation teams, and the participants were also variable. The OPDOC was used to collect observations of the workshops based on four general categories: logistics, educative content, interactivity, and community-building. For each item within the categories, a numerical 3-point rating scale was used to indicate the strength of evidence for each item.

These numerical scores were then compared to survey responses from participants who attended the workshops. Results showed that the numerical distinctions among workshops were minimal in the logistics and interactivity categories, which could suggest a need for item revision or differential weighting of items. It is also possible that some of the lack of deviation in the OPDOC scores can be attributed to the training that workshop leaders attended beforehand, designed to support leaders in creating organized and interactive workshops. Additionally, as every workshop leader already had some PD experience, it is not unexpected that the workshops were highly rated on average. In future research, we hope to link workshop characteristics with instructor outcomes, so participant survey responses will be used to further identify central components of effective PD and the rubric will be refined to identify variations in greater detail for future workshop iterations.

What's OPDOC? A Rubric for Characterizing Online Professional Development

Kyra Gallion, Tim Archie, & Sandra Laursen

Need

Professional development (PD) can help STEM educators gain knowledge and skills in research-based instructional strategies. A few dimensions of effective PD include:

- Strong logistics[1]
- Interactivity among participants[2]
- Support for implementation[3]

As more PD moves online, however, new tools are needed to describe its characteristics. This rubric was developed to evaluate online PD workshops meant to improve the teaching of undergraduate mathematics instructors.

Instrument Development

The OPDOC rubric was first used in the summer of 2022 to evaluate online workshops for a PD program. The observations included:

- 8 workshops on various topics about teaching college mathematics
- Over 156 hours of synchronous and asynchronous observation
- Variable workshop content, models, facilitations teams, and participants

Observations were then compared to post-survey feedback from participants who attended the workshops. Based on these comparisons, we made the following modifications:

- Revised broad categories to emphasize implementation of new practices learned in workshops
- Included new items based on frequently stated participant feedback
- Eliminated repetitive items
- Changed Strength of Evidence from a 3-point scale to 5-point to allow for greater nuance in coding

Acknowledgements

We thank the MAA OPEN Math leadership team and all the workshop leaders and participants who shared their work and thinking. This work is supported by the National Science Foundation award DUE-2111273. The opinions, findings, and conclusions expressed here are those of the authors and do not necessarily reflect the views of the National Science Foundation.

University of Colorado Boulder

The Rubric

The Professional Development Provider:	Strength of Evidence
Logistics	
1. Follows a schedule that is comfortably paced and honors breaks	None (1)
2. Uses technology that is clear and accessible to participants	None (1)
3. Organizes information so that participants can easily find agendas, links, resources, etc.	None (1)
Content	
4. Provides activities that are relevant to the workshop content, well-paced, and worthy of participant time and conversation	None (1)
5. Describes learning activities clearly and their function within the workshop	None (1)
6. Includes the empirical research foundation of the content (e.g., citations, verbal references to research literature, key researchers)	None (1)
7. Provides information about effective teaching practices within the context of the topic	None (1)
8. Provides information about inclusive and equitable teaching practices within the context of the topic	None (1)
Interactions	
9. Incorporates opportunities for participants to interact with each other related to training content	None (1)
10. Provides guidance during activities to ensure all participants understand the task and are being treated equitably	None (1)
11. Invites participants to express personal perspectives (e.g., experiences, thoughts on concept)	None (1)
12. Includes opportunities for participants to safely ask questions and communicate their needs to facilitators	None (1)
13. Fosters an environment of community, rapport, and openness among the participants	None (1)
Implementation	
14. Provides examples of the content/practice in use (e.g., case study, vignette)	None (1)
15. Connects the topic to participants' context (e.g., course, department, institution) and addresses potential barriers to implementation	None (1)
16.Conveys an expectation that participants are to implement workshop lessons or material into their own contexts	None (1)
17.Includes opportunities for participants to consider and/or practice implementation within their own contexts	None (1)
18.Offers continued support after the workshop (e.g. resources, check-ins, communities of practice)	None (1)

Qualitative Survey Responses

"Frequent breakout rooms and breaks helped to make the long days work well."

"I was *slaughtered* mentally and physically most days... could use longer breaks [...]"

"The workshop descriptions doesn't seem to match the actual workshop."

"The organizers did an excellent job of teaching how to do active learning by explicitly using active learning techniques."

"I loved the interactivity and random group work to meet colleagues and hear fresh ideas."

"As a group we unfortunately fell into the habit of not responding to open prompts for volunteering comments. We needed to be prodded a little more [...]"

"Giving us practical examples we can take directly to the classroom was wonderful."

"I think it would be helpful to maintain an online space for those of us in this workshop so we could share our experiences with implementing our tasks in the future."

"The workshop gave me a wealth of resources I can consult if I need help and a network of colleagues that I can reach out to!"

Quantitative Survey Responses

A comparison of post-survey responses from participants in two example workshops that ranked high and low within the initial sample of eight. The contrasts between the scores suggest participants are perceptive about differences in workshop design and facilitation that reflect elements we seek to document in OPDOC.

Conclusions and Future Work

Based on the data collected at summer 2022 workshops, feedback has already been given to the upcoming summer 2023 workshop teams to emphasize participants' needs for:

- Longer breaks
- More implementation strategies
- Follow-up support

The revised OPDOC will be used for workshops planned for summer 2023 and will be further revised as new observations and survey data are collected. Our intention is to develop a rubric that captures qualitative information to describe workshop features and that also provides quantitative scores, which together can predict or explain short-term outcomes (satisfaction, learning) and long-term outcomes (implementation of new practices).

Developing and Supporting Underrepresented Prospective Teachers' Pedagogical Content Knowledge for Teaching Diverse Students in High Needs Schools

Yaomingxin Lu
California State University, Fresno

Rajee Amarasinghe
California State University, Fresno

Sarah Hough
University of California, Santa Barbara

Keywords: Teacher Education, Professional Development, Pedagogical Content Knowledge

Having an experienced, well-prepared teacher makes a difference to student outcomes (Cardichon, et al., 2020) and retaining teachers in high-needs schools is even more challenging. In particular, teachers of students in high needs schools need to transform content knowledge into a form appropriate for the diverse interests and abilities of students by drawing on culturally and linguistically appropriate instructional strategies and by building supportive and productive classroom practices. We operationalize components of Pedagogical Content Knowledge (PCK) (Shulman, 1987,1986) and Pedagogical Ways of Knowing (Cochran, et al, 1993) using the coding framework proposed by Meir et. al (2020) which draws from the mathematical practices (National Governors Association, 2010) and sets of instructional strategies for supporting students' mathematical literacy. The purpose is to understand in particular, how participants develop and utilize PCK that speaks to teaching diverse students in high needs schools.

A mixed methods sequential case study design (Creswell & Plano Clarke, 2018) was used, and participants are five Noyce scholars who have graduated from the program and transitioned to teaching in high-needs schools. We use longitudinal evaluation data collected from these participants during their sophomore and senior years in the integrated mathematics credential program as sources, in particular beginning teacher assessment data (TAD), open-ended interview transcripts and responses to closed and open-ended questionnaires.

Our result shows that participant average scores on the Beginning Teacher Assessment were higher than campus averages and that the Noyce mentoring program increases retention of integrated mathematics credential students in the major. In addition, thematic analysis of their TAD lessons and interviews evidenced the ways in which Noyce activities supported them as they integrated understanding of student characteristics and learning context, of mathematics specific pedagogy with their strong mathematical knowledge acquired in the Integrated Mathematics Credential Program. While an integrated Math Credential program is well positioned to foster in prospective teachers' connections between subject matter expertise and pedagogical competence our results suggest that the additional opportunities offered in the Noyce mentoring program are critical in order to develop the types of pedagogical content knowledge necessary to teach in high-needs schools.

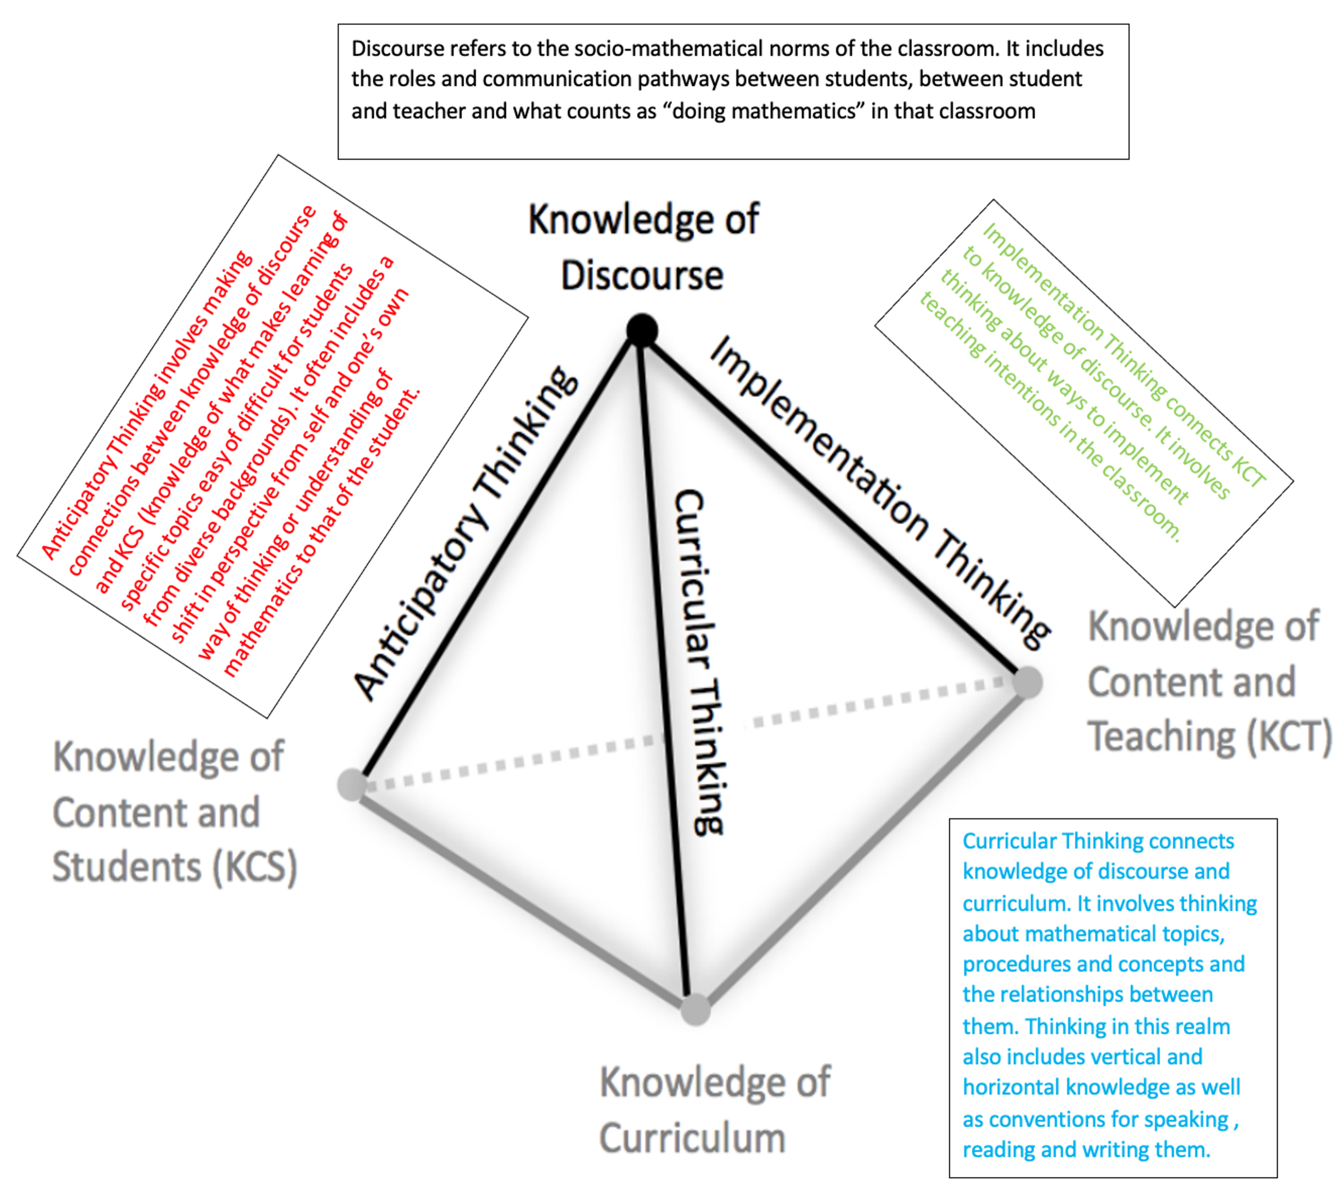
Developing and Supporting Underrepresented Prospective Teachers' Pedagogical Content Knowledge for Teaching Diverse Students in High Needs Schools

Yao Lu, Rajee Amarasinghe, Sarah Hough
California State University, Fresno

Introduction

Having an experienced, well-prepared teacher makes a difference to student outcomes (Cardichon, et al., 2020) and retaining teachers in high-needs schools is even more challenging. In particular, teachers of students in high needs schools need to transform content knowledge into a form appropriate for the diverse interests and abilities of students by drawing on culturally and linguistically appropriate instructional strategies and by building supportive and productive classroom practices. This study, set in the context of a Noyce-funded mentoring program where participants are underrepresented and talented integrated mathematics credential majors, addresses how prospective teachers can be concurrently supported in a rigorous mathematics program as they develop the deep pedagogical knowing so necessary for teaching students in high needs settings.

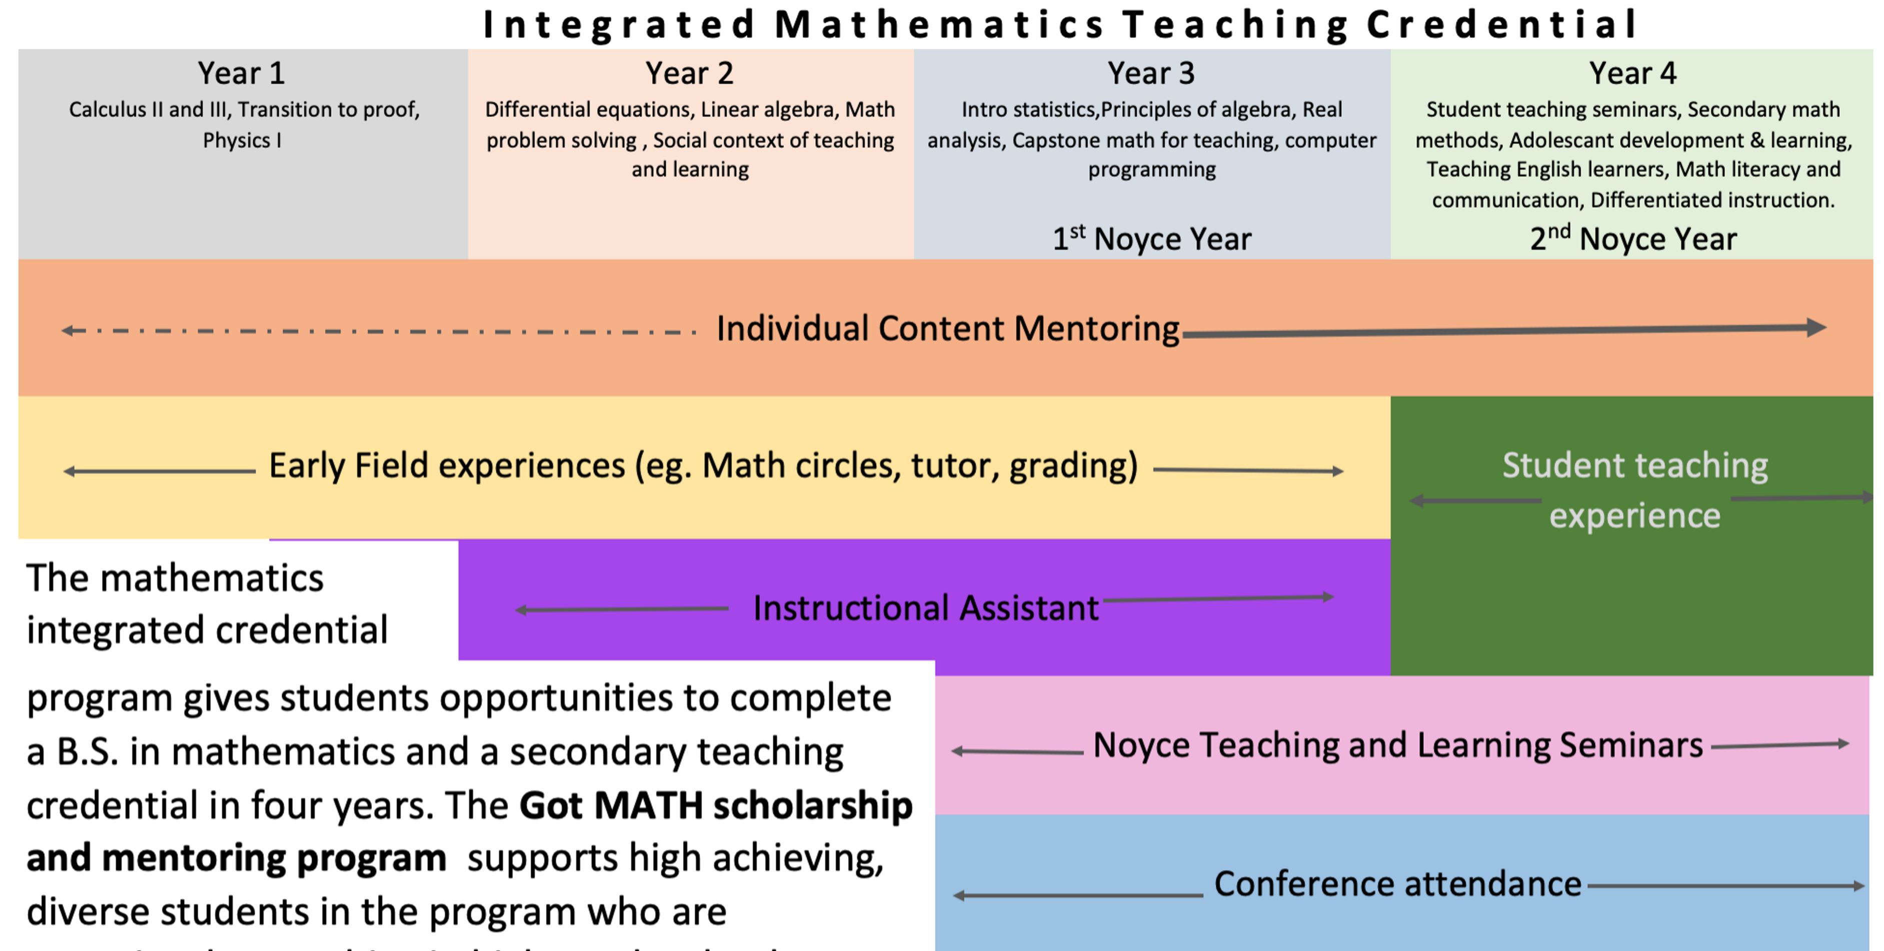
Framework for Pedagogical Content knowledge



Methods

A mixed methods sequential case study design (Creswell & Plano Clarke, 2018) was used. Participants are five Noyce scholars who have graduated from the program and transitioned to teaching in high-needs schools. We use: Longitudinal evaluation data collected during sophomore and senior years in the GotMATH program sources:

- Beginning teacher assessment data (TAD)
- Open-ended interview transcripts
- Responses to closed and open-ended questionnaires
- Reflections from teaching and learning seminars.



The mathematics integrated credential program gives students opportunities to complete a B.S. in mathematics and a secondary teaching credential in four years. The **Got MATH scholarship and mentoring program** supports high achieving, diverse students in the program who are committed to teaching in high needs schools.

GotMATH provides individual and group content mentoring. Early field experiences allow mathematical and pedagogical knowledge to develop simulataneously and Noyce Teaching and Learning seminars given by university and school based mathematics educators model math specific PCK appropriate for underrepresented students in high needs schools.

Category	Code	Example of instance	Lorry	Jacob	Nathan	Bella	Nadine
Creating a meaningful context for instruction	KCS	Using a jeopardy game context for math exam review.	x	x			
	KCT	Group work with small white boards/game format.	x	x	x	x	x
Helping students produce discourse	Anticipatory Thinking	Asking questions to promote focus on math problem solving, strategies and argument.	x	x	x	x	x
	Implementation thinking Using sentence frames and/or sentence starters to support mathematical oral and written discourse.	Student answers to strategic questions were scaffolded with sentence frames to help them justify their reasoning about a problem.	x	x	x	x	x
	Implementation thinking Using word walls	Teacher creates written strategy bank as they are discussed in groups (for later use)			x	x	
	Anticipatory Thinking Using multiple modes for language (speaking, listening, reading, writing)	White boards/notebooks/ posters/exit tickets verbally expressing solutions to near peers and whole group/using visual aids	x		x	x	x
Making input comprehensible	Implementation thinking	Vocabulary and/or syntax support		x	x	x	x
		Implementation thinking Using visuals, drawings, gestures, or realia		x	x		x
Organizing instruction	Anticipatory thinking Strategically placing students in small groups based on needs	Group members are given responsibilities for ensuring all students understand how to solve the equations, so students with stronger understanding are instructed how to give helpful hints and explain their thinking.	x	x		x	x
	Anticipatory thinking	Monitoring student work during small group work to select groups to present.	x			x	
	Socio mathematical norm	Students self-select level of difficulty of problem type and progress upward.		x	x	x	x
	KCS	Working in teacher led small groups for extra instruction			x	x	x

Table 1. Mathematical Literacy Strategies to Engage in Mathematics Discourse Used by Noyce Beginning Teachers.

Results and Discussion

Participant average scores on the Beginning Teacher Assessment were higher than campus averages and our analysis of their TAD evidenced the ways that participants used anticipatory and implementation thinking as they drew from their strong mathematical backgrounds with and understanding of students and teachings to provide opportunities for their students to participate in mathematical discourse. In particular students in scholar classrooms were given opportunities to construct viable arguments and critique the arguments of others (MP3), use appropriate tools strategically (MP5), make sense of problems and persevere in solving them (MP1), look for and make use of structure (MP7) and/or make use of repeated reasoning (MP8) while learning important content standards.

Themes from our stage II analyses show that students in the mentoring program:

1. Valued multiple opportunities during Noyce seminars to experience and reflect on practices and strategies learned during credential courses within the specific context of teaching mathematics.
2. Learned about pedagogical issues specific to students living in poverty from experienced teachers working in local high-needs schools through the Noyce seminars.
3. Gained knowledge of students and content as well as knowledge of content and pedagogy from concurrent opportunities to work as instructional assistants on campus and tutors in elementary settings while themselves learning higher level mathematics content in major coursework (offered through Noyce)

Conclusions

Our result shows that participant average scores on the Beginning Teacher Assessment were higher than campus averages and that the Noyce mentoring program increases retention of integrated mathematics credential students in the major.

- In addition, thematic analysis of their TAD lessons and interviews evidenced the ways in which Noyce activities supported them as they integrated understanding of student characteristics and learning context, of mathematics specific pedagogy with their strong mathematical knowledge acquired in the Integrated Mathematics Credential Program.

While an integrated Math Credential program is well positioned to foster in prospective teachers' connections between subject matter expertise and pedagogical competence our results suggest that the additional opportunities offered in the Noyce mentoring program are critical in order to develop the types of pedagogical content knowledge necessary to teach in high-needs schools.

Designing Activities to Support Preservice Teachers' in Promoting Generalizations

Kayla Heacock
Ohio University

Keywords: algebra and algebraic thinking

The practice of generalizing, identifying a relationship to describe multiple examples or instances of a phenomenon, engages students in algebraic thinking and allows them to identify, investigate, and represent relationships (Blanton et al., 2011; Kieran et al., 2016). Generalizing is fundamental to learning mathematics (Carraher & Schliemann, 2002; Kaput, 1999), yet students often have trouble developing (Lannin, 2005) and justifying generalizations (Breiteig & Grevholm, 2006). To first build their understanding of generalizing as a mathematical practice, we introduced a cohort of preservice secondary teachers (PSTs) to two frameworks for generalizing and asked them to use these frameworks to analyze others' teaching. Then we designed a teaching activity embedded in their methods course to help them promote generalizing among their grades 7-12 students. Ellis's (2011) generalizing promoting actions (GPAs) are teacher actions that foster the development or refinement of a generalization. Strachota's (2020) priming actions (PAs) usually precede GPAs and set the stage for more explicit attention to generalizing and prepare students to build on an idea.

We provided an outline for a lesson focused on generalizing and asked three PSTs to customize the lesson for a high school audience and to plan questions to elicit student generalizations. All PSTs used a pattern task, a visual representation of a series of objects where the number of objects changes based on a rule, as the focus of their lesson. The goal of a pattern task is to use the structure of the presented images (e.g., objects organized in arrays) to develop multiple ways of representing the rule. We chose pattern task as the focus for the potential of the tasks to promote generalizing because we believed it served as an accessible entry point for our novice PSTs.

We video-recorded each PST's teaching and asked them to watch their video and analyze the effectiveness of their practice. We coded video data for GPAs (Ellis, 2011), PAs (Strachota, 2020), and student generalizations to identify teacher actions that promoted and hindered students in generalizing. Through our analysis, we sought to understand the patterns of generalizing actions that supported students in articulating the generalizations and determine how teacher educators can support PSTs in promoting student-created generalizations.

Patterns of interactions that promoted generalizing included using multiple GPAs in a short span of time and following student-created generalizations with a new GPA to prompt them to expand or deepen their contribution. Additionally, using PAs and GPAs together helped support students in generalizing more so than using GPAs alone. The PA of naming a critical tool proved especially useful when students invented and described their own strategies. Patterns of interaction that hindered students in generalizing included using GPAs when the actions were centered on a teacher strategy instead of a student strategy or when the teacher was not able to use repeated GPAs in a series. There was not a one-to-one link between GPAs or PAs and students' generalizations, which demonstrates the complexity of generalizing. Enacting the pattern task revealed much about the shortcomings and strengths of teachers' understandings of generalizations; future research will explore how to better support preservice teachers in promoting generalizing.

Designing Activities to Support Preservice Teachers in Promoting Generalizations

Kayla Heacock
Ohio University
kh426613@ohio.edu

OHIO UNIVERSITY

BACKGROUND

- *Generalizing*: identifying a relationship to describe multiple examples or instances of a phenomenon
- Engages students in algebraic thinking and allows them to identify, investigate, and represent relationships (Kieran et al., 2016)
- Generalizing is fundamental to mathematics (Carraher & Schliemann, 2002)
- Students have trouble developing (Lannin, 2005) and justifying generalizations (Breiteig & Grevholm, 2006)

METHODS

Participants: 3 teaching fellows in one-year master's program

Learning about Generalizing: Fellows completed pattern tasks as learners and analyzed teaching videos for promoting generalizing

Data Collection: Implement pattern task activity in field placement

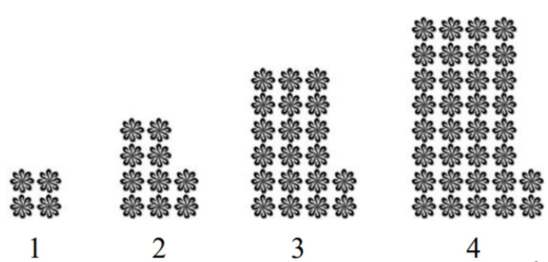
- Choose pattern task & solve in many ways
- Plan for questioning to elicit generalizations using five practices approach (Stein and Smith, 2011)

Data Analysis: Video data analyzed in 15-second segments for generalizing promoting actions and student contributions

RESEARCH QUESTIONS

1. What patterns of generalizing actions best supported students in articulating generalizations?
2. How can teacher educators support preservice teachers in promoting student-created generalizations?

SAMPLE PATTERN TASK



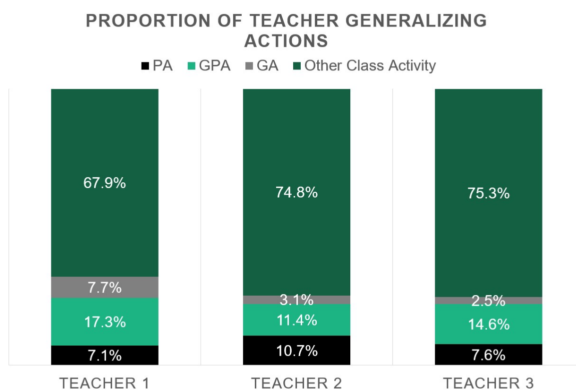
Nguyen, (2020)

FRAMEWORK

Priming Actions (PAs)[1]	
Naming a phenomenon, clarifying critical terms and tools	"Offering a common way to reference a phenomenon or emphasizing the meaning of a critical term or tool."
Constructing or encouraging constructing searchable and relatable situations	"Creating or identifying situations or objects that can be used for searching or relating. Situations that can be used for searching or relating involve particular instances or objects that students can identify as similar."
Constructing extendable situations	"Identifying situations or objects that can be used for extending. Extending involves applying a phenomenon to a larger range of cases than from which it originated."
Generalizing Promoting Actions (GPAs)[2]	
Encouraging Relating and Searching	"Prompting the formation of an association between two or more entities; prompting the search for a pattern or stable relationship."
Encouraging Extending	"Prompting the expansion beyond the case at hand."
Encouraging Reflection	"Prompting the creation of a verbal or algebraic description of a pattern, rule, or phenomenon."
Encouraging Justification	"Encouraging a student to reflect more deeply on a generalization or an idea by requesting an explanation or a justification. Includes asking students to clarify a generalization, describe its origins, or explain why it makes sense."

[1]Categories and descriptions from Strachota (2020, p. 7).
[2]Categories and descriptions from Ellis (2011, p. 316). Adapted encouraging relating and searching, following Strachota (2020), by combining these into one category.

RESULTS & DISCUSSION



Conditions that Supported Students' Generalizing:

- Teacher used multiple GPAs in short amount of time
- Teacher followed student generalizations with GPA
- Teacher used PA and GPA together to elicit and make public student thinking and connect it to multiple representations

Conditions that Hindered Students' Generalizing:

- GPA centered around a teacher strategy, not a student strategy
- Pattern task not at appropriate level for students

Other Findings

- Generalizing is complex
- There is not a one-to-one link between GPA, PA, and student-created generalizations

FUTURE RESEARCH

- Examine influence of teacher questioning on GPA and student-created generalizations
- Examine quality of PSTs' reflections on pattern tasks
- Track use of generalizing promoting actions across student teaching year

The Implications of Perspectives on MKT for the Examination of Teacher Noticing

Erin Wood
University of Georgia

Keywords: Mathematical Knowledge for Teaching, Teacher Education, Decentering

Mathematical knowledge for teaching (MKT) has been widely used in mathematics education research, with many researchers developing varying definitions. The categorization of MKT developed by Ball et al. (2008) has been influential in the study of teachers' mathematical knowledge. Their framework differentiates between pedagogical content knowledge and subject matter knowledge, and breaks these categories into subcategories that describe what the knowledge is of. While this categorization is helpful for characterizing the existence of knowledge it does not provide a mechanism for its development. The framework for MKT introduced by Silverman and Thompson (2008) does not categorize knowledge, but it does propose a potential mechanism for the development of MKT. The framework posits that MKT first begins with a personal understanding of a concept and then can be transformed into knowledge with pedagogical power via decentering. To transform their knowledge, a teacher must imagine how students might understand the content, and how students might be supported in developing an understanding consistent with that of the teacher.

While the use of student thinking in teaching has been examined in multiple ways, one particularly influential construct is professional noticing as defined by Jacobs and colleagues' (2010). They defined noticing to consist of attending to strategies, interpreting student understanding, and deciding how to respond on the basis of these understandings. A related idea is using decentering as a lens to analyze classroom practice (Bas-Ader & Carlson, 2021). When a teacher decenters they intentionally put aside their mathematical perspective and attempt to adopt the perspective of a student. They develop a mental model of their student's mathematics which informs their response to their student's thinking (Bas-Ader & Carlson, 2021).

Supporting graduate student instructors and new faculty in developing MKT and using student thinking is an important aspect of designing professional development programs. This poster will explore the affordances and constraints of using combinations of MKT frameworks and frameworks for the use of student thinking to study the relationship between MKT and teachers' use of student thinking. Using Ball, Hill, and colleagues' characterization of MKT could allow one to study relationships between teachers' knowledge in particular domains and their use of student thinking. One could map knowledge used when interpreting and responding to student thinking to domains of knowledge within the framework to understand how different domains support teachers in using student thinking. A teacher might draw on Knowledge of Content and Students to recognize a student understanding, and Knowledge of Content and Teaching to decide how to move that understanding forward. The use of Silverman and Thompson's framework aligns well with the use of decentering as a lens to examine teachers' use of student thinking. A teacher decenters to develop MKT, which supports them in decentering in the classroom. If a teacher has constructed ways that a student might understand an idea, they might assimilate a student's thinking to one of these ways. If a teacher encounters student thinking for which they do not have a viable pre-constructed model, they develop MKT as they decenter to build a model of their student's understanding. Thus, development of MKT and attention to student thinking can be seen as a reciprocal process, in which MKT supports teachers in making use of student thinking, and attending to student thinking can develop MKT.

Affordances and Challenges Associated with Euler Diagrams as Representations of Logical Implications

Joseph Antonides
Virginia Tech

Anderson Norton
Virginia Tech

Rachel Arnold
Virginia Tech

Keywords: Euler diagrams, logical implication, proof, spatial representations

Research in mathematics education has begun to capture students' epistemic experiences with logic and proof in general, and with logical implications in particular (e.g., Antonini, 2004; Dawkins, 2017; Durand-Guerrier, 2003; Durand-Guerrier et al., 2012; Epp, 2003; Roh & Lee, 2018; Stylianides et al., 2004; Yopp, 2017). However, much is still unknown about how instruction can support student reasoning and learning about logical implication. Some researchers have explored the use of Euler diagrams for representing relations between sets and, in particular, truth sets of open statements (e.g., Bronkorst et al., 2021; Dawkins & Roh, 2022; Hub & Dawkins, 2018). In our ongoing research (the Proofs Project), we use Euler diagrams in introduction-to-proofs courses as one way to represent logical implications and their transformations. We have been conducting clinical interviews with students in which we investigate their conceptual mappings between logical implications and Euler diagrams. We share preliminary findings from our initial analyses of interview data to address the following question: *What affordances and challenges do Euler diagrams present as visual-spatial representations of logical statements?*

One affordance of Euler diagrams comes from their spatial nature: they provide a means to *visualize* relationships between two truth sets. One student (Carmen) explained, "I think with the if-then statements, it helps me to think of the Euler diagrams… and thinking of a circle within a circle." Another student (Kai) commented that, while he preferred to use symbolic logic over Euler diagrams, especially for representing more complex statements, he added, "Otherwise, I think [an Euler diagram] shows relationships very clearly if you have the initial setup correct."

The spatial nature of Euler diagrams also presents particular challenges for students. For instance, ideally, the statement $P \rightarrow Q$ is mapped to an Euler diagram in which the truth set of P is a subset of the truth set of Q. Some students in our study represented this implication with P as a *superset* of Q. As Carmen explained, "The P engulfs the entire space of Q, so that if I have the statement P, then I'm definitely going to have the statement Q." Additionally, for contrapositive statements (e.g., $\sim Q \rightarrow \sim P$), visualizing the truth set of $\sim Q$ as a subset of $\sim P$ in a 2D Euler diagram in which the truth sets of P and Q are depicted first may be difficult as it requires first visualizing the complements of the truth sets for P and Q as closed regions in 2D Euclidean space. Furthermore, the containment of $\sim Q$ within $\sim P$ may be obscured for students because the resulting depiction of $\sim Q \rightarrow \sim P$ is not homeomorphic to the original. We note that, ideally, Euler diagrams for two logically equivalent statements would be homeomorphic to each other. Because these spaces *are* homeomorphic when visualized on a sphere (rather than 2D Euclidean space), we discuss potential affordances and challenges of such a representation, and how Peircian diagrams on a sphere may provide alternative spatial representations (cf. Pietarinen, 2016).

Affordances and Challenges Associated with Euler Diagrams as Representations of Logical Implications

Joseph Antonides
jantonides@vt.edu

Anderson Norton
norton3@vt.edu

Rachel Arnold
rachel.arnold@vt.edu

Purpose & Motivation

Goals of the Proofs Project

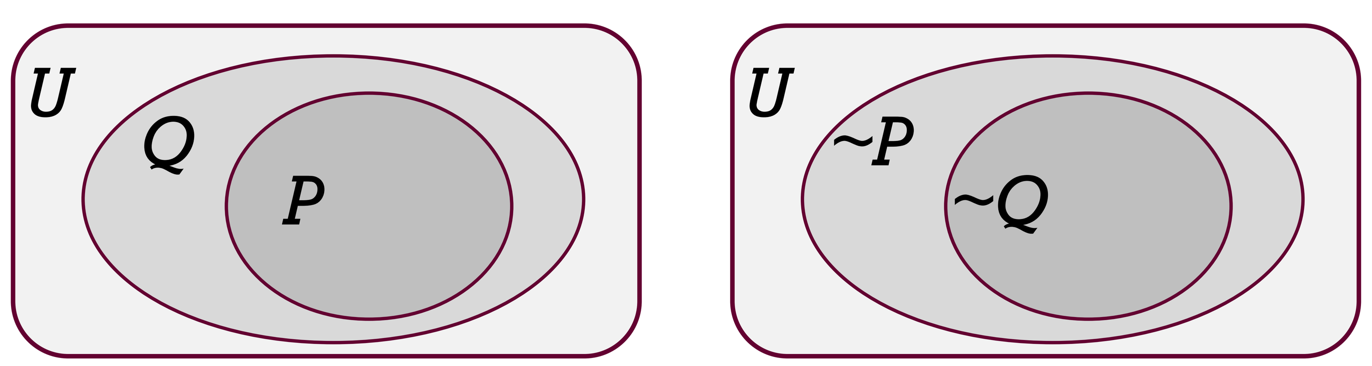
- Identify and address students' epistemological obstacles in introductory proofs courses
- Support teachers by suggesting instructional interactions that may provide students with opportunities to identify, reflect on, and overcome these obstacles

Research Questions Regarding Euler Diagrams

- How do students interpret, construct, and make sense of Euler diagrams as representations of logical implications?
- What epistemological affordances and challenges may be associated with this mode of representation?

What are Euler Diagrams?

- Visual-spatial representations showing relationships between sets
- Statement $p \to q$ represented as $P \subseteq Q$, where P and Q are the truth sets of statements p and q, respectively
- U represents the universal set, or the domain of objects under consideration



(a) (b)

Figure 1: Euler diagram representations of (a) $p \to q$ and (b) $\sim q \to \sim p$

Why Euler Diagrams?

- Hub and Dawkins (2018) suggest students can abstract the logic of conditionals by populating sets with familiar mathematical objects.
- Conditionals describe a relationship between properties. If students populate sets with those properties, they can represent the relationship spatially, as a relationship between sets.
- Dawkins and Roh (2021) have employed this instructional approach, relying heavily on the use of Euler diagrams, within their own research project.

Methods

- Classroom data from an introductory proofs course, taught in the Fall 2022 semester
- Three clinical interviews with each of four students in the course: (1) Logical Implication, (2) Quantification, and (3) Mathematical Induction and Stimulated Recall

Affordances

Visual Representation of an Abstract Relationship

- **Carmen:** "I think with the if-then statements, it helps me to think of the Euler diagram... and thinking of a circle within a circle."
- **Kai:** Stated that he prefers symbolic representations, but also said, "I think [an Euler diagram] shows relationships very clearly if you have the initial setup correct."
- Allows students to offload cognitive demands of maintaining relationships between logical structures by establishing a spatial representation

Visual Facilitation of Transformations

- Provide students with a visual aid in interpreting transformations of logical implications (e.g., negation)

Challenges

Different Interpretation of Subset Relation

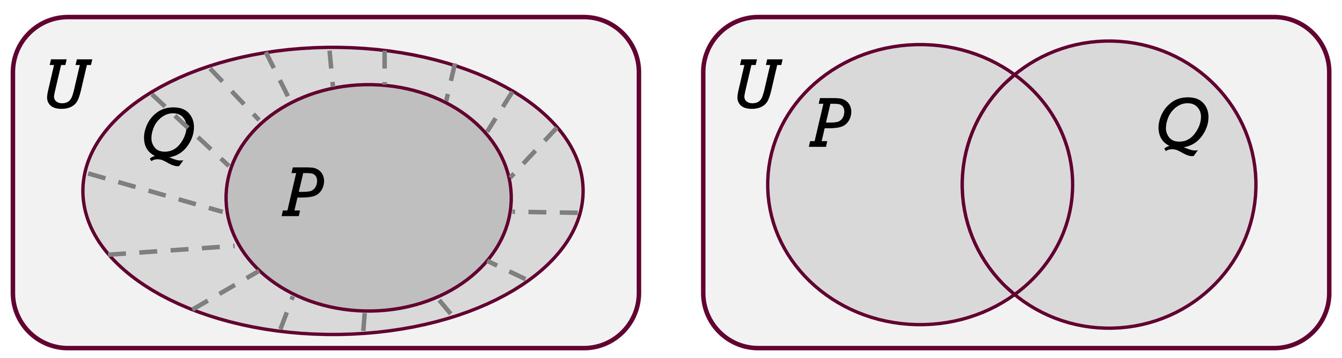
- **Carmen:** "So, if p, then q. The P engulfs the entire space of Q so that if I have the statement p, then I'm definitely going to have the statement q."
- Some students interpreted the containment of P in Q as suggesting that, if you have the space P (or statement p), then you have the space Q (or statement q)
- As **Kai** noted in excerpt above, Euler diagrams can be useful, but they require
  - structuring spatial representations of logical information in a meaningful way, along with
  - shared understanding of what set containment within an Euler diagram represents

Size Matters Not

- Qualitative nature of Euler diagrams may hide quantification from students
- Canonically, the size of a space within an Euler diagram is not an indicator of the cardinality of the set that it represents
- A circle may be used to represent a singleton set, whereas another circle (perhaps smaller than the original) could be used to represent an infinite collection

Empty or Not Empty?

- Generally, the existence of a closed space in an Euler diagram implies the space represents a non-empty set
- Not always the case: in the Euler diagram for $p \to q$, the space $Q - P$ may be empty if $q \to p$ also holds (see Fig. 2a), or the space P may be empty (vacuous case)
- By contrast, in the Euler diagram shown in Fig. 2b, $P \cap Q$ is presumed to be non-empty



(a) (b)

Figure 2: (a) $Q - P$ may be empty, but (b) $P \cap Q$ is assumed to be non-empty

Representing the Contrapositive

- Euler diagram for $p \to q$ not topologically equivalent to Euler diagram for $\sim q \to \sim p$ (compare Fig. 1a and Fig. 1b)
- One potential remedy: construct and transform Euler diagrams on a sphere (see Fig. 3)
- Starting with $P \subseteq Q$, dilate P and Q, reaching to the back side of the sphere, until only a small region not contained in Q is remaining, then invert relationship to show $\sim Q \subseteq \sim P$
- Unclear what additional obstacles this may introduce

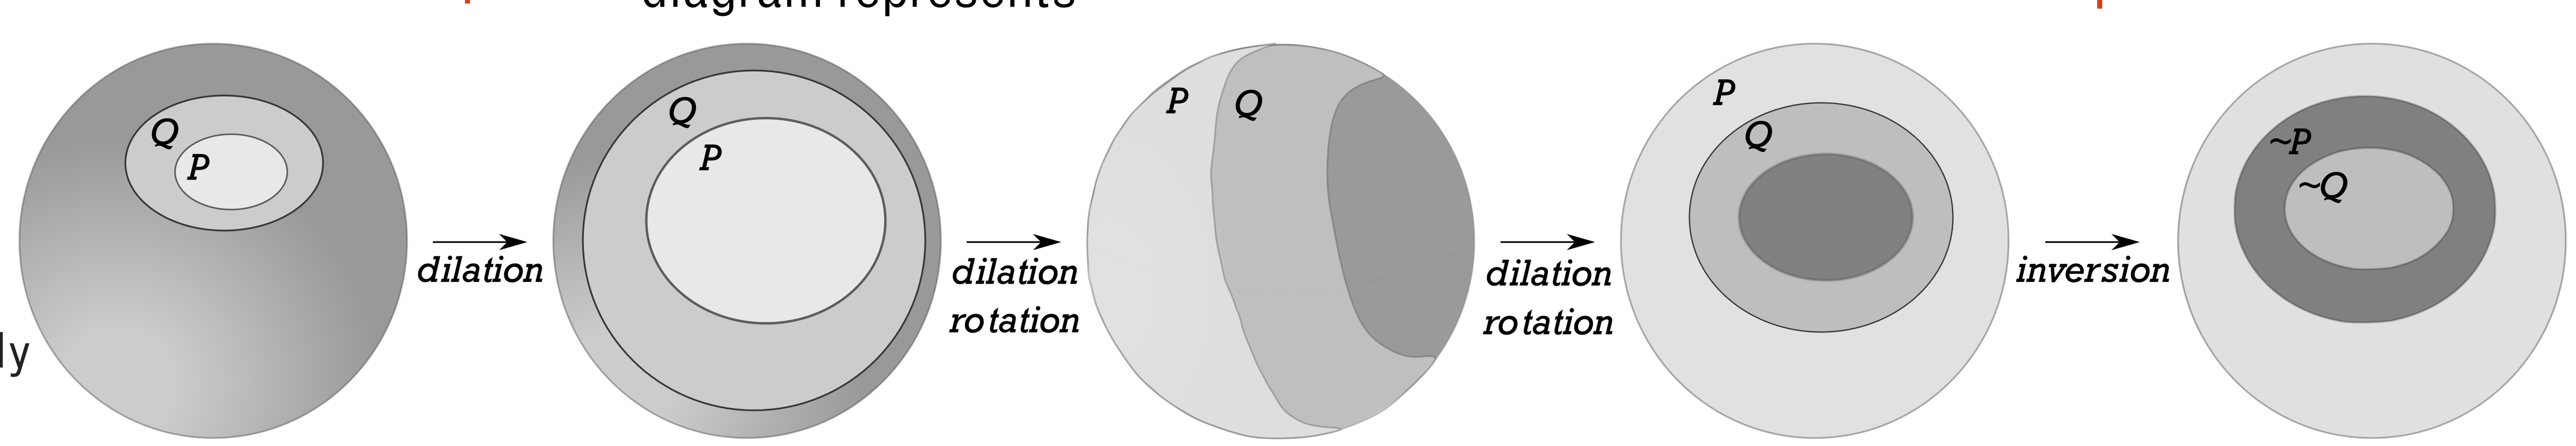


Figure 3: Transforming Euler diagram for $p \to q$ on a sphere to show equivalence to its contrapositive

Metacognition in Proof Construction: Connecting and Extending a Problem-Solving Framework

Sarah Sparks
University of Northern Colorado

Gulden Karakok
University of Northern Colorado

Keywords: Metacognition, Problem Solving, Proof

Mathematical proofs are an integral component of undergraduate mathematics education. Providing students opportunities to develop the necessary writing technique, and deductive reasoning skills to communicate mathematical ideas via proof is a central goal of undergraduate mathematics programs (Committee on the Undergraduate Programs in Mathematics [CUPM], 2015). For undergraduate students, developing these skills and utilizing them appropriately can be an arduous feat and has implications for their success in a mathematics course or program (Alcock & Simpson, 2002). Due to the difficulty and importance of proof, the mathematics education community has contributed to a varied body of research related to the teaching, learning, and cognitive skills relevant to mathematical proof.

Research in the cognitive processes related to proof construction have provided insight into how undergraduate students, graduate students, and mathematicians interact with the proof construction process. Inglis and Alcock (2012) demonstrated that the processes with which each of these three groups construct proofs varies and that proof construction is not uniform even within a group. Their participants also showed inconsistency between how they said they approach proofs and the actual processes they implemented when given a proof construction task. To address these different approaches and their implications for the teaching and learning of proofs, we need to know more about what beliefs and judgements individuals have about their own cognitive processes during proof construction, and how these impact the choices they make during this process. Metacognition, defined to be "any knowledge or cognitive activity that takes as its object, or monitors, or regulates any aspect of cognitive activity; that is, knowledge about, and thinking about one's own thinking" (Lerman, 2020, pp. 608-609) captures exactly this aspect of an individual's thinking.

Existing metacognition research in mathematics education has focused on the relevant metacognitive processes that occur during mathematical problem solving more broadly. Proof related tasks can be a subset of mathematical problem solving, and therefore many of the findings from problem-solving based metacognition research may be applicable to proof. However, research shows that there are aspects of the proof construction process that may not be addressed in other problem-solving research (e.g., Savic, 2015). The language, structure, and reasoning required in proof constructions can be viewed to be unique to mathematical proofs and form a special writing genre (Selden & Selden, 2013). Savic (2015) also found that when the multi-dimensional, problem-solving framework developed by Carlson and Bloom (2005) is utilized in context of a proof task, adjustments of the framework are needed for the proof processes; in particular, there is a need to study metacognitive processes in proof more directly.

In this poster, we discuss the research that aims to explore the phenomenon of individuals' metacognitive processes during the construction of mathematical proofs. We identify the areas of the Carlson and Bloom framework in which metacognitive processes could potentially be important for proof construction, and we will demonstrate these with active engagement during poster presentation with the audience. During this interactive poster presentation, participants will be asked to share their thinking processes on proof tasks while we highlight the aspects of their metacognitive processes.

Active Learning Professional Development Series for Both Experienced and Inexperienced Instructors

Michael Tepper
Penn State Abington

Rachael Eriksen Brown
Penn State Abington

The poster describes a pilot study following the outcome of a three-part professional development workshop to promote active learning in STEM classrooms for instructors with a wide range of teaching experience. The series introduced strategies and benefits of active learning and had participants workshop their own strategies. We share the results of an exit survey given to participants and additional observations. The survey seeks to find what kinds of faculty participate and whether the professional development series motivated instructors to use more active learning in their classroom.

Keywords: Active Learning, Professional Development, Post-Secondary Education, STEM

How do we design professional development opportunities, including those that are discipline specific and promote active learning in STEM for an audience of both experienced and inexperienced instructors? We share observations and survey results from a pilot study following a three-part professional development workshop to promote active learning in STEM classes at a university in the Northeastern United States.

The three-session workshop took place over the course of 6 weeks. In order to be flexible, each session included information and activities that built on the previous meeting but were presented in an independent way so that instructors weren't required to attend each session. The College Mathematics Instructor Development Source (CoMInDS) Library on MAA Connect was used to generate activities, including the classroom practices found in (Yee, 2021). An article about shifting the focus from the teacher to student (Webel, 2010) was used for a discussion.

Information for this study was collected though post workshop observations and participant survey questions. There were 16 participants in the three sessions, with no participant attending all three. The six-question survey asked participants about their teaching experience, their professional development experience, and their experience using active learning.

Six faculty members responded to the survey. A majority of the respondents had 6 or more years of teaching experience. While most respondents attend professional development sessions more than once per year, the majority of professional development attended was not designed specifically for teaching in STEM fields. After the workshop, most instructors said they would likely use active learning in their classrooms. Teaching responsibilities was an obstacle to participating, with many instructors arriving late or leaving early due to class schedules. While the sessions were offered in a hybrid format, most instructors preferred the online option. We found that many instructors had trouble working on open ended projects to develop their own active learning examples during the workshop.

From these results, we consider the following future questions. What scheduling incentives, and structure could be implemented to improve attendance? What improvements in the workshop structure could be implemented to improve engagement and better promote active learning? In addition, we would like to investigate ways to better integrate the different experiences, backgrounds, and variety of fields represented by the participants to improve professional development for a wide audience.

Active Learning Professional Development Series for Both Experienced and Inexperienced Instructors

Rachael Eriksen Brown
reb37@psu.edu

Michael Tepper
mlt16@psu.edu

Purpose

Share observations and survey results from a pilot three part professional development workshop to promote active learning in STEM classes. The workshop was designed to be flexible, for both novice instructors and veterans, as well as instructors with varying levels of experience using active learning.

Resources and Literature

- College Mathematics Instructor Development Source (CoMInDS) Library on MAA Connect.
- Active Learning Instructional Resource: Classroom Practices from the CoMInDS Library (Yee, 2021)
- Group Reading: “Shifting Mathematical Authority from Teacher to Community.” (Webel, 2010)

Research Question

How do we design professional development opportunities, including those that promote active learning in STEM classes, for an audience of both experienced and inexperienced instructors?

Methods

- Survey Questions
- Post Workshop Observations

Workshop

The workshop had three sessions which took place over the course of 6 weeks. Instructors were encouraged to attend as many sessions as possible. While each session included information and activities that built on the previous meeting, they where presented in an independent way so that instructors weren’t required to attend each session.

Survey Questions

Survey questions asked about the following:

- Teaching Experience
- Professional Development Experience
- Experience using active learning.

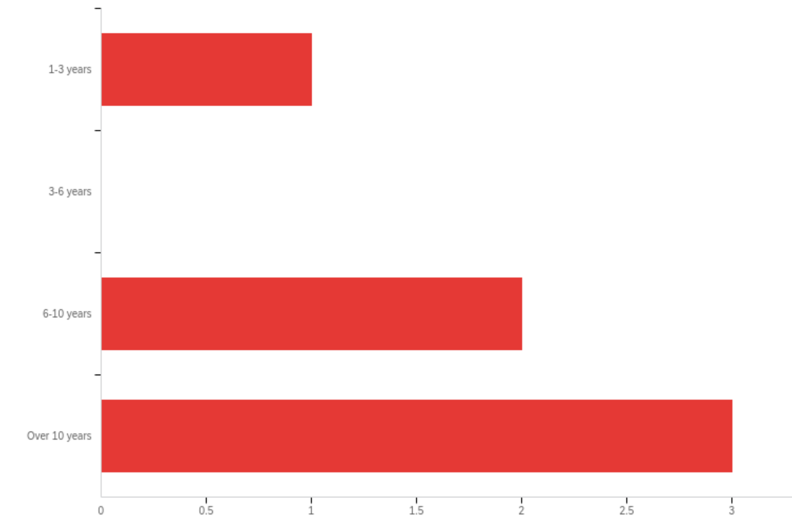
Particpants

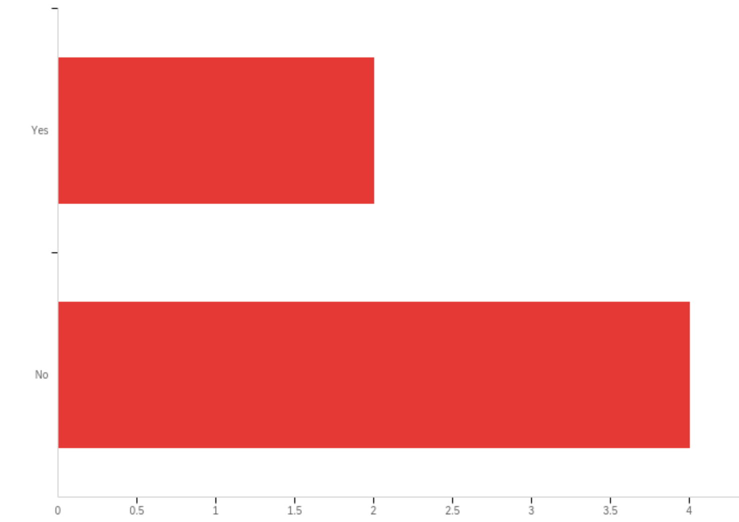
There were 16 participants in the three professional development sessions. No participants attended all three sessions, with several attending two sessions. Many participants only participated for parts of sessions due to teaching schedules.

Survey Questions and Results

Question 1: How many years have you taught?

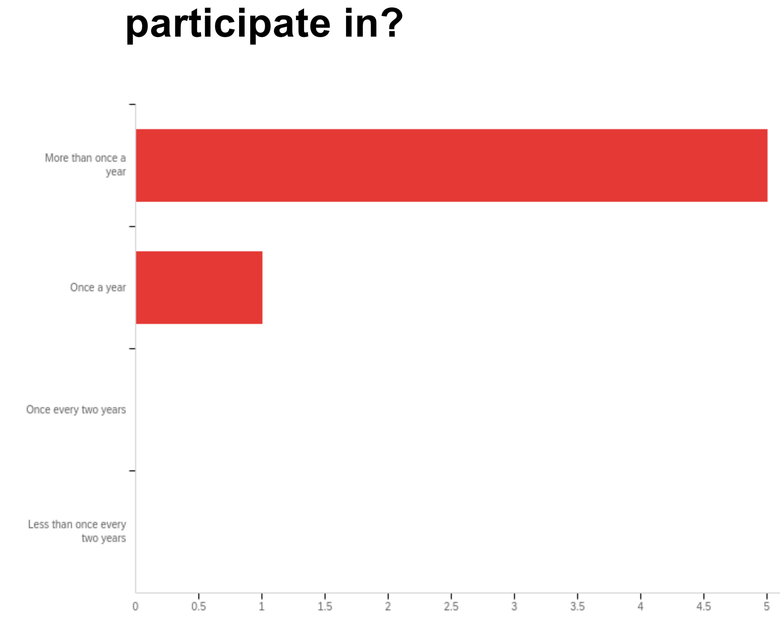
Question 2: Before becoming the instructor of record of a course, did you have any experience being a graduate or teaching assistant?

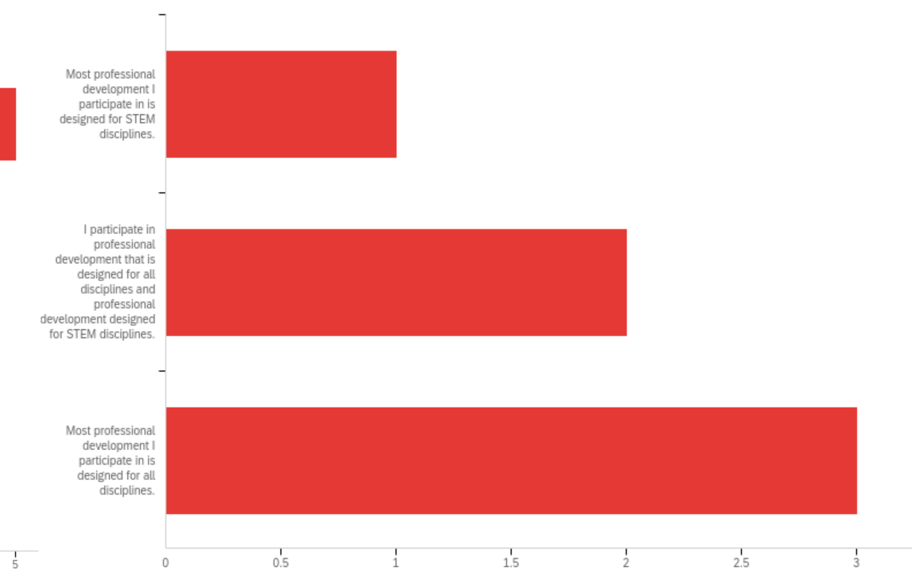




Question 3: Approximately how much professional development in teaching do you participate in?

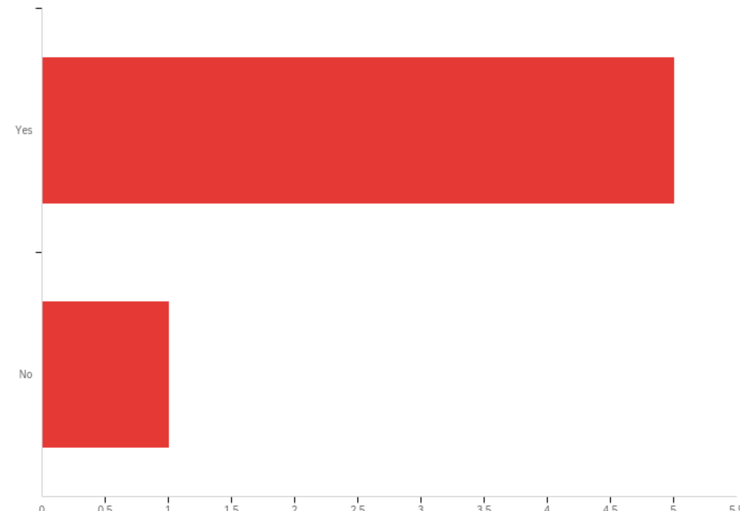
Question 4: Which of the following describes the professional development you participate in?

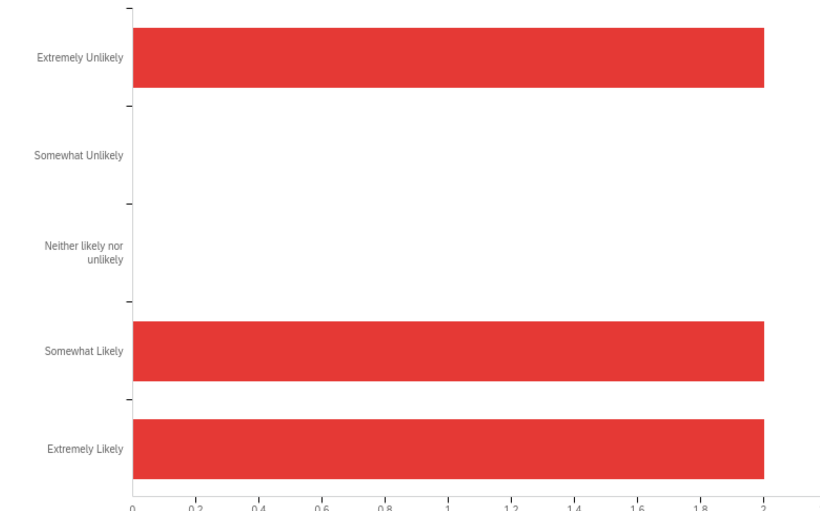




Question 5: Have you used active learning in your classes before?

Question 6: How likely are you use active learning in your classes in the future?





Findings & Discussions

Survey

- A majority of instructors attending these development sessions had 6 or more years of teaching experience.
- A majority of participating instructors did not have experience as a graduate or teaching assistant.
- Most instructors participate in professional development more than once per year.
- The majority of the professional development that the instructors attend is not designed primarily for teaching in STEM fields.
- Most instructors believe they will likely use active learning in the future.

Observations

- Teaching schedule was an obstruction to participating. Multiple instructors either could not participate or could only participate for part of the sessions due to this obstacle.
- While the sessions were available in a hybrid format, both in-person and online, most instructors participated online.
- Instructors had trouble working on open ended projects to develop their own active learning classroom activities during the workshop.

Future Research

- What scheduling, incentives, and structure could be implemented to improve attendance?
- What are improvements in the workshop structure that could be implemented to improve participation and better promote active learning?
- Investigate ways to better integrate the different experiences, backgrounds, and variety of fields represented by the participants to improve this type of professional development in STEM fields.

Acknowledgements

We would like to thank the instructors for their willingness to participate in the pilot study. We would also like to thank the administration for supporting us through the college’s Faculty Fellows program.

Confidence-to-Certainty Metacognitive Shifts for Students in Undergraduate Linear Algebra

Ethan Snow	Michael Preheim	Josef Dorfmeister
University of Nebraska	North Dakota State University	North Dakota State University

Assessing students' metacognition can help educators better understand student learning. In the present study, the authors evaluated students' pre-assessment confidence, response correctness, and post-response certainty during routine examinations in an undergraduate linear algebra course to investigate the magnitude and direction of students' metacognitive shifts (Δ meta) from mean confidence to mean certainty as compared to response correctness. Results of this study provide insights to student perceptions of their knowledge during examination performances in linear algebra and can inform efforts to improve mathematics teaching and learning.

Keywords: confidence, certainty, correctness, metacognition, metacognitive shift, correlation

Motivation and Study Objectives

Scholars have studied the alignment of confidence and certainty to response correctness (Gardner-Medwin & Curtin, 2007; Hunt, 2003; Preheim, Dorfmeister, & Snow, 2022), but Δ meta has not been empirically compared to overall correctness or performances on different types of questions (*e.g.*, multiple choice vs. process-based questions). The objective of this study is to investigate this gap in knowledge within an undergraduate linear algebra student population.

Methods and Preliminary Results

Students' Δ meta was ordered and evaluated for correlation with performance. Interestingly, five students demonstrated no overall Δ meta (boxed), and one student stood out on either end of the ordered Δ meta (Fig. 1A). Preliminary analyses show a correlation ($r = 0.43$, $p < 0.001$) of Δ meta to overall score (Fig. 1B). Confidence and certainty were separately examined with respect to ordered Δ meta (Fig. 1C). Only certainty showed positive correlation to Δ meta ($r = 0.57$, $p < 0.001$). The presentation will further describe these correlations, the five students who demonstrated no Δ meta, and the comparison of Δ meta between question types.

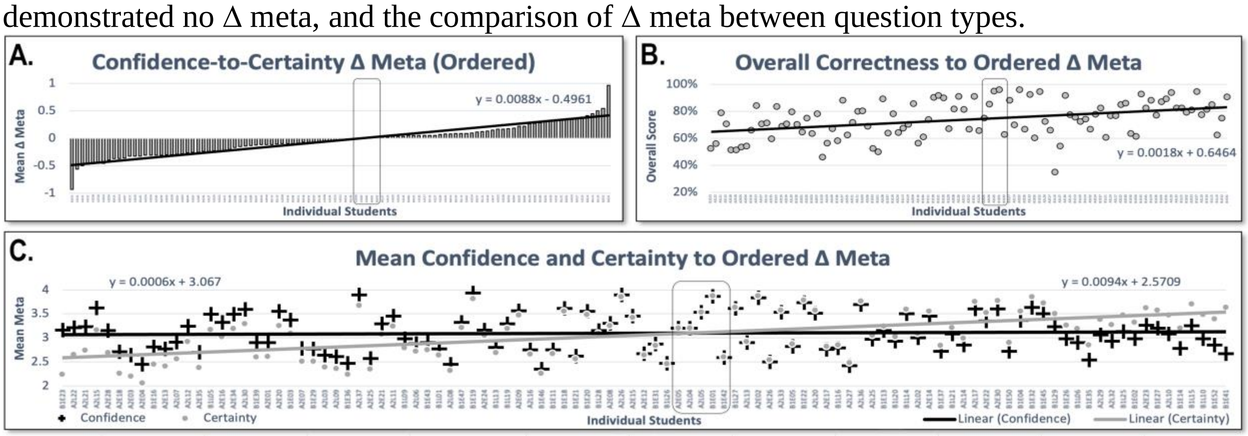

Figure 1. Correctness (B), confidence (C), and certainty (C) correlations to Δ meta (A).

Discussion and Conclusions

This study demonstrates how examining Δ meta can provide mathematics educators with a deeper understanding of student metacognition, learning, and performance, especially regarding undergraduate linear algebra and multiple choice vs. process-based examination questions.

STEM Students' Views on the Meta-Roles that Function Plays Across the Mathematics Curriculum

Brady A. Tyburski
Michigan State University

Keywords: Function, Curricular Coherence, Narrative Learning Theory, Multivariable Calculus

One of the purported goals of undergraduate mathematics is to encourage students to draw connections between the various mathematical subfields (Zorn, 2015, p. 11). The function concept—which is crucial in almost every area of mathematics—could serve a primary role in forming these connections, yet this role often goes unnoticed by students (e.g., Melhuish et al., 2020). Indeed, function is a critical recurring theme throughout undergraduate mathematics (Zandieh et al., 2017) that could be leveraged by students to increase their sense of curricular coherence across courses. This theme recurs implicitly and even explicitly in most mathematics courses, but research reminds us that students do not always take up course ideas and themes in the ways instructors intend (Clift & Brady, 2005; Lew et al., 2016). Despite this, there are few studies that speak to the ways that students leverage function as a theme to organize and make sense of their curricular experiences both within and across courses. In particular, there is much research on the metaphors students use for the *concept* of function across contexts (e.g., Lakoff & Núñez, 2000; Melhuish et al., 2020; Zandieh et al., 2017), but much less research on the *meta-roles* that students view function as serving in organizing the mathematics curriculum.

In this poster, I address two questions: (1) What do students' stories about functions reveal about the meta-roles that the function concept plays for them in organizing the mathematics curriculum? (2) In what ways do these general meta-roles appear (or not) in students' stories for functions in a specific course context? I answer these questions by analyzing the stories of three STEM students pursuing different majors who were enrolled in multivariable calculus (MVC). These stories were told during a sequence of four, 1.5-hour, task-based interviews spread throughout a semester—the first concerned the role of function across mathematics and STEM courses and the remaining interviews focused on single-variable; multivariable, real-valued; and multivariable, vector-valued functions, respectively. Using narrative learning theory and Dietiker's (2015) analytic framework for viewing the mathematics curriculum as a story, I juxtapose students' stories about the meta-role of function across the undergraduate curriculum with the stories they tell about different types of multivariable functions they encountered throughout MVC. I attend to students' stories because, as Clark and Rossiter (2008) put it, "Every day we are bombarded with a dizzying variety of experiences and we make sense of those by storying them, by constructing narratives that make things cohere. Coherence creates sense out of chaos by establishing connections between and among these experiences" (p. 62). In other words, stories are a primary representation of students' sense of curricular coherence.

Based on this preliminary, exploratory analysis, I find that students' general stories reveal developed, idiosyncratic views of the meta-role that function plays as an organizing, cross-curricular theme (e.g., "functions are like the ABCs of mathematics", "functions are kind of like canvases, and we're being trained as painters"). On the other hand, students' specific stories about functions in MVC did not explicitly leverage the same meta-roles or thematic structures that were present in their general stories. This suggests that if we want students to use function as a productive, organizing curricular theme, we must provide further reflective opportunities for students to coherently organize their course experiences with respect to this theme.

A Coordinate System Framework

Inyoung Lee
Arizona State University

Coordinate systems underlie many important topics in undergraduate mathematics, such as functions, equations, and graphs. By providing a framework that describes the aspects of coordinate system thinking, it offers a foundational framing to examine a wide range of characterizations of student reasoning in undergraduate mathematics. This proposal introduces a conceptual framework that emphasizes how one engages with an object viewed in a single coordinate system and multiple coordinate systems. The framework consists of four sub-parts: Naming, Locating, Re-Naming, and Re-Locating.

Keywords: linear algebra, calculus, coordinate system, change of coordinate system, framework

A coordinate system promotes student spatial thinking by imposing a visual aspect to undergraduate mathematics that may be abstract and computational. Many researchers have investigated how undergraduate students reason about coordinate systems when transitioning from one system to another in the context of precalculus, calculus, and linear algebra (Hillel & Sierpinska, 1993; Arcavi, 2003; Montiel, Vidakovic, & Tangul, 2008; Sayre & Wittmann 2008; Montiel et al., 2009, 2012; Lee et al., 2020; Moore et al., 2014; Hillel, 2000; Selby, 2016; Wawro et al., 2013; Zandieh et al., 2017). Despite these studies, there is no overarching framework for interpreting student reasoning across a variety of mathematical contexts. Therefore, this paper proposes a framework to provide a foundation for interpreting a wide range of undergraduate students' thinking with coordinate systems.

The coordinate system framework encompasses two fundamental processes for representing objects within a single coordinate system: Naming and Locating. (1) Naming involves assigning numbers and symbols to spatial and geometric objects, such as points, vectors, lines, and curves in accordance with conventions established by a coordinate system. For example, (2,3), <7,5>, and $y=-3x^2+5x-1$ are all examples of objects represented through the naming process. On the other hand, (2) Locating is the process of plotting symbolic expressions into visual representations, such as dots or graphs in space, using a coordinate system. An example of this process is graphing the function $y = x^3 - 10x$. These two processes can be extended to include reasoning about an object in the context of multiple coordinate systems: Re-Naming and Re-Locating. (3) Re-Naming involves describing the coordinates of a spatial object using a new coordinate system that is laid atop the object without moving it. In other words, the object does not receive a new name until a new coordinate system is imposed over its location. An example of Re-Naming would be taking a point (1,1) in the Cartesian coordinates renaming it as $(\sqrt{2}, \frac{\pi}{4})$ in the Polar coordinates. (4) Re-Locating involves plotting a symbolic expression that does not change into different spaces and transforming the shape of an object into a different shape by mapping points in the first coordinate system to points in the second coordinate system. Although the transformed location may appear different from the original, the two shapes are images of each other.

By using an overarching lens, researchers can better analyze student reasoning by focusing on how students think about each part of a problem, and how they leverage their understanding of coordinate systems to reason about multiple coordinate systems. This approach can also serve as a useful framework for teachers and researchers when designing tasks that involve coordinate systems.

EDUCATION

Narratives of math affect and math utility are co-constructed during advising sessions through talk & embodiment. Advisors take up narratives inconsistently, resulting in students being "cooled out" from pursuing mathematics.

Elena Crosley
Natalie Drobny
Emma Thomas
Claudine Margolis
Maisie Gholson

Orienting Details

Research Question:
What aspects of talk and embodiment influence the co-construction of narratives about women students in advising sessions with a man advisor?

What is Math Advising?
A 5-10 minute optional conversation between a member of the math department and an incoming undergraduate who is unsure of which math class to take. The session results in a non-binding agreement that guides the student's registration decision. The advisor and student have had no prior interaction.

Our Positionality:
We are math education researchers and trained advisors. We use Black feminist perspectives and our own experiences to inform our questions & interpretations of data.

LAB FOR THE STUDY OF
R&GME
RACE & GENDER IN MATH EDUCATION

Narratives of math affect are taken up inconsistently across sessions.

We illustrate with two sessions with women students and the same man advisor.

Session 1: The advisor ignores the student's bids to construct a narrative of positive math affect. Narratives of math utility are used to cool out the student.

Okay good. <u>Well you don't need any math for psychology.</u> Did you want to take a math class **or do you want to avoid math?**

I did. I-I- do enjoy math even though it's not really a part of psychology, but **I still really enjoy math**. Like I am thinking of taking statistics, but I wanted to. I'm thinking also of including calculus if I have enough room for it.

<u>So stats and math are two different depts here</u> and I agree that if you're going into psych you're probably gonna have to take some stats and <u>that's probably more relevant</u>. **But if you want to take math .. I encourage you to do that.**

Yeah, **I really enjoy it**. So I do want to try like, uh [more challen–

//How far did you go in high school?

I just took AP calc AB. Um, I want to know what [classes–

//Did you take the exam?

Yes. Do I have to show you the scores? {pulls out paper} Uh. I got a 5.

Session 2: The advisor repeatedly takes up the narrative of negative math affect to cool out the student. The student uses math utility to resist those efforts.

Okay. Any idea what you want to study?

Um, yeah, actually that's what I was gonna talk to you about because of the math requirement. Um, (..) **I hate math** {laugh}. [And–

//Ok. Honesty.

I went up to calc BC in high school. Got A's in the classes, did poorly on the exam **cause I hate math** and I just did it for the A w/o studying {laugh}

What did you get on the BC test?

A one, but I didn't try [Oh, ok.] Yeah, but I got an A in the class {both laugh}. So, um, uh, I want to go either premed or go to law school myself. I'm [leaning–

//<u>Well good news is that doesn't require so much math.</u>

Yeah. So I want to get like, **absolute minimum of math**.

Well you do have to satisfy a quantitative reasoning requirement, <u>but you don't have to use math for that</u>.

So the requirement.. is that different than how a grad school will look upon your transcript? Because–

Oh that's an entirely different question.

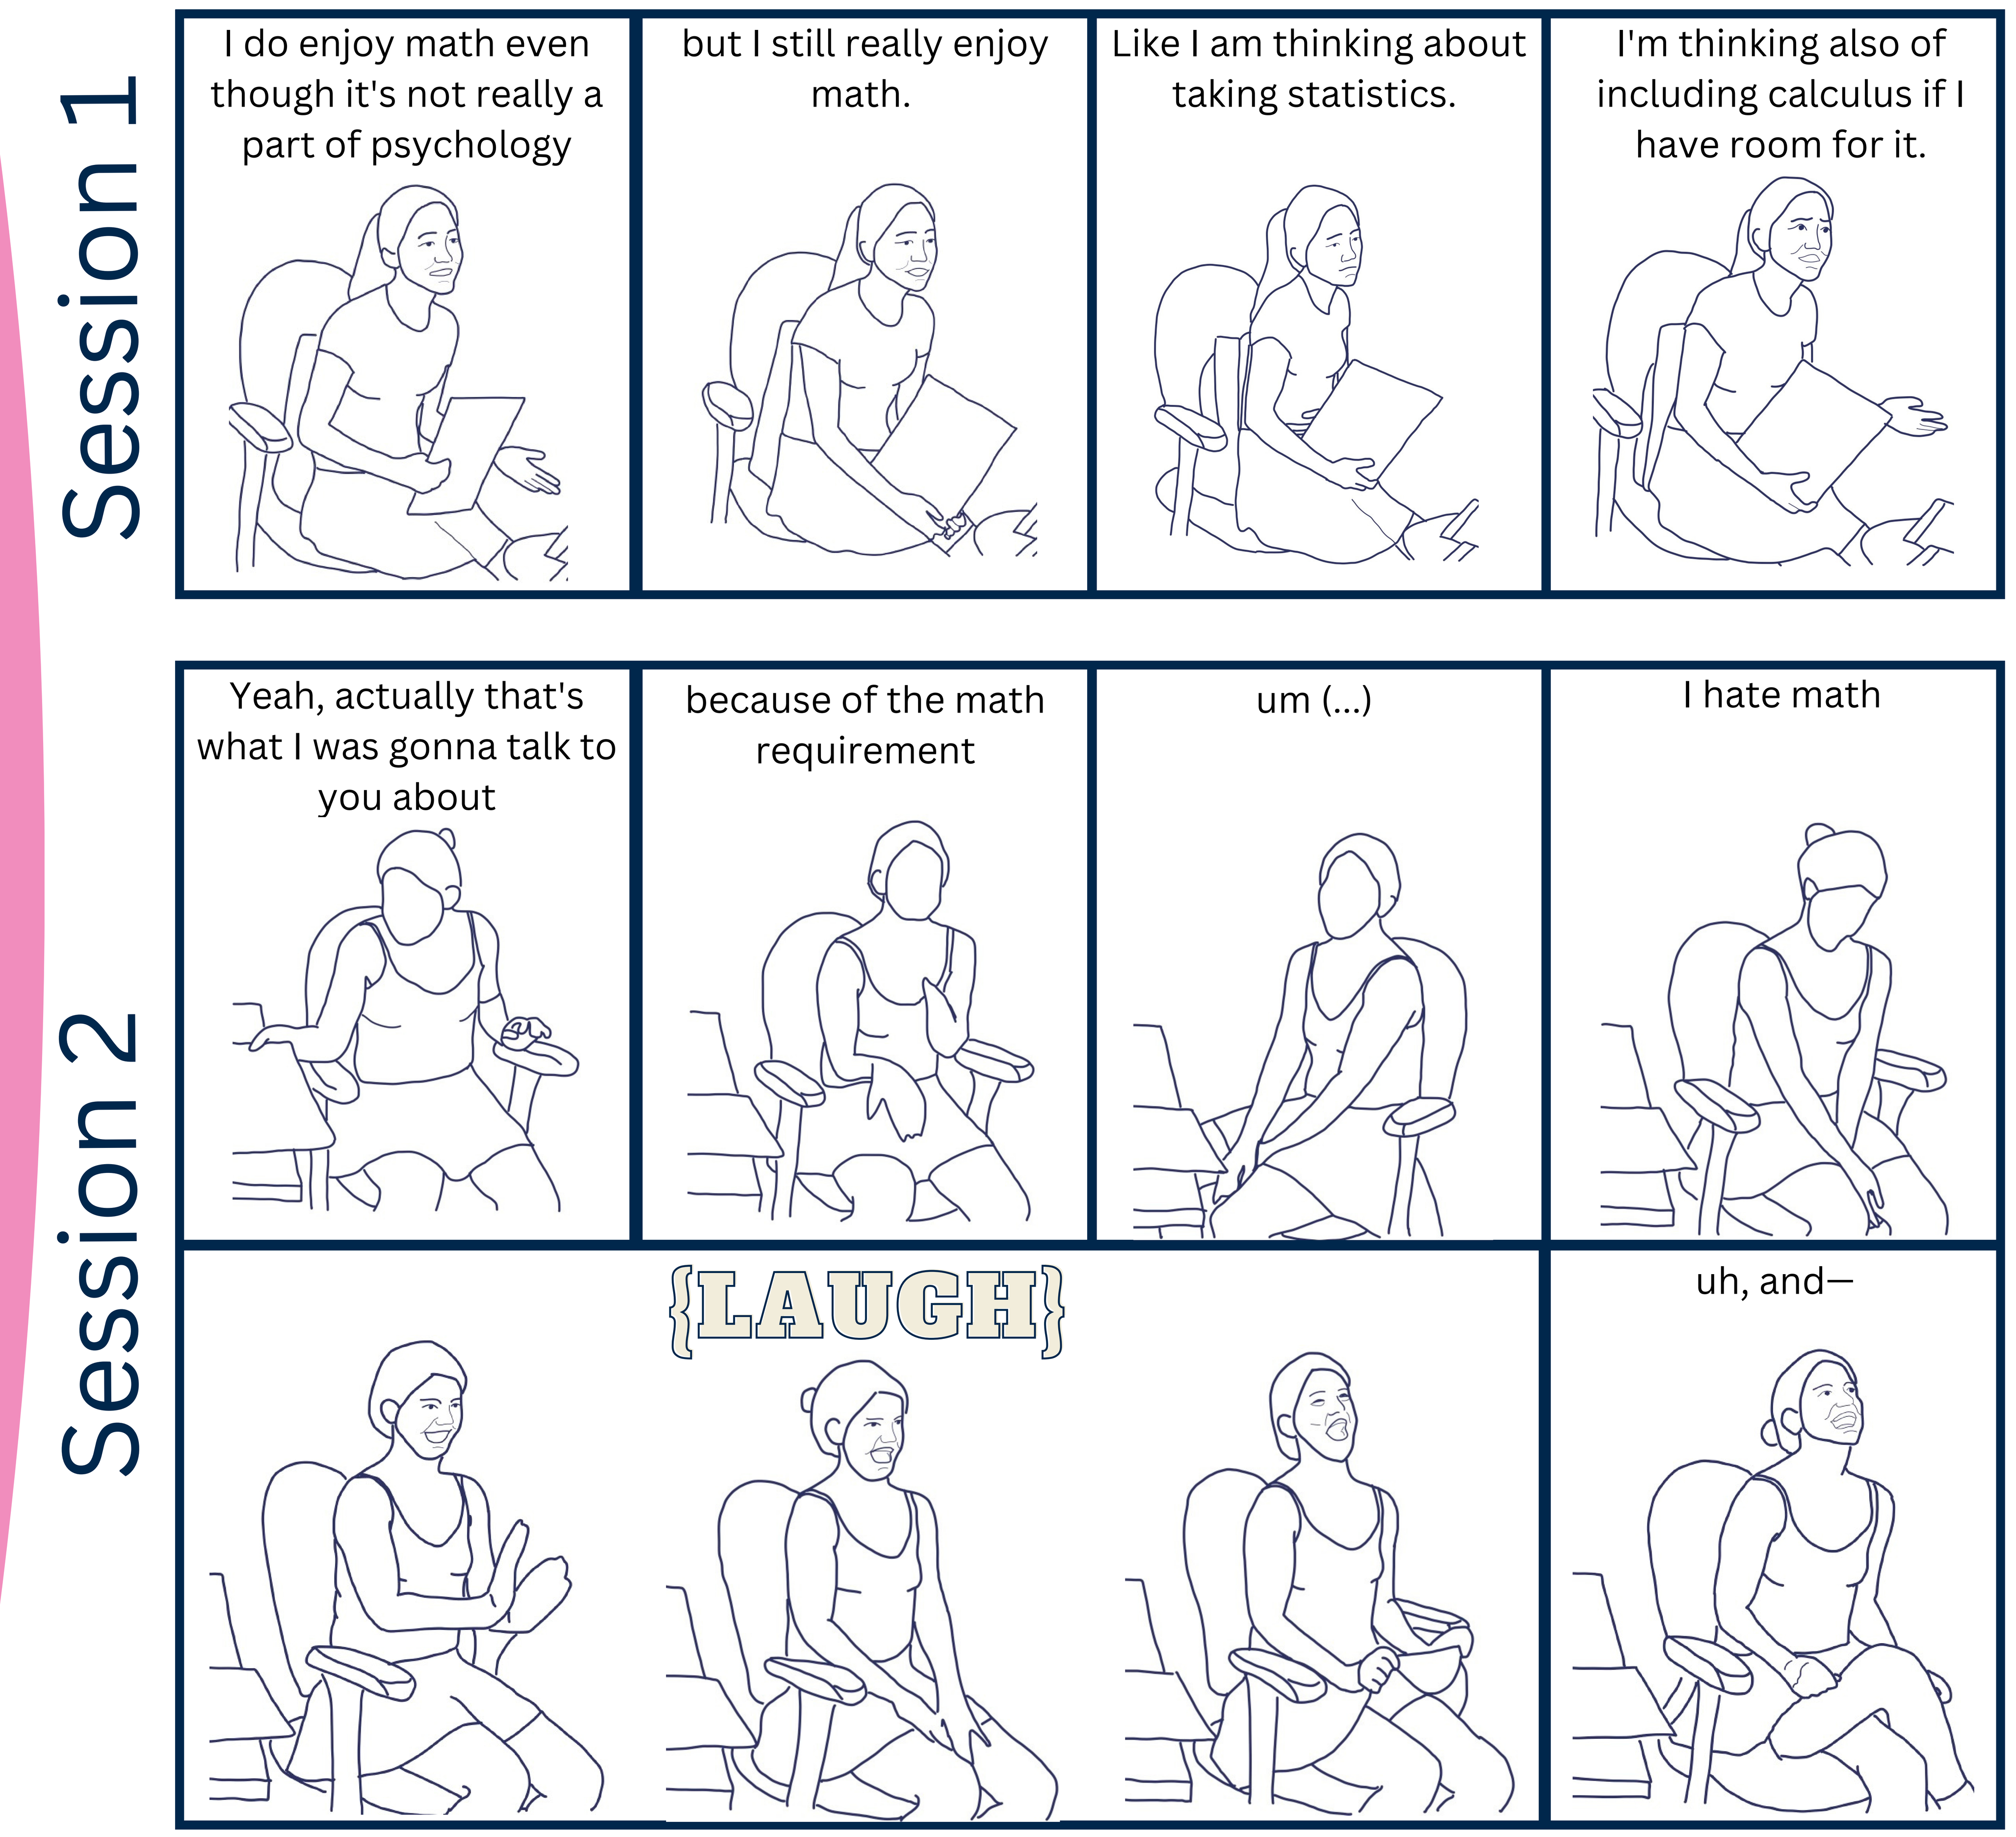
Narratives & Math Advising: We conceptualize math advising as a genre of interaction in which students and advisors co-construct narratives about the set of courses that are appropriate for the student to take. Narratives are co-constructed by the advisor and student through verbal and non-verbal interactions.

Narratives of Math Affect & Math Utility: A math affect narrative is how the student feels about math. A math utility narrative is how well math fits into a student's possible educational career.

Theory of Self-Authorship: Higher Education practitioners should encourage students to explore and design their own educational journey instead of assigning them pre-determined paths.

Why is this important? Students often change paths from orientation to graduation. Decisions that are made during summer orientation can severely limit their options in future semesters, particularly if they opt out of math.

Next Steps: Incorporating Embodiment into our Analysis



The narrative of math affect is not taken up by the advisor in Session 1, but is taken up in Session 2. Why might the advisor be taking up one narrative of math affect and not the other?
