Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) held its twenty-seventh annual Conference on Research in Undergraduate Mathematics Education in Alexandria, Virginia from February 27 – Mach 1, 2025.

The 27th RUME Conference enabled presenters and attendees the option to participate fully online such that travel was not a requirement, approximately 22% of participants were online.

The program included plenary addresses by Dr. Sandra Laursen and Dr. Megan Wawro and the presentation of 174 contributed, preliminary, and theoretical research reports and 120 posters. The conference was organized around the following themes: results of current research, contemporary theoretical perspectives and research paradigms, and innovative methodologies and analytic approaches as they pertain to the study of undergraduate mathematics education.

The proceedings include several types of papers that represent current work in undergraduate mathematics education, each underwent a rigorous review by three or more reviewers:

- Contributed Research Reports describe completed research studies
- Preliminary Research Reports describe ongoing research in early stages of analysis
- Theoretical Research Reports describe new theoretical perspectives for research
- Posters may fall into any of Contributed, Preliminary, or Theoretical and were presented in poster format. Authors contributed the poster itself, a summary of the work, or both.

The conference was hosted by Virginia Tech's Department of Mathematics. Many members of the RUME community volunteered for the Program Committee where they reviewed many submissions such that every submission was reviewed by at least one member of the Program Committee. The Program Committee aided us in putting together this program and their hard work is greatly appreciated. The Local Organizing Committee were responsible for the smooth running of the presentations and on-site activities, which would not have been possible without the help of many volunteers, and we thank them for their tireless efforts to host a conference that runs smoothly.

Thank you to all of the researchers who submitted such strong proposals and ultimately made the conference a fun and joyous event.

Sam Cook, RUME Conference Executive Coordinator and Conference Chair
Estrella Johnson, RUME Conference Local Organizing Co-Chair
Megan Wawro, RUME Conference Local Organizing Co-Chair

Program Committee

Chairperson

Samuel Cook	Boston University

Committee Members

Aditya Adiredja	University of Arizona
Naneh Apkarian	Arizona State University
Annie Bergman	Fort Lewis College
Anne Cawley	Cal Poly Pomona
John Paul Cook	Oklahoma State University
Jennifer Czocher	Texas State University
Tim Fukawa-Connelly	Temple University
Saba Gerami	Cal Poly San Luis Obispo
Neil Hatfield	Pennsylvania State University
Shandy Hauk	San Francisco State University
Billy Jackson	University of Illinois Chicago
Brian P. Katz	California State University, Long Beach
Aubrey Kemp	California State University, Bakersfield
Igor' Kontorovich	University of Auckland
Kristen Lew	Texas State University
Kathleen Melhuish	Texas State University
Hayley Milbourne	University of San Diego
Kevin Moore	University of Georgia
Deborah Moore-Russo	University of Oklahoma
Kaitlyn Serbin	University of Texas Rio Grande Valley
Jason Samuels	City University of New York
Irma Stevens	University of Rhode Island
Karina Uhing	University of Nebraska Omaha
Nick Wasserman	Teachers College, Columbia University
Franklin Yu	Virginia Commonwealth University
Zackery Reed	Embry-Riddle Aeronautical University – Worldwide
Mary Pilgrim	San Diego State University
Rachel Rupnow	Northern Illinois University

Local Organizing Committee

Co-Chairs

Estrella Johnson	Virginia Tech
Megan Wawro	Virginia Tech

Committee Members

Joe Antonides	Virginia Tech
Rachel Arnold	Virginia Tech
Ben Bruncati	Virginia Tech
Kyle Flanagan	Virginia Tech
Lindy Hearne	Virginia Tech
Jacob Lineberry	Virginia Tech
Corinne Mitchell	Virginia Tech
Modiu Olaguro	Virginia Tech
Matt Park	Virginia Tech
Tracy Proffitt	Virginia Tech

Volunteers

Megumi Asada	Rutgers University
Angel Bisson	San Diego State University
Yuxi Chen	Columbia University
Catherine Dennis	University of New Hampshire
Siqi Huang	University of California, Berkeley
Rasha Issa	University of California, Riverside
George Kuster	Christopher Newport University
Niusha Modabbernia	Simon Fraser University
Keith Weber	Rutgers University

Norms and Values Upheld by Different Mathematical Activities: Proving, Defining, and Algorithmatizing

Rachel Rupnow
Northern Illinois University

Alastair Fletcher
Northern Illinois University

Peter Sassman
Northern Illinois University

Algorithms, proofs, and definitions all play important roles in mathematics as products of research and objects worthy of study in the classroom. Nevertheless, limited research has examined mathematicians' views of algorithms or compared their views across these objects and related activities. Based on interviews with nine discrete or computational mathematicians, we highlight similarities and differences between the values associated with these mathematical activities and relative importance placed on the varied activities.

Keywords: norms, values, proofs, definitions, algorithms

The mathematical community holds many views about what it means to do mathematics. While research has previously examined individual mathematicians' beliefs about what it means to do and teach mathematics (e.g., Rupnow, 2023; Woods & Weber, 2020), new attention has been focused on the values and norms of the mathematical community (Dawkins & Weber, 2017; Rupnow & Randazzo, 2023; Vroom et al., 2024). These works have focused on mathematicians' perceptions of how particular tools like proof (Dawkins & Weber, 2017) and definitions (Rupnow & Randazzo, 2023; Vroom et al., 2024) permit particular values to be upheld via norms of practice in the mathematical community. To build on this work, we examine a third tool, algorithms, and relate it to proof and definitions as we address the research question: How do norms and values around algorithms harmonize or suggest tension with norms and values around proving and defining?

Background Literature

Mathematicians engage in a variety of disciplinary practices that occur across subdisciplines of mathematics, including symbolizing, algorithmatizing, defining, justifying (Rasmussen et al., 2005), and computing (Lockwood et al., 2019). However, most examinations of these practices or of understandings of the corresponding objects (symbols, algorithms, definitions, proofs) have occurred in isolation. Algorithms and computing have received more attention recently because of their importance to computational thinking in mathematics and science (e.g., Lockwood et al, 2019; Weintrop et al., 2016), though algorithms have sometimes been viewed negatively as reinforcing procedural (as opposed to conceptual) understanding (Kamil & Dominick, 1997).

In contrast, extensive literature has examined the roles of definitions and proofs in mathematics education. Works focused on definitions have highlighted students' frequent use of extracted rather than stipulated definitions (e.g., Alcock & Simpson, 2011; Edwards & Ward, 2004; 2008), that is, self-created definitions extracted from known examples rather than stated definitions that pre-specify (stipulate) meaning. Research has also characterized the expectations of the criteria of a definition, such as existence and specification of necessary and sufficient conditions (Harel et al., 2006; van Dormolen & Zaslavsky, 2003) and pedagogical advantages of some definitions over others (Zazkis & Leikin, 2008). In addition to this extensive work on definitions, based on interviews with algebraists, Rupnow & Randazzo (2023) highlighted values and norms of the mathematical community related to definitions and the practice of defining.

Research attending to proof and proving is also myriad. Examples include examining

different purposes that a proof can have (e.g., Weber, 2002), how different formats of instruction can align to different proof-focused pedagogical goals (e.g., Weber, 2004), different approaches to creating proofs in different mathematical subdisciplines (Dawkins & Karunakaran, 2016), how students understand proofs (e.g., Inglis et al., 2007; Stylianides & Stylianides, 2009), and differences in students' and mathematicians' approaches to creating proofs (e.g., Weber & Alcock, 2004). Additionally, Dawkins and Weber (2017) highlighted mathematicians' values and norms around proof production based on an examination of the published mathematics and mathematics education literature. Here we seek to compare and contrast mathematicians' views of algorithms, definitions, and proofs and the corresponding activity around them.

Theoretical Perspective

The Triadic Network of Justification (Laudan, 1984) is a theoretical framework that characterizes the conceptual connections among axiology, methodology, and factual claims in a community. Axiology relates to the ethics and values of a community, methodology relates to commonly accepted norms of practice in a community, and factual claims relate to what is accepted as settled fact in a community. While this framework was designed to conceptualize the nature of paradigmatic changes in the scientific community, this framework has been applied in mathematics education to characterize the values (axiology), norms (methodology), and theorems (factual claims) of the mathematical community with respect to proof (Dawkins & Weber, 2017) and definitions (Rupnow & Randazzo, 2023; Vroom et al., 2024).

Based on the existing literature (Dawkins & Weber, 2017) or interviews with mathematicians (Rupnow & Randazzo, 2023), these studies generated values upheld by specific norms related to proving or defining to characterize rationales behind practices of mathematicians. Vroom et al. (2024) used the defining norms and values to assist students in adhering to these expectations. Dawkins and Weber (2017) listed four proof-related values, each upheld by various norms: "mathematical knowledge is justified by a priori arguments", "mathematical knowledge and justifications should be a-contextual and specifically be independent of time and author", "mathematicians desire to increase their understanding of mathematics", and "mathematicians desire a set of consistent proof standards" (p. 128). Rupnow and Randazzo (2023) highlighted two definition-related values, each upheld by various norms: "clarity in and for communication" and "freedom of choice for the use and creation of definitions" (p. 303). In this study, we build on the previously observed values and norms related to proofs and definitions while also using Laudan (1984) to conceptualize values and norms related to algorithms.

Methods

The first author emailed mathematicians at R1 institutions in the United States who were listed on their departmental website as researching applied/computational mathematics or combinatorics (or a similar description). That author then conducted 60-minute remote, screen-recorded interviews with nine such mathematicians. Five participants' research aligned more with applied/computational mathematics and four aligned more with combinatorics. All names are gender-neutral pseudonyms. Interview questions focused on participants' views of algorithms and their use, proofs and proving, definitions and defining, and how these areas interrelate.

Three researchers coded the interviews in MAXQDA 2020 (VERBI Software, 2019), with at least two researchers coding each interview. We entered coding with existing norms (codes) and values (categories) for proving (Dawkins & Weber, 2017) and defining (Rupnow & Randazzo, 2023) but were open to adding new codes and categories if needed. All three researchers initially open-coded two transcripts to create norm codes and value categories for algorithms in

alignment with Laudan (1984). After discussing our open codes, we created a codebook for algorithm norms and added some new norms for proof. We then re-coded and came to consensus on the first two interviews. Finally, two researchers individually coded each of the remaining seven interviews and then discussed and came to consensus on the norms discussed. This process aligns with codebook thematic analysis (Braun et al., 2019) in that we entered analysis with some idea of the codes and categories (norms and values) we would use but were open to adding new codes as needed.

Results

We coalesced the themes (categories) we observed associated with algorithms in mathematics into three values:

1. Algorithms are useful for solving problems
2. Correctness of algorithms needs to be verified
3. Algorithms need to be clear to people and communicable to others.

Here we focus on the interplay between these values and the values for proving and defining in mathematics observed in the literature and our data. The first four of the following values for proving were introduced by Dawkins & Weber (2017), to which we added a fifth:

1. Mathematical truth is a priori
2. Mathematical knowledge and justifications should be a-contextual and independent of time and author
3. Mathematicians desire to increase their understanding
4. Mathematicians desire a consistent set of proof standards
5. Proving is socially mediated.

The following two values for definitions were introduced by Rupnow & Randazzo (2023):

1. Clarity in and for communication
2. Freedom of choice for the use and creation of definitions.

Below we highlight how these values arose in our data by discussing some of the norms (italicized) that upheld these values and then compare the values related to each mathematical practice to those in other practices.

Algorithm Values

Algorithms are useful for solving problems. The interviewees were unanimous, (n=9), in saying *algorithms are a tool*, although the interpretations of "tool" were myriad. For example, Becker took a high-level view on the definition of an algorithm and stated that "algorithms are a tool for us to systematically describe our way of thinking for a certain solution process." Similarly, Emery stated, "I'm thinking of an algorithm as meaning a procedure for accomplishing something," and explained that certain mathematical proofs can be viewed as algorithms by stating "there are constructive proofs which, in some sense, are inherently algorithms." On the other hand, Foster viewed algorithms more through the lens of a computational tool and stated, "Well, the purpose of an algorithm is always to compute something. Or to end up with something."

There was further consensus that *problems/contexts drive the use/creation of algorithms*. This norm conveys that there is a real-world problem that requires a solution, and this is the main motivating factor in algorithmic development. For example, as a researcher in graph theory and combinatorics, Emery stated that, "I mean, algorithmic research is devoted to finding procedures that will quickly answer certain questions." As a researcher in combinatorics, Harley stated that, "So I think that a problem is not really answered until you have some kind of algorithm that

gives the answer. An object is not understood until you have an algorithm that constructs it." On the other hand, as a mathematical biologist, Ira stated that, "The goal is always to help me do a computation," with the implication that there is always some motivation from a biological problem for the algorithms required in Ira's work.

Correctness of algorithms needs to be verified. All interviewees observed that *deductive logic is important for algorithms,* as algorithms involve a sequence of steps and deductive logic is required for the algorithm to flow from one step to the next. For instance, Becker stated, "So algorithms are a way of describing patterns. Generally, what happens is you notice that certain things happen when you do things in a certain order", which highlights the importance of noticing and describing the steps within the algorithm. Devin made a similar comment but focused more on the big-picture sequence of subtasks within an algorithm: "What the algorithm does, the algorithm is going to allow you to compartmentalize what is happening, what is it going to, how is it getting there, and where are you going."

All but one of the interviewees suggested that *algorithms should be presented/tested with examples*. Emery viewed examples as a check on solutions: "Considering examples can be effective in understanding what an algorithm does." Ashton also highlighted the utility of examples for showing the purpose of steps in the algorithm: "You start with the simplest example you could possibly come up with and then just slowly ratchet up the level of complexity until you hit a point where—what should happen as you do that is that each step of the algorithm becomes clear why it's needed." As someone who has worked in a variety of contexts involving applied mathematics, Foster's experience indicated the importance of testing algorithms relative to examples with known solutions: "I never write an algorithm without testing it on things. Usually, you want to test it on things where you know the answer, and you want to see how well it's doing."

Three participants also highlighted that *using/creating algorithms drives research on convergence/stability properties*. Foster stated that:

> Sometimes we worry about [the fact that the algorithm does not satisfy all hypotheses of existing theorems for convergence] a little bit, and sometimes we just compute. And it depends on how confident we are that the algorithm is working. If we're pretty sure it works, we may not stop off and prove a theorem. If we have a little bit of a doubt, something is happening we're not expecting, then we might get into seeing what we could do about showing the algorithm really does converge to the answer that we're looking for.

Note that Foster sometimes will use an algorithm without proof of convergence, but this lack of rigor can drive future work for finding such a proof.

Algorithms need to be clear to people and communicable to others. All interviewees agreed that *algorithms need to be understood (enough, depending on context)*. Harley expected deep understanding, saying, "Everyone needs to have a conceptual understanding, a big picture, and a qualitative understanding." Others also conveyed expectations for understanding, such as Cooper, who highlighted the importance of using context:

> I've had these conversations also with students, and I ask them to show it in class where it's like, "Look, this fit is fantastic. If time was going the other way, no problem at all. But if you've got a fit and you want to predict the future and that fit is fantastic except for the last three weeks, then you look for something else, right?"

On the other hand, Ashton stated: "you can develop, use, and understand algorithms without even knowing that they actually truthfully do what you think they do… and just to be clear,

sometimes it's separate because it's literally too hard" indicating that there can be situations, such as using algorithms in machine learning, where using algorithms as a black box is acceptable.

Algorithms and Proving

There are many similarities in the values common to proving and algorithms. Here we draw parallels between norms and values related to these practices. We first highlight the algorithm norm *deductive logic is important for algorithms* that upholds the value 'correctness of algorithms needs to be verified'. The argument can be made that every proof is an algorithm if one considers a sequence of logically justifiable steps starting from some assumptions and eventually reaching the desired outcome to describe both a mathematically rigorous proof and an algorithm. As noted above, all nine interviewees touched upon the importance of deductive logic for algorithms, and seven were coded for the proof norm *justification should be deductive and not admit rebuttals* that upholds the value 'mathematical truth is a priori'. Ashton stated, "a proof is an attempt to justify or argue that something is correct within a system," and Cooper stated that "If I've got a proof that is 99% correct in Mathematics, I've got nothing."

The development of both proofs and algorithms typically involves a period of inductive reasoning where various strategies are employed until either the proof is worked out in the former case, or the algorithm is constructed in the latter. The proof norm *proofs arise from inductive thinking but are written deductively* that upholds the value 'mathematical knowledge and justifications should be a-contextual and independent of time and author' was supported by seven interviewees. Foster said:

> I let them incubate for a while, and then I go to work on them more seriously and hope something drops. And I have techniques and machinery that I understand and can use, but you have to figure out which machine or which technique might be useful.

Harley stated that "…you try and see the pattern. And then you make a conjecture that this construction will produce the general object or will always produce whatever object you're looking for. And then you try to prove it. That's the hard part." Both quotes suggest the importance of looking for patterns (engaging in inductive thinking) as a precursor to writing a normative deductive proof.

While correct proofs and algorithms stand by themselves, a modification of the hypotheses of a theorem or a modification of the class of inputs to an algorithm can provide impetus for future work. The algorithm norm *problems/contexts drive the use/creation of algorithms*, upholding the value 'algorithms are useful for solving problems' is similar to proof norms of *proofs are tools for future problem solving* and *proofs lead to questions which lead to theorems (cyclic nature)* that uphold the proof value 'mathematicians desire to increase their understanding'. These proof norms were mentioned by seven and eight participants, respectively. For instance, Ashton stated, "Every proof is a possible technique you can apply in the future," Emery said, "You really try to get in and understand what the previous proof does in order to tailor it to new needs," and Harley remarked, "Generally, there will be lemmas and theorems that you can use, and you see how the tools have been applied and whether they can apply in your case." Notice these quotes all relate to the utility of knowing existing proofs for future proving.

Across the Three Practices

No matter the venue, anything mathematicians do needs to be clearly communicable to others, whether to other researchers or to students in the classroom. The algorithm value 'algorithms need to be clear to people and communicable to others', the proving values

‘mathematicians desire to increase their understanding’ and ‘proving is socially mediated’, and the defining value ‘clarity in and for communication’ all speak to the utmost importance that is placed upon the communication of mathematics to others. As Cooper states, “You got to know exactly what you’re talking about before you talk about it,” illustrating that there must be clear communication between mathematicians regarding agreed upon definitions. Harley stated, “there are proofs that are enlightening that really explain why something is true,” illustrating the point that mathematicians value proofs which clearly communicate the big ideas, over obfuscation of the important points.

Additionally, the utility of definitions, proofs, and algorithms are what imbues them with meaning. The algorithm value ‘algorithms are useful for solving problems’, the proving value ‘mathematicians desire to increase their understanding’, and the defining value ‘freedom of choice for the use and creation of definitions’ all support the idea that mathematics is more powerful when there is a larger aim in mind. Ashton illustrated the myriad utility of algorithms:

> Algorithms, to me, have-- okay, they have several purposes. One is to construct mathematical objects or examples. Another is as a proof technique. So often what you want to show is that a certain condition holds. And to do that, you construct an algorithm, prove that the algorithm terminates, and the existence of such an algorithm then demonstrates that the claimed result holds. And then a third would be just for computational purposes… I use them in all three of those ways.

On the topic of proofs, Harley discussed the utility of proofs by stating:

> So what are the purposes of proof? As I say, proofs are the binding cement or ligaments of mathematics. They’re what cement it into place, what make it solid or maybe the glue that holds it in place. Proofs are not in themselves the aim of mathematics, but they’re what hold it together. They’re what make it reliable.

Regarding defining, Ashton pointed out that definitions are in service of the mathematics, and the correct definition is important in order to be able to say something useful: “it depends on what definitions you need in order to be able to say something meaningful. So a lot of times, a theorem is only true if you restrict the definition in the correct ways.” Across these quotes, we see that algorithms, proofs, and definitions are not generally goals, of themselves, but rather tools to accomplish some broader purpose, such as solving problems, increasing understanding, or clearly specifying the limits of a claim so it can be proven.

Relative Importance of the Three Practices

Six of the participants intimated that algorithms, proofs and definitions are all equally important in mathematics. Ashton argued in this direction, stating:

> They’re all mutually supportive. So certainly, you can talk about each of those in isolation, and you should, and I do. But for me, I-- I really do want students to see that those are interrelated ideas. I mean, again, sometimes in order to define something, you have to define it by constructing it with an algorithm. And sometimes in order to prove something, you prove it with an algorithm. And sometimes what you’re proving is that an algorithm works. And sometimes in order to do that, you have to define a new thing. So these don’t have fixed roles in how they interact, right? They all interact in complicated ways and can show up in different spots.

Devin, an applied mathematician, similarly argued in this direction, stating:

> We have the clinical information, we have the model verification, and we have the theoretical proof. That’s the Holy Trinity, baby. That’s it. You are good to go. Man, you have it. And it works altogether. You need all of them working in tandem. Because a lot

> of people, they get the theoretical component, and they get the actual mathematical algorithms, and that's good. But what are these things helping you answer? They're helping you answer the real-world problems.

However, different participants expressed different views on the relative importance of the three practices in mathematics, with some interviewees pointing out that for many users of algorithms, the fact they are useful is the most important thing, not that they can be proved correct. Cooper drew on their own experience and stated, "To be a competently functioning professional, you don't need to be able to do a convergence proof like my numerical analysis colleagues. Because I've never done that for an algorithm, and yet my algorithms seem to be doing fine." Relatedly, some interviewees observed a disconnect between pure mathematicians, for whom proof is paramount, and their applied mathematics colleagues, for whom the utility of mathematical tools is more important. In response to the question of the purpose of proof in mathematics, Ira stated, "That's a loaded question. Proof is important in some branches of mathematics. It is unimportant in other branches of mathematics." In contrast, others viewed proof as more important than algorithms, such as Emery:

> I don't care so much about the algorithms except in the sense of finding such a proof, a constructive proof, which, again, is equivalent to an algorithm, but my focus is not usually on the algorithms, but rather on, again, on using them to prove something.

Still others highlighted the relative importance of definitions, such as Ira: "I tell students that clear, precise definitions are the glory of mathematics. They're the foundation. It cannot be overemphasized that a clear definition is extremely powerful."

Discussion

This study aimed to examine mathematicians' norms and values associated with the mathematical practices of algorithmatizing, proving, and defining. We observed three values related to algorithms, five related to proving, and two related to defining in our data and the literature. These included the new algorithm values of 'algorithms are useful for solving problems', 'correctness of algorithms needs to be verified', and 'algorithms need to be clear to people and communicable to others' as well as the new proof value of 'proving is socially mediated'.

Looking across the values related to the three practices, we observe similarities such as the importance of clear communication and the utility of the practice for consistency or useful applications. However, while many of our participants viewed all three practices as interrelated and mutually important, others strongly viewed some practice or practices as more important than others, potentially based on the subdiscipline of mathematics they were engaged in. Moreover, within each practice we also observe some tensions between different values, potentially related to whether the emphasis is on the process or resulting object. Proofs establish mathematical truth (given specified assumptions) beyond doubt, but proving is socially mediated and can change over time as conventions and expectations change. When defining a new concept, mathematicians have freedom to create a definition in the way that suits them, but definitions, once established, should remain consistent. Algorithms can be useful tools to solve problems, including problems that cannot reasonably be solved manually, but the process being followed in the algorithm needs to be understood, or at least verifiable to some degree, to be sure the tool is aiding in providing a true solution. Future research is needed to better understand which practices are more central to specific subdisciplines of mathematics and how to help students navigate these distinctions across different areas of mathematics and personal views of instructors.

To Whom Are Instructors Obligated?: An investigation of Individual Obligations in Quotient Group Instruction

Holly Zolt
Middle Tennessee State University

Kathleen Melhuish
Texas State University

Teaching is a complex process in which mathematicians are expected to make many decisions before, during, and after the instructional time. These decisions can be shaped by various factors such as pedagogical or content knowledge, professional obligations, or the personal beliefs and values of the mathematician. In this study, we draw on the theory of Practical Rationality as a means to examine the role that professional obligations play in the pedagogical decisions that mathematicians make. Specifically, we examine the role that individual obligations play in instruction noting that the way in which the obligation is viewed can lead to different decisions.

Keywords: Teacher Decision Making, Undergraduate Instruction, Professional Obligations

Teaching is a complex process in which instructors are expected to make a myriad of decisions before, during, and after instruction. Researchers at the K-12 literature have suggested that teacher decision making is a crucial area to better understand instruction and its impact on student learning (Fennema, et al., 1989). The decisions instructors make are affected by various factors such as pedagogical and content knowledge and belief systems (e.g., Ball, et al., 2008). In addition to individual factors (knowledge and beliefs), societal and institutional factors play a substantial role in instructor decision making. That is, instructional decisions are also informed by professional obligations that inform, justify, and constrain said decisions (Chazan et al., 2016).

In contrast to the K-12 setting, less research has explored instructor decision making at the undergraduate level. The work that does exist has primarily attended to the decision to lecture or using inquiry materials (e.g., Fukawa-Connelly et al., 2016) or inquiry practices (Shultz, 2022), and decisions made during a mandated inquiry-based linear algebra course (Mesa et al., 2020). Lande and Mesa (2016) have also examined decisions by community college faculty shaped by their status as full-time or part-time status. In general, little is known about the day-to-day decision making, especially in advanced undergraduate courses. In this report, we begin to unpack this level of decision making through a study with 13 abstract algebra instructors. We provided the instructors with five distinct images of quotient group instruction and analyzed their reflections on instructional decisions using the construct of professional obligation. In particular, we ask: In what ways do individual obligations influence the content coverage decisions made in Abstract Algebra courses?

Theory

Practical Rationality holds that instructors exist in complex environment with four types of stakeholders (e.g., Chazan et al., 2016) leading to a set of professional obligations that influence instruction. The four professional obligations are disciplinary obligations, individual obligations, institutional obligations, and interpersonal obligations. Disciplinary obligations stem from the perspective of knowledge being a stakeholder within the environment. This poses on the instructor that they are "obligated to steward a valid representation of the discipline of mathematics" (Herbst & Chazan, 2011, p. 450). This obligation holds that instructors hold their students to certain standards of proficiency, that the authentic mathematical knowledge is taught,

and that they steward authentic mathematical values and practices. Individual obligations are derived from a client perspective in which students are a stakeholder in their own education. This lends itself to the idea that the instructor is obligated to do what is best for the student (Herbst & Chazan, 2011). The notion of "best" has the potential to vary based on factors such as cultural or historical contexts (Chazan, et al., 2016). Institutional obligations stem from the institution in which the instructor is situated. This places obligations on the instructor that they attend to various policies from the institution, course schedules, and so on. Lastly, interpersonal obligations stem from the perspective that society has a stake in education. The instructor is then "obligated to share and steward their medium of interaction with other human beings in the classroom" (Herbst & Chazan, 2011, p. 450). Additionally, as is consistent with past studies on teacher-decision making (e.g., Lande & Mesa, 2016), we hold that in addition to professional obligations shaping the decisions made, the beliefs, values, and knowledge of the instructor also plays a role.

Instructional decisions are shaped by the professional obligations at play. At times, professional obligations may be in conflict. At this point, an instructor may attend more substantially to one or more obligation to make their choice. For example, a mathematician's obligation to the mathematics discipline may conflict with the required tasks in a given curriculum, an institutional obligation (Chazan et al., 2015). Similarly, a desire to follow a students' reasoning (obligation to the individual) and to enculturate students into proof norms (obligation to the discipline) may be in tension leading to what Herbst (2002) calls the double bind.

Literature Review

The literature base on instructional decision-making in undergraduate mathematics has focused on a few studies and reflections. Schoenfeld et al. (2016) and Woods and Weber (2020) examined university mathematicians using resources, orientations, and goals framework. Schoenfeld et al.'s piece argued that the synergy or relationship between pedagogical content knowledge and mathematical content knowledge influenced the decision making of the mathematician. In using this framing, they found that mathematical correctness or precision was a driving factor in decision making for mathematicians. Woods and Weber (2020) interviewed eight mathematicians about findings from five different studies related to instructional practices in undergraduate mathematics. They concluded that goals of content coverage contributed to the use of lecture practices. Mathematicians' orientation towards precision similarly contributed to the traditional "chalk-talk" practices as it was viewed as allowing appropriate formal content coverage.

A well-studied decision is the decision to lecture. Woods and Weber found that while mathematicians recognized that lecture had shortcomings, they felt it allowed them to accomplish the goals that they had for the course such as content coverage goals, modeling authentic mathematical practices, or preparing future mathematicians. In a large-scale survey of abstract algebra instructors, Fukawa-Connelly et al. (2016) and Johnson et al. (2018) found that 85% of mathematicians chose to use lecture over non-lecture curricula. Further questioning showed that mathematicians often cited time constraints or lack of resources as common reasons why. Johnson et al. suggested institutional obligations accounted for mathematicians' decision to lecture such as time constraints or lack of support from the department. In spite of reporting these perceived constraints, the participants additionally explained that they did not feel pressure to cover specific content and that their departments would possibly support curricular redesigns

suggesting the link between institutional obligations and the decision to lecture was not clear cut. Several other studies have considered some of the decisions instructors make in the context of inquiry learning. For example, Mesa et al. (2020) identified three tensions that mathematicians experienced during the implementation of a mandatory IBL Linear Algebra curriculum. These tensions were between perceptions of IBL and institutional expectations; instructor knowledge and the textbook; and a final tension with pacing of the course. These tensions were underpinned by obligations to the discipline and institutional obligations conflicting with one another. Mesa et al. reported that disciplinary obligations guided a large portion of the decisions made. While the mathematicians were constrained by the curriculum imposed by their department, the mathematicians were in turn selective about definitions, examples, and application-based problems that they used. Mesa et al. did not identify any individual and interpersonal obligations in their data, and there were no claims that could be made regarding how those obligations contributed to double-bind situation. Johnson et al. (2013) studied some of the instructional decisions made by three instructors voluntarily teaching an inquiry-oriented abstract algebra curriculum. They found that the instructors differed in the weight they gave to content coverage aims and the engaging students in authentic mathematical practice. This could reflect a tension related to disciplinary aims (both practice and content) and institutional aims (expected course coverage). The role of course coverage was even more pronounced in Mesa's (2014) study of community college trigonometry instructors whose agency to make such decisions was limited.

Across these studies, disciplinary and institutional obligations are most salient. Our knowledge of these obligations is largely in the context of major instructional choices such as the decision to lecture. The purpose of this study was to examine instructional decisions as a more micro-level by focusing on the specifics of instruction related to quotient groups with attention to obligations to the individual.

Methods

This data comes from a larger dissertation study that examined the pedagogical decisions and approaches related to quotient group instruction. Data collection for this portion of the study involved 13 mathematicians from 6 universities across the United States. These mathematicians were selected via a combination of convenience and snowball sampling (mathematicians suggested other instructors who would be good to interview either because they were thoughtful about their practice or they approached instruction differently). Mathematicians additionally met the criterion of having taught an abstract algebra course since 2019. This criterion was added for the sake of recall. These mathematicians all took part in an initial semi-structured interview where they described their approaches to teaching quotient group. From these interviews five distinct profiles of instruction were developed and shared during the second interview. It is this interview that is the focus of the present paper.

During the second interview, the five profiles or vignettes (each of roughly one page in length) captured an array of instructional decisions including both decisions related to teaching style and those related to content presentation. Mathematicians read through these during the interview (one at a time) and responded to the vignettes as they went through the interview. By examining the decisions of others, we hoped to perturb the mathematicians to be more reflective of the decisions they make and articulate the obligations behind their choices. The five vignettes will be referred to as IOAA (Inquiry Oriented Abstract Algebra), IBL (Inquiry Based Learning), Worksheet, Equivalence, and DTP (Definition, Theorem, Proof). The inquiry vignettes were

heavily student-centered with the IOAA vignette having students reinvent quotient groups from informal ideas of partitioning, and the second having students work in the formal system to develop proofs of major ideas. The equivalence vignette contained a lecture where ideas of quotient groups were rooted in equivalence relations. The DTP vignette was also a lecture-based image of teaching, but it took a traditional approach of providing major definitions including a process for constructing cosets from a normal subgroup. Finally, the worksheet vignette included a similar approach but provided students time to work on worksheets after introducing the content.

Each vignette-response interview lasted approximately 75 minutes and was video recorded and transcribed. As the mathematicians read the vignettes, they were prompted to discuss anything they noticed (positive or negative) or that stuck out to them. For consistency across interviews, there were several talking points across the vignettes that I would bring up if it did not come up naturally. Those talking points included questions regarding training mathematicians and its relation to the participants job and comparing and contrasting the various informal understandings across the vignettes, examples, or questioning practices during instruction.

The data was analyzed for professional obligations using methods described in Shultz et al., (2019). This involved identifying references to each of the four obligations using codebook descriptions developed by Shultz et al. The first author coded each interview completely. Once coded, 10% of the transcript (for each interview) was sent to a second coder. The portion sent to the second coder was randomly selected post removal of discussion not relevant to the study (e.g., talking about technical difficulties was removed before selection). At this stage, there was mostly consistency (76%) on interpretations of obligations. Any disagreements were discussed and resolved.

Results

As results are discussed, we will present some of the findings of the study related to the individual obligations that mathematicians expressed with regards to content coverage. We begin by looking at the role of equivalence within content coverage followed by an examination of mathematicians' decisions in choosing curriculum. Please note that participants in the study are referred to as Dr. A through Dr. N. The vignette instructor does not have a title.

Obligation to the Individual in Content Choices: Equivalence and Intuition

Mathematicians were presented with various formal and informal understandings of quotient groups. In the IOAA vignette, the instructor emphasized the ideas of partitioning in which quotient groups were created via identifying subsets that build a new group structure. This hypothetical vignette instructor put forth that they made the decision to not emphasize formal equivalence relations as it was unintuitive for students leaving that exploration to homework. This is juxtaposed with the Equivalence vignette in which the instructor emphasized defining quotient groups using equivalence relations and classes first then determining that the equivalence relation being explored leads to classes that form a quotient group.

The decision to focus heavily or lightly on equivalence relations were both motivated by obligation to the individual (the students). For example, Dr. D (lecturer – equivalence)[1] stated "I'm very persuaded by the idea of equivalence relations being far more intuitive than cosets. I a

[1] The tag on mathematicians refers to the vignette that I suspected they most likely identified with based on initial interview.

million percent agree with them [the equivalence vignette instructor]." In this quote, Dr. D expressed that the decision to emphasize equivalence due to obligation to students to teach in an intuitive way. Dr. A (lecturer – worksheet) also expressed that she thinks equivalence relations are somewhat intuitive for students and should be covered stating "I think it's a lot more intuitive for students than this person thinks. How intuitive and how well it fits depends on what they've seen before and what they mean about it." Thus, Dr. A is making the decision to build off what students have covered previously which was equivalence relations. In these quotes from both participants, curricular decisions are being justified by their obligation to the individual to teach in a way that is intuitive for students.

In contrast, Dr. B (student centered - IOAA) rationalized the decision to focus on partitioning rather than equivalence relations because:

> You know, I think equivalence relations are very formal and borderline impenetrable for students in terms of them having like a conceptual footing in it and it ends with quotient group structure versus I have students begin with quotient group structures, abstract that idea and then we move to cosets.

This motivation is similarly made via the lens of obligation to the individual and the desire to teach in a way that is intuitive to students. However, the instructors appeared to have different conceptions and evaluations of what is intuitive to students. We hypothesize this may connect to what is valued in the discipline (reasoning from formal definitions) and differing pedagogical knowledge for teaching.

Obligation to the Individual: Teaching Practice and the Choice to Lecture/Not Lecture

As mathematicians engaged with the vignettes, there were often claims made about various teaching styles that extended more broadly than the context of quotient groups. For example, Dr. B (student centered – IOAA) shared their reason for why they adopted student-centered tasks saying, "I don't take curriculum tasks on lightly, without really evaluating whether I think that this is something that makes sense and that this is a way that's likely to be meaningful for my students." Dr. B makes the decision to adopt tasks (in particular, IOAA tasks) based on the perception of students which is an explicit acknowledgement that there is an obligation to individuals. Other instructors commented on the IOAA vignette illustrating something "accessible" for students or providing them opportunity to deeply learn particular content (D4 in this case).

However, unlike what is established in prior research, it was often obligation to the individual that also supported the decision to lecture and not use inquiry approaches. Dr. D (lecturer - equivalence) shared concern that students would not understand the point of an activity without the lecture. Other instructors (Dr. G and Dr. H) explained they thought students would "lose interest" or become bored. Thus, there is an obligation to keep a student engaged and to lead them to a satisfying conclusion, which instructors may see inquiry activities as not meeting.

Finally, we share that for many instructors, the obligation to the individual was not treated as a monolith, but rather the obligation was to support the subset of students continuing to graduate school. Dr I (lecturer - DTP) explained that he felt "inquiry-based learning, especially in something like abstract algebra and deprive[s] anybody, that somebody that wants to go on to grad school." He explained this approach would be good for a class of high school teachers.

In this case, the decision to train mathematicians stems from the academic need of the students going on to graduate school rather than it strictly being a disciplinary obligation to

steward mathematical practice. Dr. G (lecturer – DTP) expressed a similar sentiment with regards to graduate school by saying:

> And of course, if you want your students to have a chance to get into a good graduate program, you have to make sure they are not too much behind compared to students who apply from a school at [University]. You see, Yeah, well, it's difficult because we do get these good students in our classes too. To get them, they are just not as many as at [neighboring school] And so it's hard to cater to them without neglecting the whole rest. At the same time, it's hard to cater to everyone without neglecting the good students. So, it's really difficult.

Unlike Dr. I, Dr. G (lecturer) expressed a tension between meeting the needs of the "good" students without neglecting the other students in this class. As he talked through the amount of material he should cover in class, he seemed to express two separate obligations to two separate groups of individuals – those going to grad school in mathematics and those who are not. Those two sets of obligations created a tension in how he covers and presents material.

In contrast to concerns that the inquiry is not challenging enough for students, some instructors voiced that the inquiry-based learning approach would only work in situations where students came into the course with a strong grasp on proving. Dr. K explained:

> The one thing with our [university] seniors when I'm teaching Modern algebra is, is I also feel to some extent I'm teaching an introduction to proof course. Even though they've already had an introduction to proof it, it tends to be not evident. In terms of what they come with, and one thing that one reason I stick to the equivalence classes is the definition. The definitions of reflexive, symmetric and transitive are things with. Very structured definitions that inform the structure of the proof, so I like them to work with that definition and writing proofs so this may be so there […] I think it would allow me to do a little bit more of just what are the ideas and they can handle the proofs and the definitions later. And it might also it might make this approaching a bit more feasible that I'm saying. Because if they're strong in writing formal proofs, that may be actually decent of formulating definitions for their concepts too.

We point out that such responses reflect an obligation to the student (and that this obligation is shaped by the particular population of students at a given institution) and the decision to lecture is supported by the desire to provide students with material they can succeed at.

Discussion

Due to space constraints, we shared only some of the data related specifically to individual obligations. Our guiding research question informing this report was: In what ways do individual obligations influence the content coverage decisions made in Abstract Algebra courses? We begin by discussing variation in pedagogical decisions that stem from individual obligations followed by a brief discussion about the composition of individual obligations and their role in decision-making.

Individual Obligations on a Spectrum

As a result of the data analysis, we noted that individual obligations seem to exist on a spectrum which allows for the possibility of opposing decisions to be made with the same justification. While mathematically equivalent, a major distinction between the mathematicians was how they defined quotient groups: either as a collection of cosets along with a binary operation that partition a group G (building from informal) or imposing an equivalence relation ~

onto a group G (building from formal). These alternative approaches caused a divide between what participants emphasized. Justifications regarding this divide stemmed largely from obligations to the individual. Recall that mathematicians such as Dr. A or Dr. D felt that equivalence was an important topic that required more attention than just being a portion of the homework. However, on the other end of that spectrum, Dr. B felt as if it was a better decision to not emphasize formal equivalence relations outside of the homework. All of these instructors' justifications were rooted in ideas of what is intuitive and accessible for students. That is, the same perceived obligations can lead to different outcomes, and this influences not just general approaches to instruction, but also smaller content decisions.

Tensions within Individual Obligations

Previous research such as Woods and Weber (2020) noted that mathematicians viewed training mathematicians as an important part of their job, and this goal led mathematicians to engage in lecture practices. While the data supports this conclusion, it also provided more insight into the role that individuals have in the decision-making process. As participants discussed their curricular decisions and what approaches to take, it became apparent that participants viewed their classes as having two competing groups of individuals that had a stake in what was taught in the course. As Dr. G expressed, there were students in the class who were going on to pursue more mathematics and then students who were not. In a sense there was an obligation to train or prepare the students going on to graduate school. However, the students not going to graduate school in mathematics presented a different set of needs. Dr. I framed these individuals as teachers/ those not pursuing more mathematics and those going on to graduate school. Regardless of the title given to the groups of individuals, the two groups imposed competing choices on the mathematician with respect to the content that they covered. In some cases, the instructor prioritized the students going to graduate school and in other cases, the tension remained unresolved as to what was the best course of action to take. We emphasize that the decision to lecture or not lecture was very much shaped by obligations to the individual not just towards obligations to the discipline or to the institution.

Conclusion

In this report responses from a study including 13 mathematicians regarding instructional decisions were discussed. By and large, the mathematicians' choices were influenced by obligations to the individual (the students). However, this obligation appeared to play out differently related to several dimensions including: what the instructor perceives as intuitive to students (which we conjecture may be related to both pedagogical content knowledge and distinctions between intuitive, accessible, and its meaning in deductive mathematics), what group of students is prioritized (those going to graduate school or the broader class), and instructor beliefs about what students are capable of. (such as elite students needed to engage in IBL).

As we consider future directions, we intend to further examine the role that professional obligations play in the teaching of quotient groups and abstract algebra. We note a limitation of this analysis and future analysis is that the data set is limited in terms of reflection rather than in the moment teaching decisions. Even so, we intend to expand from individual obligations to also examining the role of disciplinary, interpersonal, and institutional obligations. Furthermore, we feel that it is worth examining how these decisions impact student learning. We also intend to examine the role of intuition further. This includes investigation into what mathematicians consider to be intuitive and how that is related to the decisions that they make.

Using Schemas to Model in APOS: The Case of the Differential Calculus of Two-Variable Functions

Rafael Martínez-Planell
University of Puerto Rico at Mayagüez

Maria Trigueros
Benemérita Universidad Autónoma de Puebla

Vahid Borji
Charles University in Prague

In this report, we use the Schema portion of Action-Process-Object-Schema (APOS) theory to frame a study of student understanding of the differential calculus of two-variable functions. The use of Schemas allows us to obtain a more holistic perspective of students' understanding. Data was obtained from semi-structured interviews with eleven students. We argue that the APO portion of the theory can give detailed information about specific Schema components but that it does not inform about the interrelations between the different components. However, the notion of Schema and its instrumentalization via the notions of genetic decomposition, types of relations between components, and the triad stages of Schema development can provide a more comprehensive picture encompassing the different components of the differential calculus Schema. The notions of the scope of an instrument and the graph of a Schema are introduced to afford a visual representation of a student's Schema.

Keywords: APOS, schema, calculus, two-variable functions, differential multivariable calculus

APOS is a well-known cognitive theory that proposes that knowledge of a specific mathematical notion is constructed in stages of development, starting with the Action stage and going through the Process and Object stages of conceptualization. The different mental structures constructed in these stages can be organized in Schemas that evolve with time. When learning mathematics, students frequently meet complex situations in which different notions are interrelated to build a more developed structure. In these cases, the focus on single structures of the APO part of the theory is insufficient to capture the situation's complexity. In these cases, it is convenient to use Schemas to model understanding. Schemas provide a more holistic view of knowledge construction and development. In this article, we use the context of the differential calculus of two-variable functions (DC) to exemplify the use of Schemas and propose a way to represent graphically a student's DC Schema at a moment in time.

Literature review

Several early articles introduced APOS theory and its foundational ideas (e.g., Asiala et al., 1996; Dubinsky, 1991, 1994; Dubinsky & McDonald, 2001) with a more recent book (Arnon et al., 2014) summarizing the theory's development. The notion of Schema in APOS is developed from Piaget's ideas (1971, 1972). Since Piaget's ideas were developed in a context different from that of advanced mathematical thinking, they must be adapted to be useful in this new context. Different researchers have made their own adaptations, even for the context of mathematics education (e.g., Vergnaud, 1990), emphasizing different aspects. As with any theory, APOS grows with the contributions of the community of researchers that apply the theory to understand didactic phenomena. The need to further the application of Schemas to understand the didactics of the chain rule led a group of researchers to develop the notion of Schemas in APOS by introducing the idea of the triad of Schema development (Clark et al., 1997). Further development was spurred by attempting to discuss the complexity of a linear algebra course, leading to the notion of types of relations between Schema components (Trigueros, 2019).

Throughout the years, there has been research applying the APOS notion of Schema that deal with different notions, for example, calculus graphing Schema (Baker et al., 2000), implicit differentiation (Borji & Martínez-Planell, 2020), chain rule (Clark et al., 1997), limits (Cottrill et al., 1996), sequences (McDonald et al., 2000), two-variable function optimization (Martínez-Planell et al., 2023), differential equations (Trigueros, 2000), linear algebra (Trigueros, 2019), and modeling (Trigueros & Martínez-Planell, 2024).

The idea of a genetic decomposition for Schemas as a list of Schema components, relations between the components, and a description of the triad has been gaining traction, as may be seen in different publications (e.g., Martínez-Planell et al., 2023). This study's context is the differential calculus of two variable functions; for a literature review of the didactics of this context, we refer the reader to the survey in Martínez-Planell and Trigueros (2021). The article by Borji et al. (2023) is also helpful in this regard. It discusses different research studies on the differential calculus of two-variable functions underscoring their geometrical interpretation.

Theoretical Framework

Since APOS is a well-known theory, we only define what we need from the Schema portion of the theory. We refer the reader to Arnon et al. (2014) for definitions of Action, Process, and Object. A Schema is a coherent collection of Actions, Processes, Objects, and other previously constructed Schemas, dealing with a specific mathematical notion or topic. A Schema is coherent in the sense that the individual can determine when a problem situation falls within the scope of the Schema. This definition of Schema suggests that they may be modeled with a list of components, a list of relations between Schema components, and a description of how the Schema may develop. This model is called a *genetic decomposition* (GD) of a Schema. A GD is neither unique nor meant to describe the best way a student may learn a particular notion. The notion of types of relations between Schema components, introduced by Trigueros (2019), has proved to be useful. A *correspondence* relation is established out of habit or repetition, but the student cannot justify it. It can result from repeatedly seeing two components used in tandem or from superficial comparisons of similarities between components. A *transformation* relation groups different components in a normative way, with perhaps one of them being used to justify or explain the relation between the others. The relation is used normatively in a given problem situation, although not necessarily so across different problem situations. A *conservation* relation is used normatively and fluently across different problem situations. Properties in one structure are conserved or translated to properties in other structures so that the structures seem to be interchangeably used whenever it is convenient. Types of relations are a tool to use when deciding the stage of Schema development of a student with respect to a particular notion N. A Schema is at the *Intra*-N stage of development when the components are isolated or mostly related by correspondence relations; at the *Inter*-N stage of development when there are almost no isolated components and transformation relations start to appear, grouping different components; at the *Trans*-N stage of development when almost all the components are interrelated by conservation relations. The use of the adjectives “mostly” and “almost” in the previous definition is an acceptance of the fact that a student might be in transition from one stage of Schema development to another.

Our research questions are:

How do we study students’ Schemas for the differential calculus of two-variable functions?

What didactical suggestions can we deduce from the study of students’ Schemas?

Methodology

Eleven engineering students spanning the range from above-average (3), average (5), to below-average (3), as chosen by the professor, agreed to participate in two semi-structured interviews two weeks after completing an introductory multivariable calculus course at a mid-tier Iranian university. The two interviews were held on different days, each lasting approximately 1 hour. Interviews were video and audio recorded, transcribed, individually analyzed by the researchers, and discussed among them until a consensus was reached. There were 17 problems in the interviews[1]. The students used activities[2] designed to help them do the constructions proposed in the revised GD described in Martínez-Planell et al. (2015, 2017) and Trigueros et al. (2018). The activities used the ACE (Activities in class, Classroom discussion, Exercises as homework) pedagogical strategy (Arnon et al., 2014). In particular, students worked collaboratively in groups of three or four; each group turned in their collective work, which was promptly graded later; there were group presentations in which their answers were discussed; activities not finished in class were completed as homework; and common difficulties deduced were discussed in class. We do not detail the interview instrument or the activities since this report focuses on how Schemas were used to analyze the data.

While typically one starts research focusing on the Schema portion of the theory by proposing a GD for a Schema, this is not what happened in this study. A GD for the differential calculus of two-variable function (DC) using the APO portion of the theory had been previously proposed, tested with data from students, and revised by Martínez-Planell et al. (2015, 2017) and Trigueros et al. (2018). The revised GD was also expressed in terms of the APO portion of the theory. This was followed by a second research cycle to test the revised GD. The data obtained in the second research cycle, when analyzed using the APO portion of the theory, allowed us to obtain information about some specific components of the DC Schema: partial derivatives (Borji et al., 2024), directional derivatives (Borji et al., 2023), and slope (Martínez-Planell et al., 2022). However, focusing on the APO portion of the theory did not allow us to discuss students' construction of relations between these components and other components like tangent plane, total differential, gradient, and two-variable function, which is what we intend to do in the present study. In this report, we look at the same data but from the perspective of Schemas.

To examine the existing data from the perspective of Schemas, we proposed a list of components and relations. We start by considering the main notions that were tested with the interview instrument as components: two-variable function (F), slope (S), tangent plane (TP), partial derivative (PD), directional derivative (DD), gradient (G), and total differential (TD). To propose the relations, we ask: What can the interview instrument reveal about the relations students establish between different notions of the differential calculus of two-variable functions? The idea of the scope of an instrument proposes one answer to this question. The scope of an instrument is the collection of relations that are directly explored by the instrument or that may be introduced by the student in answering the questions in the instrument. The scope of an instrument may be represented graphically as follows. Each interview question explores at least one such relation. For example, in question 3a, we gave students the graph of a two-variable function and asked about the sign of the partial derivative at a point. A function was given (graphically), and information about a partial derivative (its sign) was requested. So, the question directly explores a relation between the Schema components of two-variable function and partial derivative. We represent a relation that is directly explored by the interview instrument with a

[1] The instrument is at https://drive.google.com/file/d/1ebXyptqwq2BAYYgkq-s02ijmpVfYBtx3/view?usp=sharing.
[2] See activities at https://drive.google.com/file/d/1cef_UjVXt9KxQemVK7hDFBioNND4CfzZ/view?usp=sharing.

solid line, as in Figure 1 (left). Further, the same question allows us to uncover other relations that students may establish. For example, in the same question, a student may decide the sign of the partial derivative by arguing about the slope of the tangent line at the point and thus use the component of slope to mediate the answer. We represent relations that students may indirectly address when answering an interview question with thinner lines, as in Figure 1 (right).

The relations that are directly or may be indirectly explored by the interview instrument are represented in Figure 2. This figure allows us to visually assess how complete an exploration of relations between components an interview instrument can afford. In this case, we see that the interview instrument allows us to inquire into the construction of many of the possible relations in the Schema.

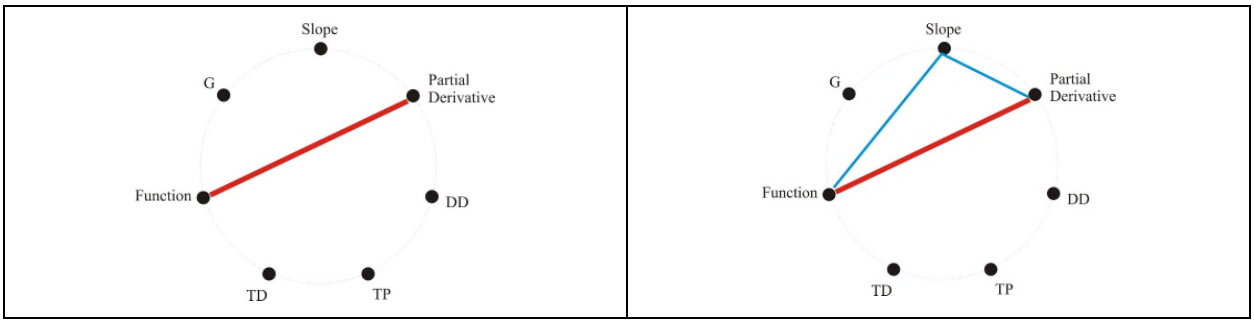

Fig. 1. Relation directly explored by interview question 3a (left) and relations that may be exhibited by a student when answering the same interview question (right).

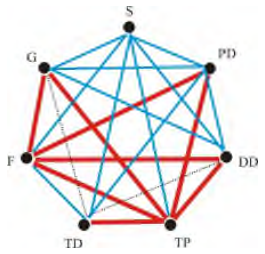

Fig. 2. Scope of the interview instrument. Relations that are directly (thicker lines) or indirectly (thinner lines) explored by the interview instrument. Dotted lines represent relations unlikely to be constructed by students.

After having analyzed the data using the APO portion of the theory, the data was analyzed again using codes that referred to the components and relations obtained from the interview instrument. For Schemas, we needed three distinct rounds of analysis. In the first round, we considered the relation established by the student in each question, if any, and classified its type. For example, if the student was given the graph of a two-variable function and asked for the sign of a specific partial derivative, we could use the codes F-S-PDc (the "c" is for correspondence), F-S-PDt (the "t" is for transformation), or F-S-PDe (the "e" is for equivalence or conservation) if the student talked about slope when answering the question, or perhaps F-PDc, F-PDt, or F-PDe if the student decided the sign based on properties of the function (increasing, decreasing) without mentioning slope. While the first round looked at the data question by question, the second round looked at it longitudinally. That is, we looked at all questions for a given student and verified that if an "e" had been used, the relation had been used in a normative way throughout the interview. We could also upgrade a relation initially classified as "t" to "e" if it had been used fluently and in a normative way throughout the entire interview. In the third round, we classified the students' Schema development as Intra-DC, Inter-DC, or Trans-DC. To

do so, we used the students' "graph of Schema development" to obtain a visual representation of the Schema development. To construct such a graph, we draw line segments between nodes equally distributed in a circle (like in the graph for the scope of an instrument), but this time, the thickness of the line segment depends on the type of transformation (conservation-thick, transformation-thin, correspondence-dotted).

Results

We first analyzed students' construction of relations and the types of relations. We only include an example of one problem situation. For a more complete discussion of the difference between conservation, transformation, and correspondence relations, see Trigueros et al. (2023). Given the graph of $z = f(x, y)$ (Figure 3), students were asked for the sign of $f_{yx}(3,0)$.

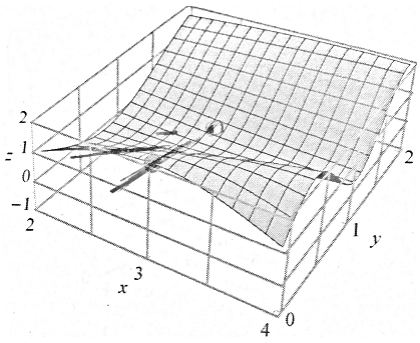
Hamid: This second partial derivative is the derivative respect to *y* and then respect to *x*. So I need to compare the slope of tangent lines in the *y* direction while we move in the *x* direction… Okay. Before the point (3,0) I consider a point like this, umm the tangent line to the curve of the surface in the *y* direction is a line like this and its slope seems to be negative because it's a decreasing line.

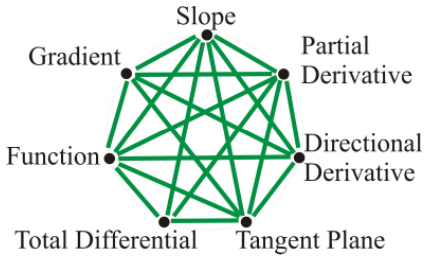
Interviewer: Why did you consider the tangent line in the y direction?

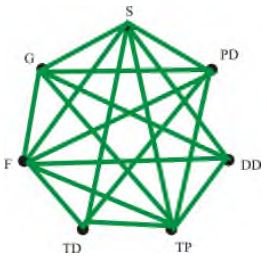
Hamid: Because the first derivative is respect to *y*.

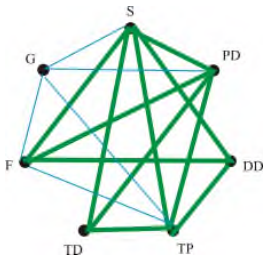
Interviewer: Okay, continue.

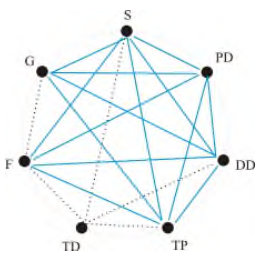
Hamid: I go in the *x* direction because the second derivative is respect to *x*. If I draw the tangent line at the point (3,0) in the *y* direction it will be umm a line like this and it's a horizontal line. Comparing the value of the slopes between these two lines we see that their changes is positive so the answer is positive.

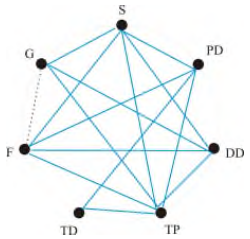


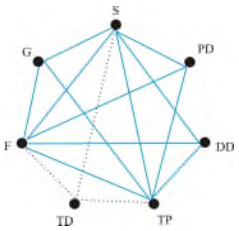


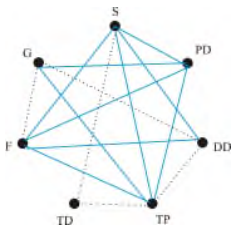


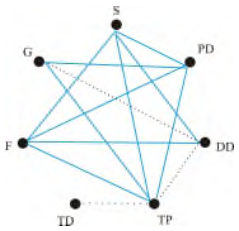


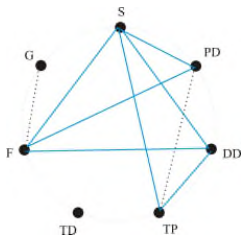


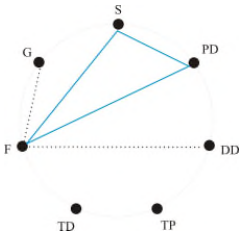












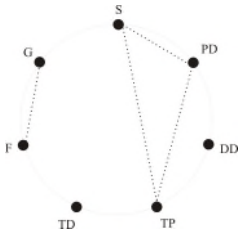


Fig. 3. Hamid's work on the question.

Hamid was given a function (F) and was asked about a (second) partial derivative (PD). He mediated his answer using slope (S) ("I need to compare the slope of tangent lines…"). So, this relation is labeled F-S-PD. His answer is normatively correct and justified, so that the relation is at least a transformation relation (F-S-PDt). Further (not shown here), his answers to questions involving F, S, and PD showed that he could move fluently between these components interpreting properties of one in terms of the other. This was done consistently and in a normative way throughout the interview. F-S-PD was labeled a conservation relation (F-S-PDe).

We then considered students' Schema development using the Schema development graphs in Table 1. Note that these graphs allow us to easily represent students' Schema development using the Intra-DC, Inter-DC, and Trans-DC triad. Results about students' Schema development can inform of their overall understanding and how to better support their learning. We don't show it

in this paper but results about students' stages of Schema development may be used to compare different didactical approaches.

Table 1. Schema development graphs of the participating students.

A1 Trans	A3 Trans	A2 transition from Inter to Trans	A5 Inter
			
A6 Inter	**A7 Inter**	**A4 Inter**	**A8 Inter**
			
A10 transition from Intra to Inter	**A11 Intra**	**A9 Intra**	
			

From Table 1, we can list the different relations between Schema components and the type of relation established by the students. This is shown in Table 2. This table will enable us to uncover the relations that seem to require more student support or increased classroom time or emphasis. This is important since it suggests possible problem situations to help students establish the relations. Thus, the investigation of students' stages of Schema development informs us about the overall performance of students and how to improve it.

Discussion and Conclusions

Our study contributes several observations pertinent to the didactics of the two-variable function differential calculus. Knowing what relations cause difficulty is useful. To see this, we consider the eight relations with the lowest total of conservation and transformation relations and consider the didactic implications of each one (Table 2). Each of F-G and DD-G have only four conservation or transformation relations. This suggests that more attention (class time and/or activities) has to be devoted to studying the properties of the gradient vector, relating it to the contour lines of a two-variable function or the level surfaces of a three-variable function, and to the direction of the largest instantaneous rate of change (largest directional derivative) of the

function. There are only four TP-TD and two TD-F conservation or transformation relations. This suggests that the relation between a tangent plane at a point, the translation to the origin of such a plane and the total differential at the point has to be further explored, together with graphical comparisons of tangent plane and function. Students should be able to think of the total differential as approximating locally the change in functional values geometrically, symbolically, and numerically. There were only two PD-DD conservation or transformation relations. We conjecture that this results from how students constructed directional derivatives (see Borji et al., 2023). They did so by exploiting local linearity and using the tangent plane at a point to talk about slopes in the *x* and *y* direction rather than referring to partial derivatives at the point. This result suggests that it is important that students not only relate tangent plane and slopes for developing the directional derivative but also relate this to the usual formula for directional derivative as the dot product of gradient vector and unit direction vector. Students did not construct the relations TD-G and DD-TD. While they would be unusual constructions and thus unexpected for students, they provide ideas for activities to help students further the coherence of their Schemas.

Table 2. Relations and types of relations established by students.

Relation/type	Conservation	Transformation	Correspondence	No rel.
Slope-Partial Derivative	3	7	1	0
Slope-Directional Derivative	3	6	0	2
Slope-Tangent Plane	3	6	1	1
Slope-Total Differential	3	0	3	5
Slope-Function	3	7	0	1
Slope-Gradient	2	4	0	5

Partial Der.-Tangent Plane	3	5	2	1
Partial Der.-Total Differential	3	1	0	7
Partial Derivative-Function	3	7	0	1
Partial Derivative-Gradient	2	4	0	5
Direct. Der.-Tangent Plane	3	4	2	2
Direct. Der.-Total differential	0	0	1	10
Direct. Der.-Function	3	6	1	1
Direct. Der.-Gradient	2	2	2	5
Tan. Plane-Total Differential	3	1	4	3
Tangent Plane-Function	2	6	0	3
Tangent Plane-Gradient	2	6	0	3
Total Differential-Function	2	0	2	7
Total Differential-Gradient	0	0	0	11
Function-Gradient	2	2	6	1

Another contribution of the study is introducing the notion of the scope of an instrument. This allows examining the suitability of an instrument to explore Schema development. The study also contributes the notion of a student's Schema development graph. It gives a visual way to represent the Schema development of an individual at a moment in time. This simplifies the analysis of students' DC-Schema development using the Intra-DC, Inter-DC, and Trans-DC triad. It can also inform possible didactical interventions, as the above discussion shows.

Partitioning Physical Attributes for Riemann Sum Approximations: Underexamined Competency

Researchers have investigated several interpretations of definite integrals and their notation, and they have recognized that one particular interpretation, Adding Up Pieces (e.g., Jones, 2013), is especially important for applying definite integrals to physics and other domains. This same research has paid less attention to how students partition physical attributes, and thus construct pieces, in ways consistent with constructing Riemann sum approximations and definite integrals. We analyzed how 8 students taking calculus-based physics courses constructed Riemann sum approximations and integrals for one task about water pressure on a tank wall. All of the students recognized that integration was relevant, but half did not partition the wall in ways compatible with constructing Riemann sum approximations or definite integrals that solved the task. We conjecture that seeing integrands as rates of change and structuring situations in terms of level curves for rates of change is a significant, but underexamined competency.

Keywords: Calculus, Integration, Coordination Class Theory

Introduction

A growing body of research has reported on students' interpretation and construction of integrals, especially when using integrals to solve problems in physics and other applications outside of pure mathematics (e.g., Cui et al., 2006; Jones & Ely, 2023; Nguyen & Rebello, 2011; Oehrtman & Simmons, 2023; Thompson, 1994a). One key issue is whether and, if so, how students connect definite integrals with adding up small amounts of a target quantity (Ely, 2017; Jones, 2013, 2015). We present interview data in which college students constructed small amounts when approximating a target quantity in one physical situation. We found that even when students interpreted integrals in terms of Adding Up Pieces (e.g., Jones, 2013, 2015), ways that they partitioned physical attributes were not always compatible with forming normatively correct Riemann sums. This implies significant competencies for applying definite integrals to problems outside of pure mathematics that to date have been left underexamined.

In the sections that follow, we review key strands of research on students' reasoning when applying definite integrals to solve problems, primarily from physics. We then summarize our methods, which were based on interviews with eight students who had credit for at least first-semester calculus and who were enrolled in calculus-based physics courses. We then present four cases in which students partitioned a physical attribute, but not in ways compatible with constructing Riemann sum approximations for definite integrals that solved the task. We use these cases to argue that current research has not paid enough attention to competencies for partitioning in anticipation of forming Riemann sums for approximating definite integrals.

Literature Review and Research Questions

Applying definite integrals to solve problems about physical situations requires reasoning in terms of quantities, such as lengths, time, work, electric charge, etc. Past research has provided a variety of perspectives on such reasoning, and much of it has been grounded in Thompson's

account of quantitative reasoning (e.g., Thompson, 1994b; 2011). One line of work has investigated different interpretations of definite integrals and their notation. Thompson and colleagues (e.g., Thompson, 1994a; Thompson & Silverman, 2008) have argued for interpretating integrals as accumulations from rates. Jones (e.g., 2013, 2015) has found that college students can interpret the $\int_a^b f(x)\,dx$ notation as indicating addition of small pieces (Adding Up Pieces), denotating boundaries of a region in the plane, and signifying a function whose derivative is the integrand. The Adding up Pieces interpretation is particularly relevant to the present study and consists of (a) partitioning a physical situation into small pieces, (b) approximating the target quantity within each partition piece, and (c) summing the small amounts of the target quantity across all of the partition pieces to arrive at an approximation of the total amount. Further work has considered whether, when using the Adding Up Pieces interpretation, students should understand those pieces as products composed through multiplication (e.g., Ely, 2017; Jones et al., 2017; Thompson & Harel, 2021). Exactly how students partition physical attributes in service of constructing Riemann sums and definite integrals, however, has not been highlighted in these studies.

A second set of perspectives has decomposed reasoning about definite integrals into layers that include ones focused on local relationships (e.g., Oehrtman & Chhetri, 2015; Oehrtman & Simmons, 2023; Sealey, 2014; Stevens & Jones, 2023; Von Korff & Rebello, 2012). As one example, Oehrtman and Simmons (2023) proposed *Emergent Quantitative Models* as a tool for tracing how students' attention shifts across three scales when constructing definite integrals. They named these scales the Basic, Local, and Global models. Anticipating the main example from our results section, a Basic model relates quantities with constant values (e.g., pressure • area = force, $P \bullet A = F$). A Local model restricts a basic model to small regions where varying quantities are approximately constant (e.g., pressure • "small amount" of area = "small amount" of force, $P \bullet \Delta A = \Delta F$). A Global model is an accumulation based on local models (e.g., sum of the small amounts of force, $\sum P \bullet \Delta A = F$). Oehrtman and Simmons made four points. First, students can derive different local models from the same basic model. To illustrate, there are at least two possible local models from the basic $P \bullet A = F$ model, $P \bullet \Delta A = \Delta F$ and $\Delta P \bullet A = \Delta F$. Second, students must make decisions about whether or not to partition. This involves recognizing that variation in values prevents constructing a close approximation using a single, global application of the Basic model. Third, students must decide *how* to partition. Fourth, students must decide whether and how to sum small pieces.

The present study makes closest contact with the third point above. In contrast to Oehrtman and Simmons (2023)—who presented a single example in which students partitioned the plane into concentric circles smoothly and appropriately for the task on which they were working—we found that for eight college students enrolled in calculus-based physics courses partitioning in service of constructing appropriate Riemann sums was not always straightforward. For the present report, we focused on one task and asked: *How did the students partition physical attributes and to what extent was that partitioning compatible with setting up a Riemann Sum and concomitant definite integral?* Although all the students recognized that definite integrals were relevant, we present examples in which they partitioned physical attributes in ways that did not lead to Riemann sum approximations and definite integrals that would solve the task.

Theoretical Framework

Our theoretical frame combines expert interpretation of definite integrals with cognitive components evidenced by students. Vergnaud (1983, 1988) has analyzed mathematical structures

for multiplying with quantities and distinguished two subtypes of situations. *Isomorphism-of-measure-spaces* (I-o-M) situations are ones where the multiplicative structure consists of a simple direct proportion between two measure spaces M_1 and M_2 (1983, p. 129). Here the direct proportion can be viewed as a rate of change. One common example is speed • time = distance, where the units might be miles/hour • hours = miles. *Product-of-measure-spaces* situations (P-o-M) are the Cartesian composition of two measure spaces, M_1 and M_2, into a third, M_3 (1983, p. 134). One common example is Newtons • distance = force, where the units might be Newtons • meters = Joules. Riemann sums use rectangular areas to model both I-o-M situations (e.g., integrating velocity to get distance) and P-o-M situations (e.g., integrating force to get work). For the present study, we focus on pressure as a rate (e.g., Newtons per square meter). More generally, if in the $f(x)dx$ notation one interprets $f(x)$ as a rate, then partitioning in anticipation of a Riemann sum involves locating subsets along which that rate is approximately constant. We that researchers have taken different positions on whether one can always interpret $f(x)$ as a rate when modeling situations with definite integral, $\int_a^b f(x)\,dx$.

Our cognitive perspective is informed by Coordination Class theory (e.g., diSessa, 2002; diSessa & Sherin, 1998; diSessa & Wagner, 2005), a strand of theory within the knowledge-in-pieces epistemological perspective (e.g., diSessa, 1993, 2006). diSessa (2002) motivated the notion of coordination classes with the following description of expert accomplishment: "The fundamental assumption behind the idea of coordination classes is that information is not transparently available in the world. Instead, we have to learn how to access different kinds. Indeed, in different circumstances, we may need to use very different means to determine the same kind of information" (p. 43). This description implies that a collection of knowledge resources allows people to see the same concept-specific information across a range of situations, a phenomenon referred to as *span*, and that different subsets of concept-related resources might be used in different situations, a phenomenon referred to as *concept projections* (diSessa & Wagner, 2005; Wagner, 2010). Foreshadowing our concluding discussion, we conjecture that students may need various subsets of resources (an issue of concept projections) to "see" rates and their "level curves" across an expanding range of situations (an issue of span). Moreover, it seems plausible that information about rates of change and level curves are not "transparently available" across both I-o-M situations and P-o-M situations.

Methods

We interviewed five students enrolled in first semester, calculus-based physics (Spring, 2023) and three students enrolled in second semester, calculus-based physics (Fall, 2023). All eight students attended the same selective university in the northeast United Sates. Each student participated in a series of three, one-on-one, semi-structured interviews (e.g., Bernard, 1994; Ginsburg, 1997). The interviews were conducted by the second author and were spaced a few weeks apart. Each interview lasted approximately 1 hour. The students worked on tasks that afforded opportunities to construct approximations through addition of pieces, consistent with constructing Riemann sums. In addition to text, several of the tasks included diagrams or graphs.

We recorded the interviews using two cameras, one to capture the student and the interviewer and one to capture close ups of written work. At the end of each interview, we collected all written work for later analysis. We used a computer to synchronize and combine the two video recordings into a single file, and we transcribed the interviews verbatim.

We analyzed videos for all eight students, attending to their moment-to-moment utterances, inscriptions, and hand gestures. In so doing, it became clear that one task in particular, the Water

Pressure task provided particularly good access to students' construction of approximations in a situation that, for them, was novel. This was in contrast to tasks where students accessed more rehearsed approaches, such as when using sampled velocity to approximate distance traveled. Furthermore, we observed a variety of approaches to partitioning in the Water Pressure task that were not well aligned with constructing normatively correct Riemann sum approximations.

Figure 1 shows the Water Pressure task used in Spring 2023, a task we adapted from Sealey (2014). In contrast to Sealey, we deliberately omitted formulae that might scaffold students' reasoning about multiplication and possible ways to interpret the $f(x)dx$ notation. Because this first group of students appeared to rely on rote recall when relating length and area units, in Fall 2023 we used a width of 4 meters and a depth of 3 feet to see how readily students would measure the tank wall area in meter-feet. One normatively correct approach to the Water Pressure task is to view pressure as a rate: so many units of force per unit of area. A definite integral for computing the total force can then be set up by attending to level curves where the pressure is constant. In this case, those curves are horizontal lines that extend from left to right across the tank wall. As a consequence, the small regions on which to approximate pressure with constant values are thin rectangles that also extend from left to right across the tank wall. Such rectangles were only one of four different approaches we observed when students connected areas and definite integrals. We discuss the three alternative approaches in the next section.

Pressure, *P*, applied across a surface area, *A*, creates a total force, *F*. Consider a vertical side wall of a tank with a width of 4 feet and a maximum depth of 3 feet (see picture below). Assume that the tank is full of water. The pressure on the tank wall increases with the depth of the water according to the following law: $P = 15x$, where x is the depth of the water (the deeper the water, the greater the pressure). Given this information, describe a method for approximating the total force from the water pressure on the wall.

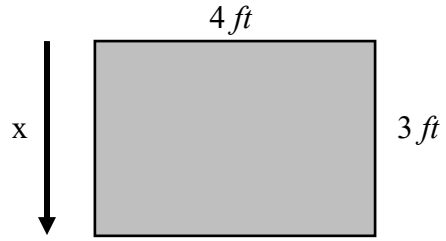

Figure 1. The Water Pressure task

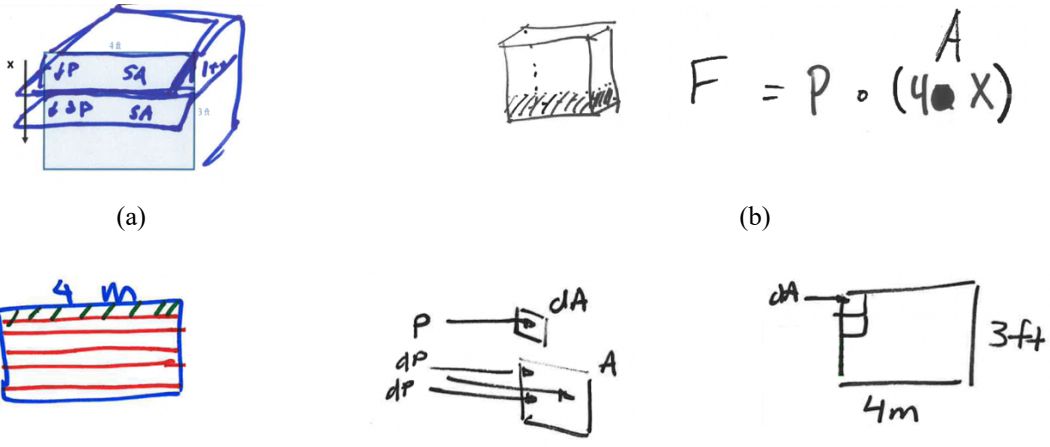
Results

None of the eight students was confident about the relationship between pressure and force, but they all recognized that integration was likely relevant and discussed the $15x$ expression at some point. Thus, they all evidenced knowledge resources spontaneously that we recognized as useful for making progress on the task.



Approach 1: Areas Are Horizonal Cross Sections Parallel to the Bottom

Iliana (SP 23) discussed adding up pieces and located areas as horizontal cross sections of the tank. She read the Water Pressure task and wrote: "To calculate the total force you would take the integral of $P = 15x$ to find the sum of all the surface areas in the tank and evaluate on the bounds (0, x)." She continued by writing "$\int 15x$" and explaining:

Iliana: I just said that to calculate the total force you would have to take the integral of the pressure, and then that is like, integral is really just like finding the sum of all the surface

areas in the tank. The like, because like the pressure is just applied across each little area for like *x* [gestured with open palms to indicate horizontal slices].

Iliana commented "I don't feel like the 4 feet of the width has anything to do with that, but it might. I am not completely sure." When the interviewer asked where Iliana saw surface area, she drew horizontal slices (Figure 2a) and confirmed that her arrows pointed "downward." Thus, her verbal explanation, hand gestures, and drawing gave consistent evidence that she imagined pressure applied to cross sections parallel to the bottom of the tank. Because Iliana may have misread the description of the situation, the interviewer asked whether she considered pressure on the tank wall. Iliana reported that she had not, quickly recognized that "the pressure is like pushing outward onto the side with the force," and stated "But my picture still, this still goes like that [retracing horizontal slices in Figure 2a]." Thus, Iliana's orientation to areas did not shift hand-in-hand with her orientation to pressure.

(a) (b) (c) (d) (e)

Figure 2. Pieces of area. (a) Iliana, (b) Alex, (c) Melinda, (d) Matthew, (e) Matthew

Approach 2: Areas Are Vertical Regions of the Tank Wall (4*x*)

Alex (SP 23) and Melinda (FL 23) made comments that referenced adding up pieces, and they discussed pressure and area as functions of *x*. As soon as he finished reading the Water Pressure task, Alex used rate language to describe pressure: "We can say that this up here is pressure, which is in some units of force per square unit area." He considered downward pressure momentarily, similar to Iliana, but then turned his attention to pressure on the vertical wall, as we intended. He explained:

> *Alex*: If we're talking about the pressure out from the water, then what we have to talk about is *P* times the area of the tank wall. So *P*, which is 15*x*, and then the area of my tank wall is going to be 4 times *x* [wrote $(4 \bullet x)$, Figure 2b]….So, I want to figure out how much pressure is being applied to that little rectangle [shaded region in Figure 2b]. So, then this would be the pressure applied across the surface area. So, this is my *A* here [wrote A above $(4 \bullet x)$] creating my total force *F* on the sidewall of the tank [completed writing $F = P \bullet (4 \bullet x)$].

An exchange later, Alex explained that "my intuition there is if I'm doing something across an area, I usually use multiplication." He then used multiplication to describe the normatively correct relationship between pressure, area, and force:

> *Alex*: It's not that I have a total number *P*, and I'm splitting it up into smaller chunks. It's that I need to make sure that *P* is being applied equally to each one of these parts of *A*. So I

would need to be multiplying *P* by *A* in order to get that force over the area, or that pressure over the area to find the total force.

Alex's comments left unclear precisely where he located "each one of these parts of *A*." Although his discussion of parts was disjoint from using a Basic model, he continued using $(4 \bullet x)$ for area as he worked on the task.

Melinda initially wrote $A = 4 \bullet (3 - x)$ and $P = 15x$. She then graphed $P = 15x$, wrote $\int_0^3 15x\ dx$, and explained approximation in terms of adding pressures at different depths: "If we, say, measure at like more points, right? At all these, all these like *x* values and then we add them all up, then we can get a better approximation of the total pressure that's going against the wall." A few exchanges later, she shaded a rectangular strip at the top of the wall (Figure 2c) and changed her area expression to $4 \bullet (x)$. At the same time, when the interviewer asked Melinda about her $\int_0^3 15x\ dx$ integral, she explained:

> *Melinda*: You would want to find like the area of like a little piece, or like one of these, right. And that would be *dx*, which is the change in *x*, times the height, which is 15 times *x* or like it follows this function. And so, to find the area of that, it's like a rectangle. So, you just multiply the base times the height and then you find the area of that.

Melinda recognized that rectangles on the wall and on her graph of $P = 15x$ referred to different combinations of quantities, but she did not connect local rectangular regions on her graph to local rectangular regions on the tank wall.

Approach 3: Areas Are Regions That Tile But Do Not Span the Tank Wall

Matthew (FL 23) considered two ways to construct a small piece. His first was to consider pressure applied to little bits of area. He wrote $F = \int P\ dA$, a first step toward a normatively correct solution. His second was to consider little bits of pressure applied over the entire tank wall. He then provided a reason for choosing the latter over the former:

> *Matthew*: I don't know if it's going to be area, *dP*, like a little bit of pressure over the entire area, or it's this total pressure over the entire space of the area. But given that the area is constant, and I guess the pressure's changing, I think I would actually not go with this and do, maybe *dP* times *A*.

Next, Matthew wrote $F = \int dP\ A$, plugged in information provided in the task statement, and arrived at $F = 4m \bullet 3\ ft \int_0^3 15\ dx$. A few exchanges later, he reiterated:

> *Matthew*: The reason I said *F* equals *dP* times *A* instead of pressure *dA*, which is the area, is because the, the area isn't changing, like the size of the, the wall isn't changing, but the pressure is with the depth of the water.

Matthew then produced drawings to indicate how he visualized his two approaches (Figure 2d). For the drawing with several arrows labeled "*dP,*" he explained, "And when you, when you sum up all these *dP*s, you would get the pressure." Figure 2e shows how Matthew responded when asked where on the wall he saw *dA*. Notice that he apparently intended to tile the wall, but not with rectangles that spanned the width of the tank wall. A few exchanges later he explained that the pressure was constant on horizontal lines that spanned the width of the tank wall, but he did not revise his approach for setting up an integral.

Approach 4: Areas Are Normatively Correct Thin Slices That Span the Tank Wall (4d*x*)

Three of the remaining four students located a small piece of area as a thin rectangle that spanned the tank wall, even if they encountered other challenges constructing and interpreting

integrals to solve the task. Jack (SP 23) quickly drew a horizontal line across the tank wall to indicate a generic small area and wrote the expressions 4 *dx*. He then used the phrase "pressure over area" and tried to reason about *P*/*A* as the integrand, a misdirection that he eventually recognized and corrected. Izsák and Sus (2024) reported on Larisa (SP 23), who generated 15 * .04 = .6*N*, a normatively correct approximation for a small piece of force at $x = 1$. She then dismissed such a small contribution as inconsequential, in essence questioning the logic of Adding Up Pieces. Torin (FL 23) generated $F = \int_0^3 15x \bullet 4\ dx$, drew lines across the tank wall, but stated repeatedly that *dx* was simply a notation that did not carry meaning in the situation. In particular, he did not connect *dx* with a small change in height. Finally, Kathrine (SP 23) generated $\int 15x\ dx$, interpreted this integral as the area under the graph of 15*x*, and discussed trapezoids for determining that area, but she made no reference to rectangular areas on the tank.

Conclusion

We examined how students partitioned a physical attribute in service of constructing an approximation in a situation that, for them, was novel. Our results demonstrate that invoking the Adding Up Pieces interpretation of definite integrals (e.g., Jones, 2013, 2015), though often necessary, is not always sufficient for constructing appropriate Riemann Sum approximations for definite integrals. All eight students we interviewed considered using a definite integral for solving the Water Pressure task, and all eight discussed Adding Up Pieces art some point. At the same time, we observed four different approaches to partitioning the tank wall. One approach was normatively correct, but the remaining three were incompatible with constructing approximations for integrals that would solve the task. This result leads us to ask what knowledge would support students' approaches to partitioning physical attributes and generating Riemann Sum approximations, especially for situations with which they are less familiar.

In the Background section, we organized past research on definite integrals into two large strands, one that has identified different interpretations of integrals and one that has delineated multiple layers of attention when generating integrals. Compared to past research, our results suggest that more precise theory is necessary if we are to account for students' reasoning about definite integrals in ways that can ultimately inform instruction. We conjecture that tools from Coordination Class theory could help. Wagner (2016) took a first step in this direction when arguing that students' various interpretations of definite integrals could be understood as different concept projections. Future research could investigate in greater detail how students connect the $f(x)dx$ notation to problem situations. As an example, Matthew's decisions were driven by the fact that the tank wall area was known and constant, which led him away from normatively correct reasoning. Future work should examine how students might look for rates of change and their level curves across diverse situations. As noted by diSessa (2002), relevant information is not always transparently available, and students may need different means to determine how to partition physical attributes when applying definite integrals to solve problems outside of pure mathematics.

Coping With Coercion in Logic: A Case study

Alan Pasos
Simon Fraser University

Rina Zazkis
Simon Fraser University

The ability to make a logical inference is at the heart of mathematical experience. However, a personal reasoning does not always follow the rules of formal logic. In this case study we focus on responses of one participant, a secondary school mathematics teacher, to scenarios involving coercive logic (the construct is defined and exemplified in the paper). This allows us to take a detailed look into what guides and what influences the participant's approaches to various scenarios. We argue for the relevance of coercive logic to mathematics education, in particular, in exploring mathematical reasoning of students.

Keywords: logic, reasoning, coercive logic, mental models, illusory inference

Logical reasoning is inseparable from mathematics. However, research has shown that the study of formal logic does not always result in improved logical derivations (O'Brien, 1973; Wason & Johnson-Laird, 1972; Johnson-Laird & Byrne, 1991; Inglis & Attridge, 2016). Moreover, while there are disagreements within psychological reasoning theories, many theoretical perspectives that explain human reasoning are strongly linked to mathematical theories, such as probability, formal logic, or model theory, to mention a few.

In what follows we situate our investigation within ample research on mathematical reasoning and logical inferences. We then introduce the notion of coercive logic and analyze responses of one participant to scenarios involving coercive logic.

On Logic and Reasoning in Mathematics Education

Numerous studies have explored diverse aspects of formal logic in mathematics education. There are studies that concentrate on negation (Antonini, 2001; Barnard, 1995), logic connectives (Dawkins, 2017; Dawkins & Cook, 2017), axioms (Dawkins, 2018), contrapositive reasoning (Stylianides, et al., 2004), and quantifiers (Dawkins & Roh, 2020), among others. A general aspect of this research is the advocacy for the understanding of formal logic as a tool that supports mathematics learning.

One of the fundamental aspects of logic and reasoning is implication (Dawkins & Norton, 2022; Dawkins, et al., 2021; Hub & Dawkins, 2018), that is, conditional statements. As mathematical theorems, or propositions in general, can be presented in a form of conditional statements, students' understanding of implication attracted interests of researchers interested in learning proof.

Conditional reasoning has an extensive literature in the cognitive sciences (Nickerson, 2015). In particular, research surrounding the Wason's selection task (Wason, 1968) showed that not all reasoning behind deduction or inference belongs to the formal logic realm; there is a lot of deduction that is context dependent (e.g., Cheng & Holyoak, 1985). Further, mathematical background of participants influences their decisions, as noted by Stylianides et al. (2004) in their study of on interpretation of contrapositive statements, in comparing everyday scenarios and the related symbolic form.

Introducing Coercive Logic

The concept of coercive logic was developed and popularized by Raymond Smullyan (1997) in his book "*The Riddle of Scheherazade and Other Amazing Puzzles, Ancient & Modern*". Smullyan (1997) defines coercive logic as "...an almost magical quality in that it forces [someone] to do something [they] wouldn't otherwise have done..." (p. 256)." (He credits the name to his son-in-law Dr. Jack Kotik.)

Example of Coercive Logic

Smullyan (1997) introduces coercive logic with a story of Scheherazade (a character from the Arabic collection of stories known as "One thousand and one nights"), who every night escapes the execution by entertaining the Sultan with stories. Smullyan changes the stories to puzzles, where Scheherazade gets the Sultan's promise to answer truthfully to one question, indicating only YES or NO. What would be the question that can spare her life? One of the suggested solutions for this logical puzzle is for Scheherazade to ask: "Will you either answer NO to this question or spare my life?". Note that the NO answer implies that neither of the two alternatives holds, but this would be the false answer, which negates the Sultan's promise to answer truthfully. As such, the only truthful answer is YES, which means that at least one of the two alternatives holds, and it must be the latter. With such a question Scheherazade can coerce the Sultan to spare her life.

Analyzing the case with the formalism of mathematical logic, we use:

N = you answer is NO ; L = spare Life

So, the given condition is "N or L", which is true if at least one of the alternatives is true.

Let us examine the outcome of each possible answer. The NO answer negates both N or L, so we get "¬ (N or L)", which is equivalent to "¬ N and ¬ L", which is a contradiction.

As such, the YES answer is the only option to avoid contradiction, because in "N or L", N is false, thus L must be true for "N or L" to obtain a valid true value.

To the best of our knowledge, there is no research in mathematics education that explicitly attends to coercive logic.

Coercive Logic, Brainteasers and Unfamiliar Environments

Paradoxes, puzzles, riddles, brain teasers, conundrums, etc. (basically any instrument that could create uncertainty or cognitive conflict) can enrich teaching and learning of mathematics (Kleiner & Movshovitz-Hadar, 1994). They have been part of mathematics and mathematics education throughout history. Scenarios that involved coercive logic have features that are similar to other kinds of recreational mathematics.

Coercive logic has characteristics related to cognitive conflict, inference, and uncertainty. These moments of doubt are opportunities to learn, teach, and learn as a teacher. Zaslavsky (2005) argued in favour of awakening certain dynamics that occur when dealing with cognitive conflict. She further mentioned that uncertainty is relevant to develop explanations and in general contribute to learning mathematics. We observe that coercive logic has the potential to become a motivational tool for the study of mathematical logic.

Scenarios of coercive logic, often presented as puzzles, are related to logic paradoxes, but there is an important difference. A paradox presents a self-contradictory statement or a situation that leads to contradictory conclusions. For example, in the famous Russell's paradox (The barber is the "one who shaves all those, and those only, who do not shave themselves". The question is, does the barber shave himself?), a barber who does not shave himself, actually shaves himself. However, in the coercive logic scenarios there is a "way out", that is, a

possibility of introducing an appropriate statement that will avoid a presumed paradox and lead to a desired outcome.

Research in mathematics education has demonstrated that asking learners to operate in unfamiliar environments can reveal their understanding of the elements of more familiar situations. For example, asking students about fractional numbers written in different bases reveals their understanding of place value (Khoury & Zazkis, 1994, Zazkis 1999); asking students to work with non-Cartesian coordinates highlights their knowledge of the Cartesian coordinate system (Zaslavsky et al., 2002, Zazkis, 2008). In a similar way, we expect to learn about participants' reasoning in the unfamiliar environment of coercive logic. In particular, we are interested in aspects of participants' reasoning and logical inference that are revealed when they respond to scenarios involving coercive logic.

The Study

Participants in our study were secondary mathematics teachers enrolled in a master's program in mathematics education. Our data sources included two written response questionnaires, which included coercive logic scenarios, and a semi-structured interview. As an introductory case study, which is a part of larger research, we focus here on one participant, Sal, whose responses were detailed and featured his approaches and hesitations.

Coercive Logic Scenarios

For the purpose of our study, we define coercive logic scenario as a fictional story culminating in a set of two conditional statements with different consequents, and a viable sought-after-statement that nullifies one or both conditionals to reach a unique valid and desirable outcome. This statement introduces a coercion. Consider the following example, used in one of our tasks:

> *You were trapped by cannibals, and they want to eat you. Their chief, who is known as a perfect logician, tells you that you can speak your last words, which should indicate your choice* (this is the story).
> *If what you say is true, then they will cook you in water.*
> *If what you say is false, then they will cook you in oil.*
> (this is the set of two conditionals)

The sought-after-statement is: *You will cook me in oil.* This statement nullifies both consequents: you cannot be cooked in water because the statements is not true. You cannot be cooked in oil, because "cook you in oil" is an implication of the false statement, and your statement is not false. In our design of coercive logic scenarios, we have constructed a variety of stories with sets of conditionals, in which the sought-after-statement leads to coercion and desirable outcomes. The participants were asked either to evaluate the given statements, or to formulate a statement that would lead to a desired outcome, such as avoiding a penalty or obtaining a reward.

Data Collection

The data collection was based on two questionnaires, administrated two weeks apart, and a semi structured interview scheduled after the completion of questionnaires.

Questionnaire 1 aimed at establishing a basic familiarity with formal rules of inference, and then introduced coercive logic scenarios. It included 6 multiple choice items. All items in Questionnaire 1 asked participants to explain their choice briefly for each case.

The first 4 items focused on conditionals with modus ponens structure, as well as 'and' and 'or' operators. In particular, acknowledging the differences in interpreting these operators in natural language vs. mathematical logic (exclusive vs. inclusive 'or'; consecutive vs. symmetrical 'and'), we were interested in participants' choices as the basis for their familiarity with formal rules of inference.

For example, Item #3 presented the following statements: (1) All flowers are red or beautiful, and (2) All Tulips are flowers, followed by questions: (i) Are all tulips red? (ii) Are all tulips beautiful? (iii) Are all tulips red or beautiful? (iv) Are all tulips red and beautiful? Item #4 presented the following: Your dinner includes an alcoholic drink or a mock cocktail with your meal. Are you having only one drink with your meal? For each question the participants had to indicate (a) Yes, (b) No, or (c) Not enough information.

Items #5 and #6 introduced coercive logic scenarios. They presented a story followed up by two conditional statements with different consequents, and a sought-after-statement to achieve the desired outcome. The participants were asked to examine the outcome of the statement. In particular, Item #5 included the Cannibals scenario presented above, with the sought-after statement "You will cook me in oil". The participants were asked to indicate (a) Yes, (b) No, or (c) Not enough information, to the two questions – Are they cooking you on oil? Are they cooking you in water" – and explain their reasoning. Item #6 included a scenario isomorphic to the Cannibals, but in a different (non-violent) context.

Questionnaire 2 included four coercive logic scenarios. Unlike items #5 and #6 in Questionnaire 1, in which the sought-after-statement was presented for participants' evaluation, the first two scenarios presented multiple choice options, only one of which included the sought-after-statement that results in coercion. In the next two scenarios the participants were asked to formulate by themselves the sought-after-statement that would reach the desired outcome. As an example, Fig 1 presents the second item of Questionnaire 2.

Scenario 2: Hogwarts

You are walking through the halls of Hogwarts School of Witchcraft and Wizardry when you suddenly bump into Professor Severus Snape making him drop all of his books and potions. He then tells you that as a punishment, he will put a spell on you. He will give you the chance to make a statement to choose what spell he'll curse you with.

You will make a statement such that

- if what you say is true, then the spell will be Petrificus Totalus (A body-binding curse that causes a person to experience temporary full-body paralysis.), and
- if what you say is false then the spell will be Obliviate (a spell that will make you forget all the content of your Witchcraft courses).

Then you have to choose one of the following statements to tell Professor Snape:

- Statement 1: You will give me the Petrificus Totalus.
- Statement 2: You will give me the Obliviate.
- Statement 3: You will either put a spell of Petrificus Totalus or of Obliviate.

Please chose one of the statements and explain the outcome of your choice.

Figure 1: Example of coercive logic scenario from Questionnaire 2

In an individual **semi-structured interview** setting selected participants were asked to examine and elaborate further on their written responses. The interviews lasted about 50 min; they were audiotaped and later transcribed. Participants were provided with an opportunity to change their responses and to reflect on their experience of addressing the questionnaire.

Theoretical Framing: Mental Models

The construct of "mental model" was initially introduced by Craik (1943) as mental representations of situations, which can be real, hypothetical or imaginary. Such models may contain perceptual qualities and may be abstract in nature. Johnson-Laird (1983) extended this idea to create a *mental model theory* of reasoning and deduction (Johnson-Laird & Byrne, 2002) Johnson-Laird (2012) summarised the three principles of the theory developed in the previous studies: (1) The principle of *iconicity*: A mental model has a structure that corresponds to the known structure of what it represents, (2) The principle of *possibilities*: Each mental model represents a distinct possibility, by capturing common features in different ways of occurrence, and (3) The principle of *truth*: Mental models focus on what is possible or true in the premisses. That is, what is impossible or deemed false is not commonly represented.

Mental model theory led to debates in the reasoning and cognitive sciences, as it advocates strongly for an effective prototype of inference non-dependent of formal rules. This prototype was able to predict systematic fallacies that cannot be explained by theories based solely on valid rules of inference (such as mental logic). In particular, Johnson-Laird & Savary (1999) introduced the notion of *illusory inferences*, that is, inferences that are compelling but invalid.

Example: Suppose that the following claims apply to a specific hand of cards, where only one of the two is true.

(a) If there is a king in the hand then there is an ace in the hand, or else,

(b) If there is a queen in the hand then there is an ace in the hand.

There is a king in the hand. What, if anything, follows?

Note that the conclusion: "There is an ace in the hand", is an invalid inference that is predicted by the mental model theory, based on the principles of possibility and truth. Given an exclusive disjunction of the two conditionals, (a) or (b), but not both, must be the case, however the further assertion – that there is a king in the hand – is definite. However, the disjunction is compatible with the falsity of one of the two conditionals. Since which one is false is unknown, there is no guarantee that there is an ace, even though there is a king. In particular, if (a) is false, the possibility of "ace in the hand" cannot be confirmed.

These illusions arise from the principle of truth. That is, the mental model for individuals who erroneously concluded "There is an ace in the hand", did not attend to the possibility that (a) in the premises can be false. It is shown that inferences that attend to truth only alleviate the illusions (Goldvarg & Johnson-Laird, 2000, 2001; Tabossi, et al., 1999).

Furthermore, according to mental model theory, people have a tendency to reason their way to consistency, that is, if they detect an inconsistency, they try to determine which premise to abandon to create consistency within a situation (for model accounts of these processes see e.g., Johnson-Laird, et al., 2000).

Attending to the case of Sal and his logical inference in considering coercive logic scenarios, we focus our research question on the particular case study: *How can mental models account for Sal's logical inference when responding to scenarios involving coercive logic*?

Results and Analysis

As mentioned above, our analysis is a case study of Sal. We chose Sal as his arguments appeared detailed but inconsistent, and, as described below, he provided unexpected ideas related to the coercive logic scenarios.

Item #4 on Questionnaire 1 is a specific question to evaluate the distinction between inclusive and exclusive "or". Sal's answer (Yes) to this question (having only one drink) points to Sal's understanding of disjunction as an exclusive 'or' in natural language. However, Sal's response to Item #3-iv (are tulips red and beautiful) was "Not enough information", which is inconsistent with exclusive disjunction. Further, for Items #5 and #6 of Questionnaire 1, which introduce scenarios of coercive logic, Sal indicated "not enough information" for each of the two questions in both items. Sal was not able to resolve the scenarios, and this can be further appreciated in his comment "we can't test whether the statement is true or not?". It appears that Sal was seeking an a-priori indication of the truth value of the claim in order to be able to examine the implication, rather than proceeding with hypothetical assignment of truth. Without such knowledge he was not able to proceed to examining the conditionals.

In Questionnaire 2 Sal chose the option that included the 'or' clause when it was one of the available choices. That is, for Item #2 he chose the statement "You will either put a spell of Petrificus Totalus or of Obliviate." Furthermore, he formulated the disjunctive statement when on the two items that invited participants to formulate a claim.

In the interview, Sal explicitly acknowledged being very confused on items #5 and #6 of Questionnaire 1. However, when asked to consider his responses to the items of Questionnaire 2, he noted, with respect to the Hogwarts scenario (see Fig. 1):

> *Sal*: But by saying this entire thing, it becomes true though, like it cannot be false [points out statement 3], this cannot be false is what I would like to say, cause whatever I say I am either gonna get either PT [refering to Petrificus Totalus] or Obliviate, right? But then the entire statement is true. So, I thought I would be getting the PT spell.
>
> *Interviewer*: Ok, how was that you come to the idea that this one is true then the second one [pointing to the second conditional] is not happening, right?
>
> *Sal*: Right, yes, that's right the second one, so I won't be getting the Obliviate if I say statement 3, it's what I was thinking.

The selection of disjunctive statement, which is tautological but true, invalidates one of the conditionals in the presented scenario. That is, the second conditional becomes irrelevant, yet the exclusive disjunction between the conditionals holds valid.

A disjunction in which components hold opposite truth values produces a tautology. Nevertheless, a choice of tautology resolved the situation for Sal, as he considers the consequent associated with truth as a preferred choice. That is, PT is preferable as it is temporary.

> *Sal*: Oh yeah, so, this PT spell says temporary full body paralysis something that's temporary. My paralysis will be gone, that's what I was thinking, versus this obliviate in that one you just forget all of the contents of the stuff that you learn from the course, right? So, I've rather had a temporary one rather than just forgetting everything that I've learnt. So, that's why I choose it, I'll go with the truth. Choose the PT one and say the truth.

This could have been an oversight in our design as we considered both choices to be undesirable and avoidable via appropriate logical coercion. However, for Sal the "truth" was associated with a desirable outcome, which is the less hurtful of the provided unfavorable choices.

During the interview Sal emphasized the fact that he wanted to choose the statement that contained a truth antecedent, and thus simplify the scenario to a unique conditional to deal with.

> *Interviewer:* I can see that there's some logic over all in the general aspect of your answers, for example, you were congruent in the choices that you were making [...] in this scenario 4 [item #4 in questionnaire 2] that you were asked to give a statement, you actually selected something similar to the previous scenario. So, the question now is: how come? Why did you decide on a statement of a similar form to the previous ones?
>
> *Sal*: If I had not read these first two questions, because it actually gave me the [pause] by saying "either or" I am making a true statement and can choose whatever I want to […] So, I wanted to get something off of the statement, so let's make a truth statement, so I think the first two question gave me a way of [pause], in my mind getting me definitive truth statements. So, then I can use that "either or" logic in here so that I am choosing the truth. So, I am making a truth statement […].

We note in this excerpt that the principle of truth manifested itself to increase the possibilities of a mental model that addresses the given logic scenario without the need to consider a possibility of a false statement. We consider Sal's responses as an example of *illusory inferences,* guided by the principle of truth.

But it is not enough to deal with one conditional to find a way out of coercive scenarios. This is clearer when there is no preference in the consequents of the conditional, such as in Cannibals scenario. It is the independent evaluation of both conditionals that allows participants to formulate or choose an appropriate sought-out-statement. Sal was not able to reason on items in which he did not identify a desirable outcome. However, when a choice was possible, he corroborated a mental model principle of truth that did not result in coercion, but allowed for a desirable (that is, less hurtful) choice.

Considering Sal's written responses, and his elaborations during the interview, we conclude that the principle of truth guided the construction of the mental models that Sal used to resolve the coercive logic scenarios. This guidance was effective in the scenarios in which there was a preference for an outcome within the coercive logic scenarios, but failed when it was necessary to construct dual mental models to deal with two conditionals presented in the scenarios.

Discussion and Future Research

Our research aimed at studying participants' reasoning and logical inference when they respond to scenarios involving coercive logic. In particular, we focused on the case of Sal and identified the prevalence of the truth principle in his mental models. Our contribution can be seen in introducing coercive logic scenarios as a method for studying participants' reasoning that may not be revealed by other means.

A limitation of the study is in our initial design of tasks that requires a minor adjustment. Our design of scenarios progressed from (a) asking participants to evaluate a sought-after-statement in Questionnaire 1, to (b) choose an appropriate claim from the presented possibilities, and (c) to formulate a claim in Questionnaire 2. However, the presented tautology and the disjunctive claim in (b) has influenced Sal's reasoning and directed his subsequent choice to an option that is "always true" and in such avoided coercion. We will eliminate such an option as we continue our research.

Our future research will explore additional theoretical constructs that may explain Sal's (and other participants') reasoning, either intertwining with mental models theory or presenting an alternative. For example, how can the notion of reducing abstraction (Hazzan, 1999; Hazzan & Zazkis, 2005) explain Sal's approach, especially the prevalence of the truth principle?

Student Understanding of Solids of Revolution: Refining a Previous Model

Deborah Moore-Russo
University of Oklahoma

Rafael Martínez-Planell
University of Puerto Rico at Mayagüez

Nick Brown
University of Oklahoma

In this study, we consider students' performance on tasks involving solids of revolution to refine a recently introduced, research-based model. An activity was designed with tasks to help students do the constructions proposed in the model. After implementing the activity in the classroom, we suggest additions to the model using data from the written responses of 22 university calculus students' quiz and exam tasks. The results provide information about the challenges that students face when dealing with solids of revolution and allow us to refine the model to add more detail that might be used to help students overcome observed challenges. We discuss some limitations of the study and share teaching implications.

Keywords: Solids of revolution, Calculus, APOS theory, Riemann sums

Introduction and Literature Review

There is considerable research on student understanding of one-variable function integration (e.g., Jones, 2015; Orton, 1983; Sealey, 2014; Thompson, 1994; Thompson & Silverman, 2008). In one of the first studies dedicated to integration, Orton (1983) found that volumes of revolution were one of the three most difficult integration topics for students; the others were Riemann sums and limits of Riemann sums. Jones (2013) observed three major meanings for symbolic forms of integrals that emerged from student data: adding up pieces, perimeter and area, and function matching that roughly correspond respectively to a definite integral's relation to Riemann sums, the area-under-a-curve conception, and the integral as an anti-derivative. Jones (2013) observed the importance of the "adding up pieces" interpretation for applications and, like Orton (1983), suggested it needed more emphasis. He later reported (Jones, 2015) that the area-under-a-curve and anti-derivative conceptions were highly prevalent, with the Riemann sum-based conception being underutilized. This underutilization was also observed by Akrouti (2020), even in tasks where using Riemann sums was the only reasonable approach. Speer and Kung (2016) observed that there is little research dealing with volumes of solids of revolution (SoR). Some studies (e.g., Paul et al., 2024) consider the use of manipulatives when teaching this topic. However, few studies unpack students' difficulties with the topic. In one such article, Mofolo-Mbokane et al. (2013) found that students had struggled with graphing skills, going from continuous to discrete (drawing approximating rectangles and visualizing rotation to decide whether to use dx or dy), translating from 2D to 3D diagrams (producing drawings), manipulation skills (computing the definite integral), and general cognitive skills (putting everything together). In another study dedicated to SoR, Andrade and Montecinos (2013) argued that students need help to interpret $f(x)$ as something more than just "the function to be integrated," coinciding with Sealey's (2014) need for an orienting pre-layer. They suggested, as did Blanco et al. (2019), that students need support to generate an image of a 3D solid starting from a 2D drawing. Given students' difficulties in visualizing SoR, Juárez and colleagues (2020) designed a questionnaire to evaluate students' skills in visualizing such solids. Later, Juárez and different colleagues (2022) designed a GeoGebra intervention to improve students' visuospatial abilities when dealing with SoR. Bernard and Jones (2016) studied the steps students chose when computing several volumes of SoR, the order of the steps, and the reasoning for this order. Their findings suggest that visualizing the rotated solid may be a factor that influences students' ability

to solve SoR problems that should be explicitly addressed. They also found that some students might not relate the differentials in the integral expression with the thickness of disks or washers and that students frequently rely on memorized procedures in setting up integral expressions. These observations underscore the need to help students visualize SoR and relate Riemann sums to definite integrals, as is done in the present study.

The research goal for this study was to use data collected from students' performance on SoR tasks to refine and suggest revisions for the theoretical model proposed by Borji and Martínez-Planell (2023) to explain how students come to understand volumes of revolution and what obstacles they might face in this process. We designed and implemented an activity to help students make the constructions proposed in the model. The results are discussed, and a revision of the model is proposed.

Theoretical Framework

We use Action-Process-Object-Schema (APOS) theory (Arnon et al., 2014), focusing only on the A, P, and O conceptions. An *action* is a transformation of a previously constructed mathematical notion that a student perceives as external, in the sense that, due to the lack of connections to other mathematical knowledge, the transformation is carried out only by memorization or following explicit instructions. When an action is repeated and reflected upon, it might be interiorized into a process. The *process* is perceived as internal since connections to other knowledge have been established, allowing students to anticipate results, generate dynamical imagery, make justifications, and perceive it as independent of representation. Different processes can be coordinated to form new processes. When a student can think of a process as an entity in itself and perform actions on it then one says that the process has been encapsulated into an *object*.

An important idea in APOS is that of a genetic decomposition (GD). This is a model of how a student may construct a specific mathematical notion. A GD is expressed in terms of the theory's structures (actions, processes, objects) and mechanisms (interiorization, encapsulation, coordination). A GD of a given notion starts as an initial hypothesis that must be tested with student data. Experimentation can lead to its verification, refinement, or rebuttal. An initial GD for SoR proposed by Borji and Martínez-Planell (2023) considered only the disk and washer methods. We will briefly summarize it here, and then, at the end of this paper, we propose a revised version that also applies to shells. The GD suggested by Borji and Martínez-Planell, which we take as our initial GD, includes prerequisites (i.e., understanding of function, area of a circular region, geometry and volume of a right circular cylinder) and has three parts:

- GD1: Geometric SoR constructed by rotating points, curves, and regions around a given axis; this allows imagining and visualizing SoR
- GD2: Geometric approximation constructed by forming small partitions, rotating the rectangles in the partition, drawing the resulting disks or washers, and comparing with the SoR being approximated; it allows imagining the approximation of the volume with an increasingly large, but finite, number of disks or washers
- GD3: Geometric-analytic volume of the SoR constructed by small partitions expressing the corresponding volume numerically, then symbolically as an extended sum, using sigma notation, then using an infinite number of disk or washers to determine the volume by taking limits and finally expressing the limit as an integral; it allows relating different representations for volume including the limit of Riemann sums and integrals

Methods

The three authors collaboratively designed an activity (https://bit.ly/4a9UNOX) with tasks 1-4 involving rotation only (GD1); tasks 5-8 involving rotation and rotation corresponding to a single subinterval of a partition for volume approximation (GD1, GD2); and tasks 9-11 involving rotation of a curve, volume approximation with limits, and volume with integration (GD1, GD2, GD3). The activity was administered in a multivariable classroom in a Southwestern US university for bonus points with 22 students who were allowed to consult with others on the assignment and to take it home to complete, if needed. The first two authors individually combed through the activity data and scored each task part using 0 (completely incorrect), 1 (somewhat correct), 2 (mostly correct), and DNA (did not attempt). The scoring agreement was 96%; the research team discussed scoring until a consensus was reached.

The data from the activity tasks were used as a first pass to study the students' understanding of SoR. Next, the first two authors jointly revisited the description of the GD of SoR found in the Borji and Martínez-Planell (2023) paper and then individually reviewed the quiz and exam task data making notes of their observations.

We also considered quiz and exam tasks (https://bit.ly/4a9l0wZ) that dealt with SoR that required the use of washers and disks. The coding scheme for the quiz and exam tasks with descriptions of observed student struggles appears in Table 1. The codes were developed jointly by the first and second authors as they combed through the data. The correctness scoring for all tasks in the activity and GD coding for the quiz and exam student data were used to complete qualitative profiles in terms of GD1, GD2, and GD3 for each student's understanding of SoR. The third author observed the students in class, reviewed all data individually, and provided input on the reported results.

Student Performance

Comparison of Performance on Activity Tasks with Quiz and Exam Tasks

First, we compare student performance scores on the activity tasks divided into GD1 (imagining SoR), GD2 (imagining rotated rectangles approximating volumes of SoR), and GD3 (converting from geometric imagery to integral expressions). Students tended to perform better with higher average scores on tasks that required GD1 only (mean: 92%, median: 100%) than on tasks requiring GD1 and GD2 (mean: 81%, median: 92%). Similarly, they performed better on tasks requiring GD1 and GD2 than those requiring GD1, GD2, and GD3 (mean: 45%, median: 41%). Activity tasks 10 and 11, which required GD1, GD2, and GD3, had 8 parts each. Of the 352 possible responses for all 22 students on the 16 parts of these two tasks, 46% were left blank (coded DNA) and another 19% were scored 0.

GD Coding

Since the activity allowed for collaboration on its tasks, the quiz and particularly the exam task data (since the exam was administered at the end of the semester) were primarily used to create a profile for each student in terms of the GD of SoR. Each researcher independently recorded this in individual notes for the student data. Upon inspection of the student responses to the tasks, the research team noted that students often struggled with prerequisite skills that had not been identified earlier. The data prompted discussion to conclude that there were additions needed to the original GD of SoR. Table 1 below summarizes the most prevalent student struggles observed on quiz and exam tasks by GD 1, GD2 and GD3.

Table 1. Codes Used for Prevalence of Student Struggles on Quiz and Exam Tasks by GD1, GD2, GD3

	Codes for Student Struggle (prerequisites denoted)	Description of Student Struggle	Frequency of Struggle
GD1	*Rotation*	Difficulty rotating or missing rotation of curve or region	20
	Axis (Prereq)	Rotation around incorrect line or axis	2
	Region (Prereq)	Difficulty determining region to be rotated when given equations that defined region	2
	Graph (Prereq)	Difficulty graphing a curve given as an equation	1
GD2	*Partitions*	Difficulty creating or failure to create rectangles to partition region	20
	Orientation	Incorrect orientation for partitions	3
GD3	*Cross-sect Area (Prereq)*	Incorrect cross-sectional area of disk or washer	24
	Radius (Prereq)	Incorrect radius for disk or washer	21
	Differential	Difficulty with differential or lack of correspondence between differential and partition	17
	Limits of Int	Difficulty with limits of integration	9

The different coded observations suggested needed refinements for the GD. For GD1, the *rotation* code is not useful since a student might not produce an image on a task and yet be able to imagine the rotated solid. While this would be less of an issue in an interview, it was a limitation of having data collected via paper-and-pencil instruments. So, not drawing a rotation might mean that the student could visualize the drawing mentally; however, it might also indicate a reticence of the student to use a geometric argument. The *axis* code denoted observations suggesting lack of a prerequisite construction to identify the axis of rotation. This prerequisite was not mentioned in the initial GD by Borji and Martínez-Planell (2023). The codes *graph* and *region* seem to result from a lack of prerequisite knowledge. Students did not correctly draw the graph of one-variable functions or determine regions bounded by one-variable functions and lines. As with the *axis* code, this was not mentioned as a prerequisite in Borji and Martínez-Planell's GD. For GD2, the *partitions* code may tell us that a student did not draw correct rectangles to partition the region but might be able to imagine the approximating rotated rectangles. It may also signal students' reticence to use geometric methods. There were also observations with *orientation* codes that all occurred when the students tried to use shells rather than washers for the problem. The initial GD did not consider shells. The revised GD describes the constructions needed for the shell method, although we are not considering such data in this paper. The many observations with the *radius* and *cross-sect area* codes moved us to add prerequisite constructions for radius and area as well as to also change GD2 to include new constructions that will have students rotating "thin" rectangles of infinitesimal width *dx* or *dy* around horizontal or vertical axes, as well as computing volumes of the disks, washers, or shells that are formed. These changes in GD2 can also help students avoid issues described in the *differential* code, and together with changes in GD3, they can also avoid those in the *limits of int* code. Now, we consider an example to show how the coding was assigned.

Figure 1 shows Student 14's work to determine the volume of the SoR obtained by rotating the region bounded by $y = -x^2 + 9$, $y = 4$, $x = -1$, and $x = 2$ about the x axis. We coded his work GD1, since he drew the boundary curves and lines as well as a rotation symbol to the right of the x axis suggesting he imagined the SoR. His work was coded GD2 since his sketched rectangle suggests he imagined rotated rectangles approximating the volume of the SoR. His work was coded no GD3 since there were errors converting from geometric imagery to an integral

expression. He used $(-x^2 + 5)$ rather than 4 for the inner radius; so, it was coded *radius*. Consequently, the cross-sectional area is also wrong and thus coded *cross-sect area*. It was also coded *limits of int* since the limits of integration were 4 to 9 rather than -1 to 2.

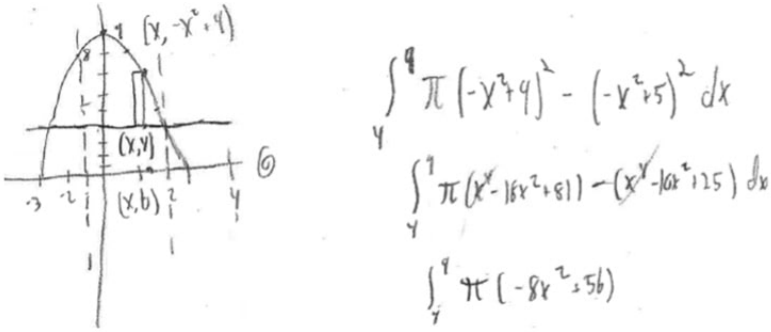

Figure 1. Student 14's response to one of the quiz tasks.

See Figure 2 for Student 15's work on the same problem. His work was coded as no GD1, and given the *region* code, for choosing the wrong region to rotate. It was coded as no GD2 and given the *orientation* code for drawing the approximating rectangle with the wrong orientation. It was coded no GD3 and assigned both the *radius* and *cross-sect area* codes since the written integral misses the radii and cross-sectional area of a washer and instead refers to a disk that is unrelated to the drawing.

Figure 2. Student 15's response to one of the quiz tasks.

Implications for Teaching Practice

Codes no GD1 and no GD2 might point to some student reticence to use geometric methods to find volumes of revolution. This may be a result of inconsistent participation in the GD-based homework tasks. Many students did not attempt the totality of the assigned tasks and may not have taken the tasks that required drawings seriously, instead producing very small, incomplete, seemingly careless sketches. This suggests that the students might have benefitted from the incorporation of the ACE (**A**ctivity in collaborative groups-**C**lassroom discussion-**E**xercises at home) pedagogical strategy that is an integral part of APOS theory. This pedagogical strategy foments student reflection, which is needed to interiorize actions into processes and encapsulate processes into objects. Awarding more credit than just a few bonus points to students for their work might have a positive effect on their motivation to complete GD-based tasks. So, the way in which the GD-based tasks are implemented is likely to play an important role.

The results also allow us to revise the genetic decomposition to include more detail. As observed in the results, we need to revisit the prerequisite knowledge of students to construct processes to identify axes, graph one-variable functions (including vertical and horizontal lines), and identify regions in the plane that are described in terms of graphs of functions and lines. The description of GD1 needs to include constructing a process to communicate (i.e., produce words or drawings) to describe a rotated planar region. Regarding GD2, a prerequisite process to

recognize cylinders, washers, and shells (obtained from rotating "thin" rectangles) is needed, as is distinguishing between the area and volume of common geometrical shapes. GD2 must be revised to make explicit the construction of processes to visualize approximating the area of a planar region with rectangles, all of which go from a given curve to another and account for the entire region, visualize the rotated rectangles as disks, washers, or shells; and recognize that the rotated rectangles are an approximation of the corresponding rotated region. Regarding GD3, even though most students did not attempt many of the corresponding tasks, students' work on the quizzes and exams suggests that the GD needs to be explicit about constructing prerequisite processes for the radius, circumference, area of a circle, as well as the volume of disks, washers, and shells. The description of GD3 also needs to be explicit about constructing processes to determine the radius of disks, washers, and shells; determining the height of shells; thinking of *dx* or *dy* as an infinitesimal thickness related to a partition of an interval, computing cross-sectional areas, relating the partitioned interval to the limits of integration, and in general, bridging the geometric and analytical representations from a finite to a generic Riemann sum and from this to imagining and expressing the limit of Riemann sums as an integral.

Revised Genetic Decomposition

The study of students' work suggests refinements are needed for Borji and Martínez-Planell's (2023) GD. The resulting revised genetic decomposition (see Table 2) addresses disks and washers as well as extending to also include shells.

Table 2. Revised Generic Decomposition for Solids of Revolution

GD0: Prerequisite ideas	• Understanding[1] of one-variable functions including algebraic and graphical representations • Understanding of horizontal and vertical lines including axes • Ability to identify planar regions defined by functions and lines whether given graphically or algebraically • Understanding of the difference between length, area and volume • Understanding of circles, circular regions, and cylinders, including related features such as radius, circumference, and surface area (including lateral area) • Understanding of volumes of disks, subtraction of volumes of figures when one is "inside" another (such as is the case with washers), volumes of shells • Understanding of sigma notation as a representation of summation • Introductory understanding of a limit of a length being zero
GD1: Geometric solid of revolution	• The action of rotating a single point around an axis is interiorized into a process of point rotation that allows imagining the resulting circle without having to do the rotation explicitly. The need to rotate curves and regions (viewed as collections of points) around an axis foments the encapsulation of the point rotation process into a point rotation object. • The action of rotating a curve around an axis and drawing the resulting surface can be interiorized into a process of curve rotation. The need to draw or imagine surfaces of revolution foments the encapsulation of the process of curve rotation into an object of curve rotation. • The action of rotating regions bounded by one or more curves of the form y=f(x) or x=f(y), one complete cycle around an axis to form a solid, drawing the resulting solid, and describing it verbally, is interiorized into a process that allows the student to imagine the formation of such solids of revolution and describe it verbally and with a drawing. The need to do actions on solids of revolution, such as computing their volume, foments their encapsulation into objects.

[1] By "understanding" a notion, we mean having constructed at least a process of the notion.

GD2: Geometric approximation by disks, washers, or shells	• The action of rotating a "thin" vertical (horizontal) rectangle of infinitesimal width *dx* (or *dy*) and with length that is either a number or a symbolic expression, rotating it around a given axis (any vertical or horizontal line not intersecting the interior of the rectangle), drawing the resulting "thin" solid and describing it verbally, can be interiorized into a process that allows imagining the formation of infinitesimally thin disks, washers, and shells. • This process can be coordinated with prerequisite processes in order to compute the resulting volumes (numerically and symbolically). • Coordination of these processes results in a process of disk, washer, shell formation that interrelates geometric, algebraic, numerical, and verbal representations. • Given a planar region defined by one or more curves of the form y=f(x) or x=f(y) and given (or having the student produce) the corresponding solid of revolution, the action of determining an interval and forming a partition of the interval with a small number (an explicit number, not a generic symbol) of subintervals and drawing the corresponding rectangles, disks, washers, or shells to approximate the volume of the solid of revolution is interiorized into a process that allows a student to imagine approximating a region with a small number of rectangles, imagine the rotated rectangles as disks, washers, or shells, and compare the volume of the rotated rectangles to that of the solid of revolution. • This process can be coordinated with the process of disk, washer, and shell formation to form a new process that allows the student to imagine partitions of an interval and corresponding planar region into many thin rectangles and approximate the volume of a solid of revolution with an increasingly large corresponding number of solid rings, washers, or shells without having to do so explicitly.
GD3: Geometric-analytic volumes of revolution	• The chain of actions of first writing the numerical approximation given by the Riemann sum corresponding to the solid obtained with a small partition in GD2 (for example, taking $\Delta x = 1$, for the solid obtained by rotating $y = x^2$ from $x = 0$ to $x = 3$ it could be something like $\pi(1^2)(1) + \pi(4^2)(1) + \pi(9^2)(1)$), then introducing variables and labeling a drawing of the previously obtained solid and writing the Riemann sum in extended form (for example, something like $\pi({x_1}^4)\Delta x + \pi({x_2}^4)\Delta x + \pi({x_3}^4)\Delta x$), then writing the Riemann sum using sigma notation (for example, something like $\sum_{i=1}^{3} \pi x_i^4 \, \Delta x$), before generalizing and finally taking limits ($\lim_{n\to\infty} \sum_{i=1}^{n} \pi x_i^4 \, \Delta x$) and representing and computing the limit as an integral ($\int_0^3 \pi x^4 \, dx$) may be interiorized into a process. • This process allows imagining the sum of volumes of a finite number of disks, washers, or shells as a numeric approximation to the volume of revolution (bridging the numeric with the geometric); allows imagining a partition of the region into rectangles of width Δx and use variables x_i rather than numbers (bridging the numeric and algebraic) to obtain and sum the corresponding volumes. • When this process is coordinated with the process resulting from GD2, the resulting process allows to imagine that a general partition into an increasing number *n* of thinner and thinner rectangles results in a better approximation (bridging the algebraic with the geometric), allows to express general Riemann sums in sigma notation and recognize the limit as the value of the volume of revolution, and allows to express the limit of Riemann sums as an integral. • The need to take the limit of such finite sums foments the encapsulation of the process into an object that identifies a limit of Riemann sums for the volume of a solid of revolution with the corresponding volume integral.

The GD-based tasks used should be revised to reflect the new genetic decomposition. They need to be class-tested using the ACE pedagogical strategy, and a new research cycle needs to be undertaken. Interviews are needed to help capture students' thinking about SoR, their meanings for the different notions involved, and the reasons for their problem-solving actions.

The Complexity Coordinating the "Product Layer" and Definite Integrals in Introductory Physics

Olha Sus
Tufts University

Andrew Izsák
Tufts University

Research on students' construction and interpretation of integrals has grown significantly over the past decade. The present paper contributes to recent research on challenges which students experience while coordinating the "product layer", $f(x) \cdot dx$, and the definite integral in applied contexts. In particular, we demonstrate a case study which examines how an undergraduate student, Matthew, linked the "product layer" and definite integral in an introductory physics task by blending mathematics, physics, and visualization knowledge resources. We analyzed Matthew's moment-to-moment reasoning by utilizing a modified dynamic conceptual blending diagram (MDCBD), coming from the dynamic conceptual blending perspective, and an expanded Visualization/Analysis/Physics (VAP)-model, as detailed in (Sus & Izsák, 2024). Our findings indicate that students' understanding of multiplication with quantities in applied integration contexts is highly complex and that neglecting the dynamic interactions of knowledge resources represents a significant gap in integration research.

Keywords: Integration, Product Layer, Knowledge-in-Pieces, Expanded VAP-Model, Dynamic Conceptual Blending

Introduction and Literature Review

Students often struggle to understand and apply the concept of definite integrals in applied contexts, particularly when reasoning about the "product layer," which involves interpreting the integral as a multiplicatively-based summation of quantities (e.g., Ely, 2017; Jones, 2013; Sealey, 2014). These difficulties become apparent when students attempt to model quantities such as distance and work using rectangular areas or other visual representations (e.g., Thompson et al., 2013; Nguyen & Rebello, 2011). While past research has explored students' general understanding of integrals (e.g., Meredith & Marrongelle, 2008; Cui et al., 2006; Yeatts & Hundhausen, 1992), less attention has been given to how they reason about this specific "product layer" within integrals.

Sealey (2014) identified the "product layer" as a complex area for students, and Oehrtman and Simmons (2023) analyzed how students construct definite integrals in applied problems, identifying three emergent quantitative models: basic, local, and global. However, their work did not examine closely how students' understanding of multiplication (in particular, knowledge resources) influences their construction of local models, or how their use of drawings affects their reasoning.

Further research by Izsák and Sus (2024) shows that students rely on various mathematical and physics knowledge resources when coordinating multiplication with definite integrals, and that these resources fluctuate based on the problem context. Visual representations, as noted by Berry and Nyman (2003), play a crucial role in guiding students' reasoning about definite integrals and are essential for reasoning about the "product layer." Research consistently suggests that integrating visual and analytical reasoning is key to fostering conceptual understanding in mathematics (Aspinwall & Shaw, 2002; Zazkis et al., 1996).

Our study aims to address these gaps by combining the approaches of Izsák and Sus (2024) with a focus on visual reasoning. We examine how students apply knowledge resources, including drawings, when coordinating multiplication with definite integrals in applied contexts.

To explore this, we use a novel methodological approach that integrates conceptual blending theory and visualization theory (Sus & Izsák, 2024). Our research questions are: *What knowledge resources do students use in their moment-to-moment reasoning about the "product layer" construction in introductory physics? How do students apply drawings in their moment-to-moment reasoning about the "product layer" construction in introductory physics?*

Theoretical Perspectives and Methodological Approach

In this section, we present theoretical perspectives and a new methodological approach which best spans the results obtained in the study. It includes three components — the knowledge-in-pieces cognitive perspective, the modified dynamic conceptual blending diagram, coming from the dynamic conceptual blending perspective (Van den Eynde et al., 2020), and the expanded VAP-model diagram (Zazkis, 2013) related to the visual conceptual blending perspective (Cunha et al., 2020).

The Knowledge-in-Pieces Epistemological Perspective

The perspective was first developed in science education research on conceptual change (diSessa, 1993, 2006) and has since been applied to topics in mathematics, such as whole-number multiplication (Izsák, 2005), functions (Izsák, 2004; Moschkovich, 1998), and integrals (Jones, 2013). It posits that reasoning is supported by diverse, fine-grained knowledge resources, which evolve from novice to expert through the construction, refinement, and reorganization of these resources. In this study, we focused on the knowledge resources students use when coordinating multiplication with a definite integral in introductory physics.

Dynamic Conceptual Blending, Modified Dynamic Conceptual Blending Diagram

Fauconnier and Turner (1998) introduced conceptual blending to model how people create new meaning by combining information from different experiential domains. Studies (e.g., Bing & Redish, 2007; Hu & Rebello, 2013; Wittmann, 2010) have applied this framework to describe students' use of mathematics in physics. In this study, we take the conceptual blending perspective (Van den Eynde et al., 2020) to analyze students' dynamic reasoning about the "product layer" in applied integration. We construct the modified dynamic conceptual blending diagram (MDCBD) through the following steps: (1) identifying and coding elements (knowledge resources); (2) listing selected elements chronologically; (3) assigning them to mental spaces — mathematics (mathematical concepts, including drawings and equations), physics (physical concepts and quantities, including drawings), symbolic (technical roles of mathematics), and blended (combinations of symbolic, mathematical, and physical ideas, including equations and drawings) and denoting them by M1, S1, P1, B1, etc.; (4) connecting selected elements with coded links; and (5) coding activated/deactivated elements and revisiting step (2).

Elements and connections are coded as more confident (e.g., "I remember") or more tentative (e.g., "I guess"), with more confident elements/connections shown as solid dots/lines and more tentative as empty dots/dotted lines. Activated/deactivated elements are marked with squared blue/red boxes, while connections are marked with blue/red solid or dashed lines, respectively. Figure 6a illustrates the MDCBD and its coding scheme.

By analyzing the elements and connections of these mental spaces, and their dynamic changes, we captured students' moment-to-moment reasoning about the "product layer" as they blended ideas from symbolic, mathematical, and physical input spaces.

The Expanded VAP-Model

Our approach builds on the VAP-model (Zazkis, 2013), which examines students' transitions between visual (V), analytical (A), and physical (P) reasoning modes in relation to graphs, functions, and physical concepts. We extended this model by incorporating five reasoning spaces: symbolic (S), mathematical (M), physical (P), blended (B), and visualization (V).

In our expanded model, the spaces S, M, and P are represented by the vertical edges of a tetrahedron, with the blended space occupying the interior. The altitude of each element within the tetrahedron reflects its activation time, moving from bottom to top. The coding of elements and their connections in spaces S, M, P, and B follows the same scheme as the modified dynamic conceptual blending diagram (MDCBD) described earlier.

Under visualization space V we consider a visual blended space complemented by a conceptual layer developed through elaboration (e.g., Cunha et al., 2020). It is represented by elements located at the base of the tetrahedron, arranged chronologically (V1, V2, etc.). These drawing elements are connected to the blended elements in space B, with coding consistent across all spaces. Figure 6b provides a schematic representation of the expanded VAP-model diagram.

Data

We conducted three one-hour, one-on-one, semi-structured think-aloud interviews (e.g., Bernard, 1994; Ginsburg, 1997) with three students enrolled in a second-semester calculus-based physics course at a selective university. The goal was to assess how these students reasoned about the integral concept in various problem situations, focusing on whether and how they constructed a "product layer."

The first interview explored students' reasoning about multiplication in four applied problem situations, none of which mentioned integrals but required multiplication followed by addition to construct a total. The second and third interviews focused on connecting definite integrals to three and four applied problem situations, respectively. We recorded the interviews with two cameras — one capturing the student and interviewer, and the other capturing the student's written work. After synchronizing the videos and transcribing the interviews verbatim, we reviewed them side-by-side with the transcripts to ensure accuracy. Throughout, we closely examined the knowledge resources students used in building the "product layer."

All students struggled at times to coordinate multiplication with the "product layer" in different problem situations. Matthew, who self-reported strong calculus skills (Calculus BC, 5), stood out. In the second interview (Water Pressure task), he demonstrated two types of reasoning about the "product layer," initially arriving at a normatively correct structure before shifting to an incorrect one. His drawings, which illustrated these shifts, helped us to visualize the connections between his analytical work and the physics context. We summarized his reasoning by focusing on his spoken language, hand gestures, and drawings.

Results

Analyzing Matthew's Moment-to-Moment Reasoning in the Water Pressure Task

In this section, we discuss Matthew's work on the Water Pressure task (adapted from Sealey, 2014) from Interview 2 (see Fig. 1). Notably, this task was novel to Matthew, minimizing the likelihood that he relied on recalled formulas or procedures from his physics or calculus courses. We first present the data Matthew produced and then analyze it using the methodological approach described earlier.

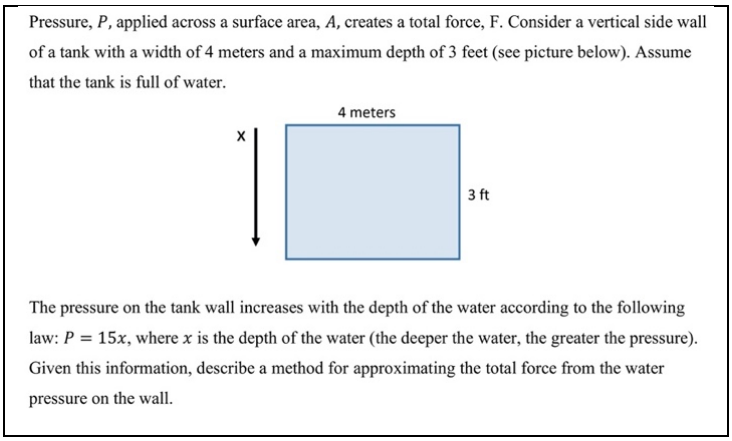

Figure 1. A Water Pressure task statement, Interview 2.

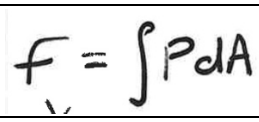
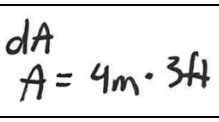
Let us remark that a normatively correct integral construction in this task would have the following representation $\int_0^3 15x \cdot 4\, dx$.

Matthew constructed an initial structure of the "product layer". Matthew began by writing down the given data which led him to think that "Each P is like the pressure on like a little bit of the area." He claimed that he did not know the actual relation between the quantities in the given problem situation: "I don't know the actual relation, so I'm just guessing." Then he stated: "I would say force is the integral of the pressure on a little bit of area (Fig. 2a). And umm the area is, well the area is constant essentially makes sense (Fig. 2b)."



(a)	*(b)*

Figure 2. Matthew's initial thoughts to approach the task.

Matthew stated that he did not see why the equation $P = 15x$ is relevant because "you would just plug, you would just maximize the pressure by putting in the maximum depth of the tank in for x." Hence, he obtained: "So, I guess P would just be 15 times 3, which would be 45."

Analysis. Initially, Matthew applied a set of knowledge resources to reason through the problem. He first considered pressure as a set of values acting on small areas, suggesting he saw pressure in relation to these areas, though it wasn't clear how he combined the pressure values. He then expressed uncertainty about the relationship between force, pressure, and area, and, based on a guess, produced an integral expression for force (Fig. 2a). This expression was tied to his initial reasoning about pressure acting on a small area, potentially aligning with the PdA notation. Finally, by examining the given data, Matthew concluded that (a) the area was constant (Fig. 2b), and (b) the depth variable x was irrelevant to the pressure formula, as knowing the maximum depth allowed him to maximize the pressure. This progression of knowledge resources showed how Matthew initially generated normatively correct reasoning (Fig. 2a) but later introduced additional reasoning (a) and (b) that competed with the correct interpretation.

Matthew shifted his reasoning about the "product layer" structure. Matthew continued hesitating about the relationship between the pressure, area, and force quantities. He claimed: "I do not know if it's going to be area dP, like a little bit of pressure over the entire area, or it's this total pressure over the entire space of the area." Assuming that the area quantity is constant, and

the pressure quantity changes, Matthew produced another integral expression to estimate the total force (see line 2 from the top in Fig. 3):

Matthew: I think I would actually not go with this [integral expression in Fig. 2a] and do, maybe, dP times A. And then you get, because then you would pull out the area, which would be 4 meters times 3 feet and dP would be 15 dx, I guess, from 0 to 3. And I guess that would be my estimation of the total force.

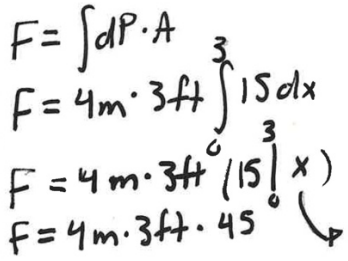


Figure 3. Matthew shifts his reasoning about the "product layer" structure.

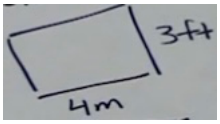
Additionally, Matthew calculated the integral value in the force expression, arrived at $F = 4m \cdot 3ft \cdot 45$, and stated: "I am not super confident in this answer because I'd say the main problem is that I'm not understanding the relationship between force and pressure and area."

The interviewer asked Matthew if he had any other thoughts or ideas to approach the given problem. Matthew answered: "I'd say that's my final one. The reason I said F equals dP times A instead of $P\ dA$, which is area, is because the area isn't changing, like the size of the wall isn't changing, but the pressure is with the depth of the water."



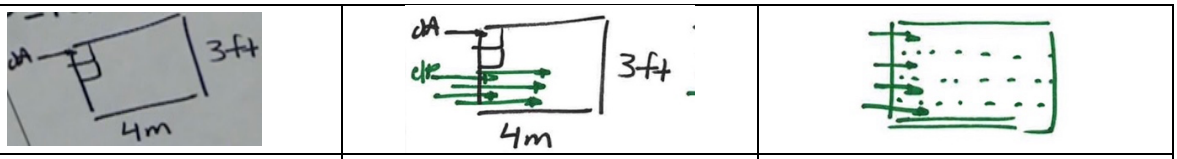
The interviewer next asked Matthew about the units attached to the 45 value in his force expression. Initially, Matthew stated he did not know the units for pressure but then provided $P = \frac{kg}{s^2 ft}$, which he justified by coordinating units for area and force.

Matthew explained his shift in reasoning using drawings. The interviewer asked Matthew whether he could explain his shift in reasoning using a picture. Matthew responded:

Matthew: So, if this is like your dA (Fig. 4a), you would have the pressure value acting on that little piece of area. And then when you sum up all the little dAs, you get this (Fig. 4b). But the reason I chose not to do that is because you already know the area in terms of constants. So, I'm assuming that what it really is, is that you have like your whole area, and you just have these little bits of pressure, these dPs acting across it. And when you sum up all these dPs, you would get the pressure (Fig. 4c).

(a)

(b)



(c)

Figure 4. Matthew's drawings for his reasoning about the definite integral.

Following his reasoning, Matthew also produced a picture for little dAs by drawing little squares on the wall (Fig. 5a) and claimed: "I wouldn't use dA here because you already know the dimensions, it's not like something unknown."

Correspondingly, the interviewer asked Matthew to produce a picture for a term dP on the wall. Matthew drew green arrows pointing to different locations on the wall and stated that each

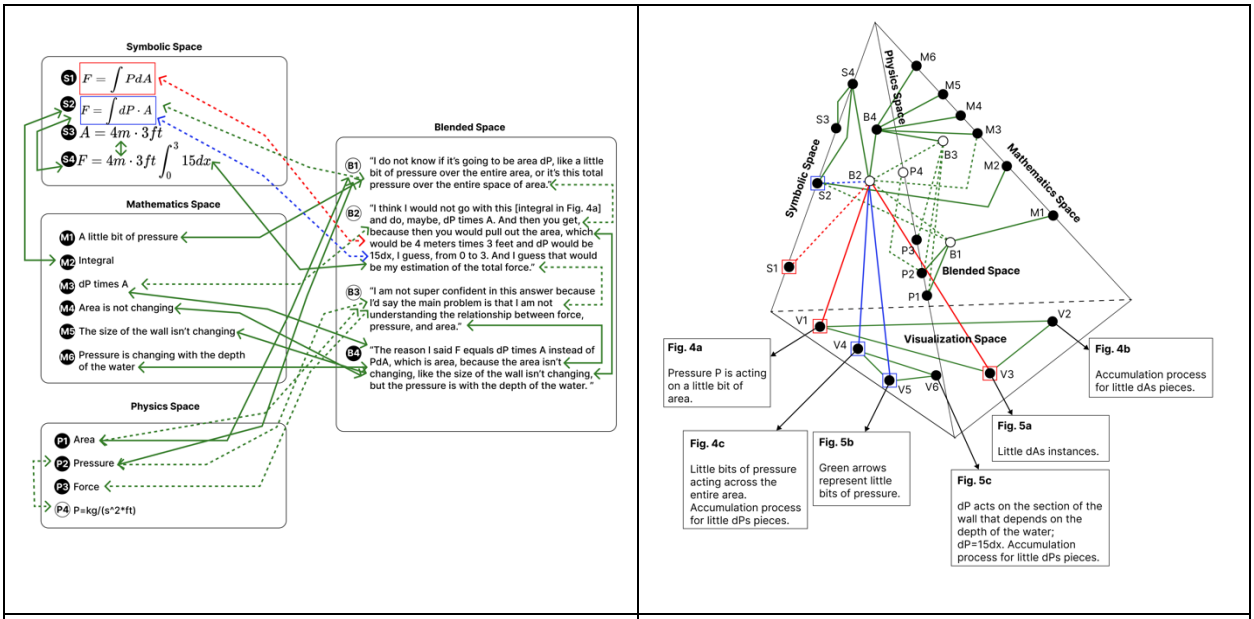
arrow represented a bit of pressure (Fig. 5b). In few seconds, he stated that it was not the best way to represent little bits of pressure. Then he produced a picture (Fig. 5c) and added: "It [pressure] is a function of depth. I would say that you would kind of have like this different sort of like sections, I guess you could say, of the area. And like each of these sections has a dP. So then when you sum up the pressure as like a function of the depth, you would get the total."

(a) (b) (c)

Figure 5. Matthew's graphical representations of dA and dP terms.

Following Matthew's responses, the interviewer highlighted differences in his drawings of the dP pieces. Matthew responded:

> *Matthew:* So, originally, I just think about [pressure] in terms of the fact that it's defined by a function of the depth. But then when I thought about that, it makes more sense to draw it like this [strips, Fig. 5c] because each bit of pressure is dependent on some sort of depth amount, like value. So, like dP is equal to $15dx$, so each little bit of depth contributes to that little bit of pressure.



After this discussion Matthew confirmed that his final graphical representation for a dA term was given by picture (Fig. 5a) and for a dP term by picture (Fig. 5c). Also, he stated that the integral expression $F = \int dP \cdot A$ made more sense to him.

Analysis. We constructed a MDCBD (Fig. 6a) to better capture a shift in Matthew's moment-to-moment reasoning about the "product layer". The diagram organizes selected knowledge resources and their connections related to the shift in the order they appeared in the transcript. This diagram is a subset of the expanded VAP-model diagram (Fig. 6b). The expanded VAP-model diagram includes drawings that illustrate Matthew's shift and will be discussed further.

The MDCBD diagram illustrates Matthew's initial uncertainty (**B1**) about his integral model in Fig. 3a. This led him to reconsider how to calculate force (**B2**), prompted by doubts about the relationship between force, area, and pressure (**B3**). By integrating knowledge resources — specifically, the constancy of the wall's area and the varying pressure — Matthew revised his integral expression to $\int dP \cdot A$ for calculating force (**S2**). His reasoning shift centered on the observation that area was "constant" while pressure changed with water depth (**B4**). Matthew also drew on knowledge of antiderivatives and definite integrals. Notably, his reasoning evolved through three models of calculating force: (a) viewing pressure as values applied to small areas, (b) considering pressure as a single value, and (c) applying small amounts of pressure to the entire area of $4m \cdot 3ft$. Finally, Matthew employed a units' coordination approach to determine the correct units for pressure, addressing an initial uncertainty about them.

The expanded VAP-model diagram illustrates a shift in Matthew's reasoning about the "product layer" structure and its connection to drawings. It clearly identifies the moment of transition (**S1→S2**) and the blended element (**B2**) that prompted the shift. During this process, Matthew produced drawings (**V4**, **V5**) that clarified to us his understanding of the expression $dP \cdot A$ and provided evidence for rejecting his initial construction, $P \cdot dA$ ("the reason I chose not to do that is because you already know the area in terms of constants") and the corresponded drawing (**V1**, **V3**). The model also reveals Matthew's transition from visualizing pressure

distributed across the entire wall (**V5**) to focusing on the pressure acting on a horizontal section (**V6**). These drawings (**V4**-**V6**) ultimately led Matthew to conclude that $dP \cdot A$ was the more appropriate structure.

(a) *(b)*

Figure 6. The MDCBD and the expanded VAP-model diagram of Matthew's reasoning about the "product layer."

The MDCBD and the expanded VAP-model diagram in Figure 6 illustrate the complexity of Matthew's reasoning and visually track the evolution of his thinking about the "product layer" structure, linking elements from five mental spaces.

Discussion and Conclusion

This study builds on the work of Oehrtman and Simmons (2023) by showing that students' reasoning about the "product layer" in definite integrals is highly complex. Our findings reveal that students integrate mathematical and physics knowledge, supported by visual representations, when reasoning about this concept.

We observed that a student, Matthew, generated two different local models from the same basic model. Initially, he constructed a normatively correct local model $P \cdot dA$, which he then extended to the global model $\int P \cdot dA$. However, he later abandoned this and developed a new local model $dP \cdot A$ with the corresponding global model $\int dP \cdot A$. This shift was guided by drawings and the physical and geometric properties described in the problem. Notably, the $dP \cdot A$ model would have been valid if Matthew had considered the pressure acting on the tank floor.

By analyzing Matthew's transitions between models and his use of drawings, we gained deeper insights into his reasoning process. While based on a single case study, these findings suggest that research on integration should pay closer attention to the diverse knowledge resources, visual representations, and their interactions that students use in reasoning about multiplication and definite integrals in applied contexts.

Acknowledgments

This research study was supported by the Graduate Student Research Competition Funding at Tufts University, Graduate School of Arts and Sciences.

Understanding-Oriented Lectures in Calculus: Practical Strategies for Enhancing Students' Mathematical Learning

Siqi Huang
University of California, Berkeley

Many instructors observe that students often rely on memorization in introductory college mathematics. However, existing literature on effective teaching strategies does not fully address the need to cultivate both conceptual understanding and deeper orientations towards understanding in students' learning. This study presents a case analysis of calculus lectures delivered by an experienced instructor at an R1 institution, revealing significant opportunities for enhancing conceptual learning and promoting stronger orientations towards understanding among students. The analysis identified four key strategies employed by the instructor: 1) framing instructional activities as a pursuit of understanding; 2) examining underlying meanings while connecting students' intuition; 3) providing motivations, justifications, and multiple perspectives; and 4) creating cognitively challenging tasks and encouraging students to embrace discomfort in learning. These simple, practical strategies do not impose significant demands on instructors yet hold great potential for helping more students approach mathematics through deep understanding.

Keywords: Conceptual Understanding, Orientations, Calculus, Lectures

Effective teaching in undergraduate mathematics classrooms is often associated with clear explanations, approachable instructors, prompt feedback, high expectations, fair assessments, interactive teaching methods, well-organized course structures, and the use of relevant examples and applications (Chickering & Gamson, 1991; Harper et al., 2019; Mesa et al., 2015). While these strategies are crucial, they may not fully address the need to foster both conceptual learning and orientations towards understanding (Huang, 2022, 2023) in students' mathematical learning. Despite recent advances in undergraduate mathematics education research (Artigue, 2016), many instructors continue to observe that students tend to rely heavily on memorizing formulas and procedures in introductory college mathematics (Burn & Mesa, 2015). This reliance on rote learning undermines students' ability to engage meaningfully with mathematics and develop mathematical proficiency (Schoenfeld, 2022).

Such a persistent issue raises a critical question: How can we better support students in developing both conceptual understanding and understanding-oriented approaches to learning mathematics? Given that most undergraduate mathematics courses continue to be delivered in lecture formats (Artigue, 2016; Johnson et al., 2018), it is unlikely that this mode of instruction will disappear anytime soon. Rather than dismissing lectures entirely, this study seeks to identify simple, practical techniques that instructors can integrate into their daily teaching practices without imposing significant additional demands. While transformative teaching methods, such as inquiry-based instruction (Laursen & Rasmussen, 2019), have made significant contributions to the field, they often require substantial resources and institutional support for large-scale implementation (Weaver, 2016). This paper specifically explores opportunities within calculus lectures, delivered by an experienced and well-recognized instructor at an R1 institution, that promote students' conceptual understanding and understanding-oriented approaches to learning mathematics. These opportunities offer great potential for low-cost, large-scale implementation

that could effectively support more students in approaching mathematics through deep understanding and enhancing their learning outcomes.

Literature Review

Mathematics education researchers have conceptualized mathematical understanding in various ways (Hiebert & Carpenter, 1992; Perkins & Blythe, 1994; Piere & Kieren, 1994; Schoenfeld, 1985; Shapiro & Stolz, 2019; Sierpinska, 1994). In this paper, I integrate Hiebert and Carpenter's (1992) view of understanding as a well-connected web of knowledge with Schoenfeld's (1985) operational definition, which emphasizes the ability to solve challenging problems. This paper focuses on the first two strands of mathematical proficiency identified by the National Research Council (2001)—conceptual understanding and productive disposition—while acknowledging the importance of the other three strands: strategic competence, adaptive reasoning, and procedural fluency.

Schoenfeld (2010) introduces the notion of orientation, which includes beliefs, values, dispositions, and biases that fundamentally shape people's behaviors in well-practiced domains such as teaching and learning. Building on this work, Huang (2023) elaborates on the construct of *orientations with respect to understanding in mathematics*, defining it as "the degree to which students exhibit an inclination towards and demonstrate an earnest concern for understanding in mathematics learning" (p. 49). Huang (2023) develops a methodological tool for measuring this construct with established validity and reliability. According to Huang, understanding-oriented students "care deeply about how things work, prioritize goals and actions for developing understanding, and are willing to put in much effort to understand underlying principles" (2023, p. 49). It is important to note that an orientation towards understanding is closely associated with a growth mindset (Dweck, 2006, 2013; Dweck & Yeager, 2019).

Previous work on orientations with respect to understanding has focused primarily on students. However, to design interventions that support the development of students' orientations towards understanding, we must first describe the types of opportunities available in various learning structures (e.g., lectures, curricula, small-group interactions) and analyze the nature of these opportunities. As a first step, this paper provides a case study of a semester of promising calculus lectures that appear to offer substantial opportunities for both enhancing students' conceptual understanding of core calculus concepts and fostering strong orientations towards understanding in mathematics learning.

Methods

This study is part of a larger investigation into students' calculus learning in a large-enrollment, first-semester calculus course at a public R1 institution. The course consists of three hours of lecture and three hours of discussion per week over a 16-week semester. Lectures are typically delivered by an instructor in a large auditorium twice a week, while graduate teaching assistants lead discussion sections of approximately 30 students on other weekdays. Each semester, over 1,400 students enroll in the course. The larger study involves observing all lectured-based instruction and three randomly selected discussion sections weekly, conducting surveys on students' learning experiences, interviewing the course instructor and graduate teaching assistants, and carrying out three rounds of task-based interviews with 57 students to gain an in-depth understanding of their calculus learning in Fall 2023. The primary data sources for this paper are 48 hours of video recordings of lecture-based instruction, supplemented by my field notes. The course instructor is a tenured mathematician who has been teaching mathematics at the university since earning his Ph.D. 12 years ago.

I used grounded methods (Charmaz, 2006; Vollstedt & Rezat, 2019) to explore the opportunities in calculus lectures that promote students' conceptual understanding and foster their orientations towards understanding in mathematics learning. Given that the connection between mathematics lectures and students' orientations towards understanding is largely unexplored in existing literature, grounded methods allowed for an iterative and flexible process where empirical data significantly informed the development of new concepts and categories (Vollstedt & Rezat, 2019). To distill video recordings into analyzable segments, I created activity logs at 20-minute intervals, partitioned the recordings into episodes, and developed verbatim transcripts with notes on the mathematical ideas discussed. In the next phase, I wrote analytic memos for each transcript, documenting emerging themes that could support students' conceptual understanding or orientations towards understanding, along with their related mathematical discourses in the classroom. I also connected these themes to relevant literature in this phase. Based on an initial list of themes developed from the previous phase, I coded all the transcripts and trained an undergraduate research assistant to independently code them as well. Disagreements in coding led to discussions on how to distinguish different codes and cluster similar ones, prompting us to revisit all transcripts to refine our code list and definitions. The coding process was iterative, requiring us to re-analyze all transcripts as new codes or revised definitions emerged. We resolved all disagreements in the process. In the final phase, we conducted a comprehensive review of all video recordings and field notes to ensure that the emerging categories aligned with our initial impression of the data and captured the whole story. This review guided our revisions to the categories to ensure accuracy and thoroughness.

Results & Discussion

The analysis revealed four key strategies that the calculus instructor employed to foster students' conceptual learning and nurture their orientations towards understanding in mathematics. These strategies are: 1) explicitly framing instructional activities as a pursuit of understanding; 2) examining underlying meanings while actively connecting students' intuition; 3) providing motivations, justifications, and multiple perspectives; and 4) creating cognitively challenging tasks while encouraging students to embrace discomfort in learning.

Explicitly Framing Instructional Activities as a Pursuit of Understanding

A central strategy employed by the instructor was the consistent and explicit framing of instructional activities as a pursuit of understanding. By using phrases such as "let's try to understand" and "I really want to understand what's going on," the instructor signaled that the goal extended beyond procedural mastery to cultivating both deep conceptual understanding and orientations towards understanding in students' mathematical learning.

This emphasis was evident in a lecture on September 12, 2023, when the instructor encouraged students to think beyond simply obtaining the correct answer. He remarked, "Many of you might know the answer, okay? But that's not the point here. *I want to really understand* how the answer relates to the definition and how we could maybe solve other problems based on this example" (emphasis added). This framing aligns with Huang's empirically based characteristics of students strongly oriented towards understanding, such as "spending time understanding confusing ideas even after getting an answer" (2023, p. 51).

In another lecture on September 21, 2023, the instructor challenged students to understand the limit of $arctan\ (x)$ as x approaches infinity without relying on the graph of $y = arctan\ (x)$. He said, "*I really want to understand* what's going on geometrically. I would like to get an explanation of what this limit is, without having to know the graph of the function. Based on

what you've learned about how we typically deal with trig expressions, what is something we can draw *to understand this*?" (emphasis added). When a student suggested drawing a right triangle, the instructor responded, "Very good idea, *let's try to understand* what $arctan\ (x)$ is in terms of a right triangle. How can we construct a right triangle using the given information?" (emphasis added). The conversation led to the creation of a visual representation, shown in Figure 1, which the class then used to explain what happens when x approaches infinity.

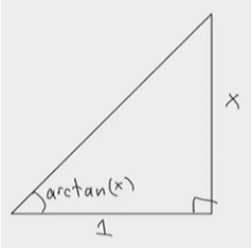

Figure 1. Understanding $arctan$ x with a triangle

This deliberate focus on understanding was also evident in a lecture on October 10, 2023, before introducing logarithmic differentiation. The instructor invited students to explore how logarithms might help finding the derivative of $f(x) = (x+1)(x+2)^5(x+3)^7(x+4)^9$ and to understand why the strategy worked. He emphasized,

> *I want to understand* why this is working. This looks like magic. It's so much easier than the product rule—but if something in math seems like magic, that just means we don't understand it well enough. So *let's really try to understand* what's going on here and why this method is working. *To make sure we understand* this method, let's go one step further and really see what's happening. (emphasis added)

The consistent and explicit framing of instructional activities as a pursuit of understanding fostered a learning environment where students were encouraged to engage deeply with the material, thinking critically, and build a strong conceptual foundation in mathematics. This approach aligns with what Huang (2023) observes to be key indicators of strong orientations towards understanding, supporting students in viewing mathematics as a sense-making activity and approaching mathematical learning through more understanding-oriented methods.

Examining Underlying Meanings While Actively Connecting Students' Intuition

The second strategy employed by the instructor involved examining underlying meanings of mathematical concepts while actively connecting with students' intuition. For instance, in a lecture on October 17, 2023, the instructor modeled digging deep into the underlying meanings of complex formulas and searching for intuitive explanations. He remarked:

> *I want to think about what this means and how we could explain this formula in a more intuitive manner.* Yes, you could use the methods from the previous class to derive this formula, but it's complicated and maybe not very intuitive. So I want to show you a way to think about it in terms of differential equations—you'll see that *this actually makes sense* and that it has to be the result. (emphasis added)

This approach aligns with Bruner's (1960) notion of uncovering "fundamental structures" in

learning. By focusing on the underlying meanings of mathematical concepts, the instructor fostered meaningful connections and supported students in seeing ideas through core disciplinary principles, both of which are crucial for developing mathematical expertise (Bransford et al., 2000; Hiebert & Carpenter, 1992; Schoenfeld, 1985). The practice of searching for intuitive explanations made abstract concepts accessible to students while nurturing their mathematical intuition, leading to more connected learning and the development of flexible mathematical thinkers (Agarwal & Sengupta-Irving, 2019; Fischbein, 2005; Schoenfeld, 2020). In the next example, the instructor clarified the meaning of derivatives using Leibniz's notation and connected it to students' visual and physical intuition in a lecture on October 5, 2023. He said:

> Let me say one more interpretation of *what this actually means*. The idea here is that dy/dx is a quotient. We can think of dy/dx as very small quantities, like Δx or Δy. Imagine you're standing on the point (x, y); then dy/dx tells you how much you need to change the y-coordinate slightly if you change the x-coordinate by one infinitesimal unit. (emphasis added)

This explanation exemplifies how the lectures supported both genuine sense-making and conceptual understanding of abstract concepts. Relating derivatives to students' common experiences, such as standing on a point and looking towards a particular direction, aligns with Boaler et al.'s (2016) work that emphasizes making abstract mathematical ideas tangible and relatable. Additionally, the instructor's use of phrases such as "I want to give you a bit more intuition of what this means," "we should see what it means visually," "I would like to find, in the real world, intuition for this theorem," and "put all the theorems apart; just think about your intuition—what would it say?" underscores his commitment to connecting mathematics with students' repertoires of knowledge (Bernstein, 1996) and fostering genuine sense-making of challenging concepts.

Providing Motivations, Justifications, & Multiple Perspectives

The third instructional strategy centered on offering motivations, justifications, and multiple perspectives to enrich students' conceptual understanding and encourage deeper engagement with mathematical ideas. Research suggests that presenting the motivations behind definitions, theorems, and proofs enhances students' ability to see how these ideas fit into the broader mathematical landscape, fostering more meaningful connections and deeper reasoning (Abramovich et al., 2019). In a lecture on September 14, 2023, the instructor exemplified this approach by motivating the formal definition of limits as well as its core components. He explained:

> I've explained the limit by saying that $f(x)$ is approximately equal to L as long as x is sufficiently close to a. But this is not a mathematically precise definition. This is not how you can base your mathematical theory on. We want to have a definition that, whatever you prove later on based on this definition, is going to be 100% true, guaranteed. So we need to make this more precise. First of all, we should probably talk about what we mean by *approximate*. Well, we can think of an error in an approximation, which is basically the difference between $f(x)$ and L, which is just $|f(x) - L|$. The smaller the error, the better the approximation. Then we also need to precisely define what is *sufficiently close*. Well, closeness—we talked about this in relation to x being approximately a. We could

> also call it approximation, but somehow it's often called closeness. It's the distance between x and a, which is $|x - a|$. Okay, these are intermediate steps. Now we are ready to make a mathematically precise definition of limits.

By breaking down the abstract concept into comprehensible parts and providing step-by-step rationales, the instructor transformed a potentially daunting definition into a logical sequence of ideas. This process of demystifying abstract concepts helped students appreciate the rigor and necessity of precise definitions, which are crucial for developing positive disciplinary identities and a sense of belonging to the broader mathematics community (Huang, 2024).

Moreover, the instructor consistently emphasized the importance of justifying ideas and understanding them from multiple perspectives. For instance, in a lecture on October 3, 2023, after algebraically proving the product rule and connecting it to more basic principles, the instructor proceeded to justify the rule geometrically. This approach aligns with research showing that connecting different mathematical representations—such as algebraic and geometric—reinforces students' conceptual understanding and encourages flexible thinking in mathematical problem-solving (Schoenfeld et al., 2023). The instructor reiterated the significance of multiple perspectives in a lecture on October 31, 2023, stating: "As I always say, it's always good to get several perspectives on the same problem because sometimes some perspectives are more useful than others. And that's the case here. So let me explain, one more time, why this limit is 2, using a different method." This emphasis on multiple perspectives and justifications reflects evidence-based practices in mathematics education, where students benefit from seeing problems approached in multiple ways (Schoenfeld et al., 2023).

Creating Cognitively Challenging Tasks & Encouraging Embracement of Discomfort

The fourth instructional strategy involved designing cognitively challenging tasks and encouraging students to embrace the discomfort inherent in deep learning. Research shows that engaging with tasks of high cognitive demand fosters deep learning and robust understanding (Schoenfeld, 2017). The instructor implemented this strategy by regularly presenting tasks that pushed students beyond their comfort zones, leading to some concerns about the difficulty of assignments. In a lecture on September 14, 2023, the instructor addressed these concerns:

> There are problems on the homework where you cannot apply the solution strategy that I told you, where you have to think deeper and somehow come up with your own solution strategy based on the intuition that I try to convey in lectures. It's not that we're giving you homework problems and we kind of forgot to give you the solution strategy. We do it on purpose. These are problems where you will actually learn something because you really have to go back to the material and learn the concepts—even though, of course, they may take a much longer time. But the goal should always be to learn the concept, not just finish the exercise.

This response illustrates the instructor's deliberate intent to challenge students and promote deep engagement with mathematical concepts. By designing tasks that required students to think deeply and critically, the instructor supported students' robust conceptual understanding.

In addition to presenting challenging tasks, the instructor emphasized the importance of embracing discomfort as a natural part of the learning process. In a lecture on August 24, 2023, he remarked:

> Mathematics can be tough, and it's normal to feel frustrated when you're trying to understand an abstract concept or working through complex problems. Don't shy away from that discomfort; instead, use it as a signal that you're pushing the boundaries of your understanding. Sometimes, the most significant learning happens when you persist…. Some students work on hundreds of problems but fall short of expected success because they don't try to really understand the main concepts. Doing more and more problems is sometimes easier than getting at the root of a misunderstanding. My recommendation to you is to embrace the feeling of unease—this is when you really learn.

This emphasis on discomfort as a catalyst for growth aligns with Dweck's (2006, 2013) work on growth mindset, which suggests that viewing challenges as opportunities for growth can significantly enhance students' learning outcomes. By framing discomfort as a natural and valuable part of the learning process, the instructor cultivated a classroom culture of resilience and growth, fostering stronger orientations towards deep understanding (Huang, 2023) among students.

Concluding Remarks

This paper has examined the opportunities within calculus lectures, delivered by an experienced and well-recognized instructor at an R1 institution over a semester, that promoted students' conceptual learning and orientations towards understanding. The findings highlight four key strategies that the instructor used to achieve these goals: 1) explicitly framing instructional activities as a pursuit of understanding; 2) examining underlying meanings while actively connecting students' intuition; 3) providing motivations, justifications, and multiple perspectives; and 4) creating cognitively challenging tasks while encouraging students to embrace discomfort in learning. Importantly, these strategies are not isolated but can be employed simultaneously within lectures and potentially other instructional structures.

This study contributes to the broader discourse on mathematics education by demonstrating that, even within traditional lecture formats, there are opportunities that instructors can leverage to support more meaningful and understanding-oriented mathematics experiences for students. Notably, the identified strategies do not require significant changes to existing instructional structures or significant time commitments from instructors. Instead, they are practical, low-cost techniques that instructors can easily learn and incorporate into their everyday teaching practices.

While this research focuses on calculus instruction in a large-enrollment setting, the strategies identified have broader implications for undergraduate mathematics education. Whether delivering lectures, following inquiry-based instruction, or employing a flipped classroom model, instructors can adapt these strategies to their contexts. These strategies offer a pathway towards transforming students' mathematical experiences by fostering both robust conceptual learning and stronger orientations towards understanding, which can directly address the concern raised by Burn and Mesa (2015) that students often rely heavily on memorization in introductory college mathematics. Future research could explore how these strategies can be scaled across different mathematical contexts and course structures, as well as how institutional support can be leveraged to sustain these instructional improvements. By implementing these strategies and cultivating a classroom culture that prioritizes understanding, we can help students develop deeper mathematical understanding and move away from unhealthy habits of memorization in favor of meaningful learning.

Examining the Relationship Between Key Points in College Students' Drawn Life Stories in Mathematics and Their Relationship With Mathematics

Sam Vancini
Pennsylvania State University

This research investigates significant moments in college students' drawn life stories in mathematics with the aim of examining implications for STEM engagement and potential reasons for gender-related differences in participation in mathematics intensive STEM fields. My research employs drawn life stories in mathematics specifically focused on students' experiences with mathematics to understand students' evolving relationships with mathematics, encompassing positive and negative experiences. Employing mixed methods analysis of visual and written mathematical narratives combined with qualitative interviews, my research explores the effectiveness of allowing participants to visualize their mathematical journeys, and quantitatively assesses the impact of recurring themes in students' drawn life stories in mathematics. This research advances our understanding of factors that influence the nature of students' relationships with mathematics, and potentially inform strategies for enhancing STEM participation and gender inclusivity, using a unique approach in mathematical narrative research.

Keywords: Mathematics Identity; STEM Participation; Gender

The United States Bureau of Labor Statistics (BLS) expects a nearly 11% increase in occupations in science, technology, engineering, and mathematics (STEM) fields from 2021 to 2031 (BLS, 2022). To ensure effective preparation of a STEM workforce that can meet these growing demands, it is necessary for both researchers and educator practitioners in STEM education to consider factors which may help students develop an interest in STEM and a belief in their STEM abilities. Thus, it is critical to avoid perpetuating historically established barriers to pursuit of STEM degrees and careers that limit the growth and diversity of the STEM workforce (Grossman & Porsche, 2014; Feder & Malcolm, 2016).

Mathematics is a useful area for this inquiry. It has been frequently referred to as a 'gatekeeper' to STEM degrees as many STEM degrees require prerequisite courses in mathematics (Bryk & Treisman, 2010; Norton et al., 2019). Additionally, most STEM fields draw on important mathematical foundations and skills. To better understand the factors that influence students' relationship to mathematics over the course of their lives, in my research I utilized an established life story narrative approach to examine students' experiences as learners of mathematics, through their early undergraduate studies (McAdams, 2001; John et al., 2020).

The process of creating and sharing life story narratives allows individuals to make sense of their past and present in a way that enables them to meaningfully anticipate the future (McAdams, 2001; John et al., 2020). Past research in mathematical narratives has been conducted primarily with preservice teachers (Towers et al., 2017). My research built on past studies by expanding the population of interest to undergraduate students more broadly as I sought to understand the factors which drive society to and away from mathematics.

A recent study in mathematical narrative research, conducted by John et al. (2020) focused on "turning points" that individuals describe in their prior histories with mathematics. In their research, they characterize turning points as either being a form of "redemption" in which individuals describe their relationship with mathematics as shifting from negative to positive, or

"contamination" in which individuals describe their relationship with mathematics as shifting from positive to negative. In my research, the term "turning points" was extended to "key points" to include both turning points and instances where an individual describes an experience that makes their existing relationship with mathematics even stronger - more positive or more negative.

While there are multiple examples of studies that utilize narratives to study relationships with mathematics, there are several ways in which this area of inquiry has had shortcomings, and thus, can be improved. For instance, one key finding from John et al. (2020) was that over half (53%) of the narrative sequences described by participants were redemptive in nature. The researchers suggest that this is likely due to a prevailing master narrative in the U.S. that places a large value on redemption (John et al., 2020; Syed, Pasupathi, & McClean, 2019). It is worth considering, then, whether there are other ways of more authentically allowing students to showcase their relationship with mathematics.

Additionally, John et al. (2020) did not provide insight into the experiences or other factors that coincided with these turning points and did not assign any sort of magnitude to identify strengths of the patterns in these factors or experiences. To address this limitation, my research utilized a novel approach to narrative research, adapted from Guillaume & Kirtman (2010), in which students have the opportunity to draw their mathematical narratives. By using an open-ended drawn approach to mathematical narratives, individuals can illustrate as many key points as they can remember and the magnitude of the impact of these key points on their relationship with mathematics. The opportunity to quantify these experiences is particularly notable as most narrative research in mathematics education has been purely qualitative in nature (Towers et al., 2017).

The potential for drawn life stories in mathematics to provide insight into critical aspects of students' experiences and resulting relationships with mathematics can also be valuable for understanding factors that have historically limited the diversity and inclusivity of advanced studies and careers in mathematics and STEM. Women in the United States have historically been and continue to be underrepresented among degree recipients in math-intensive fields such as computer sciences and engineering. For instance, while women make up 51% of the overall workforce in the United States, women comprise just 26% of the mathematics and computer scientists and 16% of engineers (NCSES, 2023).

To address this underrepresentation, more efforts to understand and mitigate barriers that prohibit women from pursuing STEM pathways are needed. Thus, this research also examined what insights drawn life stories in mathematics can provide to better understand and address gender-related differences in mathematics.

The research questions for my research are as follows:

- **Research Question 1:** To what extent do recurring themes account for key points in undergraduate students' life stories in mathematics?
- **Research Question 2:** What insights can drawn life stories in mathematics provide to better understand and address gender-related differences in STEM participation?

Literature Review

Mathematics Identity

Widespread use of the term identity among researchers in multiple fields has led to variations in how it is defined (Radovic et al., 2018; Bishop, 2012; Darragh, 2016; Grootenboer et al., 2006; Grootenboer, 2013). Given the variation in its meaning, social science researchers have

criticized the concept of identity for having a “slippery” and confusing nature (Wetherell, 2010; Radovic et al., 2018).

At the same time, identity has been characterized as the “missing link” between learning and its sociocultural context (Sfard & Prusak, 2005; Hong & Perez, 2024). From this perspective, learning extends beyond the construction of understanding and consists of becoming a new person with respect to cultural norms, practices, and interaction (Lave & Wenger, 1991; Wenger 1998). What students learn in and out of school extends far beyond the subject matter, students develop social and cultural perspectives on who they should be. The identities which students acquire then influence not only what students will learn, but what they will pursue and what they will become. Furthermore, as identities have been observed to potentially change over the course of students’ lives, identities are not considered to be static, but rather malleable (Andersson et al., 2015; Gonzalez et al., 2020).

Research on identity in mathematics education has been a growing field of study since the turn of the century (Radovic et al., 2018; Darragh, 2016); Simpson & Bouhafa; 2020). For the purposes of my research, I have adopted the definition of Boaler & Selling (2017, p.82) for mathematics identity as “the ways in which students think about themselves in relation to mathematics and the extent to which they have developed a commitment to, are engaged in, and see value in mathematics and in themselves as learners of mathematics". Furthermore, my research takes a Meadian conception of identity (Mead, 1913). Contrary to an Eriksonian conception of identity, which tends to view identity as singular and static, a Meadian conception suggests that a person's identity are multiple and constantly evolving (Machalow et al., 2020; Darragh, 2016; Lutovac & Kaasila, 2019).

Gender Identity Research in Mathematics Education

The exploration of gender research in mathematics education dates to the prolific work of Fennema and her colleagues in the 1970s (Fennema & Sherman, 1976; Fennema & Sherman, 1977). Research in the late 1970s following Fennema’s work would examine gender disparities in involvement and achievement in mathematics, along with investigations into potential factors that promote or hinder these differences (Leder, 2019). Fennema’s work was undoubtedly impactful on the field of mathematics education. As Walberg & Haertel (1992) reported, the Fennema & Sherman (1972) article was among the most frequently cited articles in the Social Sciences Education Index from 1966-1988.

Given that 72% of the STEM workforce are males (NCSES, 2023), research on the intersection between gender identity and mathematics identity has often focused on exploring the nature of persistent inequities in the STEM workforce. Some studies have shown that, in-general, males tend to have higher or more positive mathematics identities than females (Eccles & Wang, 2016; Lock et al., 2013; Cass et al., 2011, Nosek et al., 2002). Thus, recent research has explored a few different explanations for gendered differences in mathematics identity and in-turn gendered differences in the STEM workforce (Leder, 2019; Stoet & Geary, 2018; Rodriguez et al., 2020).

Mathematical Narrative Research

Narratives refer to the retelling of autobiographical accounts in a manner that conveys significance to the narrator and the listener (Bruner, 1990). Thus, the phrase “mathematical narratives” is often used synonymously with “mathematical autobiographies”. Mathematical narratives are a versatile data collection tool, allowing researchers to explore trends across a learners’ lifespan. As such, researchers have used mathematical narratives to explore several

constructs relevant to my research including affective measures such as motivation (Harkness et al., 2007; Phelps, 2010), beliefs (Eaton et al., 2012; Dewi et al., 2022), and attitudes (Ellsworth & Buss, 2000; Russo et al., 2021).

One of the largest subfields of interest in the study of mathematical narratives has been the study of turning points, aimed at understanding the events or factors that lead to shifts in individuals' autobiographies (Towers et al., 2017). The present study uses a more inclusive term "key point" to expand the definition of turning points to also include instances where an individual describes an experience that makes their existing relationship with mathematics even stronger - more positive or more negative.

In a particularly relevant case, Guillaume & Kirtman (2010) had participants chart graphs of their attitude and achievement in mathematics, in-order to analyze the turning points that individuals drew. In their research, Guillaume & Kirtman (2010) focused on the themes that emerged from their work and particularly focused on out-of-school connections that individuals discussed. For example, they found that only 42% of individuals discussed a home connection to mathematics and that of those who *did* note a home connection to mathematics, 65% fell under school-related categories such as workbooks/flashcards and tutoring/help with homework. While this study is interesting, the graphs that individuals drew were not used to their full potential. A major benefit to having individuals draw their life stories in mathematics, which my research capitalizes on, is that drawn life stories in mathematics offer an easy way for researchers to quantify turning points. In fact, individuals noted instances of turning points on their timeline, yet Guillaume & Kirtman did not classify these events in the traditional turning points framework, instead opting to simply observe patterns among the themes. Furthermore, one can measure how far a jump or drop key points cause because of having individuals draw their mathematical timelines. My research capitalizes on this potential by both examining the key points on individuals drawn life stories in mathematics, as well as quantitatively analyzing how large of shifts these key points cause.

Methods

Participants

This research was conducted at a large university in the Southeastern United States. Participants included 254 undergraduate students pursuing a variety of majors, enrolled in either MAC 2311: Analytic Geometry and Calculus 1 or MAC 1147: Precalculus Algebra and Trigonometry. In total, 214 of the participants were enrolled in MAC 2311 and 39 were enrolled in MAC 1147. These courses serve as prerequisites and general education courses for a variety of majors and hence were strategically selected as they include students pursuing both STEM and those pursuing other fields. Conducting this survey with students currently enrolled in an undergraduate mathematics course ensured that participants' mathematics experiences included postsecondary studies in addition to any insights they offered about their mathematical experiences in primary and secondary school.

Instrumentation

Data was collected using an instrument designed for participants to draw how their relationship to mathematics has changed over the course of their lives. An example of a completed version of this instrument in shown in Figure 1.

Participants were asked to think as far back in time as they can remember, about both in-school and out-of-school experiences, including people and experiences that have had a strong

effect (either positive or negative) on their relationship to mathematics and then to map out how these experiences have shaped their relationship to mathematics over time, while labeling any key points. Participants were then asked to expand on what those key points entailed on the next page and whether they would be willing to participate in a follow-up conversation to expand on their responses.

Finally, participants were asked a few demographic questions including what gender they identify as. The research question addressing gender identity gives the options of male, female, non-binary, and genderfluid; however, it also includes an open-ended option which has been recommended in recent research (Puckett et al., 2020).

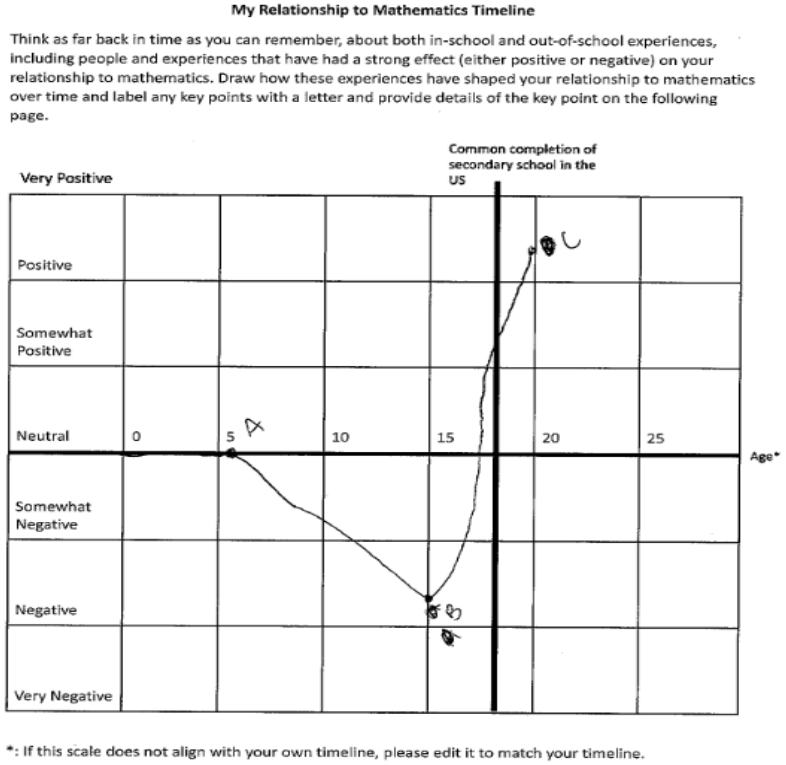

Figure 1. Example of a Drawn Life Story in Mathematics

Coding

Key points that participants described were each coded in three distinct ways. First the key points were coded deductively as either contamination, redemption, enhancement, or deterioration. These deductive codes stem from past narrative work indicating that turning points can often be seen as redemption or contamination sequences (McAdams & Bowman, 2001) and this framework has been used in the mathematical narrative space as well (John et al., 2020).

Additionally, each key point was inductively coded in two rounds, guided by the recommendations of Saldaña (2021). In the first round of coding, the descriptions of key points provided by participants were summarized. Notably, depending on the length of the participants' description of their key points, this first round of coding was not necessary in every case. The key points were then coded using pattern coding to identify emergent subthemes that underlie key points given by participants (Saldaña, 2021; Miles et al., 2014). Once subthemes were gathered, subthemes were grouped together into larger themes encompassing them. To help

ensure reliability of deductive codes, the themes and subthemes were continuously refined with the assistance of another researcher.

Finally, guided by past literature illustrating a tendency for mathematical narratives to overutilize qualitative research (Towers et al., 2017), data given by participants were analyzed quantitatively using a form of magnitude coding (Saldaña, 2021). For example, in Figure 1, key point B was coded as -1.5 as it moved the respondents relationship with mathematics from neutral down 1 to somewhat negative and then half way between somewhat negative and negative. This is one of the largest potential research benefits of having participants draw their life stories in mathematics instead of verbalizing them, as drawing allows for a more detailed and consistent way of analyzing how impactful each key point was.

Results and Conclusions

First, all 254 participants' graphs were analyzed based on the structure of the graph. The graphs were coded as "Positive" if the graphs were strictly neutral or positive, "Mixed" if the graphs ever crossed the x-axis – that is, if the participants relationship from mathematics ever went from positive to negative or vice versa, and "Negative" if the graphs were ever strictly negative. Notably, the overwhelming majority of graphs changed from positive to negative or vice versa at some point (76.77%). Additionally, it is worth noting that while there were many participants (23.23%) whose graphs were strictly positive, there were 0 whose graphs were strictly negative.

Themes among Key Points

Using emergent coding, 24 subthemes were identified among the key point responses, in addition to a robust "Other" subtheme.

Magnitude coding for each key point was broken down by themes and subthemes, and then further analyzed. Each subtheme was treated separately as positive (if the key point received an "Enhancement" or "Redemption code) and negative (if the key point received a "Deterioration" or "Contamination" code). Figure 2 shows a breakdown of the positive subthemes, by both the count and the average magnitude code applied within the subtheme.

The results from the magnitude code analysis of the drawn life stories in mathematics clearly showed two recurrent subthemes that were impactful for students both in positive and negative ways: "Teacher" and "Achievement". Beginning with the "Teacher" subtheme, participants explained a wide variety of reasons for which teachers were influential (both in positive and negative ways) on their relationship with mathematics. Some participants focused on ways in which teachers impacted their cognitive development citing reasons such as their teacher being "thorough" or "unhelpful". However, many participants spoke about affective ways in which their teachers impacted their relationship with mathematics. For example, participants described positive impacting teachers for reasons such as them being "fun", "caring", and "kind" and negative impacting teachers for reasons such as them being "not welcoming" and "rude".

Research tends to consider to what extent mathematics identity may be a predictor of future mathematics achievement (e.g. Bohrnstedt et al., 2021; Gonzalez et al., 2020); however, my research adds evidence to the inverse relationship that achievement may influence students' mathematics identities. One explanation for this may be that grades serve as an indicator for students of the extent of their belonging within the field. As such, a positive grade may strengthen or help recover a students' mathematics identity while a negative grade may deter or further damage students mathematics' identity.

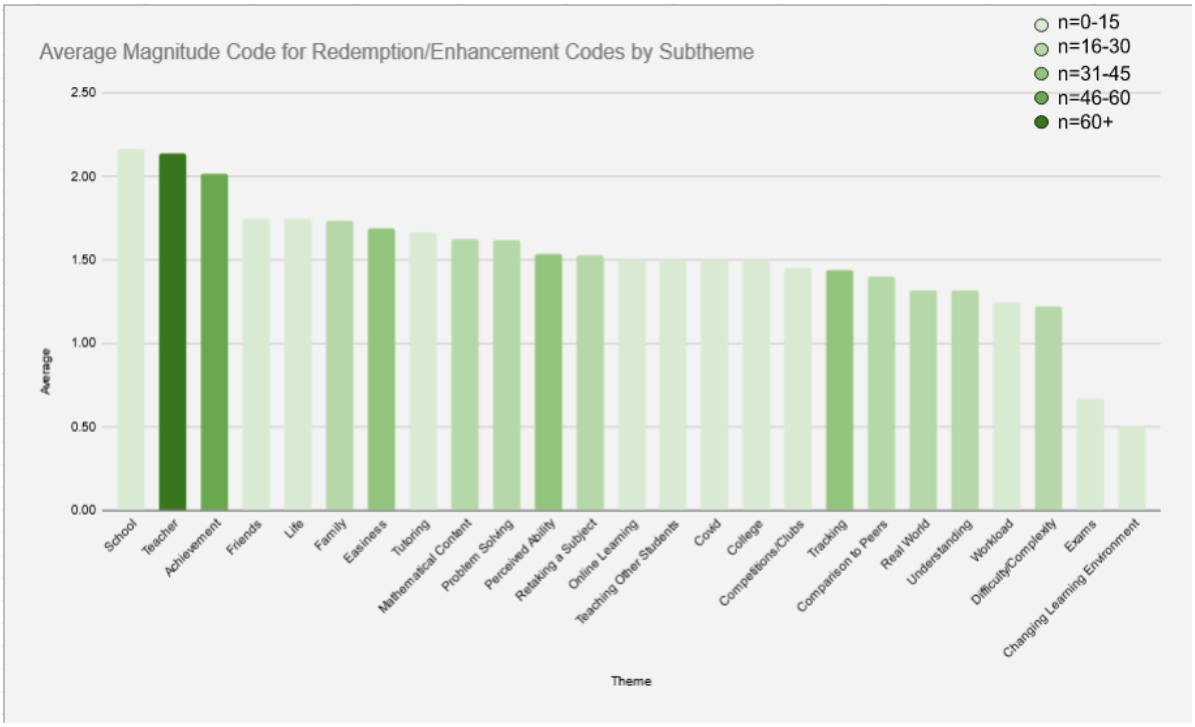

Figure 2. Average Magnitude Code for Redemption/Enhancement Codes by Subtheme.

Gendered Findings

Gender-related differences are explored in this study by examining both the prevalence and magnitude of positive (redemption or enhancement) or negative (contamination or deterioration) experiences in participants' drawn life stories in mathematics. Taking findings of both prevalence and magnitude together, with statistical significance it was shown that while positive key points were more prevalent for males than females, the positive key points that existed tended to be more impactful for females than males. This suggests that in-order to address gender-related differences in STEM participation, it may make more sense to allocate resources more towards increasing the number of positive events for female students rather than working to ensure events are more impactful for female students. For example, this finding suggests that additional celebration of achievement moments for women may not be as impactful as simply ensuring that women have more opportunities to experience positive achievement.

On the converse, insufficient evidence was found to support the notion that there was a statistically significant difference in the frequency or magnitude of negative experiences drawn on mathematical life stories between men and women. While this finding seems inconsequential, past sociological research indicates that women report more frequent negative feelings than men and that men are somewhat more likely to report that they suppress their emotions than women (Simon et al., 2004). Coupled together, the lack of statistical significance may suggest that this tool has helped male participants to more authentically share their negative emotions than a traditional survey may. There is some prior research to back this idea as drawing has shown to be a useful tool among adults as an emotional regulation technique (Drake et al., 2016; Dalebroux et al., 2008). However, in these studies drawings were used following a specific procedure with a much more in-depth protocol than my research required, so further research should be done to verify the extent to which the tool used in my research can aid in emotional regulation.

What Makes Content Knowledge *Specialized*: A Case Study of Graduate Teaching Assistants' Mathematical Knowledge for Teaching

Spirit Karcher
Florida State University

As the push for active learning pedagogies in undergraduate mathematics continues, research into the teaching practices of graduate student instructors (GSIs) has expanded significantly. This paper presents findings from a multiple-case, descriptive case study of the demonstrated mathematical knowledge for teaching (MKT) of GSIs within the context of active learning Precalculus lessons. This study aims to bridge the theoretical and practical distinctions between the MKT knowledge domains as they are used by GSIs in their teaching practice. Practical implications for the professional development offered to GSIs, as well as theoretical implications for studying the MKT construct in post-secondary settings, are discussed.

Keywords: Mathematical Knowledge for Teaching, Graduate Student Instructors, Precalculus

Several decades of research comparing active learning to traditional lectures in STEM classrooms has shown significant improvements in student learning outcomes in classrooms where active learning pedagogies are used (Freeman et al., 2014). As a result, researchers and educators have increasingly called for the implementation of active learning in undergraduate mathematics courses (Akin et al., 2023). Active learning is an umbrella term for classrooms where students engage in mathematical activities that promote higher-order thinking, such as group problem-solving and investigations (Conference Board of Mathematical Sciences, 2016). Active learning is often viewed as more difficult to implement than traditional lecture because the instructor must give over some control to allow their students to engage meaningfully with the mathematics. When student thinking is centered in the classroom, the instructor must balance opportunities for inquiry with structured guidance toward correct mathematical understandings (Akin et al., 2023). At Ph.D. granting universities in the United States, it is common for mathematics Ph.D. students to receive funding for their studies by teaching introductory undergraduate mathematics courses, such as Precalculus (Beisiegel et al., 2019). As a result, many of the introductory mathematics courses at Ph.D. granting institutions are taught solely by graduate student instructors (GSIs) (Deshler et al., 2015). It can be daunting for novice instructors, such as GSIs, to implement active learning pedagogies in their courses without clear guidance and support (Beisiegel et al., 2019). As the push for active learning in undergraduate mathematics increases, there is a concurrent push to understand the knowledge that GSIs need to implement active learning pedagogies in order to develop effective teaching supports (Akin et al., 2023). The purpose of this study is to examine the knowledge that GSIs use within their teaching practice and identify the purpose(s) within their practice that their knowledge serves.

Theoretical Framing

It is commonly accepted that instructors need content knowledge to teach effectively, but that content knowledge alone is insufficient (Ball et al., 2008). From analyzing teachers' practice, Ball et al. (2008) hypothesized that six distinct but related domains of knowledge "made up" MKT. Following Ball et al.'s (2008) seminal piece defining MKT, research about teacher knowledge has revolved around refining the theoretical definitions and creating clear delineations between the domains (e.g., Copur-Gencturk et al., 2019). Copur-Gencturk and her

colleagues (2019; 2022) conducted several quantitative studies to disentangle the subdomains of knowledge in Ball et al.'s (2008) framework. Copur-Gencturk and Tolar (2022) refined their definition of MKT to include "teachers' understanding of the mathematics, their pedagogical content knowledge (i.e., knowledge of students' mathematical thinking, their instructional practices, and the representations they use), and their ability to notice content-related issues in the moment of mathematics teaching" (p. 2). Their findings concluded that, statistically, content knowledge, pedagogical content knowledge, and content-specific noticing skills are distinct elements of MKT among their participants (See Figure 1). Copur-Gencturk et al.'s (2019; 2022) work is important in pushing forward the field's understanding of teacher knowledge from a theoretical perspective. Methodologically, however, these studies employed large-scale written assessments and quantitative analyses rather than using Ball et al.'s methodology of qualitatively examining teachers' practices, which may limit the applicability of the MKT framework for informing efforts to develop teaching supports for GSIs.

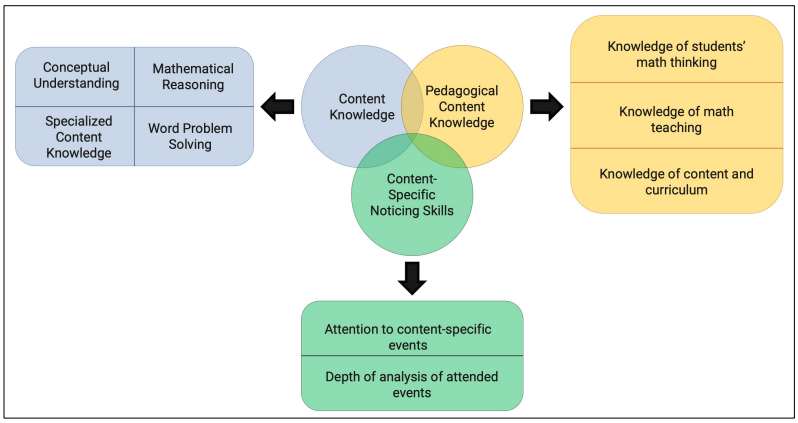

Figure 1. Mathematical Knowledge for Teaching as Conceptualized by Copur-Gencturk and Tolar (2022)

When extending ideas of MKT to post-secondary contexts, the theoretical distinctions between knowledge domains become more unclear (e.g., Howell et al., 2016; Speer & King, 2014; Speer et al., 2015). A question raised in Speer et al.'s (2014; 2015) work refers to how common content knowledge (CCK) and specialized content knowledge (SCK) are currently defined. Theoretically and practically, the concern is that knowledge considered as common for mathematics Ph.D. students versus those with only a bachelor's is most likely different in nontrivial ways. While assessing the mathematical validity of a student's response is unanimously accepted as SCK for an elementary teacher, this ability and knowledge may be considered common within the work of a Ph.D. student. For theoretical purposes, Copur-Gencturk and Tolar (2022) acknowledge that both domains overlap and, therefore, their definition for SCK is content knowledge "situated within the task of teaching, whereas the other components of [CCK] are not dependent on the teaching context" (p. 4). In other words, SCK can be operationalized as the mathematical knowledge that is used for purposes such as assessing students' mathematical reasoning, evaluating students' (potentially unconventional) solution strategies, and providing explanations of concepts to students. The study presented here is positioned to address concerns such as those raised by Speer et al. (2014; 2015) and to add to the current theoretical understanding of MKT by incorporating distinctions that come from the examination of GSIs' teaching practices. Specifically, this study is positioned to (1) identify the domain(s) of knowledge that GSIs use when using active learning pedagogies and (2) identify the purpose(s) for which their knowledge is employed when using active learning pedagogies.

Methods

This study followed a descriptive, multiple-case study design (Baxter & Jack, 2008) of mathematics GSIs for Precalculus at a large research institution in the Southeastern United States during the Fall of 2023. The study design is foremost descriptive in nature because the goal was to examine the real teaching practices of the GSIs in context and come to a more nuanced understanding of how their MKT was utilized in practice. The mathematics department at this university had recently undertaken several initiatives to improve student learning outcomes in introductory undergraduate courses. Such initiatives included creating and facilitating GSI professional development (PD) for Precalculus to support the implementation of active learning pedagogies. Participants in this study were three current Ph.D. students in the mathematics department who were GSIs for Precalculus. All of the participants in this study had completed at least two years of their programs and had successfully completed their qualifying exams. This paper presents the findings from one participant, Leona. At the time of data collection, Leona was a third-year Ph.D. candidate in Applied Mathematics. She had taught Precalculus in the year prior to data collection during the first semester when the new Precalculus units and PD were integrated into the curriculum. Leona was chosen as the first case because she was the only participant with previous experience as an instructor of record for this course.

Data Collection

MKT is employed in all aspects of a teacher's work; therefore, collecting multiple data sources is necessary to create a holistic view of the components of MKT as they are being used together (Meijer et al., 2002; Park & Oliver, 2008). To this end, data for this study were collected from two semi-structured interviews at the beginning and end of the semester, five PD meetings, and four classroom observations. The classroom data were split between two lecture classes and two active learning lessons focused on exponential functions. Data collected during the active learning lessons were the primary source used to address the following research question: How are the domains of Mathematical Knowledge for Teaching demonstrated in the teaching practices of graduate student instructors during active learning Precalculus lessons focused on exponential functions?

Data Analysis

All data were audio- and video-recorded before being transcribed using Temi. The researcher edited transcriptions for clarify and accuracy. The transcript data from the active learning lessons were chunked into "exchanges," defined by the GSIs' interactions with one or more students. Each exchange captured one distinct interaction between the GSI and their students. Exchanges would begin and/or end when the GSI stopped interacting with one group of students and began interacting with another. Each exchange served as the unit of analysis for data coding procedures. Following the chunking of the lesson transcripts, the first data analysis phase consisted of re-reading the lesson transcripts while re-watching the instruction videos. During this review, I wrote detailed descriptive memos about the exchanges. These memos focused on summarizing the interactions between the GSI and their students. The next data analysis step was assigning knowledge domain codes to each exchange. MKT knowledge domain codes were assigned based on whether the GSI demonstrated the domain of knowledge during the exchange. The codebook for the domains of MKT was created through the incorporation of Copur-Gencturk and Tolar's (2022) Content-Specific Expertise for Teaching Mathematics framework with the content-specific definitions for exponential functions from the Exponential Growth Learning Trajectory (Ellis et al., 2016). The second round of data coding

addressed the link between domains of knowledge and teaching practices. Units of analysis continued to be the exchanges. The teaching purpose codes were developed through a literature-informed, inductive method. In other words, the literature on teacher knowledge highlighted several purposes for which teacher knowledge could be used. These purposes included selecting and sequencing classroom tasks, assessing student understanding, and informing in-the-moment classroom decisions (e.g., Park & Oliver, 2008). While these teaching purpose codes were not defined in an a priori codebook, the code names and definitions were developed using a combination of language from the literature and the participant's words and actions.

Findings

I found that Leona most commonly demonstrated a combination of content knowledge and knowledge of the curriculum for the purpose of building mathematical connections between student thinking and key learning goals. Specifically, she demonstrated knowledge of exponential functions and the lesson's learning goals and task sequence when responding to students' questions and providing guided explanations (see Figure 2). Within these exchanges, Leona appeared responsive to her students' thinking and flexible in her responses or explanations. The curriculum was designed to elicit specific ways of reasoning about exponential functions. Teacher notes were embedded within the Desmos lessons, which were discussed with the GSIs during the PD meetings. The teacher notes integrated examples of common student responses with pedagogical suggestions designed to align with the goal of promoting productive covariational reasoning and building on current student understanding. Leona's interactions with her students often parallel the suggested pedagogical moves from the curriculum or suggestions discussed during the PD meetings. While her content knowledge was demonstrated throughout these exchanges, it was especially evident when she would bridge concepts and representations in ways that were not previously discussed with other GSIs or suggested by myself or the course coordinator.

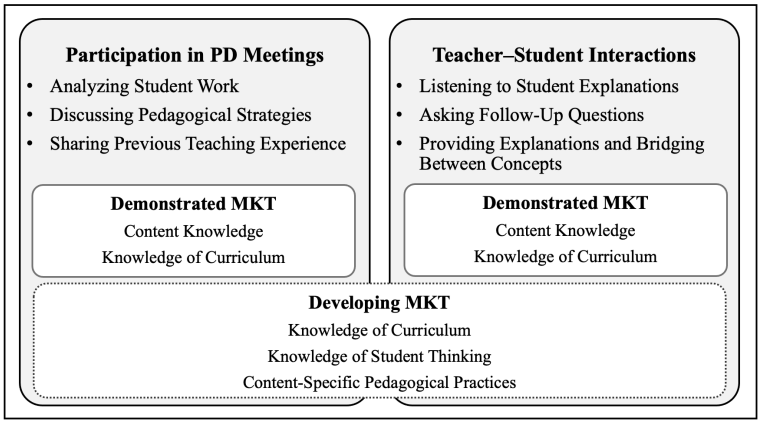

Figure 2. Visualization of Primary Finding for Leona's Case

Knowledge of Curriculum: Learning Goals and Task Sequence

One such student interaction occurred in the first of two active learning lessons, where a student was working on the questions from Figure 3. In these questions, students are first asked to identify two unknown heights (y values), given information about the amount of potion that Alice consumed (x values), and explain how they found one of the height values. Students are then given how Alice's sisters, Kadesha and Susana, found each of the values and asked to compare their own explanations with those given by Kadesha and Susana. In this one-on-one

interaction, a student asks for Leona's input on their solution because their method does not match either Kadesha's or Susana's method. The student wants Leona to check her work and help her understand the methods shown in the task.

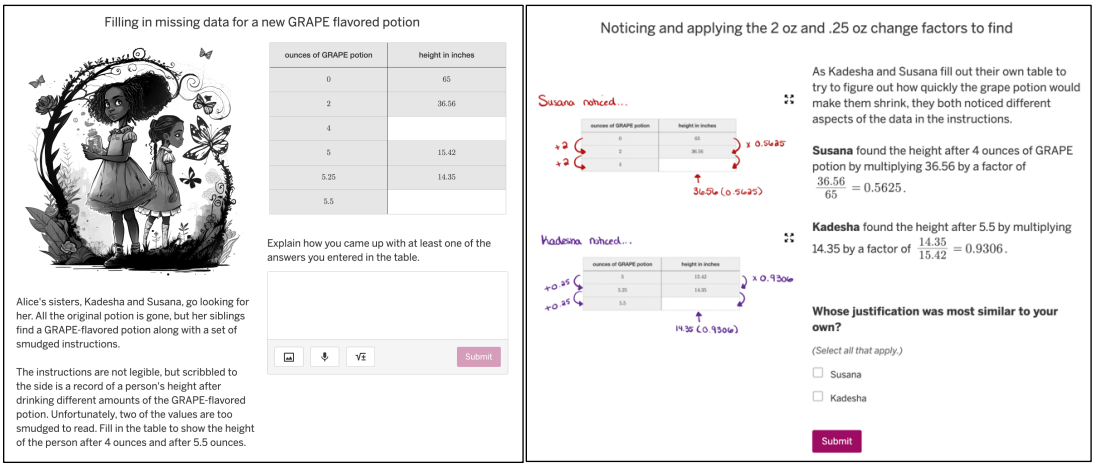

Figure 3. Student Facing Questions in Desmos Lesson

During this interaction, Leona asks the student to explain their reasoning so that she can first understand what the student has done before providing any other explanations or asking other questions. The student solved this task by substituting values from the table into the standard exponential function formula ($y = ab^x$) and solving for the base of the exponential. This lab's learning goal is for students to coordinate successive additive increases in ounces of potion with proportional multiplicative changes in height. The student's solution, while mathematically correct, relies on an algebraic representation of exponentiation, which does not push the student's understanding of the covariational relationship forward in the way that this task was intended to. Leona uses her knowledge of this learning goal and how the tasks are sequenced to inform her decision on how to structure the questions that she asks this student. Specifically, her questioning builds key mathematical connections between the student's solution strategy and those presented in the task from Susana and Kadesha. Additionally, Leona returns to the algebraic representations to help the student make another connection between the standard representation of exponential functions and a representation using the rate found by Susana. This further connection demonstrates Leona's knowledge of the task sequence because she is setting up the foundation of ideas that will become relevant in the second lesson on exponential functions.

Content Knowledge: Exponential Functions

The student in this interaction used the standard exponential function equation to find the unknown height values. Leona demonstrates her content knowledge of exponential functions throughout this interaction. Specifically, her content knowledge is being transformed into specialized content knowledge through her interaction with this student because she first must assess the mathematical validity of the student's solution and then use a series of prompts to draw mathematical connections between the student's thinking and the covariational relationships meant to be explored in this lesson. In the first part of this interaction, Leona is using her content knowledge of exponential functions and general algebraic rules to assess the validity of this student's method. There is a minor error in the student's algebra when solving for

the base x in the equation: $36.56 = 65x^2$. Leona notes that the student seems to have reversed the order of operations. In other words, the student applied a square root to the equation prior to dividing by 65.

Following this comment, Leona continues to demonstrate her content knowledge in conjunction with her knowledge of learning goals by guiding the student to draw important connections between her algebraic representation and the strategies presented by Susana and Kadesha in the task prompt. Leona draws on her understanding of exponential covariation defined by constant multiplicative proportions for successive n-unit additive changes and its connection with the algebraic representation of exponential functions throughout this interaction. In the following excerpt from the lesson transcript, Leona guides the student to make the connection regarding constant multiplicative proportions by highlighting how Susana's method finds a 2-ounce scale factor and the student's method finds a 1-ounce scale factor. Additionally, they verify that both of these scale factors will arrive at the same answer for the unknown height at four ounces (see Figure 4 for Leona's written work accompanying her verbal explanation).

Leona: But what is x changing by for you personally? For [Susana,] she did 36.56 over 65, right? Every time she does the multiplication…her original answer is 65 times this [ratio], right? This is what happens when x is increased by two. So, she starts at zero [ounces], then x equals x plus two, that's gonna be 65 times (36.56 over 65) times [36.56 over 65] again. But this ratio [36.56 over 65] is for how many?

Student: Two?

Leona: Yeah, so [Susana's ratio] is for two ounces.

Student: Okay. Oh, so there oh, oh, oh, oh, okay. Okay. Because [Susana's] is two. So then [multiplying again] would make it four. This would get you to four [ounces]

Leona: Which would get you your answer. But you are multiplying 65 by 0.75. How many times do you have to multiply by 65 to get [Susana's] same answer?

Student: Four.

Leona: Right? So, you have to do this [multiplication by 0.75] a total of four times, right? So that means every [multiplication of 0.75] is for how much?

Student: One [ounce].

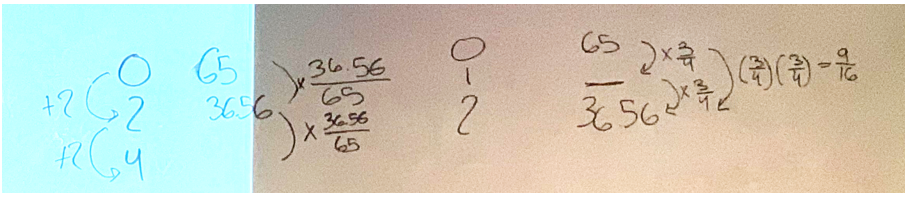

Figure 4. Leona's Written Annotations from Desmos Slides

Discussion

The overview of this finding is that Leona's content knowledge of exponential functions is used in conjunction with knowledge of the curriculum for the purpose of scaffolding interactions with students and building mathematical connections between student reasoning and key learning goals of the lesson. Copur-Gencturk and Tolar (2022) define specialized content knowledge as content knowledge used in teaching practices. In other words, content knowledge that is used for a pedagogical purpose is considered *specialized,* whereas general content knowledge refers to any content knowledge that does not rely on a teaching context. In the example above, Leona's use of content knowledge to make in-the-moment teaching decisions changes her general content knowledge into specialized content knowledge because she employs

it for a clear pedagogical *and* mathematical purpose. It is within the moments of teaching and interacting with her students that Leona uses her content knowledge, as well as knowledge of the curriculum, to inform her responses to students and how she builds key mathematical connections with students.

An important contextual piece to this finding is that the GSIs are provided with PD accompanying each active learning lesson. In these PD meetings, the GSIs are introduced to the lesson's learning goals and how the tasks are set up. They are given opportunities to work through the lessons themselves and discuss areas where they think students might need additional support. Lastly, they are introduced to common strategies that students may use and guided through collaborative brainstorming on ways to respond to students that align with the learning goals for the lessons. Leona actively contributed during these PD meetings by sharing her experiences with students from the prior semester and her strategies for implementing the active learning lessons. This is important because knowledge of the curriculum and content knowledge specific to these lessons was not something Leona necessarily possessed prior to her teaching. The PD providers specifically targeted this knowledge to support GSIs in their teaching practices. Additionally, the PD meetings provide a space for GSIs to develop knowledge related to teaching, such as specialized content knowledge, when they are participating in acts such as anticipating student thinking. The knowledge gained during these PD meetings and demonstrated in Leona's teaching is important when considering how the field makes theoretical distinctions between knowledge domains, such as content knowledge versus specialized content knowledge. Research focusing solely on the theoretical distinctions between knowledge domains may muddy our understanding of MKT as knowledge that is inherently demonstrated through actions within teaching practices. Specialized content knowledge has a history of being defined by a demonstration of specific teacher actions such as "building or examining alternative representations, providing explanations, and evaluating unconventional student methods" (Hill et al., 2004, p. 16). From my analysis of Leona's teaching practice, I believe that developing specialized content knowledge comes from her use of content knowledge in conjunction with other domains for specific pedagogical and mathematical purposes. In this case, her purpose was to understand her student's reasoning and respond to them in a productive way that guided them toward the mathematical learning goals of the lesson. These actions necessarily require content knowledge so Leona can provide clear explanations and correct mathematical reasoning. This study has practical implications for GSI PD because it offers insights into the knowledge that GSIs draw on and how it is used in their teaching practices. Specialized content knowledge can be developed or created by GSIs when they have been given time and space to think deeply about the mathematical content, learning goals, student thinking, and how these come together in the act of teaching.

This study aimed to understand GSIs' MKT by analyzing their teaching practices. The findings provide a lens into the overlapping and interactive nature of GSIs' MKT. The findings presented here support the implication that content knowledge becomes specialized when it is used in concurrence with other domains of knowledge for pedagogical and mathematical purposes. These findings have limitations related to the theoretical conceptualization of MKT and methods of inferring knowledge from observed practices. Future research should consider these limitations when designing studies. Further research should continue to refine the theoretical underpinnings of MKT and explore practical implications for GSI PD and related areas of active learning pedagogy in undergraduate mathematics education.

Reconceptualizing Smartness: Student Perspectives in the Mathematics Community College Classroom

Gabriela Hernandez

Charles Wilkes II
University of California Davis

Jan Tracy Camacho
San Diego State University

Mary E. Pilgrim
San Diego State University

This study investigates how students at a Southern California Hispanic Serving Institution (SCHSI) perceive and define smartness in the mathematics classroom. We employ a qualitative approach, analyzing narratives from an open-response survey question that asked students, "What do you think it means to be smart at [SCHSI] in math?" The findings challenge the traditional binary categorization of dominant and counter narratives, revealing a more nuanced understanding of smartness. The analysis identifies a spectrum of student perspectives, ranging from those emphasizing performance outcomes (e.g., grades, passing) to those prioritizing process-oriented approaches (e.g., understanding, effort, seeking help). The results underscore the importance of recognizing and valuing diverse forms of smartness in mathematics education, particularly within community college settings serving underrepresented student populations. By fostering an inclusive learning environment that acknowledges and supports various conceptions of smartness, educators can empower students to develop a positive mathematical identity.

Keywords: Smartness, Mathematics, Community College, Hispanic Serving Institution, Dominant Narratives, Counter Narratives, Student Perspectives

Vignette

> In Ms. Fernandez's precalculus class, students were engrossed in a test. One student finished early, standing up and turning in their paper. The teacher looks at the student and says "nice work!" This action triggered a wave of anxiety in other students, who interpreted the early completion as a sign of superior intellect and began to question their own abilities. Many students began to focus on the unfinished portion of their own test, feeling increasingly overwhelmed and doubting their own smartness.

Introduction

As educators, we possess the authority to shape or influence students' perceptions of themselves and their relationship with mathematics (Turner et al., 2013). Considering the relationship a student has with mathematics is very important to a student's identity and the role colleges serve in giving access and opportunity to STEM careers. Investigating how students learn mathematics in college, community colleges, in particular, is especially relevant to how college students are enculturated into mathematics.

Within the field of STEM specifically, the President's Council of Advisors on Science and Technology reported in 2012 that fewer than 40% of students in U.S. colleges who begin a STEM degree graduate with a STEM degree; for women and students of color who entered college as STEM majors, this number was only 20%. Indeed, community colleges alone educate half of all undergraduate students in the United States (Down et al., 2006, as cited in Mesa et al., 2014) and nearly half of all undergraduate mathematics students (Rodi, 2007, as cited in Mesa et al., 2014). Given the community college enrollment of minoritized learners and their experiences

in mathematics classrooms, more broadly, understanding these students' perceptions and experiences about what it means to do math and who can do math is valuable.

Of particular interest in this study is how students at a community college perceive smartness in their mathematics classes. In this study, we analyze narratives in an open response question from a survey meant to capture students' experiences at a Southern California Hispanic Serving Institution (SCHSI) to address the following research questions: The research question that guides this study is: *How do SCHSI students define smartness in mathematics?*

Literature Review

The way we position students within mathematics learning environments directly impacts their learning process and their self-perception as mathematics learners. Recognizing students as holistic individuals with lives extending beyond the classroom is important for understanding their identity, which is crucial for effectively supporting their success both within and outside these learning environments (Wilkes & Ball, 2020). Positive dispositions towards mathematics– where one's identity is in harmony with the field as opposed to clashing with it– can lead to persistence, agency, and confidence, all of which are useful qualities for navigating everyday life (Bishop, 2012; Brown, 2004). A key part of one's identity in mathematics is understanding the role of intelligence.

Historically, intelligence was quantified psychologically through IQ tests, which were developed in the early 1900s to identify individuals who might need additional support (Carroll, Kramer, & Dringenberg, 2019). Once adopted in the US, intelligence became a construct that was viewed as innate and fixed meaning it couldn't be changed over time (Dweck & Molden, 2000). Though not initially intended, this ultimately became a way for white privileged people to uphold their power and create and reinscribe beliefs and narratives about the intellectual inferiority of African Americans (Hatt, 2012; Darby & Rury, 2019). This perspective reinforced the idea that to be smart, used interchangeably with intelligence, means to perform identities that meet the standards of white middle-class males (Carrillo & Rodriguez, 2016). We use smartness to contrast the idea that intelligence is something that is innate as a social construct.

Smartness: A Theoretical Framework

Though smartness is something that is often perceived as "non relational, impersonal, rational, and scientifically objective," (Hatt, 2012, p. 456), many researchers consider smartness to be a social construct that give rise to the existence of its "denigrated other" (Leonardo, 2013, p. 2008) through the process of stratification and oppression of marginalized groups. When an individual is assigned smartness by an institution, it automatically affords them human capital (Hatt, 2012). Furthermore, because being good at mathematics is so intrinsically linked to smartness, and smartness is a prerequisite for personhood under the racial contract, the perception and beliefs surrounding smartness in the math classroom is of the utmost importance. One way to disentangle the features of smartness as a cultural construct is to explore the narratives surrounding it (Leonardo, 2013).

Smartness can be categorized as a dominant narrative or a counternarrative. We define dominant narratives to be the ways in which smartness often gets defined narrowly and often negatively affects learning outcomes. One dominant narrative found commonly in the literature surrounding smartness in math is that students must quickly and correctly identify solutions (Dunleavy, 2018; Boaler & Staples, 2008; Wickstrom, 2015). The most common dominant narrative is the attainment of good grades (Boaler & Staples, 2008; Louie, 2018; Wickstrom,

2015); Berry, 2008; Chang, 2017). Bishop (2012) and Louie (2018) found that a common narrative linked to smartness in mathematics is that of students not seeking help. Reinholz (2021) also found that it is common for students to perceive intelligence in mathematics to be linked to innateness.

Counternarratives are defined as the ways through which historically oppressed populations tell their own stories in order to challenge dominant narratives (Delgado, 1998, as cited in Reinholz, 2021). Dunleavy (2018) identified the ability to help one another as a disruption to dominant narratives. Bishop (2012) found that "Needing help, making mistakes, and asking questions can be perceived as face-threatening acts if those actions are seen as inconsistent with mathematics identities of being smart" (p. 53). Reinholz (2021) and Wickstrom (2015) found that some students were able to shift narratives of mathematics being innate toward the recognition of the importance of hard work.

We argue that dominant and counter-narratives are not only instantiations of the ways in which smartness is enacted, but they can also be defined as attending to process and/or outcome, which nuances how smartness is enacted. While the construct of intelligence or smart is not new, there is a dearth of research that investigates the construct of smartness in higher education explicitly and particularly in community college. In studies that do, they tend to focus on engineering and other STEM-related fields. This work contributes to the field by focusing on smartness in mathematics in the context of community colleges and addresses the nuance of how students describe what it means to be smart in mathematics classes.

Methods

Participants and Context

The study took place at SCHSI, a comprehensive two-year community college (Blind, 2018). The community college serves an ethnically, racially, and culturally diverse community in which almost 85% of the student body is from minoritized groups and Latinx students make up over 60% of the total enrollment. Despite the large number of Hispanic students, 244 STEM degrees were awarded, with only 127 (52%) of them being awarded to Hispanic students. This study is part of a larger project that aims to understand the impacts of gateway math course reform at SCHSI as a result of state legislation.

Participants included students taking mathematics classes taught by five instructors who participated in PD sessions facilitated by the [blinded] professional development team. The students were enrolled in one of the following courses: elementary statistics, pre-calculus, college algebra, and mathematics for general education majors. 103 students completed the survey. Sixty percent of the respondents identified as male and 40% as female; 63.8% of the respondents identified as Hispanic, 16.3% identified as Asian, 11.4 % identified as White, and 7.6% identified as Black; 49% of participants identified as first-generation (i.e., neither parent nor guardian completed a Bachelor's degree); and 40% of the participants declared or intended to declare a STEM major, 39% of the participants were non-STEM intending majors, and 19% were unsure.

Data Collection

Students were given a survey designed to capture their experiences in math classes. The initial survey used was modified from the Student Postsecondary Instructional Practices Survey for Mathematics (SPIPS-M). To increase students' response rates, the first author modified the initial survey used on the project to clarify questions that were ambiguous and to include open-

ended questions that focus on students' identity. The free response question being analyzed from this survey is "What do you think it means to be smart at SCHSI?" The five instructors who participated in professional development were asked to distribute the survey via email to their students. Each instructor determined incentives for students to complete the survey. Some instructors provided no incentives. Other instructors awarded points to students (i.e., extra credit on their test score). The exact choice of incentive depended on each instructor's preference, and some instructors encouraged students to complete the survey during class time, which was intended to attain a high response rate. All surveys were administered online through Qualtrics.

Data Analysis

Coding. Open coding in MaxQDA 2024 (VERBI Software, 2024) was used to analyze all data. New codes were added and old codes were refined as coding proceeded through multiple rounds. The development and use of a coding scheme were organized around the themes of smartness. Three coders collaborated, utilizing a spreadsheet to manage the data throughout seven rounds of coding. Some examples of codes that emerged from the data were: (a) good grades; (b) participation; (c) making mistakes; (d) memory; and (e) application. Some of these codes were in alignment with dominant narratives such as good grades and memory. In contrast, codes such as participation, making mistakes, and application were in alignment with counternarratives.

As we delved deeper into the analysis, we observed greater nuance than anticipated within the binary categorization of dominant and counternarratives, specifically with respect to process and outcome. To better capture this complexity, we created an axis to map the range of responses, expanding our understanding beyond a simple dichotomy of dominant and counternarratives. We then created a heat map to visualize the density and distribution of student responses across the different categories and identify areas of concentration or overlap (Figure 1).

Creation of a coordinate system. In our analysis, we found that responses involved process and/or outcome. Thus, we established a two-axis coordinate system, one of which was a continuum of process (e.g., helping others, working hard) and the other a continuum of outcome (e.g., good grades, passing class). We defined process as a dynamic and active nature of mathematical learning and outcome as a means to an end. We created a coordinate system to visualize this, with the horizontal axis representing the process spectrum from dominant to counter-narratives – left to right, and the vertical axis representing the outcome spectrum in the same way – bottom to top.

Along the process continuum (horizontal axis), the far end on either side represents the most extreme narrative associated with either dominant or counternarratives on process. For example, on the left extreme (dominant narrative) along the process axis are codes associated with learning quickly and memorizing. On the far right side along the process axis (counter narrative) are codes associated with making mistakes and helping others. Similarly, the outcome continuum (vertical axis) is structured the same way. For example, on the top of the outcome axis (counter narrative) are codes associated with applying concepts. At the bottom of the axis (dominant narrative) are codes associated with getting good grades and innateness of mathematical ability.

Each response was plotted in this coordinate system using a specific method. First, the core code of each response was identified and classified as either process or outcome-focused, and whether it aligned with dominant or counter-narratives. This initial classification determined the starting point on the coordinate system. The placement was then refined by considering

additional codes present in the response, which could shift the point along either axis. For example, the response "Passing your classes with high grades, being able to conceptualize problems and follow along with lectures" was coded as the core code of good grades (dominant outcome), but then was also coded with understanding and participation (both of which were counternarrative process). This ultimately landed the response in the lower third quadrant. To ensure consistency, we continually referred back to previously plotted responses in the same area, comparing their codes to maintain a cohesive interpretation of the data.

Findings

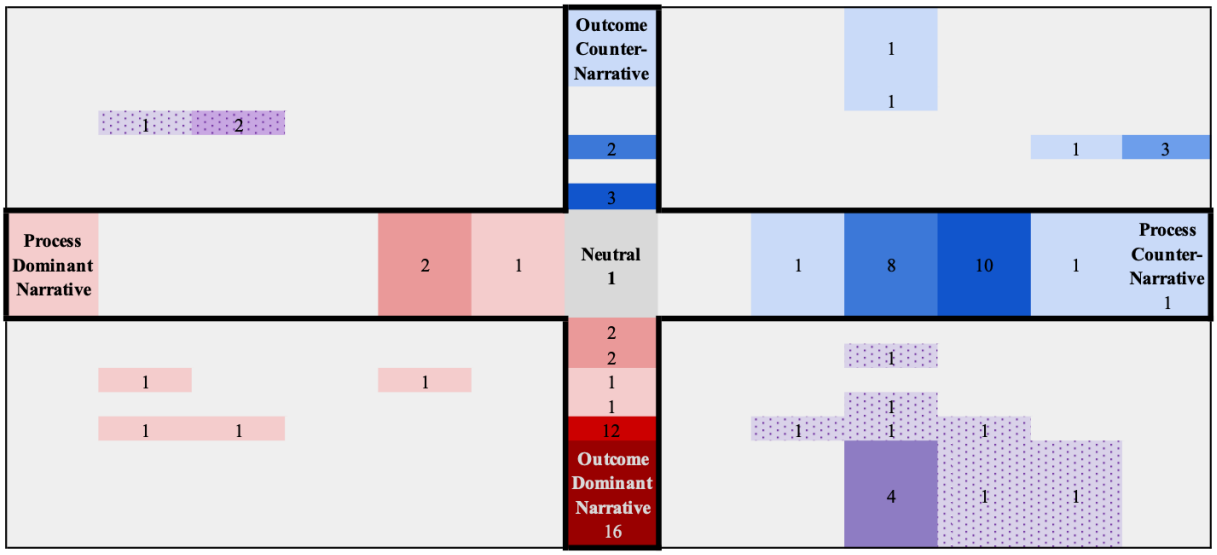

Figure 1. Heat Map generated from the responses

Axis

The highest concentration (N=28) of responses clustered along the axes themselves, rather than within the quadrants. This indicates a prevalence of simpler responses that primarily focused on either process or outcome, but not both in a complex way. Notably, the lower half of the outcome axis, towards the dominant narrative, had the highest density of responses. This signifies that the majority of responses were solely outcome-oriented and aligned with dominant narratives. For example, "getting good grades," or "Being able to get straight A's with ease." Additionally, the right side of the process axis was populated (N=18), signifying that many of the responses were solely process-oriented and aligned with counter narratives. For example, "To be willing to put in the work and learn."

Quadrant I

Quadrant I aligns with responses that contain elements of counter process narratives with outcome counter narratives. For example, one response was "To be smart in math means to understand math and be able to teach math to others." In this response, understanding math is a process toward ultimately being able to teach math to others (the outcome). Another student stated, "Be able to understand concepts and use those concepts in combinations with others to solve problems." Here, understanding concepts is the process toward the outcome of application. Quadrant I was the second most populated quadrant (beside quadrant IV), indicating that several

of the responses were indicative of alternative conceptions of smartness from both the process and outcome lens.

Quadrant II

Quadrant II aligns with responses that contain elements of dominant process and counter outcome narratives. For example, one student stated that smartness was "memorizing equations and how to apply them." This student seems to think that memorization of math is not a means to an end (an outcome) but more so is a process toward application. This quadrant had very few responses highlighting that students who tended to have dominant process narratives were unlikely to have a counternarrative outcome narrative.

Quadrant III

Quadrant III aligns with responses that contain elements of dominant process narratives and dominant outcomes narratives. There were only four responses that were placed in quadrant III. An example of one of the responses is "What I believe what it means to be smart in math is that the student is able to learn quickly and adjust quickly and be able to get the correct answers without needing homework." Here, the process is quick comprehension and adaptation of ideas and concepts with minimal help or practice (process) that leads to getting the correct answer (outcome).

Quadrant IV

Quadrant IV aligns with responses that contain elements of the counter process narratives and dominant outcome narratives. This was the most populated quadrant. Examples of responses in this quadrant are "Being able to grasp and understand the material being taught and retaining it," and "Passing your classes with high grades, being able to conceptualize problems and follow along with lectures." In the last example, the process was grounded in understanding and following along with lectures, but it seems that the outcome was to ultimately pass the class. Responses here indicate that students had counternarrative processes with respect to their ideas of smartness, however they still relied upon dominant outcome narratives.

Discussion

The analysis of student responses with respect to process and outcome revealed a significant concentration along the axes, suggesting a predominance of simpler views of mathematical smartness, focused primarily on either process or outcome. The lower half of the outcome axis, aligned with dominant narratives, was particularly populated, indicating a widespread focus on achieving specific results, such as passing classes or getting good grades. However, a notable presence on the right side of the process axis demonstrated that several students valued alternative processes like understanding concepts, putting in the work, asking for help, or helping others.

Interestingly, Quadrant I, representing counter narratives for both process and outcome, was the second most populated. This suggests that a considerable number of students held alternative views of smartness, emphasizing understanding and application over rote memorization and high grades. Quadrant II, combining dominant process narratives with counter outcome narratives, had the fewest responses, highlighting the rarity of students associating traditional learning processes with alternative notions of smartness.

The sparse population of Quadrant III further indicates the lack of an association between dominant process and dominant outcome narratives. Finally, Quadrant IV, the most populated, revealed a tension between counter process narratives and dominant outcome narratives. This suggests that while many students may appreciate alternative learning approaches, they still may feel confined to dominant conceptions of smartness. This analysis provides valuable insights into the complex and often conflicting perspectives on mathematical smartness held by students.

Conclusion

The way that educators implicitly and/or explicitly talk about smartness in the mathematics classroom is deeply influential in the way that students then conceptualize their own smartness. As illustrated in our initial vignette, the way we communicate about smartness in the math classroom, whether implicitly or explicitly, holds significant influence over students' self-perception and learning experiences. Our research underscores the importance of recognizing and valuing the diverse forms of smartness that students bring to the mathematics classroom. With an awareness of the often conflicting narratives students have of their own smartness in the mathematics classroom, educators can empower students to develop a positive mathematical identity. This is particularly crucial within community college settings, which serve a large proportion of underrepresented students in STEM fields.

By actively desettling the traditional idea of smartness in math and emphasizing the value of hard work, conceptual understanding, collaboration, and application, educators can help students move beyond narrow definitions of smartness. This shift empowers students to develop a more inclusive and expansive understanding of what it means to be mathematically capable. This approach fosters a more equitable learning environment where every student feels recognized and supported. Furthermore, we recognize that neither process nor outcome is inherently good or bad. Students operate within a system where achieving high scores is often necessary for advancement. However, integrating process-oriented approaches can enrich their experiences, broadening their understanding of smartness beyond a singular, potentially limiting perspective.

Limitations

A key limitation of this study lies in the one-dimensional nature of the data, stemming from its reliance on a single open-response question. Without the opportunity to probe for deeper insights or follow-up with participants, our analysis relied heavily on inference and interpretation. This constrains our ability to fully capture the rich complexities and nuances of student perspectives on smartness in mathematics. Future research could address this limitation by incorporating multiple data sources or employing methods that allow for more in-depth exploration of individual experiences and beliefs.

Mathematicians' Values and Norms Related to Algorithms

Peter Sassman
Northern Illinois University

Rachel Rupnow
Northern Illinois University

Alastair Fletcher
Northern Illinois University

Algorithms play increasingly important roles in mathematics as they facilitate solving complex problems both in teaching and research contexts. Nevertheless, limited research has examined mathematicians' views of algorithms or the broader goals of the mathematical community that relate to algorithms or work therewith. Based on interviews with nine discrete or computational mathematicians, we highlight three values upheld by a variety of norms related to algorithms. Of note, some of these values and norms appear to be in tension.

Keywords: norms, values, algorithms, mathematical culture

The mathematical community holds many views about what it means to do mathematics. While research has previously examined individual mathematicians' beliefs about what it means to do and teach mathematics (e.g., Rupnow, 2023; Woods & Weber, 2020), recently new attention has been paid to the values and norms of the mathematical community (Dawkins & Weber, 2017; Rupnow & Randazzo, 2023; Vroom et al., 2024). These works have focused on mathematicians' perceptions of how particular tools like proof (Dawkins & Weber, 2017) and definitions (Rupnow & Randazzo, 2023; Vroom et al., 2024) permit particular values to be upheld via norms of practice in the mathematical community. To build on this work, we examine a third tool, algorithms, which arguably is more central to K-14 mathematics instruction, though it remains important for research in discrete mathematics, applied mathematics, and various applications. Moreover, deductive logic plays a key role in both proof and algorithm creation, suggesting the interwoven nature of these practices. We thus address two research questions:

1. Which values and norms are revealed through mathematicians' purposes for creating and using algorithms in research?
2. Which values and norms are revealed through mathematicians' characterization of instruction around algorithms?

Background Literature

Due to the ubiquity of technology of modern life, computing and computational thinking have received increased attention in curricula. Computational thinking originally centered on problem solving in computer science contexts (e.g., Wing, 2006) but has since been expanded to consider other mathematics and science contexts in which computation is relevant. Weintrop et al. (2016) created a taxonomy of computational thinking in mathematics and science practices with four categories: data practices, modeling and simulation practices, computational problem solving practices, and systems thinking practices. Within mathematics, Lockwood et al. (2019) defined computing as a mathematical disciplinary practice, specifically "the practice of using tools to perform mathematical calculations or to develop or implement algorithms in order to accomplish a mathematical goal" (p. 4). Moreover, they highlighted many ways that interviewed mathematicians use computing, including for facilitating experimentation, testing conjectures, approximating, and visualizing. While we note computing and computational thinking are not exclusively focused on algorithms, algorithms are a component of these related constructs.

While many definitions of algorithm exist in the mathematics education literature, Fan and Bockhove (2014) combined many to state: "an algorithm is a fixed set of step-by-step procedures

for solving a (mathematics) problem" (p. 483). Of note, this definition suggests a procedural aspect, but leaves the relevant problem open-ended. Relatedly, algorithms have not always been viewed positively in mathematics education. Kamil and Dominick (1997) characterized algorithms as procedures that obscured conceptual understanding and argued against teaching arithmetic algorithms like borrowing and carrying for subtraction and addition, respectively. In contrast, Rasmussen et al. (2005) focused on the activity around the use of algorithms when characterizing 'algorithmatizing' as a mathematical practice. In particular, they characterized this activity in terms of how students learn to use and understand a generalizable procedure that is useful across varied contexts, and, in positioning this as a mathematical practice, attributed value to this activity. Nevertheless, limited work has attended to how mathematicians characterize algorithms or how they relate algorithms and algorithmatizing to the mathematical community's expectations about the goals of mathematical activity and how mathematics is done.

Theoretical Perspective

The Triadic Network of Justification (Laudan, 1984) is a theoretical framework that characterizes the conceptual connections among axiology, methodology, and factual claims in a community. Axiology relates to ethics and values, methodology relates to commonly accepted norms of practice, and factual claims relate to what is accepted as settled fact in a community. While this framework was originally designed to conceptualize the nature of paradigmatic changes in the scientific community, this framework has been applied in mathematics education to characterize values (axiology), norms (methodology), and theorems (factual claims) of the mathematical community with respect to proof (Dawkins & Weber, 2017) and definitions (Rupnow & Randazzo, 2023; Vroom et al., 2024). In this study, we build on Laudan (1984) in a similar way to conceptualize values and norms related to algorithms.

Methods

Mathematicians at R1 institutions in the United States who were listed on their departmental website as researchers of applied/computational mathematics or combinatorics (or a similar description) were emailed to find participants. The second author conducted 60-minute remote, screen-recorded interviews with nine such mathematicians. Five participants' research aligned more with applied/computational mathematics and four aligned more with combinatorics. All names are gender-neutral pseudonyms. Interview questions focused on participants' views of algorithms and their use for different populations in both research and teaching contexts.

Using MAXQDA 2020 software (VERBI Software, 2019), all three researchers initially open-coded two transcripts to create norm codes and value categories for algorithms in alignment with Laudan (1984). After discussing our open codes, we created a codebook of norms. We then re-coded at the paragraph level (i.e., came to agreement on the norms present in each paragraph of the transcript) and came to consensus on the first two interviews. Finally, two researchers individually coded each of the remaining seven interviews and then discussed and came to consensus on the norms present in each paragraph. This process aligns with codebook thematic analysis (Braun et al., 2019) in that we entered analysis with some idea of the types of codes we would use and desired to reach consensus on the norms in each transcript but did not enter analysis with specific norms (codes) or values (themes) in mind.

Results

After analyzing the data through open-coding, we obtained a variety of norms (codes, italicized) which we gathered into three values (themes): algorithms are useful for solving

problems, correctness of algorithms needs to be verified, and algorithms need to be clear to people and communicable to others. These values with supporting norms are shown in Table 1.

Table 1. Algorithm Values, Norms, and Frequencies.

Values	Norms	Frequency (n = 9)
Algorithms are useful for solving problems	Algorithms are a tool	9
	Problems/contexts drive the use/creation of algorithms	9
	Algorithms can be used to scaffold thinking/learning	6
	Students need support in writing/implementing algorithms	5
	Coding knowledge helpful for using/proving properties of algorithms	5
	Utility of implementation of algorithms is more important than proving correctness	4
	Using/creating algorithms drives research on convergence/stability properties	3
Correctness of algorithms needs to be verified	Deductive logic is important for algorithms	9
	Proving correctness of algorithms is important	8
	Students need support in proving aspects of algorithms	4
	Students need to develop intellectual need for proving aspects of algorithms	2
Algorithms need to be clear to people and communicable to others	Algorithms need to be understood (enough, depending on context)	9
	Algorithms should be presented/tested with examples	8
	Assumptions/clarity of an algorithm (to humans) is important	7
	People should know the limitations of algorithms	6
	Algorithms should be presented in pseudocode	3

Algorithm Values

Algorithms are useful for solving problems. This value looks at the utility of algorithms for accomplishing a variety of tasks. The first norm, *Algorithms are a tool* encompasses a variety of ways that algorithms are useful for accomplishing some other purpose, such as for solving a numerical problem, generating data or objects, or helping prove a theorem. We observed references to this norm by all nine participants. For example, Ashton described how algorithms could be used to generate useful objects: "[Algorithms] have several purposes. One is to construct mathematical objects or examples." Similarly, Emery stated that algorithms may be used to create an object that was known to exist but whose form was unknown: "For example, if a mathematical result proves the existence of some object or structure in a given context, then an algorithm may be devised to produce it." Foster, who works in applied mathematics, described one way algorithms can be used for proving: "A lot of the ways you prove existence of solutions is to use an algorithm. So the granddaddy one is the Contraction Mapping Principle, but there are lots of them." In particular, the Contraction Mapping Principle, also known as the Banach fixed point theorem, guarantees the existence and uniqueness of fixed points in a metric space and has varied applications such as finding solutions to differential equations and root finding.

Connected to the idea that algorithms can be used to solve problems, is the norm *Problems/contexts drive the use/creation of algorithms*, which was also coded for all participants. This norm highlights how the need to solve a problem in a specific context may promote the creation or use of an algorithm. For example, Gideon stated:

> Monte Carlo is anything that involves randomness, which includes applications in mathematics…And so the early pioneers in the Monte Carlo method were the math physicists who worked on the atomic bomb. And so the Monte Carlo simulations were going to give an indication of whether the damage was going to be astronomical or under control. And so that was one of the first users of the Monte Carlo sim[ulation]. But since then, the subject has exploded with millions of other applications.

Notice the need to examine random processes in a nuclear reaction led to the creation of new a new type of algorithm, which is now applicable in many other settings. While all but one participant described the idea that *proving correctness of algorithms is important* (discussed further below), four of the participants also stated that this proof may not be the most important aspect of some algorithms. The norm *Utility of implementation of algorithms is more important than proving correctness* specifies that the usefulness of an algorithm may be more important than definitive proof that it works as expected. For example, Foster said:

> Sometimes those are actually very hard problems to show that a certain algorithm, which seems to produce an answer, actually produces the answer you want it to produce. And it's not always the case it does.…I mean, there are algorithms in numerical analysis, for example, that I know of, where nobody knows that it produces the answer you want. It appears to, but there's no theorem that says, "Okay, you follow this algorithm, and you will get closer and closer to the answer you want."

Of note, even mathematicians will use algorithms without rigorous proofs of convergence or of other properties that would assure correctness of results.

The norm *Using/creating algorithms drives research on convergence/stability properties* spotlights that using or creating algorithms may lead to new research on proving properties of these algorithms. Three participants had statements aligned with this norm, such as Becker:

> One of our recent papers where we had an algorithm that was basically designed to describe how to find a stability region that's very complicated to get… Other authors had given condition[s] for determining the region, but they couldn't actually do the computations to find it because it involved a good bit of ergodic theory.…So we actually give the algorithm in the paper, but the proof of the result that the algorithm actually does that was the real meat of the paper and showing that we got the region that we claim we got, that this thing was actually doable.

Five participants discussed students needing support with algorithms as described with the norm *Students need support in writing/implementing algorithms*. For example, Harley said:

> In some ways, algorithms can be more concrete for students to understand in theory. But in practice, as I say, students will struggle with algorithms. Even though it's something that you can actually compute through steps, it's hard for them to grasp the whole thing and it gets very tedious if you actually want to work out the mechanics.

The final two norms look at how algorithms can also be helpful for learning, and types of knowledge that may be useful in working with algorithms. The norm *Algorithms can be used to scaffold thinking/learning* was coded in six respondents' interviews and describes how algorithms are helpful for scaffolding the learning process. For example, Devin stated:

> What the algorithm does, the algorithm is going to allow you to compartmentalize what is

> happening, what is it going to, how is it getting there, and where are you going. It helps you with creating that pattern. It helps you to create that sequence of understanding so that what you want to happen, there is a logical process to it, right?

Here, Devin described how algorithms can scaffold an approach to a problem by breaking it into smaller parts that can be more easily understood and connected to each other.

Finally, the norm *Coding knowledge is helpful for using/proving properties of algorithms* was part of four participants' responses. For example, Devin said:

> This is when our plan meets the real world….So this is when we use our software, right? So we translate our algorithm into a mathematical software, right? So I may use MATLAB or I may use Mathematica or something like that. And I may find these numerical [simulations] that approximate the clinical information.

Here Devin emphasized the importance of being able to translate a mathematical algorithm into computer code so it could be solved in a large-scale, real world application.

Correctness of algorithms needs to be verified. This value focuses on the importance of deductive logic and aspects of proof to algorithms. The first norm, *Deductive logic is important for algorithms*, was part of every participant's response. For this norm, participants described how algorithms can intersect with deductive logic. Ashton provided the following example:

> I want to construct a big data set....So without thinking about what's going to happen at each individual step, I'm going to think like, "First, I need a function that does this, and then the output of that function is going to go into another function that does this. And I need to range over this set of inputs or whatever," and you put it together kind of in this modular way.

Here, Ashton described building an algorithm, step by step, following a deductive process.

While some norms of the prior value especially centered utility, participants also said that it is important to prove correctness of algorithms, coded with the norm *Proving correctness of algorithms is important*, which was mentioned by 8 participants. Ira described this in the following quote: "A new algorithm has got to be analyzed for stability and accuracy before it's at all useful. I think that's just one of the essential steps in developing an algorithm.

Similar to the norm about needing to support students in writing algorithms, the norm *Students need support in proving aspects of algorithms* centers the proving aspects. Four participants were coded with this norm, such as Emery, who said:

> When students are in a mathematics course in graph theory, what they're having difficulty with is the proofs, generally. And running through an example subject to an algorithm is not so much where they find the difficulty but rather something that they use to help them with difficulties in other aspects of proof.

Notice that Emery viewed proving as generally more difficult for students than understanding algorithms, at least in their context of graph theory.

Although the previous norm noted that students need support in proving, two participants expanded on this idea in the norm *Students need to develop intellectual need for proving aspects of algorithms*. Becker described:

> …when [computer science students] started having to prove the correctness of the algorithms, they didn't like it at all which I was like, "This is a senior-level math class. Mathematicians prove things, you've got to—because I knew I had CS majors, I was like, You're going to have to prove things in here just to help you understand."

Here, Becker described computer science students as not being as interested in proving properties of algorithms, and thus a need to communicate the importance of proof to algorithms.

This speaks to the potential tension between communities in the role of proof in algorithms.

Algorithms need to be clear to people and communicable to others. The final value focuses on the clear presentation and communication of algorithms. The first norm supporting this value is *Algorithms need to be understood (enough, depending on context)*, which was part of every participant's interview. Gideon illustrates this norm in the following:

> In a calculus course, the best you can hope for is illustrate an algorithm with some pictures such as gradient descent or tangent slopes or splines. And so the picture is often the link between the theory on one side and the program on the other side.

Here, Gideon described students as unlikely to fully understand an algorithm, but with the aid of illustrations, able to understand it enough for the course. In research, sometimes mathematicians could also limit which parts of an algorithm they understand, as Devin described:

> Anytime I am into a system, I try to break it because when you figure out a problem, then you can figure out why is this a problem. And I could create more algorithms from understanding that problem. And that's how you get an algorithm from an algorithm because there [is] embeddedness in things, right? And so why was that embedded? And that's how you unfold the different models. What I'm saying is someone else may create a model which you have no idea why they created that model.

Here Devin described the importance of understanding why aspects of an algorithm work while acknowledging that not all details of the design process need to be known. In contrast, Cooper set a high standard for creating new algorithms in mathematical research:

> A colleague of mine [is] designing spectral methods that give better results for certain stiff differential equations. That's where the ball game's totally different because that's where you really have to analyze how does my code [do] what it does, why does it do it? How is it superior to what the status quo is? And is it only superior for these equations, or is it really something that could potentially be the next upgrade for MATLAB or something like that?

Cooper noted that when generating a new algorithm, it is important to establish whether and how the new algorithm is better, as well as determine some sense of the contexts in which it is better.

All but one participant had responses coded with the norm *Algorithms should be presented/tested with examples*. Ira explained this as follows:

> Oh, you can never build a reliable code without testing it on a problem where you know the answer. This is something I drum into my students. We need analytical solutions as benchmarks for the code that we're developing in order to be able to solve systems where we don't know what the answer is.

Here, Ira described the need for testing an algorithm with examples and known answers, so it may be used in cases where the answer is not known. Others highlighted the utility of examples for understanding an algorithm, such as Ashton:

> If something's just described verbally in a paragraph, that's always a real pain. And lots of mathematicians who don't do so much computation will describe things just like in this big block of a paragraph or two that's just impossible to read. So the best thing is if you put it in pseudocode, and then if the authors or if wherever you're getting the algorithm from hasn't provided an example, then you start with the simplest example you could possibly come up with and then just slowly ratchet up the level of complexity until … what should happen as you do that is that each step of the algorithm becomes clear why it's needed. So sometimes you'll have certain loops in an algorithm or certain branches that don't kick in unless you encounter a certain situation …And so for a while,

> you'll be like, "I don't know why this part's here," and you just need to find an example where it triggers it. And a good writer will give you those examples.

Here Ashton noted that good writers assist readers by providing examples that illustrate why all parts of the algorithm are useful. This segment also was coded with the norm *Algorithms should be presented in pseudocode*, which was coded in three participants' interviews, because it notes that pseudocode is easier to translate to a working algorithm in the computer language of one's choice (or to understand for oneself) than a large block of text.

Another norm, the *Assumptions/clarity of an algorithm (to humans) is important*, was observed in seven participants' interviews. Becker for example, said:

> So you have to know the constraints upon the problem itself for which this will actually give you the solution because it's generally not always going to give you all possible solutions.…So it's the same thing with algorithms. You have to understand the conditions upon which classes of problems this algorithm will actually solve.

Here Becker described the importance of looking at the assumptions of an algorithm, to make sure your system satisfies the given conditions for which the algorithm works.

The final norm is *People should know the limitations of algorithms*, which was coded in six participants' interviews. Ashton illustrates this norm with the following:

> So sometimes people will just be like, oh, okay, great, we can solve this with this algorithm. And they don't think about the fact that the algorithm doesn't see the quality of the data. And oftentimes, the algorithms that are used in science and public policy and stuff really are biased by not just the data, but by the weights that are chosen, like, you set these parameters.

Ashton noted that the quality of the outputs of an algorithm depends on the quality of the inputs as well as the weights given to various criteria, all of which can fundamentally impact the validity of results.

Discussion

This study examined nine mathematicians' norms and values related to algorithms in the contexts of research and teaching. We observed three values: algorithms are useful for solving problems, the correctness of algorithms needs to be verified, and algorithms need to be clear to people and communicable to others. Throughout the interviews, the utility of algorithms for a variety of purposes was very clear. Many uses were highlighted including using algorithms to prove or test conjectures, create examples, or find specific solutions. Participants also expected algorithms to produce correct outcomes, both based on their deductive structure and additional work focused on providing proof that algorithms have desirable properties. Clarity and communication were also viewed as important aspects of algorithms, though participants did vary in how much understanding or clarity is deemed sufficient, especially depending on context.

However, unlike prior research examining mathematicians' values and norms related to proofs and definitions (Dawkins & Weber, 2017; Rupnow & Randazzo, 2023), we saw some disagreement on the importance of some values. While some participants centered the utility of algorithms as most important, with some suggesting proof was desirable but not necessary (especially for solving real-life problems), others believed proof of accuracy or particular properties was paramount. This may in part stem from mathematicians viewing "algorithms" as encompassing different things, based on their mathematical training, common uses for algorithms in their work, and the expectations of the stakeholders they serve. Nevertheless, more research is needed to better understand mathematicians' values related to computing or algorithmatizing and how they interrelate with their view of other mathematical practices.

Undergraduate Students' Statistical Literacy in Media Contexts

Samuel Waters
University of Northern Colorado

As the uses of data in society continue to expand, it is vital to prepare students to engage with data in meaningful and critical ways. This study used a course-wide assessment in an introductory statistics course to explore undergraduate students' statistical literacy in media contexts based on Watson and Callingham's (2003) six-level construct. Statistical analysis found student performance on non-media tasks had limited association with performance on media-based tasks. Students demonstrated higher levels of statistical literacy when provided with specific prompts. Findings suggest the need to develop students' propensity for critical questioning when engaging with statistics outside classroom settings through intentional incorporation and discussion of media items in introductory statistics courses.

Keywords: Statistics, Introductory Courses

For most adults, the news media is the primary source of information about social and scientific issues (Bissonnette et al., 2021). Statistical and mathematical products in the news take on many forms, requiring multiple inter-related skills to appropriately comprehend and evaluate (Gal & Geiger, 2022). As the pervasiveness of data in everyday life continues to increase, statistics educators are exploring how to prepare students to engage with data in meaningful and critical ways (Burrill & Pfannkuch, 2023). Undergraduate introductory statistics courses provide a natural place where the development of these skills could occur. Driven by this need, the purpose of this quantitative study was to understand the statistical literacy of students in an introductory statistics course within media contexts. Statistical literacy is defined as a multi-leveled construct building from idiosyncratic task steps (Level 1) where no mathematical or statistical thinking is occurring, to critical mathematical task steps (Level 6) which involve critical engagement and questioning with the statistics in context (Watson & Callingham, 2003).

Background

While early statistics education research focused on resolving persistent challenges in developing reasoning about specific statistical ideas (Garfield & Ben-Zvi, 2007), current trends looking to the future of statistics education research include broader issues of content, pedagogy, and ethics (Burrill & Pfannkuch, 2023). One of the four emerging trends Burrill and Pfannkuch identified is social statistics, which encompasses the importance of attending to risk, critical literacy, and communication in contexts such as the media and advocacy. Burrill and Pfannkuch noted that while statistical literacy from the perspective of societal needs was recognized by Gal (2002) as well as Watson and Callingham (2003), the ideas gained limited attention. Existing research on statistical literacy spans a variety of methods and foci. Previous quantitative studies typically used multiple choice tests to evaluate the statistical literacy of students in introductory statistics courses (e.g., Chance et al., 2022). Such studies frequently show students struggle to demonstrate mastery of topics such as sampling, variation, and study design even after completing a statistics course (delMas et al., 2007; McLauchlan & Schonlau, 2016).

Many statistics education researchers intentionally investigate statistical literacy in media contexts. Watson (1997) advocated for the use of media-based tasks in courses to assess statistical thinking in social settings outside the classroom. Other studies utilized media-based

tasks to investigate student statistical literacy in general (e.g., Kaplan & Thorpe, 2010) or understanding of specific topics such as sampling (Watson & Moritz, 2000). Budgett and Pfannkuch (2010) found incorporating media into classroom activities and assessments to be effective for college students in non-quantitative majors.

Simulation-based curricula (SBC) have been growing in popularity in introductory statistics courses (Tintle et al., 2015). SBC provide an alternative to using theoretical distributions to calculate confidence intervals and p-values by simulating repeated samples to generate bootstrap and randomization distributions (Lock et al., 2021). Advocates of SBC assert they allow students to see the logic and power of statistical inference and find a balance between statistics as proof and statistics as magic (Tintle et al., 2015). Researchers identified improvements in students' statistical literacy when they engage with SBC compared to engaging in more theory-based curricula (e.g. Chance et al, 2022; Maurer & Lock, 2016). Other studies noted how simulation tools contributed to student understanding of sampling (Findley & Lyford, 2019), p-values (Reaburn, 2014), and inference (Noll et al., 2023).

While current research calls for increased use of simulation-based methods in introductory statistics courses (Tintle et al., 2015), research is less clear about how SBC help prepare students to engage with statistics in the increasingly complex media environment. This study brings together research on statistical literacy, SBC, and statistics in news media to understand how students in introductory statistics courses utilizing SBC are prepared to engage with statistical information in media settings. Specifically, this study addresses the research questions:

1. At what level of statistical literacy do students in an introductory statistics course apply statistical topics when critiquing statistics in the news media?
2. What relationship exists between students' scores on non-media-based tasks and their levels of statistical literacy on media-based tasks?

Conceptual Framework

This study adopted Watson and Callingham's (2003) six-level construct of statistical literacy, grounding statistical literacy in the need for understanding, interpreting, and communicating in real-word contexts such as the news media. Individual levels are characterized by the types of task steps students take while engaging with statistical tasks. Progressing to higher levels of the construct statistical constructs requires more nuanced statistical thinking, clearer justifications or reasoning, and deeper engagement with the task's context. Level 1 and Level 2 involve mostly non-statistical thinking, instead relying on personal experiences and intuition. Level 3 and Level 4 utilize statistical terminology and arguments with increasing amounts of justification and connections to the task's context. Level 5 and Level 6 incorporate critical engagement and quantitative interpretations concerning the data and conclusions.

This study's conceptual framework draws on Gal and Geiger's (2022) categories of statistical and mathematical products (StaMPs). Gal and Geiger conducted a content analysis of over 300 media items and identified nine categories that encompass entities appearing in media items. This study focuses on five of the nine categories to investigate students' statistical literacy of statistical topics supported by SBC: (a) descriptive quantitative information; (b) models, predications, causality, and risk; (c) data quality and strength of evidence; (d) demographics and comparative thinking; and (e) critical demands. The nine categories provide a basis for what students should be prepared for when engaging with statistics in news media contexts.

Methods

This study took place at a mid-sized, regional university in the Rocky Mountain Region of the United States. The university is an emerging Hispanic Serving Institution with a student population that is 62% White and 24% Latine/Hispanic with 42% of incoming students being first generation college students. Introductory statistics courses utilize a textbook and materials which address simulation-based methods for calculating confidence intervals and p-values (Lock et al., 2021). All 189 students enrolled in seven sections of introductory statistics were asked to complete an assessment as part of the course for a completion grade. Overall, 123 students (65.1%) completed at least one part of the assessment and consented for their responses being included in the study.

Each participant completed a three-part assessment using Qualtrics during the 12th week of the semester. Part 1 consisted of six multiple-choice questions taken from the Basic Literacy in Statistics (BLIS) assessment (Ziegler & Garfield, 2018). The BLIS assessment was selected because it was developed for introductory statistics courses at the postsecondary level that include SBC. Selected items were not embedded in media contexts and assessed participants' understanding of three statistical topics that are encountered in the news: sampling, variation, and confidence intervals. Variation and confidence intervals were selected as they are topics where SBC have been shown to be particularly effective (Chance et al., 2022). Parts 2 and 3 were media-based tasks asking participants to read a headline and short article containing information related to the same three statistical topics from Part 1. Part 2's article discussed results from a recent drug trial and asked participants to evaluate the presented argument but gave no additional prompts about what to talk about (i.e., unprompted). Part 3's article reported results of a poll and asked participants to respond to prompts referring to specific features and statistics within the article (i.e., prompted).

Participant responses were scored to facilitate statistical analysis. Multiple choice items were scored on correctness and given a zero or one, forming six variables (MCQ1, MCQ2, etc.). Topic scores (i.e., MC_{Samp}, MC_{Var}, and MC_{CI}) were calculated based on the number of correct responses on each topic (out of two) and an overall multiple-choice score (i.e., $MC_{Overall}$) indicated the total number of correct responses (out of six). Scores for the unprompted (UP) and prompted (P) media tasks were determined using Watson and Callingham's (2003) six-level construct of statistical literacy. For each task, participant responses were assigned a level score from 0 to 6 for each of the three statistical topics based on the statistical literacy level their response addressed (i.e., UP_{Samp}, UP_{Var}, UP_{CI}, P_{Samp}, P_{Var}, and P_{CI}). A score of 0 was assigned to responses that did not address the statistical topic at all, either because it was not mentioned for the unprompted task or left blank for the prompted task. Based on the three topic scores, each participant's response was assigned an overall level of statistical literacy (i.e., $UP_{Overall}$ and $P_{Overall}$). In total, there were 18 variables: (a) six individual multiple-choice question scores; (b) three topic scores for sampling, variation, and confidence intervals on each part (nine total); and (c) three overall statistical literacy scores (one for each part).

Response scores were imported into R for statistical analysis. Summary statistics were calculated for each variable. Since scores were not normally distributed, variables were treated as ordinal when conducting statistical inference. Non-parametric tests such as the Wilcoxon Signed-Rank test and Kruskal-Wallis Rank test were performed to compare scores. Correlational analysis was performed to see how different variables related to each other. Spearman's rho correlations were used due to the non-continuous nature of the variables (Agresti, 2007). Additionally, analysis was performed to determine if multiple-choice questions were strong

predictors of statistical literacy level on media tasks. Ordinal logistic regressions were used to incorporate the ranked property of the variables and explore how multiple-choice responses predict the odds of higher statistical literacy (Osborne, 2017).

Results

Performance on the multiple-choice questions ranged from 69.1% correctly answering MCQ1, which dealt with identifying a sample and population, to 16.3% correctly answering MCQ6, which asked participants to interpret the center of a confidence interval. Most students answered one to three questions correctly with the mean $MC_{Overall}$ score being 2.285 correct out of six. No participant answered all six questions correctly. Participants had the most correct responses on sampling questions, followed by variance and, lastly, confidence intervals.

Table 1provides a summary of participant scores on the unprompted and prompted media tasks. For both tasks, participants demonstrated higher mean statistical literacy scores related to sampling than for variation or confidence intervals. The highest mean was P_{Samp} (M = 3.546) and the lowest mean was UP_{CI} (M = 1.822). Overall, participants demonstrated lower levels of statistical literacy on the unprompted task compared to the prompted task on all three statistical topics and the overall score. Wilcoxon signed-rank tests were performed to assess whether the medians of the distributions of scores on the unprompted and prompted tasks were equal. Results of the tests indicated significantly greater scores on the prompted tasks for sampling ($p < .001$), variation ($p < .001$), confidence intervals ($p = .002$), and the overall score ($p < .001$). Participants also had more zero scores on the unprompted task compared to the prompted task, indicating participants were not addressing certain pieces of information within the unprompted task. For example, 40 participants received a zero on UP_{CI} as their response did not include the comparison of values discussed in the article.

Table 1: Summary of Statistical Literacy Scores on Media Tasks

Task	Sampling		Variation		CI		Overall	
	Mean	*SD*	Mean	*SD*	Mean	*SD*	Mean	*SD*
Unprompted [a]	2.237	1.616	2.051	1.524	1.822	1.583	2.839	0.961
Prompted [b]	3.546	1.314	2.944	1.478	2.537	1.632	3.389	1.134

[a] n = 118. [b] n = 108.

To investigate the relationship between participant scores across topics and task type, Spearman rho correlations were calculated for all scores (see Table 2). Analysis focused on the correlations between non-media task scores (i.e., multiple choice) and media task scores to see what relationship existed. All correlations were weak, with the strongest correlation being $\rho = .260$ between $MC_{Overall}$ and UP_{CI}. All correlations were positive, indicating greater scores in one area were associated with greater scores in other areas. Eight of the 32 correlations were significant. MC_{Var} was not significantly associated with any of the media-tasks scores. $MC_{Overall}$ had many of the strongest correlations, including significant correlations with the $UP_{Overall}$ ($\rho = .216$) and $P_{Overall}$ ($\rho = .226$). The only multiple-choice topic score significantly correlated with a corresponding media-task topic score was for MC_{CI} and UP_{CI} ($\rho = .193$).

Due to potential similarities between the prompts in a multiple-choice setting and the prompted media task, additional analysis focused on the relationships between those sets of questions. For example, MCQ1 asked students to identify the sample and population of a provided context. Similarly, the first prompt of the prompted media task asked students to

identify the sample and population. Identifying both correctly would correspond to a statistical literacy score of at least Level 3 for P_{Samp}. While participants who answered MCQ1 correctly had a higher mean P_{Samp} score (M = 3.688 vs. M = 3.143), a Kruskal-Wallis rank-sum test found no significant difference in the medians of the two groups (p = .058).

Table 2: Spearman Correlation Matrix of Multiple-Choice Scores and Media Task Scores

		Unprompted				Prompted			
		Samp	Var	CI	Overall	Samp	Var	CI	Overall
Multiple Choice	Samp	.156	.144	.157	.192*	.145	.065	.218*	.234*
	Var	.139	.092	.147	.124	.113	.071	.043	.063
	CI	.179	.003	.193*	.073	.087	.068	.083	.157
	Overall	.248**	.127	.260**	.216*	.186	.118	.169	.226*

*p < .05. **p < .01.

The significant correlation between $MC_{Overall}$ and $P_{Overall}$ was explored further to understand the relationship between students' scores on non-media versus media-based tasks. A Kruskal-Wallis rank-sum test was performed to determine if there was a difference in the median $P_{Overall}$ score between groups based on $MC_{Overall}$ score. The test reported no significant difference (p = .131), suggesting scoring greater on the multiple-choice section did not correspond to greater distributions of statistical literacy scores on the prompted media task. An ordinal logistic regression model was fit to the two scores which similarly found different $MC_{Overall}$ scores were not significant predictors of $P_{Overall}$ scores. These results are reflected in participant scores as there were 21 participants who had lower $MC_{Overall}$ scores (score of two or less) but demonstrated greater levels of statistical literacy in the prompted media task (Level 4 or greater). Similarly, six participants had higher $MC_{Overall}$ scores (score of three or more correct) but did not demonstrate higher levels of statistical literacy in the prompted media task (Level 2 or lower).

Although $MC_{Overall}$ was not found to be a good predictor for the prompted media task, another ordinal logistic regression was performed to assess the predictive power of the individual multiple-choice questions. A binary variable for each question (correct or incorrect) was used in a model to predict overall prompted score. Table 3 includes the fitted coefficients for the regression. MCQ1 (sample and population) and MCQ5 (confidence interval estimation) were significant predictors of overall prompted score (p = .027 and p = .048 respectively). The odds ratio for MCQ1 indicates people who answer MCQ1 correctly were 2.569 times more likely to be in the next higher level of statistical literacy in the prompted task (95% CI [1.118-6.012]). Similarly, people who answer MCQ5 correctly were 2.053 times more likely to be in the next higher level of statistical literacy in the prompted task (95% CI [1.013-5.223]).

Table 3: Ordinal Logistic Regression for Multiple Choice Questions Predicting Prompted Task Scores

						95% Confidence Interval	
Question	Estimate (β)	*SE*	*t*-score	*p*-value	Odds Ratio	Lower	Upper
MCQ1	0.943	0.428	2.205	.027	2.569	1.118	6.012
MCQ2	0.603	0.458	1.317	.188	1.828	0.745	4.515
MCQ3	0.295	0.389	0.759	.448	1.343	0.627	2.893
MCQ4	-0.297	0.379	-0.782	.434	0.743	0.352	1.562
MCQ5	0.719	0.363	1.979	.048	2.053	1.013	4.223
MCQ6	-0.439	0.536	-0.820	.412	0.645	0.222	1.840

Discussion and Conclusion

The study found participants in introductory statistics courses applied statistical topics at varying levels of statistical literacy when engaging with the news media. Participants had difficulties correctly answering multiple-choice questions from a standard assessment (i.e., BLIS). The mean overall multiple-choice score was 2.285 out of six and only 16.3% selected the correct interpretation of a provided confidence interval. These results are consistent with ongoing challenges in introductory statistics courses McLauchlan and Schonlau (2016) identified where students do not always demonstrate improved statistical literacy after completing a course. While Chance et al. (2022) found SBC improved student outcomes related to topics such as variation and confidence intervals, this study shows challenges persist. Participants performed better on the sampling topic questions with more than two-thirds correctly identifying a sample and population from a provided context.

Results from the media-based tasks indicated that participants typically demonstrated significantly higher levels of statistical literacy when receiving specific prompts compared to an unprompted, open-ended question. Mean scores for the prompted task were mostly at Level 3 or higher, indicating students were more often engaging in statistical thinking and justification. However, mean scores for the unprompted task were mostly around Level 2, which corresponds to more intuitive thinking and/or incompleteness in statistical engagement. The results indicate a gap that needs to be addressed. Students have knowledge and abilities they are capable of applying but are not always doing so at the same level on their own (unprompted). For example, without prompts, several students (about one-third) did not regard key statistical information such as the comparison of the effectiveness of the two drugs being discussed in the article. In most real-life situations, such as engaging with the news media, information does not come with prompting questions. The results emphasize the need to facilitate students' development of what Gal (2002) described as *worry questions* to raise when assessing the quality of information.

Results of correlational analysis on the different task scores found only weak, positive correlations between scores on non-media multiple-choice questions and the level of statistical literacy on media-based tasks. The results indicate that demonstrating statistical knowledge in one type of task was not associated with demonstrating the same knowledge in other types of tasks. One specific example was that there was no significant difference in the distribution of sampling scores on the prompted task based on whether a participant correctly identified the sample and population in MCQ1. More broadly, about 30 students scored notably higher on one type of task compared to the other. Watson (1997) noted difficulty in students demonstrating greater levels of statistical literacy in multiple-choice settings. This study's findings indicate that multiple-choice questions may provide a limited picture of students' knowledge and abilities.

Ordinal logistic regression indicated correctly answering MCQ1 (identifying a sample and population) or MCQ5 (identifying what a confidence interval was estimating) were significant predictors in demonstrating higher overall levels of statistical literacy in the prompted media task. MCQ1 being the strongest predictor could indicate the importance of the concept. Understanding the difference between a sample and a population is a critical component of statistical inference and may contribute to students' ability to demonstrate greater levels of statistical literacy with the variation and confidence interval aspects of the task.

Limitations

The study has limitations to consider when interpreting these results. The assessment took place during Week 12 of the semester. While students had been assessed on the relevant content, students may have improved their statistical literacy related to the topics in this study by the end

of the semester. Furthermore, the study only assessed students' understanding of sampling, variation, and confidence intervals which may not represent the entirety of their statistical literacy. The assessment contributed to participants' course grade, but only as a completion grade. Therefore, not all students may have responded at a level representative of their highest ability. There are possible limitations related to decisions about scoring such as the inclusion of the zero score. Importantly, zeros indicated the topic ideas students did not engage with for the tasks; zeros did not indicate participants had no statistical literacy related to the topic.

Implications

The study emphasizes the importance of supporting students' applications of statistics in real-life settings and the practice of critical questioning. Instructors and course developers should consider how to incorporate media tasks into class activities to provide opportunities for students to practice working in these contexts. Such tasks allow for discussions surrounding how statistics are presented in the news media and how the presentation can differ from textbooks and academic journals. These practices can help prepare students to engage with statistics in social settings, such as the news media (Burrill & Pfannkuch, 2023). When assessing students' statistical literacy, instructors should consider multiple forms of assessment and contexts to provide students with different opportunities to demonstrate what they know.

Further research should continue to explore how students approach statistics in media contexts. Qualitative research such as task-based interviews can provide additional insights into students' thinking and approaches to media items. In particular, research can investigate what students pay attention to or find important in these settings and explore the kinds of resources students draw on when evaluating statistical claims. Teaching experiments or other methods could be implemented to see what kinds of tasks, prompts, and activities are most effective in promoting critical questioning and higher levels of statistical literacy.

Students' Perceptions of Differences Between Physics and Mathematics Classes

Jeffrey M. Rabin
UCSD

Andrew Meyertholen
UCSD

Brian Shotwell
UCSD

Student learning of physics is built on a foundation of mathematical knowledge. Accordingly, physics education research has devoted much study to students' use of specific mathematical content in specific physics contexts. More generally, though, students also experience various "cultural" differences between the (mathematics) courses where they learn this content and the (physics) courses where they apply it. Researchers have discussed these cultural differences, but to our knowledge they have not investigated whether students are aware of them, or students' beliefs about how these differences may affect their learning. We used a survey questionnaire and individual interviews to study this in a group of math-physics double majors (or majors in one with minors in the other). These students are indeed aware of many such cultural differences, cite many classroom examples, and have strategies to cope with them.

Keywords: physics education, mathematics, disciplinary cultures

Introduction

The physics education literature has extensively studied students' use of mathematics in their physics coursework (Caballero et al., 2015). Often this focuses on specific mathematical techniques in specific physics contexts, such as students' use of vector calculus in electromagnetism (Bollen et al., 2015). However, some authors have also pointed out more general "cultural" differences between mathematics and physics which likely affect students' ability to make use of mathematical knowledge in a physics context (Redish and Kuo, 2015). We interpret this idea broadly to include, for example, the standards of proof or derivation of mathematical facts, the ways that mathematical notation is used, how approximations are used and justified, and the use of potentially ill-defined concepts such as the Dirac delta function.

An illustration of such a cultural difference, in the use of function notation, is provided by "Corinne's shibboleth", attributed to Corinne Manogue (Dray and Manogue, 2002). Mathematicians and physicists are claimed to give different answers to this question: If $F(x, y) = x^2 + y^2$, then what is $F(r, \theta)$? Mathematicians should treat the function arguments as dummy variables and answer $r^2 + \theta^2$, while physicists typically assume that F represents a physical quantity that can be expressed in either rectangular or polar coordinates, and answer r^2.

Our interest is in whether students themselves are aware of such cultural differences and how they may impact their learning, and whether they have coping strategies to deal with them as they apply their mathematical knowledge in physics. We studied these questions through a survey of double majors in mathematics and physics at our institution, plus interviews with a subset of the participants.

Purpose and Theoretical Background

The purpose of this exploratory study was to learn whether undergraduate students are aware of the cultural differences in the treatment and use of mathematical content between their mathematics and physics courses, how they see these differences as affecting their learning, and what coping strategies they may employ. Our understanding of cultural differences here is consistent with that of Rabin et al. (2021), which explored obstacles to interdisciplinary communication between STEM fields arising from different practices around notation,

terminology, modeling, and rates of change. On the other hand, it is distinct from the notion of disciplinary cultures in Reinholz et al. (2019) which refers to the administrative organization of the disciplines within the university setting. We were particularly inspired by the work of Redish and Kuo (2015), who point out that "Math in science (and particularly math in physics) is not the same as doing math. It has a different purpose – representing meaning about physical systems rather than expressing abstract relationships" (p. 563). We interpret the construct of cultural differences very broadly, and indeed our students discussed a wide range of topics ranging from specific mathematical content to the teaching styles and assignments in their mathematics and physics courses. One could frame our questions in terms of transfer of learning from mathematics to physics, but we think the issues are broader than that, and not unidirectional.

The authors are two physicists and one mathematician having a postgraduate physics background. In formulating our survey and interview questions, we drew upon our own experience and the literature cited above.

Our research questions were:

1. Are undergraduate double majors aware of cultural differences between mathematics and physics, and differences in the presentation and usage of mathematical content between their physics and mathematics courses?
2. What do they cite as major differences in "common" mathematical content?
3. How do they perceive these differences as affecting their learning?
4. What coping strategies do they employ?
5. What specific classroom experiences do they cite?

Participants and Methods

We designed our study to include all undergraduate double majors in mathematics and physics at our institution. The rationale was that such students would have taken enough high-level courses in both disciplines to have experienced a range of cultural differences, content areas, and teaching styles. These would include proof-based mathematics courses beyond the basic calculus sequence. There were fewer double majors than we had hoped, so we decided to add students majoring in either discipline and minoring in the other. By email we invited each of them (36 in all) to complete a survey questionnaire in exchange for a gift card, obtaining 20 completed surveys. Following an initial analysis of these, we invited a subset of students to be interviewed in person, with another gift card as compensation. There were 11 completed interviews in all, which were audio recorded and transcribed.

The surveys asked students' opinions about specific mathematical topics that we suspected might be problematic, such as Fourier series/transforms, infinitesimals, and linear algebra; differences in notation between students' physics and mathematics courses; and differences in the standards of proof or justification between the two fields. We asked whether they have strategies for coping with differences in presentation of "the same" topic in their physics versus mathematics courses, and whether they have advice for mathematics or physics instructors about presenting such cross-disciplinary content. We also included the "Corinne's shibboleth" task since we have not seen published data on it in the literature.

Interviews were semi-structured, following a general script but allowing for detours to explore student comments in more depth. In addition to asking students to expand on their survey answers, we asked what they thought the role of mathematics in physics was; how mathematics and physics classes "feel" different; and whether seeing the same topic presented in both a mathematics and a physics class had facilitated or impeded their learning of it. We tried to keep

our questions unbiased, not showing favoritism to either mathematics or physics, and open-ended to allow students to bring up topics we might not have expected.

After an initial analysis of the surveys, we selected students to interview whose comments we wanted to explore in more depth. All surveys and interview transcripts were read multiple times by all authors, and discussed as a group. Surveys and interviews were analyzed thematically (Terry et al., 2017), coding ideas that multiple students brought up and consolidating them into general themes. Our results below also include student comments that were less frequent but worth exploring in future research.

Results

Theme 1: The Nature of Mathematics and Physics

Our students perceive mathematics to be deductive, standardized, and highly structured, whereas physics to them is more inductive, flexible, and eclectic. This applies to the nature of argumentation or proof in each field, the presentation of material in lectures, and the homework and exam problems posed. They find mathematical proofs highly structured, with logical steps spelled out in detail and named theorems cited as justifications. Derivations in physics look more like calculations, relying on known techniques from algebra or calculus without explicit justifications. When words appear in a physics derivation, they may actually interrupt the flow of the reasoning to introduce a physical assumption or approximation. Students feel that mathematical proofs contain all the reasoning needed to understand them, whereas they may have to stay after class to ask their physics instructor to explain the steps of a derivation if they want to fully understand it.

Topics presented in mathematics courses are fully developed from definitions and axioms, whereas mathematical methods used in physics may be introduced without complete justification and simply illustrated through specific examples. Students understand and accept that mathematics is used as a tool in physics, and this tool need not be fully justified from first principles.

> My math classes have been, they have, like a familiar structure … they have some motivation, they have some definitions, a theorem, and a proof … Whereas in physics I feel like it's kind of been more all over the place. Like the transitions between when somebody's giving like a heuristic argument or an actual proof of what they're trying to show, it's a bit blurry. [Interview, double major]

Students find homework and exam problems in mathematics to be quite standardized and predictable in terms of what a correct solution should contain, even across different courses. In contrast, they see wide variation in expectations across physics courses, and are unsure what methods or approximations are allowed in homework solutions:

> I can get full credit on the assignment even though I don't know why the thing I just applied works in this instance…you can BS the physics assignment and still get 100 on it, even though you don't understand why the stuff you're writing works…in a math homework assignment, if you BS the homework assignment you're not getting 100 on it…because you're going to be missing some crucial steps in your proof, and you know

you're missing those crucial steps, and when a proof is complete you feel it. [Interview, physics major]

Theme 2: Physics "Tricks"

Students referred to some uses of mathematics in physics as "tricks," which includes two distinct categories. Some tricks, such as interchanging the order of derivatives and integrals, could be mathematically justified but this justification may be omitted in class. Others are physically motivated approximations. Both were sources of confusion for students.

We were surprised that physical approximations were considered problematic by many students. Often these rely on Taylor series expansions, a topic that many students felt was insufficiently emphasized in their calculus courses. But even the small-angle approximation for a pendulum raised questions. Why not give an exact solution instead? Won't the error accumulate over time as the pendulum swings? Why not give a rigorous error bound, as would be the case in a mathematics class? Why not retain additional terms in the Taylor expansion? We suspect that students' prior mathematics classes have contributed to a general preference for exact solutions and an aversion to discarding information by approximating.

> I've taken real analysis, when you do real analysis and you're giving the approximation functions for equations in that class like the Taylor expansions, they of course give you the error and they prove why the error works and they are like, this is how we minimize the error to make sure that there is as little error as possible. We weren't given anything like that [in the physics course]… I personally find it a little bit confusing to have that stuff and then not have any explanation for why these work the way they do and like what the margin of error is and how we can minimize that margin of error, especially since it feels like it would be important. [Interview, mathematics major]

Theme 3: Preparatory Mathematics Courses

In general, students felt that it was most helpful to learn specific concepts first in mathematics courses and then to see them applied in physics. The sequencing of their mathematics and physics courses did not always allow this, however. Vector calculus in mathematics, followed by its use in electromagnetism, was cited as a successful example of this synergy. Those students who took complex variables in math prior to quantum mechanics were also pleased with the foundation they had gained. In contrast, students felt that their introductory linear algebra course did not provide enough background for quantum mechanics, and that their physics instructors were not always aware of this. Our basic linear algebra course typically gets to eigenvalues at the very end, and does not cover Hermitian operators or complex vector spaces. Also, eigenvalues in quantum mechanics are often not calculated by the standard characteristic polynomial method taught in linear algebra. Most students had not taken a second linear algebra course, which does cover spectral theory in more depth.

Many physics departments provide a "mathematical methods" course that can function as a bridge between mathematics and physics. Mathematical topics are covered in more depth than in other physics courses, but still with physical context provided for them. Along with more applied courses in the mathematics department, students did find these useful for connecting physics and mathematics. We view such courses as "trading zones," a term from anthropology that has been adapted to describe interdisciplinary settings where mathematicians and physicists, for example, might interact using a common language (Galison, 2010). Such courses have considerable potential to help students coordinate their mathematical knowledge with its physical applications.

Other Topics, Not Part of Major Themes

Infinitesimals

We anticipated that the common use of infinitesimal amounts of charge, displacement, or work in physics might conflict with students' prior experience in calculus, where limits are emphasized and infinitesimal or differential quantities may be considered meaningless on their own. Students did express some confusion about the ways in which differentials were *manipulated* in physics, which they included in their lists of "tricks," but were generally not bothered by their supposed infinitesimal nature. Some recognized infinitesimals as an alternative way of expressing the concept of limit, which could be translated into that language if required.

> I know that if I cancel them [infinitesimals] then I would be able to get an answer pretty easily, but there's a reason that I was stuck on this problem for an hour and it wasn't that I didn't see that I could cancel them, it was that I kept looking at it and saying, well why can I do that? [Interview, physics major]

Fourier Transforms

Many students cited Fourier transforms (or series) as a particularly challenging mathematical technique they encountered in physics. This seemed to be because they encountered them early, in a lower-division optics course, without prior exposure in any mathematics course. They felt that the technique was presented simply as a tool without a clear mathematical derivation. Also, although a Fourier transform has the form of an improper integral, it is rarely evaluated from the definition of improper integrals provided in calculus. Rather, "tricks" such as completing the square in the exponent are used. Some students were unfamiliar with complex numbers and confused by the switch from sines and cosines to complex exponentials. In quantum mechanics the Fourier transform converts between the position and momentum representations, but students did not always see how this interpretation was justified. Its use in quantum mechanics is also linked to the Dirac delta function, which has problematic aspects of its own for students. A mathematics major commented that since quantum mechanics violates our physical intuition, it makes sense that its mathematical tools (for example, the delta function) would also violate our mathematical intuition!

> I personally felt like there was a lot of like tricks that are used in the Fourier transform that are just kind of well-known and you just have to look up … I didn't know they were tricks, so I would like try to actually solve them. And it would take me so long, and I would like get together with friends, try to like, solve these problems … And then we just look it up, and then it's actually quite easy and it's just like a well-known fact, or whatever. [Interview, physics major]

Corinne's Shibboleth

We asked students this question in the "bare" form cited in the Introduction, without placing it in a physical context as did Dray and Manogue (2002), thinking that this might eliminate possible bias toward the "physics" response. However, we did add this follow-up question: could you imagine a physicist or mathematician giving a different answer than you did? We found that *every one* of our students gave the physics answer r^2 (or, in two cases, simply r – probably an algebraic error rather than a distinct interpretation), indicating that they interpret the variables meaningfully as rectangular and polar coordinates. Only one (a double major) answered the

follow-up by saying that the mathematics answer was possible, and that the physics answer is technically an abuse of notation. We are not surprised that undergraduate students would interpret the variables concretely as coordinates. However, even mathematics majors did not suggest the standard mathematical function syntax when prompted for an alternative answer.

Notation

The only specific example of conflicting notation (really a convention) between mathematics and physics classes that students cited was the reversal of the symbols θ and φ for the three-dimensional spherical coordinate angles between the mathematics and physics literature. They got used to it, however. Other conventions that were mentioned were the use of complex exponentials versus sines and cosines as well as the placement of factors of 2π in Fourier analysis.

Discussion

We found that our students are indeed aware of many cultural differences between physics and mathematics, and how these impact their learning. Sometimes they found it beneficial to have both a mathematical and a physical perspective on common topics, sometimes lack of coordination between courses in the two disciplines impeded their synthesis of these topics. Students' strategies for coping with these differences included consulting online resources, asking professors for clarification, and mentally separating their "physics understanding" from their "math understanding."

Our study is subject to several limitations. Although we contacted every student at our institution who was a double major in mathematics and physics, or majoring in one and minoring in the other, our sample was still small: 20 surveys and 11 interviews. The students we interviewed all had senior standing at the time, and therefore might have taken many of the same classes with the same instructors. Some of our findings may reflect characteristics of those instructors rather than the course content or culture as such. We are also on the quarter system and our curricula may differ from semester-based institutions. We did not observe systematic differences in the responses of our subpopulations of double majors, mathematics majors, and physics majors, but our small sample size would not support such claims in any case. It would be desirable to conduct a similar study at multiple institutions, with more students, allowing for some quantitative analysis of the results.

Recognizing the small sample size, we cautiously make some pedagogical suggestions. Greater awareness of the cultural differences identified here would be beneficial to both physics and mathematics instructors. Both should be familiar with what is taught in the other discipline and the relative sequencing of prerequisite courses. Students themselves suggested that physics instructors make supplementary mathematical resources available for topics that are taught rapidly, or not in depth, in class. Physics instructors might pay more explicit attention to motivating and justifying approximations and other "tricks".

Examining Ways in Which Students Engage With Sets of Outcomes in Combinatorics

Elise Lockwood

John Paul Cook
Oklahoma State University

Lockwood (2014) articulated the importance of sets of outcomes, suggesting that a "set-oriented perspective" is a productive way of thinking for students as they solve counting problems. While this construct has indeed proven useful, it remains quite broad. In this report we aim to provide more detailed insight into the variety of ways students engage with outcomes while counting, exploring ways that we might elicit robust set-oriented perspectives in students. We present data from student interviews that were designed to elicit engagement with sets of outcomes, and we report on a variety of ways in which students worked with outcomes as they solved problems. We highlight contrasting cases that emerged in these interviews, making the case that there is room for nuance (and differences) in students' engagement with sets of outcomes in counting.

Keywords: Sets of outcomes, Combinatorics, Discrete mathematics

In combinatorics education, researchers have drawn upon the notion of a set-oriented perspective, which is "a way of thinking about counting that involves attending to sets of outcomes as an intrinsic component of solving counting problems" (Lockwood, 2014, p. 31). This perspective has been used in a variety of combinatorial contexts, including combinatorial proof (e.g., Lockwood, Reed, & Erickson, 2021) and computing (e.g., Lockwood & De Chenne, 2020), and it has been highlighted as a potentially productive way of thinking that may help orient students toward successful counting (e.g., Lockwood & Gibson, 2016; Soto et al., 2022).

In such work, the set-oriented perspective itself has remained rather broad, a high-level construct that promotes a general approach toward attention to outcomes. However, studies have (even implicitly) revealed variety in students' use of outcomes. Students may largely attend to specific outcomes (e.g., Lockwood & Reed, 2020), students may create partial lists of outcomes, or they may partition entire outcome sets (e.g., Lockwood, 2014). Based on such observations, we were motivated to better understand and explore ways in which students might, in practice, engage with sets of outcomes. Doing so would help paint a more nuanced picture of students' engagements with outcome sets, and might eventually enable us to elaborate and clarify the construct of a set-oriented perspective. We are broadly trying to answer the following research question: *In what ways do undergraduate students engage with sets of outcomes as they solve counting problems?* More specifically, in this report, we address the question: *In what different ways do students leverage sets of outcomes to solve counting problems?*

Literature Review and Theoretical Perspectives

Sets of Outcomes and a Set-Oriented Perspective

We frame our work within Lockwood's (2013) model of combinatorial thinking. When solving counting problems, students variously attend to *formulas/expressions, counting processes,* and *sets of outcomes*. Formulas/expressions are numbers, operations, variables, or relationships that yield the cardinality of some outcome set. Counting processes are real or

imagined procedures for enumeration, and outcome sets are the elements being enumerated by a counting problem (Lockwood, 2013). In this paper we focus on the ways that students engage with the set of outcomes while solving various counting problems. Aligned with Lockwood's model is the notion of a set-oriented perspective. Harel (2008) described a *way of thinking* as a cognitive characteristic of a mental act; we take a set-oriented perspective (Lockwood, 2014) to be a way of thinking about the mental act of solving counting problems. This construct builds upon Lockwood's (2013) model, in which sets of outcomes are a central component. Lockwood and others have used this set-oriented perspective to frame students' combinatorial reasoning.

Prior work shows evidence of students reasoning about particular outcomes as they solve counting problems. Describing an equivalence way of thinking in combinatorics, Lockwood and Reed (2020) gave instances in which students compared and contrasted particular outcomes with the goal of determining whether two outcomes should be considered equivalent. When solving a problem about distributing identical lollipops to children, the students contrasted outcomes {1,2,3} and {3,2,1} (which children received a lollipop). They realized the two were equivalent, saying, "So you would be counting this [{1,2,3}] in a different combination, but really it wouldn't be an additional combination, because it's all the same, so this [{3,2,1}] is pretty much the exact same thing. It's just 123. […] because all the lollipops are the same" (p. 11). This is one way in which students may engage with outcomes and was integral to Lockwood and Reed's (2020) students' developing a set-oriented perspective.

In another example from Lockwood (2014), we see a contrasting way in which students reason about sets of outcomes. Here, a student was trying to count 8-letter passwords with at least 3 Es, reasoning that he could count all possible 8-letter passwords and subtract those with 0, 1, or 2 Es. We infer that the student partitioned a set of all possible passwords into subsets of desirable and undesirable passwords. In this common "total-minus-bad" approach, students engage with the set of outcomes by conceiving of the desired set in relation to some broader set, a different usage than the identification of particular outcomes in the previous example.

Other studies have made the case for the value of focusing on sets of outcomes and a set-oriented perspective (e.g., Erickson, 2022; Soto et al., 2022; Wasserman & Galarza, 2019). However, none of these studies specifically identified qualitative differences in how students reasoned about sets of outcomes. Our goal in this report is to detail some of the different ways in which students may engage with sets of outcomes when solving a variety of counting problems.

Local vs. Global Perspectives toward Sets of Outcomes

In framing our results, we also draw upon a distinction between local and global engagements with sets of outcomes (cf. Hamdan, 2006 and Cook et al., 2022). We characterize a local perspective as focusing on one or more particular outcomes, without necessarily taking into account the entire set of outcomes. It is local in that the focus is on particular elements rather than the broader structure. In contrast, we characterize a global perspective on a set of outcomes as a focus on the set as a whole, rather than emphasizing only specific elements.

In Lockwood and Reed (2020), the student's comparison of outcomes 123 and 321 as being equivalent suggests a local perspective on the set of outcomes; the students focused on two particular outcomes and drew a conclusion about what was being counted and which formula to use. In contrast, Lockwood's (2014) student's use of the total-minus-bad strategy suggests a global perspective on the set of outcomes, not appealing to particular elements of the set but rather to some overall structure of the entire set. This distinction between local and global

perspectives toward outcomes is one way to characterize students' engagement with the set of outcomes; it is one dimension across which we analyzed our data.

Engaging with Outcomes with Numerical vs. Structural Areas of Focus

We also highlight a distinction reflected in students' engagement with outcomes that relates to the focus of the outcome-related activity. In working with outcome sets, one may emphasize the cardinality of the sets, emphasizing or exploring the numerical properties, relationships, or patterns in those cardinalities. For example, Lockwood et al., (2015) reported students creating lists of outcomes among several small cases and noting numerical patterns among them. This suggests what we could call a *numerical focus* as they engaged with sets of outcomes. In contrast, students may focus not on cardinalities and numerical patterns, but rather on features or structural aspects of the set of outcomes. Students in De Chenne and Lockwood (2019) noted structure in lists of outcomes to determine the *nth* outcome in a given list. Here, a focus was on structural regularity in the set, and not on any numerical patterns. This distinction represents another dimension across which we analyzed our data.

Methods

The data we present is from a series of task-based clinical interviews (Hunting, 1997) conducted with 9 students (3 graduate and 6 undergraduate) at a large public university in the United States. We present results from interviews with Kyle and Erin (pseudonyms) – undergraduate students who had taken or were taking discrete mathematics at the time of the interview. These were part of a broader study exploring student uses of equivalence in counting.

The students solved various counting problems on an iPad and described their work, and both the students and the screen were videorecorded. During and after their problem-solving activity, the interviewer asked hypothesis-confirming questions to enable post-interview inference into the students' understandings of formulas, concepts, and strategies. If the students were unsure of a solution, or were unable to proceed after some initial work on the problem, the interviewer often encouraged them to try smaller examples of the same problem. To provide opportunities for students to engage with sets of outcomes, the interviewer would at times suggest exploration of a pre-generated outcome set (of a smaller case). For instance, the interviewer might have provided a pre-generated set of arrangements of 1, 2, 3, and 4, and the student could use the GoodNotes app on an iPad to select and drag any outcome to a different location on the screen, creating their own organizations of the provided outcome set.

Data Analysis

To identify ways in which students engaged with sets of outcomes, the second author reviewed all of the interviews and flagged episodes in which students specifically leveraged outcomes or outcome sets in their problem-solving process. (An example of students *not* leveraging outcome sets would be a student identifying the wording of a problem with a particular solution type, making statements like "This is a combination problem.") This researcher articulated broad themes and categories for the flagged engagements, drawing upon the local/global and numerical/structural distinctions. The first author then also reviewed all of these episodes that featured sets of outcomes. Together, via discussion, the first and second authors chose representative episodes to highlight illustrative distinctions among students' engagement with sets of outcomes.

For this paper, because of space constraints, we limit ourselves to presenting just a handful of episodes to highlight ways in which students engaged with outcomes. Also, especially given the

fact that students were at times encouraged to work with whole sets of outcomes, we are not making claims about their spontaneous use of outcome sets, nor are we reporting on frequencies in a meaningful way to suggest that some are much more common than others. Rather, we seek to make the point that, even within this interview context where they were at times encouraged to engage with outcomes, students' means of leveraging outcome sets were far from monolithic. This all highlights the point that there are multiple ways in which students may engage with sets of outcomes, and allows us to progress towards elaborating nuance about what might be entailed in the way of thinking that underlies a set-oriented perspective.

Results

In this section, we provide some key distinctions in students' engagement with sets of outcomes. Because of space limitations, the goal here is to provide contrasting, detailed examples of students engaging with sets of outcomes.

Distinction 1: Local vs. global engagement with outcomes in a single student

We begin by contrasting two cases with Kyle, focusing on his work on two problems.

Kyle's work on the Groups of Students problem. First, we see Kyle's work on the Groups of Students problem: *How many ways are there to split a class of 20 into four groups of 5?* Kyle initially considered a process of successively selecting five students, reflected in the expression C(20,5)*C(15,5)*C(10,5)*C(5,5). But he noted that this process would yield redundancies, saying "That feels like just kind of the obvious way to go about it, but I feel like doing it this way is where I'm going to miss out on the redundancies." He went on to specify, "If we chose the first five, and then the second five, third five, and the fourth five. Yeah, and but then, just reversing the order where it's fourth five, third five, second five and first five, then that's redundant in that sense where it's not unique for groups of five, but it would be included in this [expression]." We interpret here that Kyle articulates one specific outcome generated by the process of successively choosing students, namely, one which partitions the students into 1-5, 6-10, 11-15, and 16-20. But he realized that the process would yield the same partition in different orders.

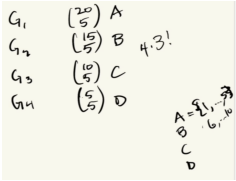

Figure 1. Kyle's work on the Groups of Students problem, in which he specifies a particular outcome

He continued working and specified the outcomes, assigning labels to the groups of A, B, C, D, as shown in Figure 1. He said, "Like if I said, uh, I would say A, B, C, D, then that's like, uh, one through five and then totally same for six and so on, so forth." Ultimately, Kyle realized he could arrange the groups of that partition in 4! ways and so the final solution would be C(20,5)*C(15,5)*C(10,5)*C(5,5)/4! (we omit details due to space). We claim Kyle's work here represents a local engagement with sets of outcomes. We infer this since he articulated specific outcomes - at no point attending to some broader organization of the entire set of groupings. Even more, he first explicitly articulated groups as a particular outcome – namely, splitting into four groups of 1-5, 6-10, 11-15, and 16-20, as groups A, B, C, D. So, he mediated attention to potential redundancies in the counting process by locally attending to specific outcomes and whether different arrangements were distinct.

Moreover, Kyle leveraged this local engagement to then generate the cardinality of the duplication, noting what counting processes might lead to similar arrangements of the outcomes. Notably, he did not just engage in numerical pattern matching, but considered what 3! and ultimately 4*3! might mean in terms of arranging specified groups of his specific outcome. With this local perspective, Kyle focused on forming and organizing iterations of a particular outcome, which he extended to the rest of the outcomes without explicit reference to a global structure.

Kyle's work on the Decreasing Numbers problem. In a contrasting example, Kyle was solving the Decreasing Numbers problem: *How many ways are there to form decreasing sequences of 3 numbers from the numbers 0-9?.* He did some initial work establishing cases based on the leading digit, but was overwhelmed by the number of cases. The interviewer then gave Kyle a set of outcomes to work with (as noted, this was an intentional intervention) – he was provided a written set of arrangements of the numbers 1-4 (Figure 2a), and encouraged to try and solve a smaller version of the problem: *How many ways are there to form decreasing sequences of 3 numbers from the numbers 1-4?* Kyle began by partitioning the set into four (ignoring the first digit), and highlighting the desirable decreasing 3-digit numbers, as seen in Figure 2b. This process led him to arrive at an answer of 4!/6, which yields the four desirable outcomes that he highlighted. In observing the set of outcomes, he noted, "Within each one of those permutations, only one of them is a decreasing sequence."

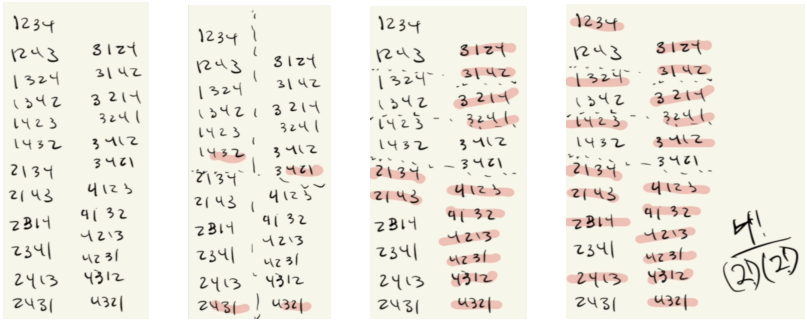

Figure 2a-d. Kyle's manipulation of sets of outcomes that were provided for him

Kyle expressed a desire to consider what might happen in other cases, so the interviewer prompted him to stay in the smaller 1-4 case but now consider decreasing sequences of two numbers. With a fresh list of outcomes, he again began to work with the set of outcomes. In Figure 2c, he partitioned the set according to the first two starting numbers, and he realized that he could exclude some outcomes. Here, he decided to highlight outcomes that were excluded, "this time I'm going to highlight the ones that I'm excluding." In Figure 2c, he first excluded outcomes that had the same two starting digits in different orders (so, for example he kept 1234 and 1243, and he excluded 2134 and 2143). Then, in Figure 2d we see within the remaining pairs that started with the same two digits, he excluded those whose last two digits were not in decreasing order (he excluded 1234 and kept 1243, for example). He related this process to his expression of 4!/(2!2!); the first division by 2! was for the arrangements of the first two digits, and the second division by 2! was for the second two digits. Kyle arrived at a correct expression having partitioned the set of outcomes and made note of equivalent outcomes in the set.

We feel that this episode shows a different approach to outcomes for Kyle, where he immediately started to partition the set into outcomes in which he was interested. Notably, though, he considered the desirable outcomes as they related to the entire set, and he then used equivalence and division to figure out a more general formula. We highlight this episode to show

the same student reasoning about sets of outcomes in a qualitatively different way. Here, Kyle was adopting a global perspective – he started with the whole set and partitioned it, connecting the operation of division to his partitioning activity. We maintain that his treatment of the entire set of outcomes is different from his approach on the Groups of Students problem, where he built up the set of outcomes and considered particular elements.

Distinction 2: Different Global Perspectives Among Students

It may be natural to think that, if students had access to an entire list of outcomes, they would use them in similar ways. However, in our data, we found that even though we gave students entire sets of outcomes, they did not always use them in the same way. In contrast to Kyle's previous example, we look briefly at Kyle's work on the Towers problem and then Erin's work on the Passwords problem. In addition to noting the problem-by-problem variety of ways that students engaged with outcome sets, we also make the point that there was variety even in the context of the same intervention. Said differently, students did not use entire sets of outcomes for the same purposes.

Kyle's work on the Towers problem. The Towers problem states: *Silas is making "towers" from 3 green, 4 red, 2 yellow, and 8 orange blocks. Using all 17 blocks, how many different "towers" could Silas make?* Kyle became stuck initially, and the interviewer suggested he try a smaller case with 2 green and 2 red blocks. Kyle was provided the same list of arrangements of 1-4 as in Figure 2, but 1 and 2 were labeled red and 3 and 4 were labeled green. Seen in Figure 3a, Kyle first used the provided outcome set to pick out the 6 desired outcomes in the subcase, and then proceeded to hypothesize a formula/expression to generate the 6 outcomes (Figure 3b).

Figure 3a-c. Kyle's use of outcomes in the Towers Problem

In contrast to his work on the decreasing sequences problem, here the provided set of outcomes was used as a source from which the desired outcome set was generated. Then, the desired outcome set was used for its cardinality, and the first outcome "RRGG" was used as a representative from which Kyle conjectured a counting process (and the paired 2*C(3,1) expression) to generate the representative outcome. In this episode, we see Kyle using the outcome set to generate a known cardinality (6) from which counting processes and formulas/expressions could be hypothesized.

Erin's work on the Passwords problem. Similar to Kyle's work on the Towers problem, Erin engaged in numerically-motivated uses of the outcome set for the Passwords problem: *A password consists of four upper-case letters. How many such 4-letter passwords contain at least one E?* Erin initially approached this problem by first selecting a position for the E to go (C(4,1)) and then filling in any remaining position with 26 letters; thus her answer was C(4,1)*26^3. This overcounts, as passwords with more than one E are counted multiple times by this approach.

The interviewer again suggested a smaller case: *How many 3-letter passwords of A, B, C contain at least one A?* The interviewer provided an entire set of outcomes for this smaller case

(Figure 3a). Erin used this list as a means to count a total of 19 outcomes, and then spent an extended period of time attempting to find known counting formulas that calculated to 19, noting that 19 being prime provided a difficulty for her. After some time, the interviewer drew her attention to the case of AAA being generated three times in her original solution, and she solved the problem by generating the cardinality of each sub-case (passwords with just 1, 2, or 3 As), connecting the subsets of outcomes and the expressions that generated those subsets. She was encouraged that her listing activity and expression resulted in a count of 19.

Figure 3a-b. The set of outcomes provided to Erin, and her work on the problem

In this final case, Erin used sets of outcomes in multiple ways. First, she used the provided set of outcomes only for its cardinality, before attending to formulas/expressions exclusively. We note this not to criticize Erin's work, but to emphasize that simply giving students outcome sets is not sufficient for them to partition the set, manipulate it, seek some structural regularity, or even focus on particular elements within that set. Ultimately, Erin then produced her own full list of outcomes that reflected her imagined counting processes for the subcases. We see this as Erin taking personal ownership of the outcomes as relevant to her process of construction.

Discussion, Conclusion, and Avenues for Future Research

We have provided contrasting cases that illustrate different ways in which students engage with outcome sets. This highlights distinct approaches to outcome engagement that ultimately suggest a diversity of experiences students might have when developing a set-oriented perspective. We now discuss some potential implications of our findings.

One point of discussion is that much of the research has made a case for the importance of having students engage with sets of outcomes, but we have shown evidence that more nuance and distinction is needed to elaborate more specific ways in which students engage with outcomes and with sets of outcomes. We have shown some potential axes of distinction in engagement with outcomes, but more work is needed to operationalize distinctions between engagement types, particularly in pursuit of ways to elicit a set-oriented perspective.

We have also shown that simply providing students with opportunities to manipulate outcome sets is not sufficient to engender certain kinds of engagement with outcomes - having them partition, identify structural regularity, or even focus on certain outcomes did not always necessarily occur even when students were provided with organized lists of outcomes. More work can explore what kinds of supporting directions or activities might be effective in helping students to engage in productive outcome-related activities. Additionally, in providing outcome sets, we note that there are some limits to how many outcomes can be presented to students; this emphasizes the importance of leveraging smaller cases.

Further, we have in this paper mostly shown students' engagement with outcomes in just a few problems. There is more to be explored about how engagement with outcomes more broadly develops into a stable way of thinking and thus a set-oriented perspective (Lockwood, 2014).

Acknowledgments

The study reported here was part of a project funded by the National Science foundation – DUE #2055590.

Pedagogical Moves Related to Analogy that Support a Unified Understanding of Eigenequations in a Quantum Mechanics Class

Kaitlyn Stephens Serbin
University of Texas Rio Grande Valley

Megan Wawro
Virginia Tech

We analyze the pedagogical moves related to analogies used by a quantum mechanics instructor to support a class community in developing a shared unified understanding of eigenequations across the contexts of linear algebra, spin, energy, and position. We characterize an instructor's pedagogical moves as he engaged students in analogical reasoning. Some moves include posing tasks conducive to analogizing; preparing, soliciting, and scaffolding students' participation in analogical reasoning; using deictic gestures and inscriptions; juxtaposing symbols representing the analogized concepts; and explicitly highlighting the sameness of the analogized concepts. We exemplify these pedagogical moves with analytical descriptions of illustrative class episodes. We discuss how these moves can support the class community's expansion of their common ground by fostering the development of the class's shared unified understandings of eigenequations.

Keywords: Pedagogical Moves, Analogy, Eigentheory, Linear Algebra, Physics

Quantum mechanics students reason about eigentheory in various contexts, including spin, energy, and position, with eigenequations forms such as $\hat{x}|x_i\rangle = x_i|x_i\rangle$, $\hat{S}_z|+\rangle = \hbar/2\,|+\rangle$ and $\widehat{H}|E_n\rangle = E_n|E_n\rangle$. It is nontrivial to abstract the shared structure of these eigenequations and recognize them as instantiations of the same concept with analogous interpretations. Reasoning about a concept across contexts entails having a *unified understanding* of the concept: a coherent awareness of similar structure, a recognition of distinct instantiations as examples of the concept, and an ability to reason about the concept without reference to specific contexts (Lee & Heid, 2018; Serbin, 2023). Researchers have characterized students' unified understandings in various math contexts (e.g., Bagley et al., 2015; Cook et al., 2023; Melhuish et al., 2020), but there is little research on how instructors can help students develop unified understandings in physics. Recognizing eigenequations from varied contexts as instantiations of the same concept can be facilitated by analogizing (Gentner, 1983; Glynn, 1989; Richland et al., 2004). By analogizing across spin, energy, and position, physics students can generalize the structure of eigenequations that correspond with the mathematization of those quantum mechanical systems. In this study, we investigate how an instructor's analogizing might contribute to the class's taken-as-shared (Saxe & Farid, 2021) unified understanding of eigenequations. Our research question is: What pedagogical moves related to analogies can be used by a quantum mechanics course instructor to support the class community in developing a shared unified understanding of eigenequations?

Literature Review

Reasoning about eigenequations and their objects (operator, eigenvectors, eigenvalue, equal sign) and operations (matrix-vector multiplication and scalar-vector multiplication), individually or in coordination, is conceptually complex (Thomas & Stewart, 2011; Wawro et al., 2019). For instance, Wawro et al. (2024) found that for $Ax = \lambda x$, quantum mechanics students held either a *relational view* of the equal sign (the resulting object Ax on one side of the equal sign is the same as the resulting object λx on the other side) or a *functional view* of the equal sign (the matrix A acted on or transformed an input x and produced λx). Physics students must make sense of these coordinated constituent objects in varied quantum mechanical systems (Karakok, 2019; Wawro

et al., 2024) and interpret eigenequations in terms of their physical referents (e.g., Gire & Manogue, 2012; Her & Loverude, 2020). This may involve recognizing eigenequations like $\hat{S}_z|+\rangle = \hbar/2|+\rangle$, $\widehat{H}|E_n\rangle = E_n|E_n\rangle$, and $\hat{x}|x_i\rangle = x_i|x_i\rangle$ as all sharing a structure or interpreting the symbols associated with that structure as meaning "transformation that reproduces the original" (Dreyfus et al., 2017, p. 10) or "to operate is to act" (Pina et al., 2024, p. 7). Physics students sometimes perceive conceptual incompatibility between the meanings they hold for eigenequations in different contexts. For example, interpreting an eigenvector as being stretched by λ is nonsensible in a spin context where eigenstates are of unit length (Wawro et al., 2024).

There is little research on how instructors can support students in cross-contextual reasoning about eigenequations. Karakok (2019) demonstrated a physics professor's focus on supporting students' understanding of objects within an eigenequation by frequently asking students, "What kind of a beast is this?" (p. 9) while pointing to symbols in $A\vec{v} = \lambda\vec{v}$. The professor's explicit focus on symbols seemed to foster students' understandings of them. Attending to meanings of symbols in eigenequations may support students in developing unified understandings of them.

Theoretical Perspectives

Having a *unified understanding* of a concept involves recognizing seemingly disparate notions from different contexts as instantiations of the same concept with a shared overarching structure (Lee & Heid, 2018; Zandieh et al., 2017). Researchers have characterized students' unified understandings of mathematical concepts across contexts in linear algebra and abstract algebra, such as functions, linear transformations, homomorphisms, inverses, identities, and factorization (Bagley et al., 2015; Cook et al., 2023; Lee & Heid, 2018; Melhuish et al., 2020; Serbin, 2021, 2023; Zandieh et al., 2017). These studies documented how students reason about the relationships, similarities, or shared properties among instantiations of a concept (e.g., additive or multiplicative inverses) and recognize them as the same concept with the same overarching structure that holds regardless of context. Such reasoning can develop as students "unify their existing understandings of seemingly unrelated mathematical concepts by identifying structural similarities among the concepts, thereby increasing the extent to which the relations among the concepts in their minds become more coherent" (Serbin, 2023, p. 4).

Developing unified understandings of a concept may involve *analogical reasoning*, "the ability to perceive and operate on the basis of corresponding structural similarity in objects whose surface features are not necessarily similar" (Richland et al., 2004, p. 37-38). Gentner (1983) characterized analogy as a mapping from a source domain to a target domain that preserves relations between objects and attributes in them. A *source domain* is a collection of knowledge that can be applied in a new domain, the *target*, to develop new knowledge. *Objects* are whole entities, parts of entities, or a collection of entities. *Attributes* are characteristics or properties of objects, and r*elations* are associations between objects, attributes, or other relations. When analogizing, one maps objects, attributes, and relations from the source by corresponding them with objects, attributes, and relations in the target and drawing inferences about them (Holyoak & Thagard, 1989; Novick & Holyoak, 1991; Richland et al., 2004). Hicks (2020) classified analogical reasoning activities as: exporting aspects from the source, importing aspects to the target, recalling knowledge about the source, distinguishing differences between the source and target domains, and adapting the target to accommodate for those differences. Glynn's (1989) teaching with analogies model has six instructional strategies: "(1) introduce target concept, (2) recall analog [source] concept, (3) identify similar features of concepts, (4) map similar features, (5) draw conclusions about concepts, and (6) indicate where analogy breaks down" (p. 208). Instructors can use these strategies as they engage students in analogizing.

Finally, *common ground* (Clark, 1996; Saxe et al., 2015) includes the, at best, taken-as-shared "knowledge of word meanings and norms for communication, shared knowledge that enables successful communication and coordinated action" (Saxe & Farid, 2021, p. 640). Common ground "gets built up in strata" (Clark, 1996, p. 120), where "every new piece of common ground is built on an old piece" (p. 119). It is constituted over time via communicative displays by class members, thereby expanding the class's taken-as-shared understandings.

We coordinate the theories of unified understandings, analogical reasoning, and common ground to characterize how a professor's pedagogical moves facilitate a class in developing a taken-as-shared unified understanding of eigenequations. Analogizing instantiations of a concept is a way for instructors to help expand the class's common ground and develop a taken-as-shared unified understanding of that concept. We consider an analogy's source domain to be a subset of a class community's common ground. An instructor can make analogies by mapping objects, attributes, and relations from that source to a target. In mapping these objects, attributes, and relations to the target, new objects, attributes, and/or relations are created and can become part of the common ground. The common ground thus expands, and the target becomes part of a new source from which further analogical mappings can be made. This common ground expansion by analogizing contributes to the class's development of a taken-as-shared unified understanding.

Methods

Data for this study come from transcribed videos of whole-class discussions and lectures in a senior-level quantum mechanics course at a public university in the northeastern US. The class met for 50 minutes and used a spins-first textbook (McIntyre, 2012). We analyzed 22 class days. We found segments in which the instructor analogized eigenequations and enacted pedagogical moves that could support the class in developing their understanding of eigenequations. We took such instances in the data as indicative of the class community expanding its common ground for eigenequations, such as by recognizing different forms as instantiations of the same overarching concept while attending to any shared property, use, or aspect of structure. We analyzed the episodes in terms of Gentner's (1983) structure-mapping theory for analogies. We identified the given analogy's source domain, target domain, and what objects, attributes, relations, or higher-order relations were being mapped between to the two domains. Such analyses helped us answer our research question by indicating the class community's progress toward developing a taken-as-shared unified understanding of eigenequations, which is part of the class's common ground.

We used deductive and inductive coding (Miles et al., 2013) to identify pedagogical moves in the segments. *Pedagogical moves* are "discursive acts an instructor performs during instruction to accomplish an instructional goal" (Serbin et al., under review). We focused our analysis on instances when the instructor gave vocal, written, or gestural communicative displays in which he described at least two different concepts with similar features. We made an a priori codebook containing pedagogical moves for supporting analogical activity from Hicks (2020) and Glynn (1989), from which we deductively coded. We then, through inductive coding, created new codes to describe other pedagogical moves in the data. These new pedagogical moves are given in Table 1 and are exemplified in the Results. We wrote memos (Maxwell, 2013) on how those moves seemed to support the class's development of a unified understanding of eigenequations.

Results

We summarize two class episodes from Day 5 and Day 19 that illustrate Dr. Holmes's pedagogical moves that occurred while the class engaged in analogizing eigentheory concepts.

Table 1. New Pedagogical Moves for supporting Analogical Activity

Pedagogical Move	*Description*
(1) Posing a task conducive to analogizing	Assigns a task or problem that prompts students to engage in analogizing two or more concepts.
(2) Preparing students to look for similar objects, attributes, or relations in source and target	Primes the students to identify features shared by two concepts, perhaps by suggesting there is a similarity that the students should find.
(3) Scaffolding students in identifying and mapping objects, attributes, and relations	Provides support to students as they analogize two concepts, e.g., asking guiding questions that direct students' attention to the shared features of the concepts.
(4) Juxtaposing symbols representing objects in the source and target	Writes symbols that represent concepts being analogized in a way that the symbols are aligned or near each other.
(5) Using deictic gestures	Uses their body to make gestures (McNeill, 1992) that emphasize corresponding aspects in the source & target.
(6) Using deictic inscriptions	Writes an inscription that points to or emphasizes corresponding aspects in the source and target domains.
(7) Soliciting student participation to map objects, attributes, and relations from the source to the target	Invites students to verbally contribute their ideas in the class discussion as they engage in analogizing aspects in the source and target domains.
(8) Explicitly highlighting sameness of aspects in the source and target	Verbally claims that two aspects in the source and target domains are equivalent or the same.

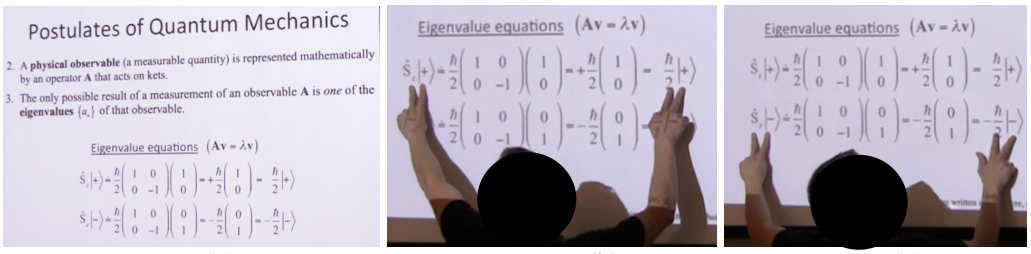
Analogizing the Eigenequation $Av = \lambda v$ with the Spin Eigenequations $\hat{S}_z|\pm\rangle = \pm\frac{\hbar}{2}|\pm\rangle$

On Day 5, the instructor, Dr. Holmes (pseudonym), used several pedagogical moves to guide the class in analogizing the canonical eigenequation $Av = \lambda v$ and the spin eigenequations:

Dr. Holmes: When you have a matrix [points to A, see Figure 1a], you have eigenvectors [points to v on the right side], right. Do people remember what what's special about an eigenvector, for a matrix, for a given matrix? What makes it eigen-esque-ish?

Student: When it's operated on by A, it only scales.

Dr. Holmes: That's right… eigenvectors don't rotate at all, they only scale. If you operate A on this particular eigenvector [points to Av], all you get is some scaling factor times the original vector [points to λv], alright. That's the magic. Those are magic vectors.



Dr. Holmes *recalled aspects of the source domain*, which included the canonical eigenequation and its operator, eigenvectors, and eigenvalue. He *solicited student participation* to *recall* these objects, relations among them (the matrix-vector relationships), and their attributes ("it only scales," "magic vectors"). He called out the ubiquity of $Av = \lambda v$, claiming, "we can write these for our operators," *explicitly highlighting the sameness* of the eigenequations' existence for operators in the source and target domains. He *introduced the target domain*, which included the spin eigenequations and their components. These pedagogical moves of *recalling, soliciting, highlighting*, and *introducing* prepare the class community to expand its common ground by setting the stage to introduce eigenequations for the first quantum mechanical context of spin.

Dr. Holmes: This equation [points to $Av = \lambda v$] is sort of canonical, right. People write these all the time for linear algebra, for matrix-vector relationships. And we can write these for our operators. I have the $S\ z$ operator … we're gonna have the value, we're gonna have the matrix, and we're gonna have the operators … You operate the $S\ z$ [points to $\hat{S}_z$ then $|+\rangle$] on the up spin state. Right, we have this matrix [points to

matrix]…and you operate it on the 1, 0 state [points to $\binom{1}{0}$]… if you do that, you get h bar over 2 times the vector you started with. So this is the eigenvalue part [points to two ends of equation (Figure 1b)]. Same thing for this, you get a negative h bar over 2 on the bottom [points to two ends of equation (Figure 1c)] for the down state.

He *identified* and *mapped (exported and imported)* similar objects (e.g., value, matrix), relations, and attributes from the source to the target domain. He *mapped the relation* between the operator and the eigenvector by claiming, "You operate the $\hat{S}_z$ on the up spin state," which was parallel to what he said about the canonical eigenequation: "You operate A on this particular eigenvector." He also *mapped a relation* by saying, "you get h bar over two times the vector you started with" which was similar to his claim: "All you get is some scaling factor times the original vector."

Dr. Holmes also used the moves of *gesturing* and *juxtaposing symbols* while analogizing. On the slide, he *juxtaposed the placement of the symbols representing objects in the source and target*. He vertically aligned the two spin eigenequations underneath the canonical eigenequation (see Figure 1a), which had the potential to support the class in recognizing the shared structure of the different eigenequations as matrix-eigenvector product on the left and eigenvalue-eigenvector product on the right. Dr. Holmes accompanied this with *using deictic gestures.* He used two fingers on each hand to simultaneously point to each of the two objects ($\hat{S}_z$ and $|+\rangle$) on the left and the two objects ($\hbar/2$ and $|+\rangle$) on the right (see Figure 1b). He then lowered his hands to point to the corresponding objects in the other spin eigenequation (see Figure 1c). These deictic gestures helped *map the relations* between the objects in one eigenequation to the other, so the class could see that those relations were preserved. We posit these moves of using juxtaposition and deictic gestures could serve to expand the class's common ground, thus contributing to the class's development of a unified understanding of eigenequations. The class had an opportunity to recognize different eigenequations as instantiations of the same concept with the shared structure regarding the objects within the eigenequations and the relations among those objects.

(a) (b) (c)

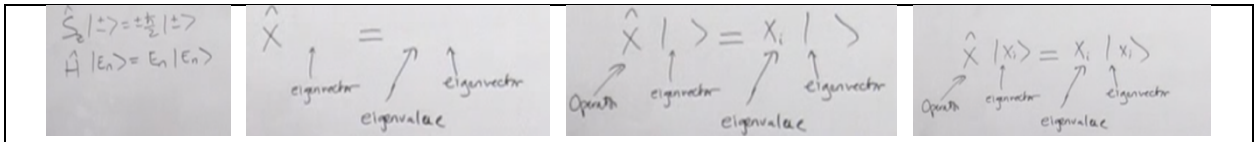


Figure 1. (a) Slide projected during class on day 5. (b, c) Dr. Holmes's deictic gestures juxtaposing eigenequations

Analogizing the spin and energy eigenequations with the position eigenequation

On Day 19, Dr. Holmes used various pedagogical moves to help the class analogize the source spin and energy eigenequations $\hat{S}_z|\pm\rangle = \pm\frac{\hbar}{2}|\pm\rangle$ and $\hat{H}|E_n\rangle = E_n|E_n\rangle$ with the target position eigenequation $\hat{x}|x_i\rangle = x_i|x_i\rangle$. He first *posed a task conducive to analogizing*: "Write down an eigenvalue equation for an operator $\hat{x}$ that represents (1-D) position." He launched the task by explaining: "We've measured all these other things… spins…and energies, right? But let's say we want to measure the position of a particle… If it's a thing we're measuring, then it has all the properties of the other things we're measuring." He *recalled the source domain* and *prepared students to look for similar attributes* of objects in the source and target domain. After students worked on the task, Dr. Holmes wrote $\hat{S}_z|\pm\rangle = \pm\frac{\hbar}{2}|\pm\rangle$ and $\hat{H}|E_n\rangle = E_n|E_n\rangle$ (Figure 2a)

and continued: "I want an equation like this...We're talking about positions, by saying operator $\hat{x}$...If I want to write an eigenvalue equation where that's my operator, what is it going to tell me? What do these eigenvalue equations tell me, in general?" Dr. Holmes *identified and mapped (exported and imported) similar features of the concepts*, mapping "what these eigenvalue equations tell me" from the source to the target. He also *provided scaffolding for identifying and mapping objects and attributes* in the source for students to map to the target. They continued:

> *Dr. Holmes:* If I operate on an eigenvector [points to $|E_n\rangle$ next to $\widehat{H}$] with that operator, what is this [points to E_n in $\widehat{H}|E_n\rangle = E_n|E_n\rangle$] then? [*Student:* A scalar]. What do I need here? [draws an arrow to the right of $\hat{x}$, writes "eigenvector"]. I need an eigenvector, and I need that same eigenvector here [writes "=", leaves a space, draws arrow to a third space, writes "eigenvector"]. What do I need there? [points to space after "="] (see Figure 2b).
>
> *Students:* A scalar. The position.
>
> *Dr. Holmes:* The position. But yeah, that's the eigenvalue. [writes x_i after "="] (Figure 2c).

(a) (b) (c) (d)

Figure 2. Dr. Holmes's symbol forms written on the board during the Day 19 episode.

Dr. Holmes first *mapped the operator and eigenvector $\widehat{H}|E_n\rangle$ objects* from the left side of the source eigenequation to the objects $\hat{x}__$ in the target, with the space labeled as "eigenvector." In doing so, he *juxtaposed the operator and eigenvector symbols in the source and target*. This was supported by his *use of deictic gestures and inscriptions* (arrows) to highlight the correspondence between operator, eigenvector, and eigenvalue objects in the source and target eigenequations. He again *used deictic gestures and inscriptions,* saying "I need an eigenvector, and I need that same eigenvector here" and drawing arrows. This *mapped the relation* between the eigenvectors in the source eigenequations to the relation between those in the target eigenequation. By asking "what do I need to go there?" he directed the class's attention to the eigenvalue in the source and to its position in the target. He affirmed the student responses. He *solicited student participation to map objects* and *juxtaposed eigenvalue symbols in the source and target* eigenequations.

Dr. Holmes continued, "Now we're going to be in space space, as opposed to energy space or spin space, so you really have to keep these things straight in your head." This *distinguished the attributes of objects in the source domain and target domain.* Dr. Holmes continued by next focusing on how to symbolize the eigenvectors in the position eigenequation they were creating:

> *Dr. Holmes:* What should I use as how to represent an eigenvector of position? Like given some of the conventions we have for writing stuff [points to Figure 2a], what would be- [points to space for left eigenvector in target eigenequation]?

Students: x_i. x ket.

> *Dr. Holmes:* Yeah, well first, it better look like that, right [writes kets $\hat{x}|\ \rangle = x_i|\ \rangle$, Figure 2c], and what do I want to put in here? [*Student:* x_i] x_i right? [writes $|x_i\rangle$, Figure 2d]. That's fine. Because what the convention was, this is the eigenvalue for the eigenvector, right?

In asking students how to write a position eigenvector given conventions they had for writing spin and energy eigenequations, Dr. Holmes *used deictic gestures* to direct the class's attention to the source eigenequations, *recalled the source attributes* of how eigenvectors are written, and *prepared students to identify similar attributes of eigenvectors in the source and target*. He also

solicited student participation to map the attributes of eigenvectors from the source to the target. Considering the student responses, Dr. Holmes *exported source attributes* and *imported them to the target* that eigenvectors are symbolized as kets and labeled by corresponding eigenvalues. This *mapped the relation between eigenvectors and eigenvalues from the source to the target*. Dr. Holmes used a variety of pedagogical moves to engage the class in analogical reasoning as they created an eigenequation in their new position context, which we posit contributed to the class developing a unified understanding of eigenequations as they came to recognize them from three quantum mechanical systems as instantiations of the same overarching concept. Dr. Holmes used gestures and arrows to juxtapose $\hat{S}_z|\pm\rangle = \pm\hbar/2\,|\pm\rangle$ and $\hat{H}|E_n\rangle = E_n|E_n\rangle$ from the source with $\hat{x}|x_i\rangle = x_i|x_i\rangle$ in the target. Together the class mapped objects (operator, eigenvectors, and eigenvalue) with their attributes and relations among the objects from the source contexts of spin and energy to the target context of position. His moves fostered the class's awareness of the shared properties among three distinct eigenequations, which expanded the common ground and contributed to the class's development of a unified understanding of eigenequations.

Conclusion

Engaging students in analogical reasoning can foster their unified understandings of a concept. Thus, we investigated the pedagogical moves a quantum mechanics instructor used to engage students in analogical reasoning. We identified eight pedagogical moves (Table 1) and described their potential to foster a class's development of unified understandings by expanding its common ground. Our characterization of pedagogical moves is the primary contribution of our study. The moves that stand out as most salient overall in our data set include juxtaposing the symbols that represent objects in the source and target domain, using deictic gestures, and using deictic inscriptions. These moves fostered the class's awareness of the shared structure among eigenequations in three different contexts and contributed to the class's development of a unified understanding of eigenequations. Given their productivity, we encourage instructors to use these pedagogical moves to analogize concepts and guide students to develop unified understandings.

Another contribution of this study is its connection of the theoretical constructs of analogical reasoning (Gentner, 1989), unified understandings (Lee & Heid, 2018; Zandieh et al., 2017), and common ground (Saxe et al., 2015). Studies have focused on individuals' unified understandings of mathematical concepts (e.g., Bagley et al., 2015; Cook et al., 2023; Melhuish et al., 2020; Serbin, 2023) but not yet on a class community's unified understanding. We posit that a class community can develop a unified understanding of a concept and thus expand its common ground by analogizing different instantiations of the concept. The class maps objects representing that concept, its attributes, and relations among that concept and others from the source to the target domain. Then, the target becomes part of the common ground, and the class comes to recognize those different examples as instantiations of the same overarching concept. When students engage in analogical reasoning, they can make connections between concepts, which is conducive to developing unified understandings of mathematical and physical concepts.

Lastly, we acknowledge some limitations to our methodology that could impact the interpretation of our findings. We cannot explicitly link the instructor's pedagogical moves with development of each student's unified understandings. Thus, we can only claim that his pedagogical moves related to analogizing were potentially conducive to guiding the class's shared unified understandings. It is outside the scope of this study to analyze individual students' unified understandings of eigenequations, so we suggest this as a direction for future research.

Prospective teachers need hands-on experience in the field before they can independently manage their own classrooms. Although experiential learning is widely acknowledged for its benefits, its implementation in content-focused mathematics courses for prospective K-12 teachers remains limited. To address this gap, mathematics content courses for future teachers should offer experiences that extend beyond traditional classroom settings. One effective approach to achieving this is through incorporating service learning experiences. This paper explores the integration of service learning into three distinct mathematics courses for prospective K-12 teachers, including two upper division mathematics courses, highlighting how this approach was implemented in each course. Results suggest service learning in upper-division mathematics courses benefits prospective teachers by fostering experiential learning, enhancing collaboration, communication, and career skills, as well as deepening engagement with course content and the community.

Keywords: prospective K-12 teachers, service learning, geometry, capstone courses

Introduction

Prospective teachers (PTs) must gain experience in the field before taking charge of their own classrooms (Jackson et al., 2018). Service learning (SL) has been incorporated into teacher education programs around the globe as a teaching strategy to allow PTs to connect theory, practice, and community (Bates & Lin, 2015; Jackson et al., 2018). SL is "a pedagogical and learning strategy used in schools and communities around the world and has produced positive social, emotional, and cognitive growth among students" (Clark, 2017, p. 2). Further, it integrates community service and academic learning, allowing students to contribute to the needs of the community while applying content learned in the classroom (Carrington & Saggers, 2008; Mortari, Silva, & Ubbiali, 2019; Verducci & Pope, 2001). SL methodologies strive to inspire students, offer valuable services to others, establish links between universities or schools and their communities, and offer genuine incentives for introspection (Jackson et al., 2018; Lee & Statham, 2010). Many studies found that participating in SL components of a course enhanced students' understanding of necessary skills and their ability to perform tasks and skills aligned with course learning outcomes (Anderson et al., 2019). Engaging with K-12 students via SL deepens PTs' capacity for empathy, understanding, and encourages them to view students as community members with whom they have a responsibility and desire to connect (Chambers & Lavery, 2012).

Despite the generally favorable reviews of experiential learning, researchers have observed there is a notable scarcity of literature on its application within content-focused mathematics courses designed for K-12 teachers. This gap highlights the need for further research and exploration to better understand how experiential learning can be effectively incorporated into mathematics courses for students majoring in mathematics with a teaching emphasis.

In this study, we explore the following two research questions: (a) What do PTs perceive as the most valuable learning opportunities and skills gained from their involvement in SL activities within content-focused mathematics courses designed for K-12 teachers? (b) How do PTs view the relevance and usefulness of SL experiences in their mathematics courses on their future careers?

Conceptual Framework

Our conceptual framework is based on Carver's (1997) model for experiential education, in which student experience is central. Carver defined this experience through three interconnected facets: agency (A), belonging (B), and competence (C). Agency involves students' self-awareness and their ability to create growth opportunities. Belonging refers to students' integration into a community where they contribute and feel connected. Competence involves acquiring and applying new knowledge and skills. Additionally, the student experience can be seen both as a process and an outcome of the SL experience. Past experiences influence current experiences, making student experience a process and in the end, an output.

The development of ABC occurs as students face challenges, learn from mistakes, and grow as a person. The outcomes include acquiring new skills; becoming more adaptable; and gaining self-respect, peer respect, and a sense of safety. The learning environment supports ABC development through both setting characteristics (resources, behaviors, and shared values) and program characteristics (active learning, authenticity, future connections, and drawing from past experiences). Active learning directly involves students in the learning process while authenticity guarantees that the learning experience is genuine and relevant. Connecting to the future allows students to apply their knowledge to long term goals. These elements contribute to a positive student experience, encouraging PTs to implement similar experiential approaches with their students. We expand on Carver's model by incorporating the future intention of using similar activities or pedagogies as those used during their SL experience (see Figure 1). With positive student experience, we believe that teacher candidates are more likely to view the relevance and usefulness of the SL experiences on their future careers.

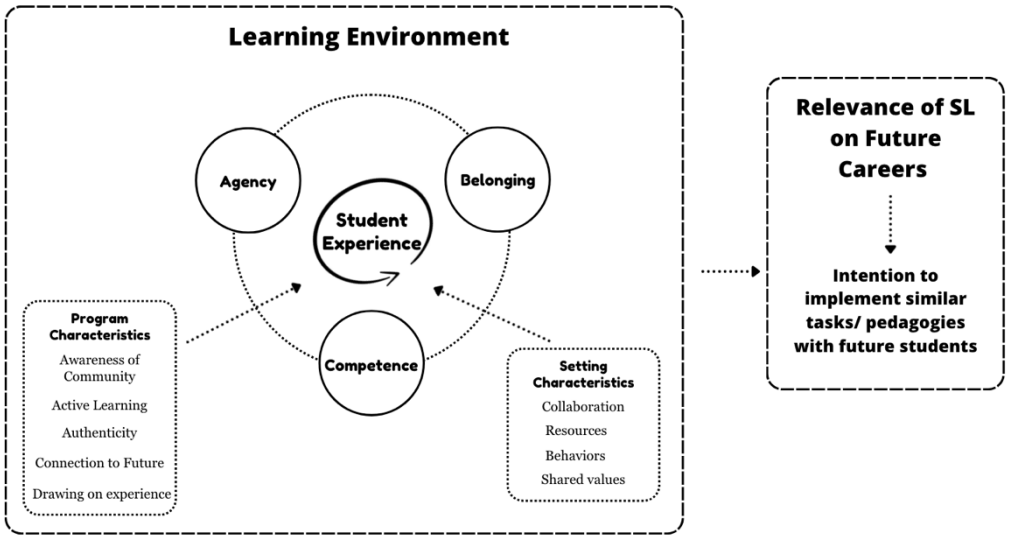

Figure 1. A conceptual framework for experiential learning for PTs (adapted from Carver (1997)).

Methodology

Study Participants

This study was conducted at a public institution on the West Coast of the United States. Participants included 38 students from three SL designated mathematics courses; 36 of whom were planning to become future K–12 teachers. The three courses included in the study were: College Geometry (eight students enrolled), an Elementary Mathematics and Learning Process course (10 students enrolled), and a capstone Mathematics course (20 students enrolled). Both College Geometry and the capstone courses were for math majors in the Teaching Emphasis track.

Course Context

In the College Geometry course, students examined the axioms and theorems of Euclidean geometry and compared various geometric axioms and theorems of Euclidean, non-Euclidean, and finite geometries. In the Elementary Mathematics course, students explored the relationship between mathematics and how it is learned. They expanded their knowledge of K-8 mathematics and explored how to positively impact children's attitudes toward and understanding of the subject. The capstone course provided a culminating experience that bridged the gap between the advanced mathematics studied in college and the mathematics taught in secondary schools. Throughout the course, students explored the nature of mathematics, with the overarching goal of connecting their experiences as learners to effective mathematics teaching.

Service Learning

Each student completed 10 hours of SL in the College Geometry course, five hours in the Elementary Mathematics course, and 26 hours in the capstone course. The SL activities involved (co)facilitating hands-on mathematics sessions with K-12 students, teachers, or seniors, solely based on content learned in the class. In the capstone course, 20 of the 26 SL hours were dedicated to tutoring middle and high school students.

In the College Geometry course, students learned about various finite geometries, such as 3-point geometry, Fano's geometry, and Young's geometry. They applied these concepts to create Spot-it games with three symbols per card, four symbols per card, five symbols per card, etc. Students also explored the application of Young's geometry in the SET card game. They developed presentation materials and hands-on manipulatives and facilitated sessions at a Wellness Program for seniors aged 65 and above, a Senior Living community, and a local Conference for middle school girls.

In the Elementary Mathematics and capstone courses, PTs facilitated various non-curricular, hands-on math activities for high school students from two local schools. They first presented the topics or worked on them with their peers in class, made modifications, and planned their sessions. Some of the topics included applications of number theory, logic, and geometry. Activities included Gerrymandering, Rook's move, etc.

Data Collection

Data was collected through pre- and post-surveys, and beginning- and end-of-semester reflections on students' SL experiences. The pre- and post-surveys included several Likert scale questions, ranging from "strongly agree" (5) to "strongly disagree" (1), along with open-ended questions. The pre-survey questions were adapted from Manolis (2004), while the post-survey

questions were adapted from the University of Georgia - Office of Service-Learning survey (2015). The end-of-semester reflection was adapted from the Campus Compact's "The What? So What?? Now What??? Reflection Model" (Rolfe et al., 2001). "The What?" component describes the event, i.e., facilitating the activities. The "So What" component examines the event's significance in relation to classroom concepts and personal experiences. The "Now What" component reflects on future actions that relate to the broader context of using mathematics in the "real world."

Data Analysis

We used descriptive statistics and an a priori and descriptive coding process (Miles et al., 2014) to interpret the data. The first round of coding involved members of the research team identifying and categorizing codes guided by Carver's conceptual framework on student experience. One PT was counted twice, as they were enrolled in both College Geometry and the Capstone course in successive semesters. In the beginning semester reflection, none of the students had prior experience with SL in a mathematics course before taking the SL courses associated with this study. Four students self-reported having previous SL experience in their education courses, and four other students reported having SL experience through Child and Adolescent Development classes, an art class, or through tutoring students in English.

Research Question (a): What do PTs perceive as the most valuable learning opportunities and skills gained from their involvement in SL activities within content-focused mathematics courses designed for K-12 teachers?

Out of 35 responses in the post-survey, 15 students strongly agreed, and 12 students agreed that the SL component of this course helped them develop their citizenship skills. Eighteen students strongly agreed, and 15 students agreed that the SL component made them more aware of their responsibilities as community members. Seventeen students strongly agreed, and 15 students agreed that the SL component helped them gain more knowledge about the community they worked with and the issues it faces. Twenty-two students strongly agreed, and 10 students agreed that the SL component helped them see how the material covered in the course could be useful in everyday life or in other situations. Nineteen students strongly agreed, and 14 students agreed that the SL component enriched their application of classroom knowledge. Fifteen students strongly agreed, and 18 students agreed that the SL component helped them to develop functional life skills, such as problem-solving, critical thinking, communication, and assertiveness.

From the end-of-semester reflections, student experiences are highlighted through three interconnected facets: agency, belonging, and competence. For agency, a majority of PTs felt a stronger connection to their future roles as teachers or envisioned themselves pursuing teaching in the future after participating in the SL sessions. PTs found it valuable to gain even a small glimpse of what being a mathematics teacher might involve. One PT wrote, "My goal is to become a math teacher and just getting a small insight to what that would be like is nice. It feels good to help people understand even if it is a small game like Spot it." PTs also gained confidence in their ability to teach and support other students within their peer group, with one PT noting that, "a service learning project is not an easy event to execute and through my performance as an individual I was able to not only regain confidence in myself, but also aid others in my group." Most importantly, PTs reflected on issues facing their communities. A PT in the capstone class wrote,

> From my hometown community, there were issues with lack of educational resources and education as a whole (especially mathematics as a subject) was not taken seriously. I

> intend to solve these issues to allow proper education be easily accessible to ensure the success of the students I teach in the future.

For belonging, PTs valued getting to know members of their community and showed a genuine interest in connecting with others on a personal level. One PT enrolled in the College Geometry course wrote, "I feel there was also merit in simply being there and interacting with people, listening to their stories and conversing about a myriad of topics, the simple act of interacting was welcomed." Through community involvement, PTs were also able to engage in generational sharing. During the SL events, PTs were eager to share what they learned in the classroom and became more open to learning from community members. A PT in the College Geometry class working with seniors wrote,

> I want to help others, I want people to learn from me as much as I want to learn from others. I want to be a part of my community, working with others and lending a helping hand in any way I can.

In terms of competence, several PTs felt a sense of accomplishment through teaching. One PT wrote, "Teaching has a way of being rewarding that goes beyond simple thank you's. Seeing those you have mentored grow as learners and then in return want to be a positive influence themselves is amazing." Another PT mentioned the relevance to the application of mathematics, saying, "Something new I learned about my service topic is that it is [not] just about math or geometry. It's about how we can use this math or geometry and apply it to real-world problems to solve them." Other PTs claimed that this experience enhanced their communication skills, with one PT writing that "facilitating the event allowed me to hone my communication and leadership skills, as I guided students through the various activities and encouraged their participation. I also was able to modify the games for students who needed it." Another student reflected on how the SL experience challenged them to make impromptu decisions and produce solutions to challenges they experienced during the SL events, saying,

> There were a lot of English Learning students that came to visit and finding ways to communicate the rules and get them involved was truly a challenge. In my group we did not have a native speaker to assist the students the best we could, but we managed to get by and adapt. I think I personally grew because of this as I was forced to find ways to communicate the material I was teaching to my visitors.

For student experience (as output), it was observed that students found SL to be rewarding and useful for them. Two students enrolled in the College Geometry course stated, "It has really benefited me as a person so doing the service learning with the seniors […] was very rewarding because it's a completely different age group than I'm used to." and "It's very rewarding, seeing people understand things, and knowing that you were a big part of that." Additionally, students asserted that they felt fulfilled (output) by participating in SL. One student wrote, "Learning new things is extremely fulfilling and helpful to people." Furthermore, many PTs expressed that SL allowed them to actively learn the course content. The SL experience aligned well with the content students were learning in their SL mathematics course. One student wrote, "This service-learning experience complimented with what I am learning in the class because the activities always revolve around geometry models and games." The same student then stated that "One new information that I learned about geometry during service-learning was the icosahedron, a platonic solid, because I've never heard of the shape, and I was able to make a model out of paper strips." In addition, students reflected that they experienced personal growth as a learner by interacting with individuals from different age groups and diverse backgrounds. A student in the College Geometry class wrote,

> I grew as a learner as I was able to interact with people who were out of my age range and people who came from different backgrounds and different world[s]. Meeting people who are younger than me […] gave me a brand-new perspective on how they act and view education.

While another geometry student shared, "My motivation has definitely changed from one of completing these projects for credit to completing them to better the community I am now part of." Students were also given the chance to reflect on their past experiences as students and how they can make an impact. One student wrote in their reflection,

> It is important to me that those teaching have a passion towards teaching and care about their students. I've had teachers in the past who just show up and don't care about what their students are learning. This made learning in the classroom miserable. I want students to feel heard and understood. I want them to care about what they are learning so that they can grow up and pass it on. I hope to be a passionate teacher who cares about her children.

Research Question (b): How do PTs view the relevance and usefulness of SL experiences in their mathematics courses on their future careers?

Many PTs shared that they plan to adopt some of the practices they learned through SL in their future careers as teachers. Among the courses from which we collected data, 28 out of 38 participants expressed that their experience with SL has provided them with insights into how they want to teach in the future. The students developed clear and concrete ideas about how they would apply the tools they learned through SL, with one student reflecting, "In the future, I want to use what I learned from these outreach activities in my teaching. I will be adding fun, hands-on games and puzzles to my lessons to get students more involved and help them engage in math."

Another student shared that their experience with SL has better prepared them to obtain their teaching credential, saying,

> This experience taught me the value of collaboration and the importance of working together towards a common goal. As I prepare to start my credential program at [University] and begin my placement at [High School], I am excited to apply the insights and skills I gained from this event. I am eager to create lesson plans that are engaging, culturally responsive, and collaborative. I want to ensure that my students see the relevance of math in their daily lives and feel confident in their ability to succeed.

Through SL, the undergraduate students could see themselves as future and current educators, gaining valuable tools and experience that will help them succeed in the future by making mathematics engaging and relevant to their future students. One student reflected,

> Participating in this event was a significant learning experience for me as a teacher. It taught me the importance of making math engaging and relevant to students' lives. Through hands-on activities and interactive games, I witnessed firsthand how students' enthusiasm for math grew when they saw its real-world applications. This helped me grow in my ability to create inclusive and interactive learning environments. I learned to tailor activities to students' individual needs and interests, ensuring that every participant felt valued and motivated to learn.

Some students demonstrated an eagerness to share mathematics with their future students in a way that combats negative stereotypes and seeks to avoid issues like math anxiety or other negative experiences with mathematics, with one student sharing that, "By attending this event, I learned much about how I can diverge from traditional mathematics education and teach it in a

more exciting and grounded way, which I hope will help absolve mathematics of its negative connotation." It is known that teachers pass math anxiety to students, so having teachers be more cognizant of this and how they can tailor their classroom to their teaching styles will benefit their future students greatly.

Additionally, of the remaining 10 of 38 students who did not clearly indicate an intention to use what they learned through SL in their future classrooms, seven of these students expressed that SL confirmed their desire to teach in the future. Therefore, 35 of the 38 study participants reported that SL gave them confirmation that they want to teach mathematics in the future and gave many of them ideas about how they will be able to engage their future students in mathematics.

Conclusion and Discussion

Written reflections from PTs offered valuable insights into their perspectives on their SL experiences in the (upper-division) mathematics courses. Our results provide support for incorporating SL into upper-division mathematics courses, offering significant benefits for students planning to become teachers, whether at the elementary, middle, or high school level. Through SL, students can engage in experiential learning within their upper division mathematics courses and develop essential work skills, including collaboration, communication, and practical career competencies. Students developed a stronger connection to their future roles as teachers or envisioned themselves pursuing teaching in the future. They strengthened their collaboration and interaction with others in the community. Many students expressed that SL allowed them to actively engage with the course content and complemented what they were learning in class.

Well-designed SL experiences enhance classroom learning and help students not only grasp the content but also develop career-ready skills. This is especially important for undergraduates in upper-division mathematics courses who are preparing to become K-12 teachers. There is no need for PTs to wait until the credential program or student teaching, where the focus is primarily on curricular instruction, to gain teaching experience. SL can demonstrate how and why upper-division mathematics can be meaningfully used in lesson planning for middle and secondary students. Further research is needed to explore the development of upper-division mathematics SL courses that can offer valuable experiences for PTs.

From "Struggle" to "Acceptance": Andy's Narrative of First-Time Teaching and Her Frames

Johan Benedict Cristobal
University of Nebraska-Lincoln

Using narrative analysis on experiences from Andy, a mathematics graduate student instructor, teaching for the first time, I address the question: How do frames of teaching and learning compare before, during, and after teaching for the first time as the main instructor? I focus on Andy's frames while reconstructing her semester-long experience, attending to the events that shaped her perception of these frames. For one, her "business" frame of teaching that she entered the semester with was at odds with her newfound responsibilities as the content instructor. This and other findings discussed have implications for the professional development and mentoring of future mathematics content instructors, including how newer instructors might be better oriented to manage and attend to classroom events.

Keywords: frames, noticing, graduate student instructors, narrative

The landscape of research on frames and teaching has no doubt explored the influence that frames have on the practices instructors enact. For one, the way instructors frame mathematics as a discipline and the learning of mathematics can result in responding to students in drastically different ways (Cristobal, 2024; Louie et al., 2021). These differences in frames may also result in perpetuating a culture of exclusion (Louie, 2017; Thanheiser, 2023). As a response, there have been strides, through professional development, in nudging educators towards asset-based frames of their students' contributions to the learning process (Bastian et al., 2024; Scheiner, 2023).

One corner of this landscape which requires more exploration is to understand how frames change outside of programs designed to nudge them. In other words, what requires more exploration is how do frames change as an instructor teaches day-to-day (or course-to-course). Therefore, the research question guiding this study was: *How do frames of teaching and learning compare before, during, and after their first-time teaching as Instructors of Record?*

This contributed report stems from a larger study that aimed to understand the experiences of mathematics graduate student instructors (GSIs) before, during, and after their first semester of teaching as the instructor of record. The perspective of GSIs is important for mathematics education to know and understand (Miller et al., 2018). In particular, for this study, the transformative experience of teaching for the first time provided a research space to explore how frames change. I report on one GSI's experience teaching for the first time which provides insight into how frames of teaching and of learning change in teaching.

There are multiple contributions drawn from this report. For practice, professional development (PD) leaders can develop resources to preemptively address difficult situations drawn from these experiences. Relatedly, I have hypothesized that graduate school is where future college faculty's teaching philosophy and practice begin to form. Therefore, a theoretical contribution of this study is adding to the array of experiences that future instructional faculty may bring when they enter the profession.

Motivation from the Literature

From a brief search, there appears to be little literature on how mathematics instructors' frames change. Two exceptions are Scheiner (2023) and Thanheiser (2023). Scheiner (2023) analyzed written reflections from prospective teachers before and after their experience in a

semester-long course designed to shift their frames with regards to student thinking. He found that within intentional design towards critical reflection of how instructors framed students' thinking, the prospective teachers were able to shift from deficit-based to strength-based frames. Thanheiser (2023) discussed three frames that mathematicians may have about the subject of mathematics itself. These three frames coincided with her career-long changing perception of what mathematics is.

This study is motivated to further the understanding of how instructors' frames change. Whereas Thanheiser provided a glimpse into how frames of mathematics can evolve, her anecdote happens over a large timescale. Whereas Scheiner demonstrated that an intentional PD program can indeed shift instructors' frames, he did not demonstrate such shifts or changes in the absence of intentional PD. The study did not intend to change instructors' frames, only to understand that if frames changed during an instructor's first semester of teaching, how do the frames compare. However, by asking instructors to reflect on their teaching and learning of mathematics, their frames changed. Fortuitously, this report filled gaps from Scheiner (2023) and Thanheiser (2023) by demonstrating that frames can change during a semester of teaching when instructors are asked to reflect on their teaching and learning of mathematics.

Theoretical Perspective

The theoretical focus of this narrative exploration is on frames. Frames (Goffman, 1986) are the interpretive contexts that participants of a given situation use in order to quickly interpret information, filter the details, and decide how to appropriately proceed. In addition, frames are conceptualized as a facet of teacher noticing, where the way one frames the teaching or learning mathematics influences the ways in which they attend, interpret, or respond to situations in the classroom (Louie et al., 2021; Scheiner, 2021). As exemplified by Jessup (2023), a situated and socially constructed conceptualization of noticing, and also frames, allows for the consideration of the instructors' histories that shape how they notice.

This study focused on instructors' frames of their teaching and their students' learning by building upon the analytic framework in Cristobal (2024). In this framework, frames of teaching could be understood as interpretive contexts that support instructors' perception and enactment of (1) what their role is in the classroom as the instructor, (2) what professional knowledge (Kunter et al., 2013) is relevant or valuable in the act of teaching mathematics, and (3) what type of interactions are favored or useful in fulfilling their role and achieving the intended mathematical learning goals.

Similarly, an instructor's frames of (student) learning can be understood as interpretive contexts that support instructors' perception and enactment of (1) what instructors must do for students to learn intended content, practices, and orientations, (2) what content, practices, and orientations should instructors attend to in the classroom, (3) what type of interactions are favored or useful in fulfilling their role and achieving the intended mathematical learning goals, and (4) where the class fits into students' schedules (or career paths) and what challenges competing responsibilities could pose to their learning.

To address the research question, change is conceptualized as change in or across one or more of these seven aspects of the framework.

Data and Method

This report focuses on the results of narrative analysis of Andy, a GSI, during her first semester of teaching College Algebra. Andy was chosen because her narrative illustrated the possibility of how frames change during a semester of teaching and when asked to reflect on her

frames. The data used in this report comes from a larger study of mathematics GSIs that aimed to understand the experiences of mathematics GSIs before, during, and after their first semester of teaching as the instructor of record. In this paper, "instructors of record" are responsible for the content-delivery and assessments of an undergraduate mathematics course.

To reconstruct narratives surrounding frames, I conducted multiple interviews before, during, and after each participant's first semester of teaching, conducted weekly observations, and collected weekly journal reflections. I followed a grounded theory approach during collection (Charmaz, 2006), meaning that subsequent collections were informed by the previous. For example, each new observation began to focus on aspects of teaching and learning that I had noticed in the prior weeks' data, such as GSI's ways of responding to student questions.

To organize all these forms of data, I utilized the three-dimensional inquiry space (Clandinin & Connelly, 2000). The three-dimensional inquiry space involves *interaction* (encompassing personal and social themes), *continuity* (encompassing past, present, and future), and *place* (encompassing physical context and space). These dimensions are used to organize the narratives towards restorying – the process of reorganizing narratives to some chosen structure (Creswell & Poth, 2018). I expand this structure to organize analysis towards both reconstruction of the narrative and theoretical saturation (Miles et al., 2019) about the nature of how frames change.

Within each dimension of the inquiry-space, I continued the grounded theory approach through multiple rounds of constant comparative analysis (Glaser, 1965). First, I focused on themes that relate to frames of teaching, then I focused on themes that relate to frames of student learning. This allowed for an understanding of each dimension for a robust reconstruction of the narrative. After the initial reconstruction, I met with each participant to discuss the accuracy of the narrative.

Findings

In these findings, I illustrate Andy's change in frames by narratives from before, during, and after Andy's first semester of teaching.

Before the Semester

Andy's story starts two weeks before the summer teaching orientation for mathematics GSIs. Andy and I discussed her experiences as a student and her understanding of what it meant to teach and learn mathematics. Then, I asked her to recall a difficult experience as an undergraduate student. She shared that she struggled in a particular physics course that had multiple, seemingly disconnected topics, and expressed a desire for a thread to tie the topics of a course together. For her, instructors should attend to some thread that ties the topics of the course together for the student, an aspect of her frame of student learning.

For Andy, learning mathematics is a collaborative, social endeavor. She expressed that "because you remember certain things that stood out to you as elegant and useful, and other people remember different things from lecture," it was important for students to work and learn together. Thus, student-to-student interactions were highlighted in how she discussed learning.

The process of learning, to her, involves repetition and seeing the "underlying" structure of a problem, filling this "skeleton" with substance from the given information. Therefore, for her, the instructor is there to introduce the structure and choose examples that have clear substance.

When I asked Andy to complete the sentence, "Teaching mathematics means…" She bluntly answered "struggle" and explained further, "[Students] are expecting you to teach them a useful skill which to them will always only be a useful skill…knowing in your head [that] there is like a beautiful structure to it that they don't want you to give them… And you kind of have no right to

make them want more from it, and it's like a struggle." This spoke towards an interpretive context for where her teaching fits into students' career paths, grim as that context may be. Thus, as an incoming instructor, she conceptualized that teaching will be a struggle.

Focusing more on teaching, she believed that teaching is about passing down knowledge from the past, inviting students to participate and appreciate the subject. A skillful teacher, to her, is one with sufficient content knowledge that builds the cohesive story amongst the different topics in a mathematics course. Further, a skillful teacher can encourage students to see multiple points of view to help develop understanding of some mathematical structure. Andy believed that she had the necessary content knowledge. While she admitted that she lacked the necessary confidence, she was willing to try and motivate why we learn algebra to future students.

This was where Andy's frames of teaching and of learning were at, before entering her classroom. It is important to reiterate that she had never taught before, but with her experiences as a student, she was able to voice her conceptualizations of teaching and possible practices she can aspire to enact.

During the Semester

A few weeks passed and it was time for the first day of class. Andy walked into a tight room full of 40 students with varying levels of comfort with the subject. One student already expressed concern about failing and Andy quickly responded with assurance that they won't fail if they put in the work. Throughout the 75-minute class, Andy primarily lectured and often asked if explanations made sense or if anything needed to be reiterated.

In our discussion immediately afterward, she informed me that it didn't feel right to ask them to come to the board and present on the first day. Then, I asked Andy why she allowed some students to leave early when they asked for her permission. She responded that, "I'm providing a service, I'm not their mother," and she didn't feel it was her place to enforce them. This sentiment of providing a "service" was echoed again in her journal reflection at the end of the week, where she wrote: "I felt like I wasn't useful to my students" and "I felt like I didn't know what I was teaching." She wanted to be more useful to them through having clearer definitions and explanations. We agreed that perhaps it was just a consequence of the first day of classes.

However, as the weeks went by, it became clear that her students leaving early and not fully participating in the course was a reality attached to this teaching. The observation notes, the journal reflections, and our conversations mentioned this in some form or another. In our following interview, I asked her how she viewed her role in this classroom, and she shared:

> *Andy (Interview, Week 5)*: My role in the classroom is as someone who's seen the material before and is comfortable with it to try to relay what I know about it in a more approachable way to people who will need to make use of it in the future… I kind of feel like I am providing a resource by structuring the information in a way that I think helps get the idea across. But if they don't want to pay attention or do the work that I'm asking them to do, ultimately, that's them refusing a service they're paying for.

Andy's frame of teaching from before was still there (passing down knowledge), but it had gained a dimension that I labeled as "business." This "business" frame of teaching was apparent in almost all aspects of her teaching. To Andy, her role was still passing down past knowledge, but there is a pressure to package that knowledge neatly and succinctly. Her professional knowledge was focused on content knowledge, and how she can deliver this service with little confusion to the consumers. During observations and our conversations afterwards, it was clear

that she preferred to interact with students individually. She could provide the best service when she only had to attend to one person, rather than multiple, varying levels of proficiency. In the structured interviews throughout the semester, Andy expressed regrets about not being able to provide the best service. For example, after the second exam, she shared that she didn't know what old review material was allowed to be shared with her students. She expressed that it would not have been too much work to make her own review materials but, given her other responsibilities as a graduate student taking graduate-level courses, it was not doable.

Similar to her frames of teaching, Andy's frames of student learning also began to crystallize under a label. I labeled her semester's frame of learning as 'encode-decode'-ing languages and communication which she elaborated on multiple occasions:

> *Andy (Interview, Week 5)*: So, after some weeks teaching this class, I would say that learning math is learning how and why information is *encoded*, and how you would unambiguously *decode* that information.
>
> *Andy (Interview, Week 12)*: They should see like a conventional system for communication. And after seeing that convention in some context, see how it can... uh... illuminate, for lack of a better word, extra information and structures hidden in the information.

Since the goal of learning is to understand encoding and decoding communication, Andy would explain every step of a solution and being as unambiguous as possible whenever she wrote up a solution on the board. She shared in an interview that she hoped that her students learned from her that "you can express the same idea to as many people as possible" while being unambiguous.

In her journals, she consistently set "encourage students to talk to each other more" as a weekly goal. Andy began lessening the time she spent presenting on the board while students sat silently, and she shifted towards discussions at the individual or table-group level. Through this encode-decode frame, she would walk around the room addressing student questions without a writing utensil. When we discussed this, she shared that she wanted the students to be the ones writing as she facilitates their thinking aloud. Andy emphasized that if there was no one asking questions during group work time, she would slowly approach the table that had gone silent.

> *Andy (Interview, Week 5)*: I think usually that there's one of two things happening. The one that is more applicable, I think, to the "what do you look for if you don't hear obvious signs of help" is that both of them are stuck on the earlier question. But one of them moved forward rather than continuing to read onto the question that they didn't know how to do. The other one would be that the student that's ahead knew how to answer that question, but not how to explain it to their partner, or their partner didn't feel comfortable asking them to explain it.

With this 'encode-decode' frame of student learning, Andy also understood that learning is not a trivial task, and that language can be "ambiguous" and confusing. She was also aware of how college algebra is a graduation requirement for her students, and that the necessary skill this course imparted on students is the ability to decode seemingly ambiguous language. Another orientation Andy attended to is students' confidence to succeed. She recalled telling a student, "Frustration is allowed, but shame is not," when the student expressed feeling discouraged about their intelligence.

After the Semester

In light of her experience, Andy said she would like "to honor students experiences as people learning the material" as opposed to how she would have preferred to experience the material. Her 'encode-decode' frame of learning was not faulty, but rather she realized her explanations were too rigorous for what one might expect from a college algebra course. She still views mathematical learning as similar to learning a language and disambiguating information. However, because of her teaching and a particular experience in her own coursework this semester, she realized that there is value in adhering to some mild lack of rigor.

> *Andy (Interview, Post-Semester)*: [talking about squishing, lassos, and ropes] Seeing that picture just helped me like on a gut instinct. I see this picture and know what I have to write down… I think I've been overzealous rather than fundamentally wrong. Like, I do think that at the end of the day it's nice to arrive at a point where you can say this works because of XYZ… But I think I should have given more patience and importance to, "Here are some gut feelings that you can have about this."

On the other hand, Andy viewed her 'business' frame of teaching in a less favorable light. While framing her teaching as providing a well-crafted service did help her interact with individual students, it became stressful to manage her classroom. A consistent theme throughout the semester had been her apprehension in demanding students to engage, pay attention, and not leave class early. Andy unpacked where this 'business' frame stemmed from:

> *Andy (Interview, Post-Semester)*: For me, I had the luxury of being able to spend time on my schooling if I wanted to… and so, of course, it's easy for me to be like "oh, this is a business. If you want to learn what I'm teaching you in class, then you will dedicate the time to or you won't."

Andy does not believe this 'business' frame of teaching will change since, to her, this was a consequence of the current attitudes towards what a college education is. However, similar to her frames of learning, Andy realized that she needed to motivate her teaching, not just through her content knowledge, but by also drawing on more pedagogical content knowledge (Kunter et al., 2013). While she believed it was too late to change her classroom's dynamic, she realized it was part of her role as instructor to ask for students' engagement and attention.

Before the semester had begun, Andy shared that, to her, teaching mathematics meant "struggle" between wanting to show the beauty of mathematics and how students might only want to be shown the useful skills from mathematics. I did not remind her of this, but asked again, "Complete the sentence: teaching mathematics means…" She responded:

> *Andy (Interview, Post-Semester*): Acceptance, I think, like you're always gonna want your students to see the beautiful thing... I think I said something similar, but maybe a little bit more cynical at the beginning. It's like you want them to see the beautiful thing, they don't necessarily care about the beautiful thing. But you have to accept that you're gonna try to show them something nice, and maybe they won't get it, but they'll at least have had to have thought about it for a little bit, and that's something.

Discussion

This report aimed to gain insights into how frames change in a shorter time scale and in the

absence of intentional PD. I also aimed to address the question: *How do frames of teaching and learning compare, before, during, and after their first-time teaching as Instructors of Record?*

Andy's frame of teaching began as a 'I am passing down knowledge from the past to students, inviting them to appreciate the subject.' Then, as the semester progressed, her frames of teaching met with the realities of teaching, mostly the unexpected responsibilities with classroom management. While this new frame still had the essence of giving knowledge, it was packaged in this interpretation of teaching as a business. After the semester, Andy accepted her 'business' frame of teaching, while updating her understanding of what her role is in the classroom. She is both passing down knowledge and enforcing some classroom management.

Andy's frames of student learning began with three distinct themes: (1) there is a thread connecting the course topics together, (2) understanding an underlying mathematical structure comes from repetitive collaborative problem-solving, and (3) the 'struggle' between the beauty and immediate usefulness of mathematical concepts. Then, as the semester progressed, these three themes shaped or combined to become her 'encode-decode' frame of student learning.

Thus, this report reaffirmed that, even in the absence of intentional PD, frames of teaching and of student learning may still change within a semester. Andy's frames before and during teaching coalesced and crystallized because of her experience in the classroom. While she felt herself beholden to her early-formed frames during the semester, she also knew how to better them for her future courses by adhering less strictly to rigor and more on intuition building. At least in Andy's narrative, frames of teaching and of learning do not *drastically* change, but they do strengthen in their clarity and how it informed and will inform Andy.

Implications and Future Direction

One lesson learned from following Andy's semester is towards PD of novice instructors. Andy's main struggle in the semester had been classroom management, and how she was not aware that it was part of her responsibility as a college mathematics instructor. It is tempting to simply tell GSIs that it is 'par for the course,' but this lack of awareness may stem from a disconnect between instructors' expectations and realities of teaching. Therefore, PD might serve novice instructors like Andy better if PD includes stories from previous instructors that demystify the realities of teaching at their institution. In addition, asking instructors to reflect on their teaching and learning is one way to shift their frames.

This study was in a particular setting and context of a new instructor. Thus, exploration of experiences from different settings is necessary to grasp how frames change. By understanding how day-to-day or course-to-course experiences (re)shape instructors' frames of teaching and of learning, we may also further understand how teaching practices perpetuate. For example, Andy accepted that her 'business' frame was her reality because of larger societal forces, which may speak to instructors believing they have no power to change attitudes towards mathematics.

I mentioned how Andy felt regret about not providing students with more review materials before their exam because she had to attend to her own coursework. Andy was not the only GSI in the larger study who felt the pressures of competing responsibilities of a GSI. While GSI PD does prepare new GSIs with ample structure for content, materials, and assessment for their teaching responsibilities, it might better serve the GSIs if PD also included ways to juggle the competing roles of being an instructor and being a graduate student.

Acknowledgments

The author thanks Andy for sharing her classroom and vulnerability for this discussion.

Aspects of Culture and Context which Shape Frames of Teaching and Learning

Johan Benedict Cristobal
University of Nebraska-Lincoln

Sociopolitical lenses applied to frames research have affirmed that frames are culturally constructed. A subsequent curiosity, then, is to uncover what aspects of culture and context shape an instructor's frames with respect to teaching and learning mathematics. To this end, this study followed three mathematics graduate student instructors during their semester of teaching for the first time. Through a grounded theory design, informed by critical theories, the author found themes within beliefs, values, and norms were salient in these teaching experiences. One consequence of this study is giving names to the aspects of culture and context which shape frames. This insight is valuable for understanding how to shape asset-based frames.

Keywords: frames, culture, sociopolitical, critical lens, graduate student instructors

Culture is ever-present in our lives. The collection of cultures we attached ourselves to, both willingly and by birth, informs how we move through society. It ranges from the small things to the large, like what utensils are used to eat or how language is used. Culture is typically an unspoken force that informs ways of living, with its major elements being symbols, language, norms, values, and artifacts (e.g., Conerly et al., 2021). In addition, the context which an individual is in may dictate what aspects of their culture they draw upon. For example, a school cafeteria, a fancy restaurant, and one's kitchen all dictate different behaviors and norms.

Consequently, culture and context also shape instructors' ways of teaching (e.g., Hofstede, 1986). A review of college mathematics teaching in proofs-based courses found that whether an instructor used instructor-centered or student-centered approaches was largely informed by the instructors' beliefs of what is the best form of teaching (Melhuish et al., 2022). In addition, the norms instructors enact may also differ if the type of course they teach is a computational course or a proof-based course (e.g., Dawkins, 2009). Focusing on culture and context together, Dreher et al. (2020) explored how East Asian (Taiwan) and Western (German) cultures approach teaching and found that different cultural norms informed their different ways of teaching.

This report uncovers the aspects of culture and context which shape an instructor's way of teaching. This study followed three mathematics graduate student instructors (GSIs) teaching as the main instructor for the first time and focused on their frames of teaching and of learning as a proxy to understand their ways of teaching. Teaching for the first-time is a formative period of one's instructional career, where students become educators (e.g., Smollin & Arluke, 2014). This period provided a space for me to notice the aspects of culture and context which inform these GSIs' understandings of what it means to teach and learn mathematics. Thus, this report is guided by the research question: *What aspects of culture and context were salient in the experiences of mathematics graduate students teaching as instructors for the first time which could be attributed to influencing their frames?*

The influence of culture and context on frames has been demonstrated and exemplified (e.g., Jessup, 2023; Scheiner, 2021). However, these studies discussed how the general concepts of "culture" and "context" shape instructors' teaching practice. This contributed report named aspects of culture and context which shape frames of teaching and of student learning. This report also aims to address the culture of exclusion (Louie, 2017) by unveiling and naming parts of *any* culture which could pervade mathematics classrooms.

Theoretical Perspective

The theoretical stance of this study is that an instructor's ways of teaching can be understood from the ways the instructor has framed their teaching and their students' learning. In general, frames are used by individuals to understand a given situation and quickly interpret information, filter the details, and decide how to appropriately respond (Goffman, 1986). In one way, frames have been understood as a facet of noticing – the ways in which instructors attend, interpret, and respond to teaching situations (Louie et al., 2021; Scheiner, 2021).

This study focused on instructors' frames of their teaching and their students' learning by building upon the analytic framework in Cristobal (2024). Frames of teaching can be understood as interpretive contexts that support instructors' perception and enactment of (1) what their role is in the classroom as the instructor, (2) what professional knowledge (Kunter et al., 2013) is relevant or valuable in the act of teaching mathematics, and (3) what type of interactions are favored or useful in fulfilling their role and achieving the intended mathematical learning goals.

Similarly, an instructor's frames of (student) learning can be understood as interpretive contexts that support instructors' perception and enactment of (1) what instructors must do for students to learn intended content, practices, and orientations, (2) what content, practices, and orientations should instructors attend to in the classroom, (3) what type of interactions are favored or useful in fulfilling their role and achieving the intended mathematical learning goals, and (4) where the class fits into students' schedules (or career paths) and what challenges competing responsibilities could pose to their learning.

Inspired by Louie, Adiredja, and Jessup (2021), this study drew upon critical race theory (CRT; Delgado & Stefancic, 2001; Ladson-Billings & Tate, 1995) in order to understand the culture and context which entrench teaching. I further drew upon two CRT-informed frameworks: community cultural wealth (Yosso, 2005) and critical whiteness study (Harris, 1993). In this view, culture referred to "behaviors and values that are learned, shared, and exhibited by a group of people" (Yosso, 2005, p. 76). Furthermore, this study was primarily concerned by the context that these GSIs were teaching in a predominantly white institution (PWI). More specifically, this study aimed to understand how the four functions of 'whiteness as property' (Harris, 1993) surfaced in the ways GSIs framed their teaching and their students' learning. See Figure 1 for a summary of each function. The study was concerned if these four functions materialized in how GSIs viewed mathematical knowledge.

Rights of Disposition Whiteness can be transferred ownership.	**Right to Use and Enjoyment** Whiteness can be used to accomplish and exercise power and enjoyed through affordances of privilege.
Reputation and Status Property Whiteness has a reputation, a thing of significant value, and having that meant having a certain status.	**The Absolute Right to Exclude** Whiteness can be interpreted, not by an inherent unifying characteristic, but by the exclusion of others who are "not white".

Figure 1. Summary of the four functions of 'whiteness as property' from Harris (1993)

CRT afforded the understanding that culture, of whiteness or of students of color, can either empower or discourage individuals. As a lens for empowerment, community cultural wealth extended the notion of 'wealth' which members of communities (of color) may draw upon for empowerment (Yosso, 2005). As a lens for discouragement, the culture of exclusion (Louie, 2017) can be understood as parallel to whiteness as property wherein mathematics knowledge is treated as property which can be transferred, used to exercise power, enjoyed for its privileges, has a reputation in society, and which individuals may be excluded from receiving.

Data and Method

The interview and observation data used in this report came from a larger study of three mathematics GSIs teaching for the first time as instructors of record: Andy, Carlos, and Jacob (pseudonyms chosen by the participants). "Instructors of record" are responsible for the content-delivery and assessments of an undergraduate mathematics course. These GSIs taught at a large, Midwestern, public predominantly white research university. Interviews were conducted before, throughout, and after the fall semester, a total of five interviews with each GSI. Weekly classroom observations were gathered throughout the semester for each GSI. The GSIs taught intermediate algebra, college algebra, or a mathematics course for liberal arts.

Following a grounded theory format (Charmaz, 2006), multiple rounds of coding were done to address the research question. The first rounds identified salient themes inductively (Miles et al., 2019) within each GSIs' interviews, with close attention to how each discussed teaching and learning mathematics. Using the observation data, further trends were identified, either substantiating a theme found in the interviews or becoming new themes. Then, the themes were grouped under categorical labels aligned with the aspects of culture which surfaced. To address context and whiteness as property, the themes were coded as either treating or not treating mathematics knowledge as property, using the guiding question: "does this theme speak towards one of the functions of property? If so, is it challenging the notion or perpetuating it?" These themes were further labeled using the four functions identified in Harris (1993). Finally, using the analytic framework, connections were made between themes and the supports frames of teaching and of learning provided to the instructor.

Results

In these findings, I name the aspects of culture (behavior, values, and norms) and aspects of the context (of being at a PWI and the lens of 'mathematical knowledge as property') which surfaced in the analysis of GSIs' experiences with teaching for the first time.

Aspects of Culture

Behaviors refer to how individuals act. Across these GSIs, it was an unsurprising theme that they behaved like novice instructors such as with classroom management. Furthermore, this behavior materialized in a fear of appearing incompetent or unprepared while they teach. Another behavior that was salient across was attending to students who were silent during group work. When asked how they decide which table group to approach during their group work sessions, all interpreted the silence as not knowing what to do or ask. For Carlos, silence even took precedence over vocalized struggle.

> *Carlos (Week 5 Interview):* Something that would take precedence is if… they're just like looking at it like this, staring without writing anything. At least the other people… they're talking and like sort of trying. And so, a table that can't even start a problem… that would take precedence over a table that is like struggling with a problem.

Values refer to what individuals consider to be important or beneficial. In this case, the focus was on what the GSIs valorized about teaching, learning, and overall experience during their semester which informed their teaching practice and the beliefs about their practice. Here, each GSI spoke of instances when their expectations and beliefs about teaching were challenged by the realities of teaching. This could be a positive challenge. For example, Jacob found the experience fun as opposed to scary.

Jacob (Week 15 Interview): It was less scary than I expected. I think that they [Course Convener] did a good job of like giving us support… I was sort of unsure about [teaching mathematics for liberal arts], but it was actually a lot of fun.

But it could also be a negative challenge. Since he valued providing extensive feedback, Carlos found that grading and providing written feedback took up more time than anticipated. Andy found that students preferred the quick ways of solving a problem rather than what she preferred: the most general (and sometimes technical) way of solving a problem. Across all of them, they discussed the challenge of being both a graduate student attending to their coursework and an instructor attending to their students' learning.

Norms largely refer to the rules and expectations with respect to behaviors (Homans, 1966). For this context, norms referred to rules and expectations which govern discussion in the classroom (Cobb, Yackel, & Wood, 1992). All these GSIs faced challenges on what to attend and emphasize in discussions: algorithms versus conceptual ideas and rigor/technical language versus intuition. In Jacob's case, he preferred to interpret students' full understanding of a concept in the class; always responding with "explain your thought process" to a student's answer. But the online exams of his convened course emphasized correct execution of algorithms to input answers in a box. As mentioned before, Andy preferred rigorous explanations as opposed to quick shortcuts, and she learned quickly that intuition is as important as rigor was. As for Carlos, his students expected him to expand on student's answers. For example, Carlos' students might present their final answer to the class, but it became an expectation (according to Carlos) that Carlos would expand on the process laid out by the student.

One salient theme that overlaps behavior, value, and norm within the data was the difference between lecturing on the board and talking with individual students during class or in office hours. Each highlighted an awareness that they can explain things better when they do not have to account for the varied array of learning styles across the classroom. Within individual conversations, Andy, Carlos, and Jacob were able to tailor how they spoke to a student. This related to how each GSI valorized discussion in the classroom, and Andy even considered individual conversations as being where true learning happens.

Andy (Week 7 Interview): I tend to rush when I'm at the board, and I think I tend to do things in less detail at the board, as a sort of appetizer, so to speak… It's for people who want to meet some degree requirements, and then, like small groups is actual learning, I suppose.

Analysis resulted in an understanding that, broadly, each cultural aspect of behavior, value, and norm had influence on each GSIs frames in one way or another. For one, being novices influenced their frames of teaching. For example, Andy struggled with her role as the instructor with respect to classroom management, because the behaviors she relied on as a novice instructor focused on lecturing and attending to students' questions. The GSIs' particular attention to silence in the classroom also informed their frames of students' learning. An important aspect of learning, to them, was discussion between students and between instructor and individuals. They all understood that their teaching and their students' learning benefited from smaller group interactions.

The conflicts raised from expectations versus reality, algorithms versus conceptual ideas, rigor versus intuition also informed the GSIs' developing frames. For Carlos, he may have

valued giving extensive feedback to students as part of his frames, but the reality of being a GSI meant he needed to prioritize other aspects of teaching and learning that might be more beneficial to his students. For Andy, coming to terms with the reality that students do not want rigor meant changing what she must do as the instructor in order for students to learn the content promised by the course syllabus. For Jacob, algorithms became something that needed attention alongside the conceptual ideas because of the nature of assessment in his course.

Aspects of Context

Here, I report on the findings which address the concept of 'mathematics knowledge as property' as a way to understand the context of teaching mathematics at a PWI. I have opted to keep the discussion and quotes in this section unnamed so as to prevent singling out a GSI. This discussion is not meant to vilify the GSI and their possible contribution to a culture of exclusion. Instead, I focus on how insidious and pervasive these functions or aspects of 'whiteness as property' may be in the context of teaching.

In this light, 'rights of disposition' materializes in the context of mathematics as treating mathematics as a static body of knowledge which can be given to a person willing to receive it. Therefore, an education in mathematics is simply the passage of knowledge. This was somewhat salient in some GSIs discussion of their role in the classroom as the expert, and skillful instruction entailed flexibility in being able to pass down abstract concepts. However, one GSI added that mathematics as a subject encapsulated many ideas and concepts which cannot be easily essentialized under one definition. They further shared that, beyond just receiving a portion of this large body of knowledge, they hoped their students also learned that:

> "[Mathematics] is sort of like a living subject... It wasn't handed down to us from God, that it was constructed by humans to solve real world problem."

This spoke towards the collaborative view of teaching and learning these GSIs have, countering 'the absolute right to exclude' function of mathematics as property. These GSIs spoke against this function that mathematics could be used to exclude (i.e., a math person versus not). To all of them, learning mathematics involved discussion, participation, and engagement among *all* the students in the classroom. Observations of all GSIs also confirmed their attempt and insistence on every student participating and engaging. This spoke towards their frames of learning in that in order to learn, students must join in the conversation. One GSI made it a goal to teach students how to be "a good classmate" through the mathematics group work they do.

The discussions surrounding their status as novice instructors involved their fear of being perceived as an incompetent instructor. Though it does not directly speak to mathematics as property which afforded them 'reputation and status property,' this fear could be interpreted as not having a certain reputation because of mistakes in lecture or answering students' questions. This spoke towards their frames of teaching; in how they understood their role in the classroom or the expectation of it: a perfect instructor.

Lastly, the function of 'right to use and enjoyment' where mathematics can be used to exercise power and enjoy privileges did not surface in the analysis. Instead, it was counteracted by multiple experiences. For one GSI, they wanted to create an "egalitarian" classroom, where everyone is equal and can contribute to how they want to learn. This also spoke against the previous function of property as regardless of one's previous mathematical background, they were treated as equal to their peers. Another example of countering this function of property was seen in all GSIs' discussion of honoring students' preferred way of learning. All GSIs made

changes to their teaching practice as the semester progressed to accommodate students' preferences. One GSI even dedicated time in their time-constrained class to explicitly address the mid-semester evaluations and how changes would be made going forward in the semester. The changes they made also changed their frames of teaching and of student learning, as they learned what interactions or practices they should enact based on students' input.

Discussion

This contributed report aimed to name aspects of culture and context which shape an instructor's way of teaching. As a proxy to understand an instructor's ways of teaching, this report focused on instructor's frames of teaching and learning. Thus, I asked: *What aspects of culture and context were salient in the experiences of mathematics graduate students teaching as instructors for the first time which could be attributed to influencing their frames?*

This report shared some aspects of culture (behavior, value, and norm) which were salient in these GSIs experiences. Behaviors centered on their novice identities and how silence from students was a sign of confusion during work sessions. Values focused on their expectations versus the realities of teaching and how reconciliation had to be made to accommodate these realities. Norms surrounded their conflicts about what to emphasize in discussion. I found that these aspects of behavior, value, and norm overlapped when each GSI discussed their preference in teaching to smaller groups or individuals as opposed to the full classroom.

Moreover, through a lens of critical whiteness study, this report also shared how aspects of context (teaching at a PWI) surfaced in these experiences, either perpetuating or countering the treatment of mathematics knowledge as property. Some GSIs might have conceptualized mathematics teaching as a passing of knowledge, somewhat perpetuating a view of mathematics knowledge as property. However, all of them fervently countered the notion that mathematics knowledge should be used to exclude through their belief that true learning of mathematics occurred in discussions with peers. All the GSIs professed the value in discussions and working together with peers to learn mathematics and enacting practices that valorized collaboration amongst students. I hypothesize that the view of mathematics as a body of knowledge perhaps stemmed from the convened structure of the courses. In other words, the GSIs were handed and asked to teach a course, its curriculum, and its materials with very little say on what is taught and when in each course. There was no evidence from these GSIs of perpetuating the notion that mathematics can be used for reputation or as a conduit to exercise power and privilege.

These aspects of culture and context both influence these GSIs' frames of teaching and of learning. Behaviors, values, and norms shaped the actions they understood as appropriate in the classroom and what their role was in fulfilling their desired learning outcomes for their students. Furthermore, though this analysis did not address all supports of frames, I infer from these findings that GSIs' understandings of the professional knowledge relevant to their course (frames of teaching) and how their course fits into students' academic career (frames of students learning) may also be informed by the values and culture instructors bring into their classroom.

Implications and Future Direction

The main concern of the study was to uncover aspects of culture and context which shape an instructor's way of teaching in order to understand how frames may be shaped or changed. In that light, behaviors, values, and norms were salient aspects of culture which informed instructors' frames of teaching and frames of student learning. Then, attending to inclusive, collaborative practices were salient aspects of context which informed these frames. With these insights, professional development leaders may focus on a combination of behaviors, values, or

norms which shape future instructors' understanding of what their role is in the classroom and how to better attend to equitable learning experiences for their students. Andy, Carlos, and Jacob were privileged in that the courses they taught were convened which provided structure to their teaching, which may have had its impact on the understanding that teaching is an act of passing down a body of knowledge. But this convened structure may have also forced them to attend to more collaboration as that was the emphasized method of instruction during their department's new instructor orientation. Therefore, a departmental or professional development emphasis on collaboration in mathematics courses may be one way to counteract the pervasive nature of the culture of exclusion of mathematics.

The PWI context where this study occurred motivated the exploration of 'context'. In particular, the study approached 'context' through the specific avenue of how 'whiteness as property' or 'mathematical knowledge as property' surfaced in these GSIs experiences. More research in different regions and contexts should be conducted in order to further understand aspects of context which shape frames. These contexts do not necessarily need to use lenses from CRT, perhaps more simple aspects of context may be explored such as the type of course taught (e.g., computation-heavy versus proof-based) or logistical constraints (e.g., 16-week courses versus 10-week).

Lastly, this study built on the growing literature of mathematics GSI development as instructors and their overall experience in graduate school. While the perspective of the GSI is important, it is also not the only one. Experienced instructors, who have been entrenched in their local community and culture, may have drastically different opinions on what aspects of culture and context have shaped their frames of teaching and of student learning. There is much more ground to explore in this area of frames, culture, and context.

Acknowledgments

The author thanks Andy, Carlos, and Jacob for participating in this study, despite the many competing duties of a GSI. The experiences they shared for this report and the larger study is what made this dialogue happen.

How do Introduction-to-Proof Textbooks Explain Conditionals? Mathematical, Natural-Language and Hybrid Examples

Lara Alcock
Loughborough University

Rentuya Sa
Loughborough University

Mathematics defines the propositional conditional 'if P then Q' as the truth-functional material conditional: it is false if P is true and Q is false, and true otherwise. This is counterintuitive with respect to natural language in that 'missing-link' conditionals (with true but unconnected P and Q) are considered true, as are conditionals with false antecedents. How is this reflected in the examples used by introduction-to-proof textbooks? Do these use natural-language conditionals in their explanations, or avoid them in favour of mathematical conditionals? What characteristics do their chosen examples share, and where do they diverge? We address these questions using a theoretically informed qualitative analysis of content on conditionals in 17 commonly recommended introduction-to-proof textbooks. We consider advantages and disadvantages of different approaches in relation to research in philosophy and psychology as well as in undergraduate mathematics education.

Keywords: conditional, example, implication, logic, reasoning.

Introduction

Undergraduate mathematics students encounter numerous mathematical conditionals, in theorem statements and in more informal claims and conjectures. In content courses, most of these are *universal conditionals* (also called *generalized conditionals*, Durand-Guerrier, 2003) of the form 'if $P(x)$ then $Q(x)$', interpreted to mean '$\forall x$, if $P(x)$ then $Q(x)$'. It is important for students to distinguish such conditionals from their converses and inverses, so that they can avoid errors in constructing and validating proofs (e.g. Selden & Selden, 2003).

In introduction-to-proof courses, students might also encounter *propositional conditionals* of the form 'if $P(x_0)$ then $Q(x_0)$', where x_0 is a specific object. They learn that these are treated according to a *material* interpretation, so that 'if $P(x_0)$ then $Q(x_0)$' is false if $P(x_0)$ is true and $Q(x_0)$ is false, and true otherwise. This gives the truth conditions that we want because it means that a universal conditional is refuted only by examples that we understand as counterexamples. However, it is peculiar in relation to natural language. In everyday settings, people tend to think that 'missing-link' conditionals – e.g. 'if bats have wings then Paris is in France' (Bourlier et al., 2023) – are false or nonsensical, not true. They also usually think that for cases where $P(x_0)$ is false, 'if $P(x)$ then $Q(x)$' is irrelevant rather than true (Newstead et al., 1997).

How is this reflected in the examples used by introduction-to-proof textbooks to explain conditionals? Do texts use natural-language conditionals to support understanding of the material conditional? Or do they avoid natural language, giving up possible analogies in favour of more clear-cut mathematical examples? Do they include missing-link or false-antecedent conditionals? To address these questions, we analysed examples used to explain conditionals in commonly recommended introduction-to-proof textbooks. We consider advantages and disadvantages of different approaches in relation to research in philosophy and psychology.

Theoretical Background

The mathematical conditional has a stipulated meaning: the propositional connective 'if-then' conforms to the standard truth table for the material conditional (Table 1, with illustrative

content). This connective is truth-functional, meaning that the truth value of 'if $P(x_0)$ then $Q(x_0)$' depends only upon the truth values of $P(x_0)$ and $Q(x_0)$. As noted above, it underpins the mathematically desirable interpretation for universal conditionals: the universal conditional 'if $P(x)$ then $Q(x)$' is not falsified by cases where $P(x_0)$ is false or $Q(x_0)$ is true (Edgington, 2020). For instance, the conditional 'if x is a circle then x is an ellipse' is universally true – it is not falsified by circles, non-circular ellipses, or squares (see Table 1).

Table 1. Truth table for the material conditional with 'if x is a circle then x is an ellipse'.

	circle	ellipse	if circle then ellipse
circle	T	T	T
(impossible)	T	F	F
non-circular ellipse	F	T	T
square	F	F	T

However, adopting the material interpretation requires sacrifices because we usually subject natural-language conditionals to an *inferential* reading, assuming that the consequent is caused by the antecedent or otherwise follows reliably from it (Douven et al., 2020). This makes missing-link conditionals sound false or nonsensical. Also, we are usually uncomfortable with with false-antecedent cases, considering conditionals irrelevant in these (Newstead et al., 1997). The picture is further complicated by the fact that natural language often allows 'if' to be interpreted as 'if and only if'. This is fairly standard in conditional promises, threats, and statements about permission (Nickerson, 2015): from 'if you mow the lawn, then I will give you \$5', a person could reasonablly to infer that if they do not mow the lawn, they will not receive \$5 (Cummins et al., 1991).

In mathematics, we carefully distinguish 'if' from 'if and only if'. But otherwise the pragmatics is similar. In theorems and other claims, we usually assert 'if $P(x)$ then $Q(x)$' or '$P(x) \Rightarrow Q(x)$' only when proposing that for all relevant x, $Q(x)$ follows deductively from $P(x)$. Thus, we would happily say that 'if n is divisible by 6, then n is divisible by 3' is true and 'if n is odd, then n is prime' is false. However, we would not usually consider the corresponding propositional conditionals individually. These sound natural when a universal conditional is true and the truth value of the antecedent of a corresponding propositional conditional is unknown, as in 'if 4,686 is divisible by 6 then 4,686 is divisible by 3' (Epp, 2004, p.17). But the natural-language use of conditionals to indicate uncertainty (Grice, 1989) means that they sound unnatural where the truth values are known:

- if 12 is divisible by 6 then 12 is divisible by 3 (true-true case so true);
- if 9 is divisible by 6 then 9 is divisible by 3 (false-true case so true);
- if 8 is divisible by 6 then 8 is divisible by 3' (false-false case so true).

They sound even more unnatural when a universal conditional is false:

- if 3 is odd then 3 is prime (true-true case so true);
- if 9 is odd then 9 is prime (true-false case so false);
- if 2 is odd then 2 is prime (false-true case so true);
- if 8 is odd then 8 is prime (false-false case so true).

These sound strange because we cannot infer primeness from oddness; the '2' and '8' cases sound additionally awkward due to their false antecedents.

Introduction-to-proof texts therefore have issues to consider in the examples that they use. They could engage with the peculiarities of the material conditional, highlighting missing-link

and false-antecedent cases. Or they could focus primarily on conditionals that are more 'natural' in everyday language and in mathematics in that they are universal and submit to inferential interpretation. These choices will have consequences: students' understandings of mathematical concepts are heavily influenced by their experience with examples (Sinclair et al., 2011). Even if a text defines the material conditional clearly, the examples it uses for illustration will influence students' conceptual understanding. In the study reported here, we investigated what introduction-to-proof texts do by asking, for their example conditionals:

1. What balance is struck between mathematics and natural language?
2. What proportions have inferential versus missing links?
3. What other features are evident (propositional vs. universal, specifc content, etc.)?

Method

We assembled a list of introduction-to-proof texts commonly recommended in the US and the UK. The US list was compiled by David & Zazkis (2019); it contained one book per course. The UK list we compiled by identifying introduction-to-proof courses and using websites or contacting lecturers to acquire book lists. Of 66 courses identifiable via the UCAS website of UK university degree programmes, we acquired lists for 52 (nine did not have a list, and five did not respond to enquiries or follow-ups). The US and UK lists were not equivalent because UK courses do not usually have a single 'course book' or identify a main book on their list. We do not consider this a methodological problem because we were not trying to conduct a representative survey; we simply wished to select texts that students were likely to consult.

From the two lists, we identified all books recommended at five or more institutions across the two countries. One of these had no specific content on conditionals, one had minimal content, and four discussed only universal conditionals, usually with a focus on distinguishing a conditional from its converse (Alcock & Sa, in press). We do not discuss these further. The 12 texts that discussed both universal and propositional conditionals are listed in Table 2, together with recommendation numbers in the US and the UK.

Table 2. Texts Analysed, with Numbers of Recommendations.

For each text, we listed all example conditionals in the section(s) where conditionals were explained, regardless of whether these were expressed using 'if-then' or 'implies'. We also included biconditionals and conditionals deliberately formulated differently, e.g., 'You can run for president only if you are a citizen' (Velleman, 2006, p.49). Counting was not straightforward because some texts used the same conditional multiple times to make or clarify different points. Because we were interested in the content used, we decided that a single conditional used multiple times would count once. Across the 12 books, we identified 162 conditionals in total.

Analysis and Results

To address Research Question 1, we classified each conditional as *mathematical* or *natural-language*; we also introduced a third category, *hybrid*, because some texts included conditionals involving content of both types. Illustrations appear below.

- *Mathematical:* If x is even then x^2 is even (Houston, 2009, p.64).
- *Natural:* If you pass the final exam, then you will pass the course (Hammack, 2013, p.43).
- *Hybrid:* $\pi = 3 \Rightarrow$ Paris is the capital of France (Smith et al., 1997, p.11).

This classification revealed considerable differences in approach, as documented in Table 3. Some texts used very few conditionals, sticking to mathematical content; some used mainly natural-language conditionals; some used lots of each. Only three used hybrid conditionals.

Table 3. Counts of mathematical, natural-language and hybrid conditionals in the analysed texts, with sub-classification as having inferential or missing links.

	Houston	Chartrand et al.	Smith et al.	Velleman	Eccles	Rosen	Hammack	Epp	Stewart & Tall	Lay	D'Angelo & West	Sunstrom	Total
Mathematical													
Inferential	21	3	13	1	3		7	7	1	7	2	7	72 (45%)
Missing	1	5	7		2					1			16 (10%)
Natural													
Inferential	12	1	2	16	1	8	2	16		3		4	65 (41%)
Missing						1		1					2 (1%)
Hybrid													
Missing			3			1		1					5 (3%)

To address Research Question 2, we classified each conditional as having an *inferential* or *missing* link. All hybrid conditionals had missing links – these were used to make the point that the truth value of a propositional conditional does not require a link between its antecedent and consequent. Some texts made the point explicitly; others relied on readers to notice what they were supposed to learn. Illustrative mathematical and natural-langauge conditionals with missing links appear below (these contrast with the inferential links above).

- *Mathematical:* $(\pi < 3) \Rightarrow (1 + 1 = 2)$ (Eccles, 2007, p.12).

- *Natural:* If computers are machines, then Babe Ruth was a baseball player (Epp, 2004, p.26).

Table 3 shows that the texts' example conditionals overwhelmingly had inferential links[1]. Five texts included none with missing links, and those that did use them included only small numbers. This presumably reflects the fact that while introduction-to-proof courses commonly cover the material propositional conditional, mathematicians are primarily interested in developing students' understanding of universal conditionals.

To address Research Question 3, we sliced the data differently, classifying the conditionals as *propositional* or *universal* with additional (sub)classifications to distinguish features relevant to the theoretical background. Four conditionals were peculiar in some way and did not fit our classification scheme[2]. The remaining 158 did, and we discuss each classification in turn.

Twenty condtionals (~8%) were unambiguously *propositional*. Of these, four were hybrid and had missing links (like the example above). Two were natural-language; these had a missing and an inferential link respectively (again, see above). The remaining 14 were mathematical; nine had missing links and four had inferential links either with a false antecedent or in a false claim. One (from Epp, repeated below) had an inferential link but uncertain truth values of the antecedent and consequent, so worked particularly well with both the logic of the material conditional and the pragmatics of natural language.

- If 57 is prime, then 3 is odd (Chartrand et al., 2018, p.20).
- $-1 = 1 \Rightarrow 1^2 = 1$ (Houston, 2009, p.65).
- If 4,686 is divisible by 6, then 4,686 is divisible by 3 (Epp, 2004, p.17).

Thirty-four conditionals (~22%) had *ambiguous* status in relation to the propositional/ universal distinction because they used natural language (one was hybrid) and invoked a named person (sometimes 'I') or a physical situation. Six of these were promises and two were threats; the remainder were more general assertions. Asserted with clear specific referents, these would be propositional. However, all had inferential links between antecedent and consequent, and readers were usually asked to consider how they would apply in multiple situations, so they were effectively treated as more general claims. Some would naturally be interpreted in line with the logic of the material conditional, others less so; as noted above, everyday promises and threats would often be interpreted as biconditionals.

- If it stops raining by Saturday, then I will go to the football game (Lay, 2014, p.4).
- If you do not get to work on time, then you are fired (Epp, 2004, p.20).
- I am not American implies that I am not Texan (Houston, 2009, p.73).
- If John didn't go to the store, then we're out of eggs (Velleman, 2006, p.44).

The remaining 104 conditionals were unambiguously *universal*.

Of the mathematical universal conditionals, 50 (~33% of the total) were *universal assertions*. Two involved more than one variable; we classified these as having missing links but note that a link is possible with additional specification. The remaining 48 were mathematical claims that could be theorems or conjectures; two were clearly intended to have uncertain truth value, nine were clearly false, the remaining 36 were clearly true. Readers were often invited to consider these in relation to specific cases and thereby to consider propositional conditionals, but their statements were universal.

---

[1] Two conditionals did not fit this classification: Lay's (2014, p.7) 'If roses are red, and violets are blue, then I love you' and D'Angelo & West's (1999, p.32) 'If S is "This book was published in the year 73', then $S \Rightarrow P$ is true'.

[2] Those in footnote 1, plus Smith, Eggen & St Andre's (1997, p.11) 'If $4n > 10$ then 1 is prime' and Rosen's (2007, p.7) 'If today is Friday, then $2 + 3 = 5$'.

- $f(a) = 0 \Rightarrow a > 0$ (Eccles, 2007, p.14).
- If $x^2 > 5$, then $x^3 + 12x + 4 < 3$ (Houston, 2009, p.64).
- If p is a prime number, then p is odd (Hammack, 2013, p.57).
- $x > 0 \Rightarrow x + 1 > 1$ (D'Angelo & West, 1999, p.32).

A further seven mathematical universal conditionals (~4%) referred in their antecedents to *specific objects*. These are interesting from a theoretical perspective because such statements are common in mathematics and are technically universal but represent a sort of extreme case – universal statements 'normally' allow multiple different cases for a true antecedent. For some, a student's prior experience might lead to natural consideration of false antecedent cases; for others, it is harder to imagine that it would.

- If $x = 3$ then $x^2 = 9$ (Sundstrom, 2016, p.58).
- If $x = 2$, then x is a solution to $x^2 = 2x$ (Smith et al., 1997, p.14).

Finally, ten mathematical universal conditionals (~6%) captured *universal definitional* relationships, either standard definitions or local definitions constructed for a specific task. A further six (~4%) were definition-like in using categorical *inclusion* relationships. We note that standard definitions are biconditionals, but this and their status as definitions was only sometimes highlighted. Categorical inclusions clearly conform to the logic of the material conditional (in a sense, all mathematical conditionals capture categorical inclusions, but this was more explicit here).

- $a < 0 \Rightarrow |a| = -a$ (Smith et al., 1997, p.14).
- If $g(m,n) = n^2 + n + m$, then $g(n,n+1) = (n+1)^2$ (Lay, 2014, p.22).
- If a real number is an integer, then it is a rational number (Epp, 2004, p.82).

Of the natural-language universal conditionals, five (~3%) captured *universal inclusions* due to category membership or geographic location. These correspond clearly to the logic of the material conditional, so it is perhaps surprising that they were not more often used. Eleven (~7%) we classed as *universal associations* because they had inferential connections, but these arose from human conventions or plans or observations rather than category inclusions or physical causes. Fifteen (~9%) were *universal permissions, promises or threats*. As noted before, these would not always be interpreted according to the logic of the material conditional. Often, they would support pragmatically valid *denial of the antecedent* inferences: for the last two below, the hearer might reasonably infer that if there are not ten people, the lecture will not be given, and that if they do not clean their room, they will not be allowed to watch TV. Such pragmatic issues were sometimes but not always discussed.

- Being an article of clothing is necessary for being a glove (Houston, 2009, p.72).
- If x is a student in this class, then x has visited Mexico or Canada (Rosen, 2007, p.43).
- You can work here only if you have a college degree (Lay, 2014, p.5).
- If at least ten people are there, then the lecture will be given (Velleman, 2006, p.49).
- If you do not clean your room, then you cannot watch TV (Sundstrom, 2016, p.57).

Discussion

This work addressed three research questions about examples used in introduction-to-proof texts' discussion of conditionals:

1. What balance is struck between mathematics and natural language?
2. What proportions have inferential versus missing links?
3. What other features are evident (propositional vs. universal, specifc content, etc.)?

In answer to Question 1, the balance of mathematical versus natural-language conditionals varied dramatically by text: authors do not agree on how to use different content. In answer to Question 2, a large majority of conditionals had inferential links. In line with our theoretical framing, we suggest that this reflects a mathematical interest in true universal conditionals: these can be treated inferentially, and mathematicians are interested in the corresponding proofs. In answer to Question 3, only about 8% of the conditionals used were unambiguously propositional; a further 22% could potentially be propositional but were arguably treated as universal claims. Of the unambiguously universal conditionals, a large proportion (33% of the total) were mathematical claims that could form theorems or conjectures. Smaller proportions of the mathematical conditionals had specific-object antecedents or involved defining or categorical inclusion relationships. Universal natural-language conditionals were spread across inclusions, associations, permissions, promises and threats. Of these, the inclusion relationships most naturally conform to the logic of the material conditional.

This analysis reveals the complexity of choices facing textbook authors and instructors. What influence might their choices have on student learning?

Using conditionals with inferential links has advantages and disadvantages. Students will likely find these 'natural', but they obscure the fact that the truth value of the material conditional depends only upon the truth values of its antecedent and consequent. So their likely utility depends upon the goal. If we want to teach students how to to interpret the conditionals that they will encounter in content courses in undergraduate mathematics, then the collective emphasis is probably reasonable. At least, it is reasonable if we assume that students will overlook the peculiarities of the material conditional. For students who notice those, explanations are somewhat thin on the ground (see also Alcock & Sa, in press).

If the aim is to teach the material conditional as part of mathematical logic, then the examples offered provide only partial exposure to relevant issues. Only some texts confronted the peculiarities head on, explicitly writing out propositional conditionals in order to reflect upon how they relate to the material conditional interpretation. Most avoided this by presenting universal conditionals and inviting thought about how they apply to particular cases. As we know that people often consider conditionals nonsensical when they have missing links (Bourlier et al., 2023) and irrelevant in false-antecedent cases (Newstead et al., 1997), more substantive discussion would likely be needed in order to help students connect their understanding of familiar mathematics or everyday situations to formal logic.

We conclude with two issues worthy of note. First, those conditionals that most naturally conform to a material interpretation were mathematical and natural-language conditionals capturing inclusions in the form of categorical or geographical relationships. Permissions, promises and threats are riskier as these are often interpreted as biconditionals; this does not mean that we should avoid them, but we suggest that they might need more in-depth discussion. Second, we saw only one use of a simple and clearly true inferential universal conditional applied in cases where the truth value of the antecedent would be unknown (Epp, 2004, p.17, 'if 4,686 is divisible by 6, then 4,686 is divisible by 3'). This seems particulary useful in linking mathematical logic with everyday pragmatics, and we suggest that the educational effects of exposure to this and other types of example merit theoretical consideration and empirical testing.

Learning Approaches in an Introduction to Proofs Course

Jason Guglielmo
Arizona State University

Olivia Bruner
Arizona State University

Norman Contreras
Arizona State University

We take a situated cognitive perspective to better understand how undergraduate students utilize study resources in their introduction to proofs (ITP) course, particularly compared to their use of these resources in pre-proof courses. Prior research has shown that the transition to proof contains an increase in expectations of rigor compared to previous undergraduate mathematics courses. However, less is known about how students select particular study resources to meet these new expectations. We conducted task-based interviews with four undergraduate students enrolled in an ITP course to better understand the study resources they employed in both pre-proof and proof-based contexts, and the potential motivating factors behind adjustments to study methods. We found that students attempted to migrate previously used resources as well as adopting new resources and were motivated to adjust some study habits due to the novelty of the ITP context, a lack of relevant resources, and instructor modeling.

Keywords: situated cognition, transition to proof, study resources

Studies on the *transition to proof*, or the transition of undergraduate students from pre-proof courses into upper-division undergraduate and graduate proof-based courses, have pointed to difficulties students often face during this transition due to "an expectation of greater student autonomy, a change in the nature of the objects studied, and the seeming unapproachability of professors" (Selden, 2012, p. 39). We hypothesize that this transitory period in students' mathematics learning could affect the resources they access for studying and/or the ways they use particular resources. In this study, we wish to better understand (a) in what ways student learning approaches may differ between pre-proof and proof-based mathematics courses, and (b) what aspects of their introduction to proof (ITP) course potentially motivate these adjustments.

By *learning approaches*, we refer to both (a) the materials, tools, and/or relationships that individuals use for learning (*resources*), and (b) how individuals use these resources or the actions the individual takes for the purpose of learning (*resource uses*). This construct is similar to that of study habits (Alcock et al., 2020; Hora & Oleson, 2017) in the literature, but with an emphasis on both the resource *and* its use. By doing so, we hope to go beyond broad categorizations for study resources used by students and better understand the nuances of why they choose particular resources to use in their ITP course. Specifically, our guiding research questions are:

(1) What learning approaches do students in an ITP course utilize when presented with proof-based tasks?
(2) When students express differences in learning approaches between pre-proof and proof-based contexts, what motivating factors are associated with these differences?

Understanding what motivates students to adjust their learning approaches during their transition to proof will help researchers and educators better support future students in this transition.

Relevant Literature

Research on students' achievement in ITP courses has found that the transition from pre-proof to proof-based mathematics courses is not seamless for undergraduate students (Moore, 1994; Smith et al., 2017; Stylianides & Stylianides, 2009). Students often must reconceptualize intuitive mathematical understandings into formal definitions (Selden, 2012) and struggle to develop self-regulated (or independent) learning strategies in ITP contexts that allow for personal reflection and improvement of learning strategies when current methods are ineffective (Talbert, 2015). We conjecture that student difficulty in transitioning from pre-proof to proof-based mathematics courses may be exacerbated by students struggling to either adopt new learning approaches or adapt old ones within ITP contexts. This may be aggravated by the diversity of content and approaches in ITP courses (David & Zazkis, 2020) which could make many of the resources students may have previously used, such as standardized mathematics help websites or online tutoring services, less applicable or helpful.

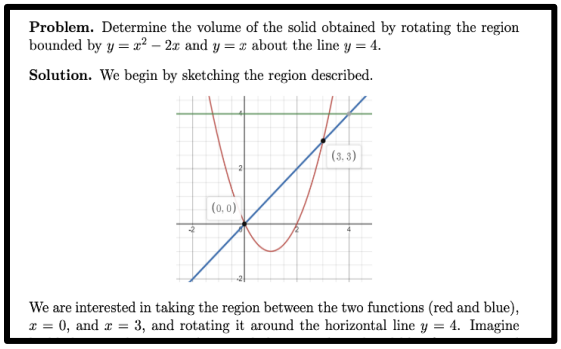
Given the unique and varied nature of ITP courses and the challenges students face in adapting to them, it is valuable to further understand the learning approaches students employ as part of this transition. Robbins et al. (2004) conducted a meta-analysis of higher education studies on psychosocial and study skill factors, finding that college students' academic-related skills impacted their retention and academic goals. In STEM contexts, research on undergraduate students' use of learning approaches is still mostly exploratory, with studies largely working on characterizing students' digital resource use (Aguilar & Puga, 2020; Ogan et al., 2015) or broadly identifying their study habits through self-reports (Alcock et al., 2020; Hora & Oleson, 2017). We intend to contribute to this area by focusing on learning approaches students adapt during their transition to proof, to enable future work in determining which are effective in meeting the unique challenges of ITP.

Theoretical Perspective

We take a situative view of learning in this research project, meaning the environment in which mathematics is learned is inextricably linked to the knowledge that is created (Lave & Wenger, 1991). This perspective acknowledges learning as fundamentally distributed, enacted, and social (Roth & Jornet, 2013). This understanding of cognition leads us to an interest in learning approaches that includes the physical materials referenced and used by students, as well as the actions they take during their learning process and the individuals they work with. In particular, we highlight the following underlying assumptions within this theoretical framework (based on the work of Greeno, 1998): (a) both behavioral skills and conceptual understandings are aspects of participation within a social practice, and (b) changes in the environment (e.g., physical/temporal location, participants present, etc.) lead to distinct conceptual understandings. We use these key assumptions to orient our study design and methodology, as explained below.

Proof-based course environments have unique expectations for the skills and conceptual understandings the students possess, as demonstrated in the literature (Selden, 2012; Stylianides & Stylianides, 2009). This observation, combined with assumptions (a) and (b) from our situated cognitive perspective, leads us to believe that students' learning will change because the situations are unique. That is, since the content and expectations in ITP are distinct from previous math classes, it is reasonable to assume that student approaches to learning will vary within this new context. We assume that since there are some similarities between pre-proof and proof-based courses, including lecture-based instructional style and references to foundational mathematics skills such as algebra and arithmetic, students will initially attempt to adapt their already generated math class "tools" to a new context (Brown et al. 1989).

Methods

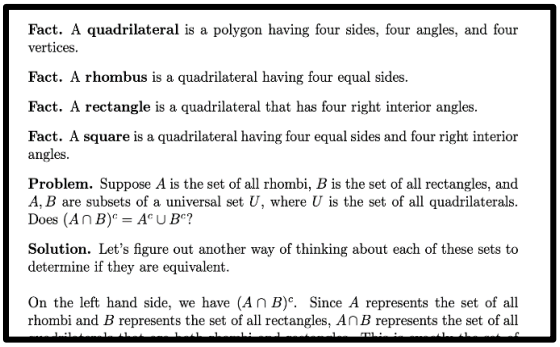


Study Design and Participant Selection

Task-based interviews were conducted with four volunteer students enrolled in a single ITP course at a large public university in the southwestern United States. This research project began as a class project, and the ITP course selection was predetermined for the class project. Students were recruited who had completed a calculus course within the last two years to prioritize recent experiences with the two contexts of interest. The four focal students were interviewed mid-semester, between the first and second summative assessments (Exams 1 and 2).

Informed by our situative perspective on learning, task-based semi-structured interviews (Mejia-Ramos & Weber, 2020) were utilized to explore the learning approaches used by students in pre-proof and ITP courses, as well as motivations for these choices. While our theoretical perspective lends itself to physical classroom observations, practical constraints led us to leverage individual task-based interviews to simulate pre-proof and proof-based classroom environments, an approach with precedent (Roorda et al., 2015; Ticknor, 2012). Ultimately, we assumed that presenting students with pre-proof and proof-based mathematics contexts through these different tasks would encourage students to reflect on different mental processes and potentially unique learning approaches.

Task Design and Data Collection



The interviews contained both contextual and task-based questions. The contextual items included general questions about the participant's goals and experiences in recent math classes (both pre-proof and their ITP course). Four tasks were created, two proof-based and two pre-proof, to simulate the contrasting environments. The tasks were presented as problem statements with worked solutions, as shown in Figures 1 and 2, so the student was not expected to produce an answer to the prompt.

Problem. Determine the volume of the solid obtained by rotating the region bounded by $y = x^2 - 2x$ and $y = x$ about the line $y = 4$.

Solution. We begin by sketching the region described.

We are interested in taking the region between the two functions (red and blue), $x = 0$, and $x = 3$, and rotating it around the horizontal line $y = 4$. Imagine

Figure 1. Pre-proof task example.

Fact. A **quadrilateral** is a polygon having four sides, four angles, and four vertices.

Fact. A **rhombus** is a quadrilateral having four equal sides.

Fact. A **rectangle** is a quadrilateral that has four right interior angles.

Fact. A **square** is a quadrilateral having four equal sides and four right interior angles.

Problem. Suppose A is the set of all rhombi, B is the set of all rectangles, and A, B are subsets of a universal set U, where U is the set of all quadrilaterals. Does $(A \cap B)^c = A^c \cup B^c$?

Solution. Let's figure out another way of thinking about each of these sets to determine if they are equivalent.

On the left hand side, we have $(A \cap B)^c$. Since A represents the set of all rhombi and B represents the set of all rectangles, $A \cap B$ represents the set of all

Figure 2. Proof-based task example.

After being presented with each task and given time to review them, the participants were then asked the primary orienting question: *Imagine this was a type of problem you are expected to know how to complete in your class. What study resources might you use to prepare for this type of problem?* Follow-up questions were then asked for each resource mentioned by the student, having students (a) reflect on their use of this resource in their pre-proof and ITP courses; and (b) note any factors that influenced their adoption, adjustment, or removal of learning approaches between contexts. One researcher interviewed the students, while the other researcher(s) present acted as witnesses, keeping memos and supervising the protocol execution

for consistency and quality. These interviews were video- and audio-recorded using Zoom conferencing software.

Data Analysis

Thematic analysis (Braun & Clarke, 2012) was used to systematically organize the data set into groups based on students' learning approaches, then compare these groups to identify themes about the factors motivating any changes in these learning approaches. Following Braun and Clarke's six-phase approach, interview recordings were auto-transcribed by Zoom, then manually cleaned and reformatted by a research member. During this process, data familiarization (phase 1) also occurred as the team made memos regarding notable learning approaches. The research team developed initial codes (phase 2) for one transcript across three domains: (a) *Resources*, or specific tools/processes mentioned by the student; (b) *Resource Use*, or ways of implementing a Resource mentioned by the student; and (c) *Motivators*, or explanations given by the student when noting Resources or Resource Uses that changed between pre-proof and proof-based contexts. Resources were generally given shorter descriptions and corresponding tags for easier sorting; Resource Uses and Motivators were generally given longer, low-inference descriptions that might include direct quotes from the text.

After consensus was reached on the initial transcript, the remaining three transcripts were coded by individual team members, adding new tags and revising prior descriptions, which were reconciled and then reviewed through member checking. Each resource tag was re-checked for internal consistency once all transcripts were coded. The research team then developed and reviewed themes (phases 3 & 4) related to the Resource Uses and Motivators mentioned by students. This was a recursive process of moving between the whole dataset and individual coded chunks while discussing patterned or unique findings with the research team. This process led to the development of three themes (phase 5) that illustrate different Motivators mentioned by students for their change in resource use between pre-proof and proof-based contexts. These are further elaborated in the Results below (phase 6).

Results

Results are presented in two parts as relevant to our research questions. First, we discuss the various learning approaches (Resources and their associated Resource Uses) mentioned by students in ITP contexts. Then, we outline the three themes that illustrate common Motivators for change in learning approaches. Student quotes will be used throughout, with the four student names being anonymized with the following pseudonyms: *Aaron, Basil, Chris,* and *Dana*.

Learning Approaches in ITP

Students mentioned a variety of resources and resource uses that they leveraged when presented with proof-based problems. Table 1 below displays a selection of tagged Resources that were mentioned by at least one student while reflecting on a proof-based practice problem, alongside the different Resource Uses students mentioned for these resources in the proof context. Some Resource categories are specific actions taken by students, such as attending instructor Office Hours. Other categories, like Brainstorming and Visual Aids, are more broadly defined, as students would provide different levels of specificity for more general actions, like thinking over a problem statement or visualizing different aspects of the statement. As for the Resource Uses, students would occasionally mention using certain resources simply to find other, more relevant ones. In particular, students often mentioned using the resources of Internet Search and Homework Assignments to find additional practice problems.

Table 1. Selection of resources students mentioned in proof contexts, with associated uses.

Resource	Description	Associated Uses in ITP
Homework Assignments	Reviewing past (assigned or unassigned) homework problems, including review of instructor comments and/or online homework site feedback	• To find practice problems • To identify patterns in problems
Peers	Working with other students outside of class time, whether online or in-person (or unmentioned)	• To compare answers with others • To "double-check" work with another
Practice Problems	Using practice problems that are similar to the current problem	• To get familiar with similar types of problems • To see a given solution path for a similar problem
Visual Aids	Drawing pictures, diagrams, or other visual aids to represent mathematical ideas	• To visualize geometric objects, function graphs, sets, or set relationships mentioned in problem context
Internet Search	Searching for information about similar content as the problem, with or without specifying an online search engine	• To find similar problems • To review a concept from ITP
Brainstorming	Thinking about or mentally reviewing material; writing down ideas, thoughts, processes, or scratch work; and/or verbalizing ideas to self before formally writing down solution steps	• To prepare oneself and take in the information

We also note that these are not all of the Resources mentioned by the students. Some resources mentioned in proof contexts, like Online Messaging and Question Patterns, were cut for space. Students also mentioned using some resources, including Computational Devices and Online Text Material, only in pre-proof contexts. This list is not meant to be an exhaustive list of resources used by students in ITP courses, but rather a starting point, developed from interviews with four students.

Motivating Factors for Changes in Learning Approaches

Three themes were developed to highlight consistent factors that students mentioned as Motivators for change in their Resource Use between pre-proof and proof-based contexts: *Novelty of Proof Content, Relevance of Resources,* and *Instructor Modeling & Course Structure*.

Theme 1: Novelty of proof content. Students mentioned changing their learning approaches in light of the novelty of the new content in their ITP course. Generally, participants noted a difference in how problems were structured in their course compared to pre-proof courses. As

stated by Dana, "[ITP course] isn't really, you know, solving problems. It's more just finding relationships between things […] they're just completely different kinds of problems." These differences were often characterized as an increased level of complexity or abstraction in the problems. In response to these differences, some students would alter their Resource Use while retaining the Resource itself between pre-proof and proof contexts. For instance, Chris noted that due to concepts in ITP being "fairly abstract," he had increased use of office hours compared to pre-proof courses. Similarly, Basil noted a decrease in his use of online materials, stating that "you can't check a proof like that online [*laughs*] that's not, that's not how that works."

The most common motivation for change due to this new math context was the ability for the same problem to be answered sufficiently with different approaches. All four participants mentioned this as a motivation for change. Dana, Chris, and Aaron cited increased difficulty in using the Resource of Question Patterns, noting that "[ITP] is just harder, because, like, it's more than two patterns for more questions," and "some things I can't [do based on memory], just because again, there's not always one correct answer for everything." Dana particularly mentioned that this decreased the effectiveness of the Practice Problems Resource for her because the variety of solutions made it so she was unable to check her work. In sum, the novelty of the mathematical context in ITP, in terms of both the complexity of questions and multiplicity of solution paths, was related to students' adjustment of their learning approaches.

Theme 2: Relevance of resources. The second theme highlights how some students utilized learning approaches based on the perceived relevance of these approaches to their learning needs. For instance, one student did not use office hours in their pre-proof course, because all lectures were recorded, making additional in-person sessions unnecessary. In cases where students would try to implement a previously used learning approach in ITP, multiple participants commented on struggling to find resources that matched the nuances of their proof problem statements. Basil shared his reluctance to use internet searches, stating, "I would not look up on the internet for this problem, 'cause there'd be way too many miscellaneous things that I would not want to look at. I'd get some third-grade geometry stuff that would show up." This illustrates a common challenge mentioned by students of sifting through irrelevant material, which can overwhelm students with content that doesn't directly help them achieve their learning goals.

Students conjectured that this irrelevancy of material was related to the diverse and inconsistent ways ITP courses are taught. Aaron expressed,

> I think the material is not maybe taught exactly the same between different colleges and even different classes in every college. I feel like each professor's ideas about proofs and kind of the important groups to teach are different […] I think it would be hard to find specific videos on exactly what we were learning.

This mirrors what David & Zazkis (2020) found when noting the various ways ITP courses are implemented in the U.S. The wide variety of online resources available for pre-proof courses contrasts with the specificity required in proof-based learning, where students struggled to find resources that they found relevant to their ITP course content.

Theme 3: Instructor modeling & course structure. Finally, we noted that change was sometimes motivated by the format of the ITP course itself. The *Instructor Modeling* portion reflects moments when students explicitly mentioned adopting a resource after seeing their instructor using or advocating for the resources during instruction in their ITP class. Aaron and Dana mentioned instructor modeling as a reason for their adoption of certain resources in ITP. When it came to Brainstorming, Aaron noted, "our professor makes us think a lot before we talk

to our group mates. She's like, 'look at it for like 3 or 4 min.' So, then I just do that. And then I guess that kind of just stuck." Aaron mentioned not using this resource previously in calculus contexts, instead choosing to "start writing stuff down almost immediately." Similarly, Aaron mentioned using set diagrams and drawings of geometric shapes in ITP explicitly because the instructor used that resource in class while not finding a need for visual means in calculus. Dana had a similar relationship to the Visual Aids Resource, finding that set diagrams were a great way to visualize material in ITP, despite preferring equations to graphs in calculus contexts.

Generally, this theme represents the recurring instances where students mentioned the overall structure and content of the course (and the implementation of that content) as a motivator for resource adoption in their ITP course. One such motivator was the allotment of class time to use particular resources. Chris used the Peers resource in ITP but not in calculus contexts, noting that, "I think [ITP course] is special, because we had peer discussion. We, I also wanted to, like, note down my thought process during it. But in Calculus 2, [it] is pretty much like taking notes from the professor." Because Chris was explicitly given the time to talk with peers in their course, he utilized that resource. Other such motivators include being given additional unassigned homework problems that could serve as Practice Problems, accessing course slides that served as a notetaking guide for Class Notes, and leveraging handouts given as Course Materials. Though these aren't motivators specific to ITP courses, they seem to indicate a necessary condition for the use of some resources: to be allowed access and permission to use said resource in the course.

Discussion

Overall, the themes noted in these students' motivators for changes in learning approaches paint a picture of the transition to proof as being one of uncertainty and novelty, echoing what has been previously found about the challenges of the transition to proof (Selden, 2012; Stylianides & Stylianides, 2009). The students reflected on using a variety of learning approaches in their ITP course, both adapting resources from pre-proof math classes and adopting new resources. They also commented on the factors that motivated some of these changes in learning approaches. We noted the novelty of the material leading to difficulty and struggle, the resources lacking relevance to their course context, and a reliance on instructor modeling for effectively studying in the ITP course as themes in motivation. The overall student discomfort in the midst of transition is exemplified by Chris, who said, "Sometimes [in ITP course], like, the concept is fairly abstract. So, I would have to, like, go to office hours to ask for, like, more detail [...] but in calculus, everything that I learned is pretty much, like, computable. Like, you can calculate it easily. So, it's more thorough." While this is a single example, the comments and tone of the students we interviewed indicated a general discomfort and feeling of uncertainty, especially noting the loss of calculation, a solving technique they felt comfortable with.

This research project serves as a starting point for better understanding the types of resources used by students in ITP courses, particularly compared to previous learning approaches they applied in pre-proof contexts. Future work may expand on this study by increasing the number of participants or leveraging the list of student-mentioned learning approaches to run a broader survey-based study asking students to reflect on their use of some of the mentioned learning approaches. In light of our last theme, if instructor modeling and course structure are motivating to adopt new learning approaches, these components could be used intentionally to foster effective approaches and support students as they are introduced to the novel and abstract world of proof.

"I Only Have One Black Student… With a Sample Size of One, It's Hard to Say": A Critical Analysis of Epistemology in Mathematicians' Racial Sensemaking

R. Taylor McNeill
Michigan State University

Mathematics departments nationwide are tasked with addressing racial inequities, including students' racialized experiences in calculus courses. Faculty must interpret racial information critically to advance equity through change initiatives. However, mathematicians often hold colorblind views of instruction that are reinforced by mathematics epistemological values, such as neutrality and objectivity. It is, thus, unclear whether mathematics epistemology inhibits the advancement of racial equity within mathematics departments. This analysis reports on racial sensemaking among 22 mathematicians at a research-intensive university amidst a reform effort to improve Black and Latin students' calculus experiences. Guided by theories of epistemic culture, I compare mathematicians' mathematical interpretations of racial phenomena with those proposed by critical race theory. Findings exhibit how mathematicians conflated contextualizing racial information with stereotyping, and focused on quantities without recognition of students' lived experiences or the social justice implications of their arguments. Implications are provided for using epistemology as a lever for change.*

Keywords: epistemology, mathematics faculty, critical race theory

Study Purpose & Background

Postsecondary mathematics is rife with racial inequity. For example, at the entry level, racialized pressure and isolation in undergraduate calculus can demand additional labor from Black and Latin*[1] students to persist in science and mathematics fields (Battey et al., 2022). At the faculty level, racial dynamics in mentorship and collaboration can contribute to differences in early-career support and faculty development (McNeill & Jefferson, 2024). While these racial issues are, arguably, produced by mathematicians, mathematicians are also tasked with remediating such inequities. For example, research aiming to advance calculus instruction recommends that mathematics departments collect and interpret local data to guide improvements (e.g., Zazkis & Nuñez, 2015). Research focused on practitioner inquiry into higher education inequities emphasizes that faculty must approach such work with equity-mindedness to resist colorblind or deficit interpretations of racial phenomena (Dowd & Bensimon, 2015). However, faculty in mathematics often hold colorblind interpretations of instruction (McNeill et al., 2022; King et al., 2023). It is unclear, then, whether mathematics faculty are prepared to critically interpret racial data when these same racial phenomena may escape their awareness in their teaching and other professional work.

How one curates and interprets information to generate knowledge is a question of epistemology. Disciplinary epistemologies can influence how faculty consider racial issues in their professional work. For example, in a study exploring equity in doctoral admissions, Posselt (2015) found that disciplinary theories, epistemologies, and methodologies shaped committees' perceptions of applicants' qualifications. For example, in the highly quantitative field of

[1] The term, Latin*, is inclusive of all genders (Salinas, 2020). Our use of Latin* avoids the patriarchal use of "Latino" to describe people of Latin American descent.

economics, "economists not only looked for quantitative expertise; they also relied primarily on quantitative measures to gauge quantitative expertise" (p. 818), while philosophers were "deeply uncomfortable with the false precision" (p. 821) of quantitative rankings. These different epistemological orientations played a role in committees' reliance on racialized metrics for evaluating applicants. Similar evidence of interplay between disciplinary epistemology and racial equity has also been found in mathematics departments. For example, mathematics departments can employ seemingly-neutral quantitative metrics for faculty evaluation that invisibly reward traditionally white achievements while neglecting Black women faculty's less traditional scholarly work (McNeill & Jefferson, 2024). Similarly, mathematicians' views of mathematics as fixed and pre-existing parallel common perceptions of students' mathematics ability as fixed and innate, reinforcing inequitable practices like tracking (Burton, 2004).

In the social sciences, the epistemologies promoted by critical race theory (e.g., Delgado & Stefancic, 2023) have become an accepted standard for antiracist thinking. However, mathematical thinking holds a privileged position in society (Gutiérrez, 2013) and many mathematicians believe that mathematical thinking is the purest form of reason (Burton, 2004). For this reason, developing mathematicians' capacity for addressing racial inequity may require unsettling deeply entrenched ways of thinking that are believed to be superior.

The present analysis uses the context of a calculus program's equity-oriented reform effort to examine mathematics epistemological values (MEVs) in mathematicians' racial sensemaking. To inform mathematics faculty development initiatives that seek to advance racial equity, the present analysis explores the following questions. What role do MEVs play in mathematicians' sensemaking about racial (in)equity in undergraduate calculus? How do these mathematical interpretations of race compare to those established through critical race epistemologies?

Epistemic Cultures

Knorr Cetina's theory of epistemic cultures (1999) guided the analysis. Epistemic cultures are "cultures of knowledge societies" (p. 241). More specifically, epistemic cultures arise when an "internally referential" (p. 2) community generates and codifies knowledge based on a largely shared set of epistemological values. Disciplinary communities, such as mathematicians or critical race theorists, are examples of such communities as they each hold values and practices related to the creation of knowledge that are largely distinct from everyday thinking. I hold these two epistemic cultures as the subject of examination and summarize their epistemologies.

Mathematics Epistemological Values

Although there is no universal definition of mathematics, mathematics can be characterized as relating either to proof or to application (Hacking, 2014). Mathematicians generate knowledge from the epistemological practice of proving claims via arguments based in formal logic and reliant on axioms. Although applied mathematics is intertwined with proof-based mathematics, applied mathematics is often distinguished by its use of computations which "proceed in a mechanical way by set rules" (Hacking, 2014, p. 145).

The notion that mathematical arguments constitute "proof" highlights common perceptions of mathematical claims as unequivocally, universally true or false (Burton, 2004; Hacking, 2014). Indeed, when studying how mathematicians generate knowledge, Burton (2004) found that 90% of mathematicians held an objectivist, positivist view of mathematics as existing independent of human thought. Beyond this, mathematicians tended to view mathematics as "the highest form of rationality" (p. 6), and as governing the nature of reality, even beyond the scientific. However, as with all human endeavors, the mechanisms for building mathematical

knowledge are socially constructed (Knorr Cetina, 1999). For example, there are ambiguities related to what constitutes formal logic and what constitutes an axiom (Dutilh Novaes, 2011; Shapiro, 2004). Furthermore, despite framings of mathematics as objective, aesthetics, affect and intuition play centrally in mathematicians' knowledge generation (Burton 2004).

Critical Race Theory & QuantCrit as Epistemological Values

CRT originated in legal studies and theorizes how race and racism operate in U.S. society. Characterizations of CRT vary, but share a core set of beliefs including: (1) CRT recognizes that racism is endemic to American life; (2) CRT expresses skepticism toward dominant legal claims of neutrality, objectivity, colorblindness and meritocracy; (3) CRT challenges ahistoricism… [and] presumes that racism has contributed to all contemporary manifestations of group advantage and disadvantage along racial lines; (4) CRT insists on recognition of the experiential knowledge of people of color; (5) CRT is interdisciplinary; and (6) CRT works towards the end of eliminating racial oppression as part of a broader goal of ending all forms of oppression (Mastuda et al., 1993, p. 6). CRT can also be seen as a set of epistemological values describing ways that knowledge about race and racism is generated. For example, CRT suggests that the lived experiences of students of color are valuable sources of knowledge about race and racism, while ahistorical, decontextualized comparisons of mathematics achievement among white students and students of color are less robust sources of knowledge.

CRT has primarily been engaged in qualitative contexts and some scholars "remain skeptical about the possibility that numbers can ever fully capture the 'material impact' of intersectional racism" (Gillborn et al., 2018, p. 169). However, given the power and utility of numerical information in American society, a quantitative extension of CRT, known as QuantCrit, has been developed that incorporates similar principles. In addition to CRT principles of advancing social justice and understanding racism as ordinary in American society, QuantCrit takes as given that: (1) Numbers are not neutral; (2) Racial categories are socially constructed; and (3) Data cannot speak for itself and must be contextualized by the experiential knowledge of people of color.

Methods

Research Context and Participants

This study took place at Wesselman University, a large, elite, predominantly white, research-intensive university in the southern U.S. During the 2022-2023 academic year, the mathematics department had approximately 30 tenure-track faculty, 20 postdoctoral faculty, 10 senior lecturers, and 25 doctoral students. The demographics of the entire teaching staff were approximately 70% white and 85% male. During the same year, the domestic undergraduate population was roughly 40% white, 20% Asian American, 10% Black, 10% Latin*, 5% multiracial, and 5% unknown race.

In 2020, university administration identified a need to improve the calculus program, particularly to ameliorate racial disparities in calculus grades and attrition from STEM majors. A research team began a collaboration with the Wesselman mathematics department in Spring 2021 to support this reform effort. Our partnership took three phases: (1) Documenting Black and Latin* students' experiences in calculus; (2) Exploring instructor and stakeholder sensemaking about racial equity, and (3) Facilitating professional development with calculus staff. The present analysis is based on data from the study's second phase.

Prior to the beginning of the Fall 2022 semester, instructors teaching calculus I courses were invited to participate in the study at an in-person meeting of calculus staff, and again through

email. Faculty who were stakeholders in the calculus reform effort, such as the department chair, the coordinator for calculus courses, the director of undergraduate studies, and members of the "rethinking calculus" committee, were also invited to participate through email. All who expressed interest participated. In this report, I describe participants in aggregate to preserve anonymity given the unique departmental context. The 22 participants consisted of 11 calculus instructors (five lecturers and six doctoral students) and 13 stakeholders (seven tenure-track faculty members, five lecturers, and a postdoctoral scholar), with two participants serving in both instructor and stakeholder roles. Participants were majority white and men.

Researcher Positionality

In alignment with CRT's rejection of objectivity, I do not detach myself from the present analysis, but instead harness my personal experiences at the juncture of mathematics and social science contexts as a source for knowledge production. I am a white transgender person that holds doctoral training and faculty experience in both mathematics and education fields. While I perceive myself as belonging to the epistemic culture of critical race theorists, my past and present experiences immersed in the culture of mathematics have allowed me to engage either set of epistemic machinery with relative ease. I leveraged this ability while coding to critically evaluate the epistemological underpinnings of participants' reasoning.

I spent three and a half years in partnership with Wesselman mathematics, serving as a researcher, a calculus instructor, and an instructor educator. I frequently experienced the epistemological conflicts that this analysis formally characterizes first-hand. This first-hand experience, combined with my prolonged collaboration with Wesselman mathematics, contribute to the study's trustworthiness.

Data Collection and Analysis

Data consists of interviews which were semi-structured, audio recorded, and transcribed verbatim. Interviews averaged one hour in length, with stakeholders participating in one interview and instructors participating in four. Interview questions solicited participants' perspectives on the role of race in calculus courses and related changes to the calculus program. As examples, stakeholders were asked, "How do you think proposed changes to calculus courses would impact Black and Latin* students' experiences?" Instructors were asked, "How do you see race playing a role in students' experiences or opportunities for success in your course?"

The theory of epistemic cultures guided a data analysis that followed an open, axial, and selective coding scheme (Strauss & Corbin, 1998). Two sets of open codes were used to flag data for implicit epistemological values. One set of open codes captured participants' use or rejection of MEVs. This included instances where participants discussed numbers, used mathematical language (e.g., "sample size," "it follows that"), or otherwise employed mathematical reasoning (e.g., testing a generalization by looking for counter examples), as well as instances where participants framed mathematical thinking as irrelevant or unhelpful. These codes helped to understand how participants did and did not use MEVs in their racial sensemaking, addressing the first research question. Another set of open codes flagged epistemological orientations to race, including excerpts that agreed or contrasted with the CRT and QuantCrit.

Axial coding found connections between the two sets of open codes, addressing the second research question comparing mathematical and CRT interpretations of racial phenomena. Specifically, axial codes identified categories at the intersection of these open codes, where included excerpts engaged or rejected MEVs in similar ways, and shared a common relationship

with CRT epistemologies. Lastly, selective coding extracted thematic relationships between MEVs and CRT epistemological values.

Findings

Although data contained instances in which participants rejected MEVs or engaged MEVs in ways that aligned with CRT epistemologies, participants most often engaged MEVs uncritically in ways that contrasted with CRT epistemologies. In what follows I demonstrate three themes that arose: (1) Using quantitative arguments to naturalize racial inequality; (2) Focusing on representation over experiences; and (3) Conflating contextualization with stereotyping.

Using Quantitative Arguments to Naturalize Racial Inequality

Participants engaged epistemologies of mathematics in their interpretations of large-scale information such as racial disparities in students' grades across disciplines. It was common for participants to question the methods by which large-scale statistics were calculated, as well as their interpretation. Through this, participants framed racial inequity as minimal and exempted themselves from responsibility for remediating racial inequity. For example, some participants denied that racial disparities in grades were cause for concern in mathematics, arguing that grade inflation in other departments produced compression that simply made racial disparities appear less pronounced: "Once you normalize students' GPAs by GPA average in departments, it's not clear how much the problem is centered in math." Similarly, another participant argued,

> This [racial] disparity [in grades]… the statistics were not done right because you have to divide by the variation, the sigma... mathematics classes could have a huge variation, while, let's say English can have a very small variation. If you do that, then everybody is actually falling correctly more or less.

The use of the word "correctly" is notable as it naturalizes the unequal distribution of grades among racial groups. However, its juxtaposition with statistical computations makes this subjective naturalization of racialized grades appear objective. Other participants similarly used quantities to naturalize racial disparities.

> I don't know what the expectation is from the university for the calculus classes… Less people who are Black, Latinos, to fail?... All of them, they don't want to fail?... Let's say you have all of your Black and white students get a similar SAT score, [but] Black students [are] doing worse in calculus. Then that, to me, that's a great problem. But if students with around the same SAT score stay around the same, more or less, then to me that's a lesser problem.

Expecting students with similar standardized test scores to have similar levels of achievement in calculus is a mathematical framing that may seem neutral because it suggests that Wesselman mathematics courses do not exacerbate racial disparities. This frames the perpetuation of preexisting racialized disparities in mathematics achievement as natural.

These interpretations contrast with the epistemological values of CRT and QuantCrit. The idea that any mathematical framing of racial issues is "correct" relies on notions that mathematics is objective. This directly opposes QuantCrit's position that numbers are not neutral and contrasts with CRT's rejection of objectivity. Furthermore, these examples argue against remediating racial inequities in students' grades, conflicting with CRT's social justice aims.

Focusing on Representation Over Experiences

Participants' focus on racial representation to the exclusion of acknowledging students' racialized experiences also illustrated the influence of MEVs. For example, when I shared preliminary findings with the department showcasing narratives from Black and Latin* students,

I heard that faculty had "disagreements with your presentation" because "the data was not quantitative." Instead, participants often focused on percentages and probabilities, neglecting the human experiences that accompany these figures. For example, when interpreting a Black student's narrative of racial hypervisibility when participating in a class where white students dominated discussion, one participant reasoned,

> If there is one dominant student in the class, race aside, your odds of being the dominant student in the class are one in however big the class is. And if you are already in a minority of the people in that class, your odds of being the dominant... it's like these differences are exacerbated by the very fact that they're already in a minority.

The participant uses the mathematical meaning of "minority" (a number that is less than half of the total) and frames racial inequity as a byproduct of the class's racial representation rather than resulting from issues of power and privilege. Participants focused on probabilities and representation even when describing their goals for advancing racial equity. When responding to the same prompt about racialized participation dynamics, another shared,

> I would guess that I'm fitting into fairly standard trends in terms of participation. I think I can get my minority students to speak up a little bit… Yesterday, I think I had two Black students speak up, actually, when I asked questions. So, I'm getting some in there. But... even accounting for probabilities, I would say my white students are much more willing to speak up, even compared to Asian students.

The participant's reflection implicitly frames Black students speaking in class as the goal and does not consider the quality of their learning experiences. Their remark that two Black students spoke, combined with their consideration of probabilities, frames racial equity as numerical.

Both CRT and QuantCrit emphasize the importance of lived experience as a source of knowledge. The QuantCrit value of contextualizing numerical information within experiential knowledge directly contrasts with participants' inattention to students' affective experiences.

Conflating Contextualization with Stereotyping

Participants were extremely hesitant to provide racial interpretations of their instructional observations. Although this was not explicitly mathematical, participants' engagement of mathematical language such as "sample size" and "conjecture" suggested that their sensemaking was influenced by MEVs. For example, when asked their perception of whether race played a role in a successful white student's performance, one participant shared, "Everything I'm about to say is conjecture… but I think she's Russian. Russia has a strong mathematical culture… maybe there's something there." The term "conjecture," in the context of mathematics, describes an act of generalizing from one or more cases to make a universal claim. The participant's hesitation to provide a racial interpretation, combined with their use of "conjecture," implicitly suggests that they equate interpreting racial observations with generalizing or stereotyping. This is also evidenced in the following excerpt, in which a participant was asked to describe their racial observations related to participation in their classroom. The participant, unprompted, voiced skepticism about the validity of a racial generalization one might draw from their observation, using MEVs as justification: "I only have one Black student. He doesn't participate a ton… With a sample size of one, it's hard to say. Is that all of the Black students, or that this one guy is kind of quiet?" The participant's consideration of the "sample size" suggests that knowledge of race should rely on statistically significant trends. Given that generalizing is a common and valued mathematical practice while placing information in a sociohistorical context is relatively less common, it is possible that MEVs shaped participants' misunderstanding of tasks which asked them to contextualize their instructional observations.

CRT and QuantCrit presume that racism is ordinary in American society and plays a role in producing present-day inequities that fall along racial lines. This includes inequities in prior educational opportunities or access to classroom participation. Furthermore, CRT's refusal of colorblindness encourages consideration of racial elements of events that may be seemingly neutral at face value. Hence, a CRT perspective would presume that race plays a role in students' calculus experiences while holding an antiessentialist assumption that race influences students' learning in different ways.

Discussion & Implications

K-12 mathematics education scholars have long critiqued school mathematics as grounded in white, middle-class values that perpetuate racial oppression (e.g., Ladson Billings, 1997). Postsecondary mathematics has been historically shaped by the same global forces of white supremacy and antiblackness (McNeill & Jefferson, 2024; Bishop, 1990; Hottinger, 2016). However, interrogation of the mathematics discipline at this level has been much more limited. Some scholarship has illustrated how dominant epistemological values in mathematics can reinforce the oppression experienced by students of color (Adiredja & Zandieh, 2020; Street 2024). The present analysis extends these findings, demonstrating that dominant epistemological values may reinforce oppression, not just when students' engage with mathematics, but in any context where mathematical thinking and racial issues collide. For example, Adiredja and Zandeih (2020) describe how linear algebra examples produced by women of color and based on their everyday experiences could readily be dismissed as "idiosyncratic" (p. 254) in the dominant mathematical view. The present analysis illustrates that mathematicians may readily dismiss the racial experiences of individuals as idiosyncratic more generally, potentially because dominant epistemologies of mathematics assign little value to individual cases.

Implications for Developing Mathematicians' Critical Consciousness

Faculty development programs focused on issues of equity are becoming more commonplace (Castillo-Montoya et al., 2023). However, equity-focused development programs for mathematics faculty demonstrate mixed efficacy (e.g., Ching, 2018). The present findings demonstrate that mathematicians' sensemaking about race exhibits mathematical features. This suggests that developing racial consciousness may require mathematics faculty to critically re-evaluate the epistemic machinery they employ to consider racial issues. However, given the privilege that mathematical thinking receives in society, it may be unlikely that mathematics faculty doubt their epistemological approaches. Those engaged in developing mathematics faculty racial consciousness should consider making critical epistemological approaches explicit for faculty and addressing epistemological conflicts that faculty raise.

Implications for Research: Conceptualizing a Critical Mathematics Epistemology

The present analysis demonstrates ways that mathematical and antiracist thinking conflicted. However, this is not to say that mathematical thinking is inherently oppressive. A body of research in K-12 education contexts has worked towards reconceptualizing mathematics as critical and liberatory (e.g., Gutiérrez, 2018; Gutstein, 2012; Martin, 2019). Despite the fact that people of color practice mathematics at all levels, critical postsecondary mathematics is undertheorized. Critical race epistemologies suggest that the lived experiences of mathematicians of color may be a valuable resource for such knowledge generation. Future research should explore how mathematicians of color engage mathematics in critical sensemaking to support an epistemic culture change in mathematics.

Identifying and Categorizing Instructor Considerations for Active Learning Implementation

Ben Bruncati

Lindy Hearne
Virginia Tech

Keith Weber
Rutgers University

Estrella Johnson
Virginia Tech

Tim Fukawa-Connelly
Temple University

In this paper, we discuss our experience collaborating with mathematicians to increase their use of active learning pedagogy in a proof-based linear algebra course. We use this experience to attend to three primary research objectives. First, we identified three primary categories of instructor considerations that would determine whether or not they would incorporate a proposed strategy. Second, we observed and made sense of which of these were most prominent for these mathematicians. Third, we determined what combination of considerations needed to be satisfied to warrant the implementation of a strategy by these mathematicians.

Keywords: Active learning; changing pedagogical practice; linear algebra; university mathematics instruction

When Michelle Artigue (2016) reflected on her career as a researcher in undergraduate mathematics education, she lamented that one of the field's biggest weaknesses was its lack of impact on how undergraduate mathematics courses were taught. Specifically, Artigue was alarmed by the "insufficient dissemination of research results towards the relevant communities or practitioners, and the very limited influence of our research on university teaching practices." (p. 12). Indeed, it is still the case that most university mathematics courses are taught predominantly by lecture (Fukawa-Connelly et al., 2017; Johnson et al., 2018; Johnson, 2019), even though effective, research-based, alternatives are available and have shown positive effects on student learning outcome (see Freeman et al., 2014).

To redress the lack of impact of undergraduate mathematics education research, Artigue (2016) recommended that mathematics educators form "collaborative projects, building and negotiating, jointly with mathematicians and other university teachers, problématiques that make sense for all those involved, and meet their respective interests and needs" (p. 12). In this study, we follow Artigue's suggestion of utilizing collaborative teams between mathematics education researchers and mathematicians to offer insight into instructional change. We describe a collaborative project between mathematics education researchers and mathematicians in which we together attempted to integrate active learning pedagogy into mathematicians' lectures in a proof-based linear algebra course.

In conducting this study, we found that some active-learning activities that seem easy to integrate into a lecture from the perspective of mathematics education researchers were rejected as infeasible from the perspective of the mathematician. Our research aim here was to better understand features of active learning strategies that contribute to their feasibility. In order to do so, we needed to identify considerations, such as obligations and goals, held by the mathematicians we were working with. We then considered the features of the instructional strategies in relation to these considerations to determine what combination of criteria needed to be met for a suggested instructional strategy to be feasible.

Literature Review

Fukawa-Connelly et al. (2016) found that among lecturers "56 percent agreed (and 26 percent more slightly agreed) with the statement I think students learn better when they do mathematical work (in addition to taking notes and attending to the lecture) in class" (p. 279). Yet when mathematics educators have observed class meetings in university mathematics courses, active learning strategies were rarely used (e.g., Fukawa-Connelly et al., 2017). It may be the case that some mathematicians feel that the questions that they ask during class time are sufficient to engage students and have them actively think about the material, or it may be the case that some mathematicians believe the limited active learning that teacher questioning provides is all these teachers can offer if they have the obligation to cover the course material (Woods & Weber, 2020). Alternatively, some mathematicians might be unaware of plausible alternatives to lecturing and still others might feel they lack the time to learn a new way of teaching due to other professional obligations (Johnson et al., 2018). Or perhaps, mathematics educators do not fully understand what it means, to mathematicians, for students to 'do mathematical work' in class. Perhaps this is partially due to "active learning" itself not being well-defined.

Braun et al. (2017) observed that, although recommendations to introduce active learning into university mathematics classrooms are commonplace, there is not a shared understanding for what active learning pedagogy is. In this paper, we follow the Conference Board of the Mathematical Sciences in defining *active learning pedagogy* broadly, where active learning pedagogy refers "to classroom practices that engage students in activities, such as reading, writing, discussion, or problem solving that promote higher-order thinking" (as cited in Braun et al., 2017, p. 124). In other words, active learning in which students are engaged in some activity involving mathematical content that does not involve passively listening to a lecture or practicing procedures. One approach is to use short active learning activities, such as think-pair-share questions or clicker questions, which can augment lectures. While these activities have been used in primary and secondary mathematics classrooms, as well as university physics classrooms (e.g., Crouch & Mazur, 2021), they have been the subject of limited research in undergraduate proof-based mathematics courses (Melhuish et al., 2022, but see Alcock, 2018, and Iannone & Miller, 2019, for exceptions).

Herbst and Chazan (2003) observed that when mathematics teachers do not adapt reform-oriented recommendations for changing instruction, some mathematics educators attribute this to the teachers suffering from a "lack of knowledge or a paucity of vision" (p. 3). Herbst and Chazan argue that this stance is counterproductive. Teachers are not free to teach in any manner that they choose. Rather, they chose to honor obligations to their discipline, to their students, and to their institutions (Chazan et al., 2016). Many instructional decisions, especially in choosing whether to use, or how to adapt, reform-oriented instruction, involve managing conflicting obligations. Here, in understanding our mathematicians' reactions to suggested instructional strategies, we are looking to understand their obligations and their goals for instruction.

Context and Methods

This study took place at a large northeastern university in the United States and involved a collaboration between mathematics educators and mathematicians, where both groups worked together in six weekly meetings to incorporate active learning strategies into a proof-based linear algebra course. The course presented an axiomatic treatment of abstract vector spaces and linear transformation on those spaces and covered topics such as eigenvectors and eigenvalues, the

Jordan canonical form and its associated theorems, and inner product spaces. The research team included the three final authors and four mathematicians agreed to participate in this study. All meetings were recorded over Zoom and transcribed. Only three of the four instructors could fully attend meetings regularly, so only three were included in this analysis.

During each meeting, the mathematics education research team proposed an active learning pedagogical strategy that mathematicians were asked to incorporate into their lessons. After a strategy was agreed upon, its implementation was discussed. The implementation involved choosing specific questions (e.g., if an exit ticket was to be used, what would the specific prompt be?) and the practical issues of how the strategy would be employed in the classroom context (e.g., if an exit ticket was to be used, how would the prompt be given to students and what student artifacts would the instructor collect?) In general, the mathematics education research team would provide mathematicians with an array of questions which mathematicians could then choose to use or adapt. In following meetings, the groups would debrief on how the active learning strategy went, what benefits and shortcomings this might have had from the mathematicians' perspectives, and what changes might be needed for this to be viable in the future.

In analyzing transcripts from the six collaborative planning meetings, we used the method of constant comparison through the grounded theory approach (Strauss and Corbin, 1994) to form a preliminary codebook. First, we began by looking at the data through the lens of Obligations, Instructor Goals, and Features for Implementation. Then, we flagged instructor comments which aligned with these larger themes, resulting in a codebook including these three categories as parent codes. Subcodes were identified by looking for commonalities and recurring themes within each parent code.

The Obligations category included *Time*, *Institutional*, and *Student Preference* as subcodes. The Instructor Goals category included *Building Math Understanding* and *Attending to Social/Emotional Needs of the Student* as subcodes. The final category, Features for Implementation, included *Ease of Use*, *Features of Question Posed*, *Mathematical Features of Question*, and *Student Cognitive Resources and Perspective* as subcodes. Then, we checked for co-coding to observe potential relationships between (1) obligations and features and (2) features and goals for these three linear algebra instructors. Below are three tables defining the subcodes from each category with examples and occurrence counts between all three instructors.

Table 1. A table of Obligations subcode definitions with examples and counts of their emergence.

Obligations			
Subcode	Definition	Example	Count
Time	Available time for class meetings and to cover topics.	"My biggest adversary in the classroom when I'm teaching is the clock on the wall."	74
Institutional	University-set expectations for the course	"The material should really emphasize vector spaces which are not $\mathbb{R}^n$	50

Table 1. A table of Obligations subcode definitions with examples and counts of their emergence.

	and students' prior knowledge.	because otherwise it's 250 material."	
Student Preference	What students are likely to do or how they will react.	"If you ask them to watch a video, I suspect a lot of them will not watch. That is the problem."	37

Table 2. A table of Instructor Goals subcode definitions with examples and counts of their emergence.

Instructor Goals			
Subcode	Definition	Example	Count
Building Math Understanding	Developing students' mathematical rigor and intuition.	"There are students who understand the mechanics and the concepts, but what they have difficulty with is the flow of the logic."	84
Social/Emotional Needs of the Student	Engaging with students, attending to what they want to learn, and potential social influences.	"One thing that I'm trying to get out of active learning is a chance to talk to the students one on one… they'll ask questions they're embarrassed to ask."	44

Table 3. A table of Features for Implementation subcode definitions with examples and counts of their emergence.

Features for Implementation			
Subcode	Definition	Example	Count
Ease of Use	Planning required to implement.	"This is something I should have in my pocket. I need to know what I'm giving at the end."	74

Table 3. A table of Features for Implementation subcode definitions with examples and counts of their emergence.

Features of Question Posed	Easy to comprehend or short questions.	"I wanted to make these so that students don't need a lot of time and can just get to what they want to decide."	38
Mathematical Features of Question	Questions emphasizing particular math concepts.	"What's wrong if you just define the distance as the inner product of a vector within itself?"	85
Student Cognitive Resources and Perspective	Instructor beliefs about students' abilities.	"If you want them to create something, that's impossible for the beginning. So I have to give them an example."	37

Results and Discussion

Using Atlas.ti software, a table of code occurrences was developed to identify the prominent Obligations, Instructor Goals, and Features for Implementation influencing the use of suggested strategies by the three linear algebra instructors. The predominant Obligation from the collective analysis was *Time* which was referenced 74 times between all three instructors. The predominant Instructor Goal was *Building Mathematical Understanding* which was discussed 84 times. The predominant Feature for Implementation was *Mathematical Features of Question* which was mentioned 85 times. Although these aspects were identified to be most significant in the collective analysis, other key factors surfaced when investigating the respective profiles of the three instructors.

Time was the most referenced Obligation and *Building Math Understanding* was the most prominent Instructor Goal for all three instructors respectively; however, variation emerged between instructors regarding the Features for Implementation category. The primary Feature for Implementation for both Instructor C and Instructor Y was *Mathematical Features of Question*. Of all three categories, Instructor C spoke most often about concerns regarding the *Mathematical Features of Question* which was followed by *Time*. Instructor Y also spoke most often about the *Mathematical Features of Question* and *Time*. However, Instructor S primarily discussed *Ease of Use* and *Building Math Understanding*. *Mathematical Features of Question* was one of the least mentioned considerations for Instructor S.

In addition to how frequently certain topics were mentioned, the instructors expressed their openness to more engaging practices such as student discussions but would conclude that there was simply not enough time allotted. This underscores the need to align with institutionally imposed obligations and its precedence over instructor interest. Similarly, instructors' need to attend to specific mathematical features stems from this dominant institutional priority to cover required content and distinguish the course from its calculation-based predecessor. Instructors at

times chose to modify questions to attend to these considerations and reinforce their goal of building students' intuition and rigor. With these findings, the first two authors constructed Figure 1 to showcase the collective impact of the most commonly discussed institutional requirements and student-related considerations on the implementation of proposed strategies.

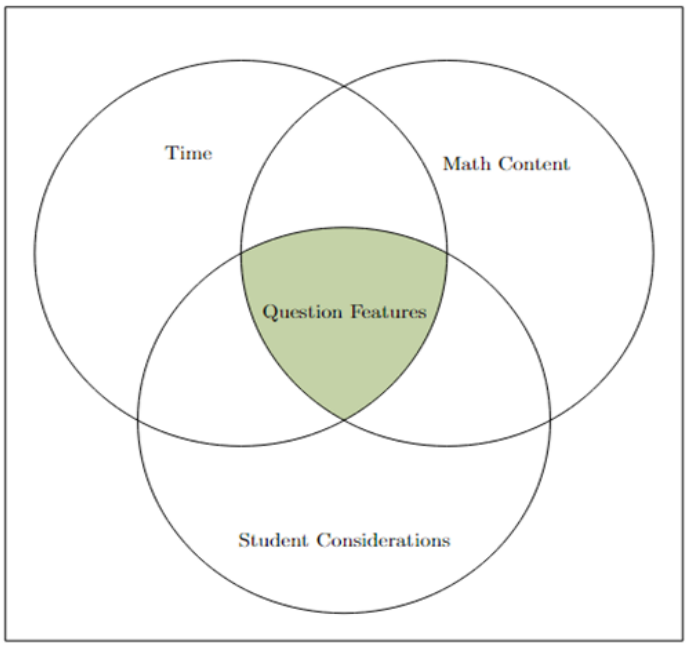

Figure 1. A three-circle Venn diagram illustrating the prominent considerations for implementing a proposed strategy.

Considering its prevalence from the collective analysis, Time reserves its own circle of the diagram. Time impacts some previously mentioned considerations for implementation, such as needing to satisfy university-set course expectations and the planning required to do so while incorporating a new strategy. Math Content was assigned its own circle given the emphasis placed on Building Math Understanding and Mathematical Features of Question. Finally, Student Considerations encompass the collective influence of Student Preference, Social/Emotional Needs of the Student, and Student Cognitive Resources and Perspective. Although these may not have been as commonly mentioned compared to the other two circles, each instructor did attend to how their students may respond or did respond to their efforts to implement a strategy or expressed beliefs concerning their students' mathematical or cognitive abilities.

This Venn diagram also provides the criteria these instructors deemed important to satisfy when considering implementing a proposed strategy. More specifically, the nature of the questions being used for a proposed strategy sits at the intersection of all three circles. Short, easy to comprehend, and mathematically precise questions seemed to be perceived as the most feasible option for instructors to adapt and incorporate into their lessons and planning. The instructors expressed that shorter and easy to comprehend clicker questions would meet their need for questions that could be answered quickly to alleviate timing concerns and reduce anticipated difficulty unrelated to the mathematical content. Mathematical precision was also

emphasized, especially by Instructor Y and Instructor C, to mitigate potential issues regarding term definitions and emphasize the significance of aspects such as vector spaces.

To distinguish this course from the previous, conceptual questions seemed to be of greater interest than calculation-based questions, which may also be due to interest in quicker questions. Additionally, such questions which also pinpoint whether a common misconception has been addressed or not was observed to be an important feature. A final component which resonated with all instructors was planning certain questions to be given after students had time to reflect on what they had learned outside of class time. The instructors expressed apprehension toward providing Exit Tickets on concepts students had just learned based on their beliefs that students would not fully understand the concepts that soon. Instructor S, for instance, instead chose to incorporate Do Now activities in the following class to check students' understanding of previous concepts before introducing new material.

Conclusion

Due to our small sample, we cannot claim that our results generalize to other mathematicians or to a context beyond a proof-based linear algebra course. In particular, we do not have grounds to claim that the obligations or goals that we outlined would be shared by other mathematicians or that others would agree with the features that made instructional strategies more feasible would be valued by others. However, we are able to make some observations about what appeared to matter most to these mathematicians as they considered implementing different active learning strategies.

In essence, the interaction between time spent covering the mathematical content and addressing student understanding is important as a constraint for the group of instructors we assessed. It was important for researchers to find the most time-efficient way to determine student understanding of the mathematics involved if they are hoping for their strategies to be implemented. This suggests that research requires the input of instructors who are aware of the most common misconceptions in the material to bridge the gap between research and what happens in the classroom. These findings also suggest that instructors may have found Do Now activities more time-efficient than Exit Tickets based on their intuition regarding students' window of retention.

Technology has become an integral part of undergraduate mathematics, particularly the use of technology to solve problems (i.e., the use of computation). In probability and statistics, this push has resulted in several projects designing and assessing tools that are conjectured to be advantageous to students and their learning. Despite this trend, minimal research exists on how students perceive the use of computational tools in their courses. As such, we designed a brief survey for students enrolled in introductory probability and statistics at a university in the Northeastern United States. Using thematic analysis, we qualitatively analyzed these survey responses to explore their perceptions of the integration of computation into their courses. Three themes were identified, relating to features of tools, augmentation of actions, and long-term benefits. This exploration of students' perceptions allows us to better understand their views on computation and the need for professors to make instructional goals explicit.

Keywords: Computation, Probability and Statistics Education, Student perceptions

There have long been pushes for the further integration of technology into educational settings (e.g., Bray & Tangney, 2017). While technology has been implemented in education in several ways (e.g., instructional videos), we are focused on computation (i.e., technology as a tool for solving problems) and computational tools (i.e., devices with computational capabilities). To that end, we follow diSessa's (2018) framing of the use of computation, as a form of literacy (i.e., computational literacy), shaping communities' activities.

According to diSessa (2018), mathematics is particularly well positioned to incorporate the use of computation. Indeed, there have been a number of studies probing the use of computation in mathematical contexts (Chan et al., 2023). These studies have identified a growing interest in the use of computation (Weintrop et al., 2016) and a range of tools being used within mathematics education (e.g., Scratch, MATLAB; Chan et al., 2023). This is further evidenced in the context of probability and statistics through calls to promote the inclusion of computation as a means of exploring and visualizing concepts (e.g., Carver et al., 2016).

Despite the growth in the use of technology and computation, specifically, in mathematics education, a question emerges as to students' perceptions of their use of computation. Namely, past research has identified the positive effects of using computation on learning statistics (Wilensky, 1995), features that computational tools should include (e.g., interactive capabilities; Johnson & Berenson, 2019), and a breadth of reasons for using computation (e.g., career preparedness; Nolan & Temple Lang, 2010), but it is not clear what students think about their professor's decision to use computation in their courses. In this study, we were guided by the following research question: *What are undergraduate mathematics students' perceptions of their professor's reasons for integrating computation and specific computational tools into their probability and statistics course?*

Literature Review

The origins of the value of modern computation in mathematics trace back to the work of Papert (1980) and the creation of Logo, a programming language that has been argued to offer unique perspectives and learning opportunities in mathematics. Since Papert, many new computational tools have been designed and the positive potential of computation in mathematics has been demonstrated (Bray & Tangney, 2017).

For example, Wilensky (1995) presented a study where computation led their students to understand an apparent mathematical paradox. Specifically, Wilensky had students use the computational tool of Starlogo, a programming language. The paradox explored in this study arises when tasked to find the probability that a chord of a circle, chosen at random, is longer than the radius of the circle. Mathematically, one's method for picking a random chord determines the solution and there are at least four valid methods (i.e., the answers to this question include ½, 2/3, ¾, and $\sqrt{3}/2$). In the study, after a student produced a solution (e.g., by constructing a chord through a process of fixing a point on the circle and letting the chord's endpoint vary), the researchers presented a different method for selecting a random chord and the resultant solution. After wrestling with the apparent paradox (i.e., two different, mathematically correct, solutions to the problem), the students were prompted to use programming to simulate the problem context. Through the process of writing the program, the students came to a crossroads about how to construct the chord. For many students, this process of programming resulted in the realization that one's decision on how to construct a random chord was the determining factor in the probability you derived. Wilensky argued that the use of programming was fundamental to this discovery and allowed students to gain new insights.

In another study, Basturk (2005) identified a difference in learning outcomes in a study that compared the performance of graduate students enrolled in an introductory statistics course with a computation lab to students who took the same course without a lab. In the treatment, the SPSS statistical software was used by students who met for an extra 40 minutes a week to work on computer exercises and use real data sets to apply concepts learned in lecture. Researchers found that students who used computation scored statistically higher on midterms and final exams than control students. Basturk concluded that SPSS was a useful tool for introductory statistics.

Beyond students' mathematical performance and thinking, the integration of technology has been conceptualized as an influential part of probability and statistics instruction (Nolan & Temple Lang, 2010). Nolan and Temple Lang (2010) argued that the use of computation is an important aspect of preparing students for their future careers because practicing statisticians are continually using and being influenced by advances in computation. As such, it is important for students to learn statistical content using computation and learn broader computational skills (e.g., data structures, debugging) that allow them to adapt to future tools. Despite the influence computation can have on students, it is unclear whether students or even instructors are aware of these advantages to using computation in introductory statistics courses.

Several studies have assumed the importance of computation in introductory statistics courses and sought to identify what tool best serves students. For example, Johnson and Berenson (2019) designed a study which ranked seven different computational tools along 11 different categories. The goal of this project was to identify specific aspects that made certain tools better for teaching and learning statistics. Three of the categories were classified as utility related (e.g., availability in the workplace, cost) and the remaining eight were classified as performance related (e.g., simplicity of access and downloading, user friendliness). Johnson and Berenson concluded that JMP, a menu-driven statistical software, served these criteria the best

and was a strong option for introduction to statistics. While some professors may have a similar list of considerations when choosing a computational tool for their courses, it is unlikely that these considerations are made explicit and that students are aware of the benefits of a given tool.

While several projects have identified reasons supporting the use of computation, it is possible that students do not perceive these affordances. For example, Povey and Ransom (2000) analyzed their undergraduates' journals kept over the course of a semester using computational tools like graphing calculators, Logo, and Excel and identified several surprising perceptions their students held about computation. Within these journals, "tales of resistance" (p. 48) toward these tools were identified. Specifically, students expressed concerns about being overly reliant on the tools, a lack of motivation in mathematics stemming from the use of the tools, and a lack of reflection produced by the speed and black-box nature of tools. While this study is from over two decades ago, it is reasonable for a disconnect to be present between the instructional goals of the use of computation and how students perceive the goals of computation as a whole.

Indeed, students' perceptions of their professors' goals do not always align with professors' goals. Lew et al. (2016) conducted a study comparing real analysis students' perceptions of the key points of a lecture to their professor's intended key points. Lew and colleagues reported a disconnect between what the professors of the study intended for their students to attend to and what students made note of as important. Similarly, this disconnect between objectives and students' perceptions has been identified in the use of instructional videos (Weinberg & Thomas, 2018). As such, inquiry into students' perceptions of why their professors integrated computation into their course is a needed lens for the use of computation in mathematics education.

Methods

Participants and Survey Design

To understand student perceptions of instructor goals for integration of computation into their probability and statistics course, we designed and administered a survey to students in an introductory probability and statistics course at a large, private, university in the Northeastern United States. This course was selected because the official course description mentions the use of computation. Each semester, this course is taught by five to eight different professors and serves over 400 students. Professors are given full authority to decide which computational tool they will use and how they will use it. A recruitment email was sent to eight professors who were teaching or recently taught the course, asking them to send out the survey to their students.

In the survey, students were provided a definition of computational tools, which we described as "a piece of technology used to solve problems and draw conclusions," and then they were asked who their professor was, to describe their background experience using computation, and to list the computational tools that were used in their class. Finally, two open-ended questions were posed: (a) "Why do you think your professor incorporated computation, **generally**, in your course?" and (b) "Why do you think your professor had you use that **specific** tool in your course?". We refer to these as the general and tool specific questions, respectively.

We received 106 responses from students from six different professors' classes. While no computation was required as a prerequisite, most students reported some background experience with Excel or Python. All students reported using at least one of three computational tools in their course: Minitab, R, or Python. Minitab is a menu-driven software built for statistics. R is a programming language used for statistical computation and visualization. Similar to R, Python is a programming language frequently taught in introductory computer science courses.

Thematic Analysis

As described by Braun and Clarke (2006), the six phases of thematic analysis were used to identify patterns in our students' responses. Phase 1 began by reviewing student responses and summarizing each response into short low inferential phrases. For instance, one student said, "[computation was used] in order to help visualize certain concepts through digital means." We captured this as *tools can be used to visualize concepts/graphs/data.* During this phase, several responses were omitted because the students did not respond to the question posed. For example, some students took the survey as an opportunity to complain about their professor. For the general question, 13 total responses were omitted, and two responses were omitted from the specific tool question. In Phase 2, initial codes were induced. To do this, the brief summaries from Phase 1 were grouped in Lucidchart according to patterns of meaning. After these groupings were established, initial code names and definitions were determined. Next, all survey responses were coded. Importantly, codes were non-exclusive and multiple codes were applied when survey responses contained multiple perceptions. To ensure inter-rater reliability, Phase 2 culminated with all data being coded by two of the authors. Any discrepancies were discussed and negotiated. Phase 3 and Phase 4 consisted of rounds of thematic mapping of the induced codes, which allowed us to identify themes present in the data. Themes were then defined in Phase 5. This entire process was iterative, with the authors refining definitions, changing code names, and re-clustering themes to ensure an accurate description of student responses.

Results

Through our thematic analysis, three themes and 14 codes were induced (Table 1). In this section, we define our identified themes, outline each of the codes within the respective themes, and provide characteristic student responses for each code. Codes are italicized for clarity.

Table 1. Themes and codes inducted from students' perceptions

Themes	Codes	
Consideration of a Tool's Features	Preference of Professor Student Background Ease of Access Ease of Use	Built for Statistics Availability of Resources Versatility
Actions Augmented Using Computation	Ease of Calculation Exploration of Parameters and Data	Use for Visualization Collaboration
Longer-Term Benefits of Using Computation	Conceptual Understanding Use for Applications	Career Readiness

Consideration of a Tool's Features

Consideration of a tool's features captures the perception that computation and computational tools were used because of the affordance of the attributes related to computation, generally, or of a specific tool. Most occurrences of this theme came in responses to the specific tool question (71% of responses to the specific tool question contained at least one of the codes for this theme, compared to just 9% of the general question responses). In total, this theme has seven codes (see Table 1).

The first two codes of this theme, *preference of professor* and *student background*, relate to users' previous experiences with computation. *Preference of professor* captures students' perception that the tool used was preferred by or familiar to the professor. For example, one student said, "[Python] might just be the tool the professor likes working with." Similarly, *student background* captures students' perception that their or their peers' previous experiences with computation influenced the integration of computation. For instance, several students felt their professor was aware that many students were computer science majors. One student claimed, "a significant portion of us have experience working in Python through our majors."

Our next two codes focus on the perception that their professor chose computational tools that were easy to get ahold of and use. *Ease of access* captures the perception that computation or a specific tool was used because it was easy to find online, freely available through the university, or conveniently integrated into specific types of notebooks (e.g. Google Colab). For example, one student stated, "R was used in the Google [Colab] application, which …[made] it accessible to all students." Alternatively, *ease of use* captures the perception that a tool was easy to learn, approachable, and intuitive. One student said, "Minitab is relatively simple and easy to understand even in your first session." 47% of students evidenced *ease of use* in their responses to the tool specific question, which was the most common perception evidenced in our data. Furthermore, 67% of the responses coded as *ease of use* were from Minitab users.

The final three codes of this theme center on attributes of the design of a specific computational tool. The code *built for statistics* captures the perception that a tool was used because it had features which made it particularly suitable for a probability and statistics course (e.g., having built in statistical functions). For instance, a student said, "R is built for statistical analysis and computation… R just has the functions already built in". Similarly, *versatility* captures the perception that a tool was adaptable to other contexts (e.g., other problems, classes, academic settings). One student claimed, "[Python] is a very versatile tool and can be adapted for usage far outside of this course." For this student, the use of Python was a strategic one, which we interpreted as being a part of teaching students a tool that has a breadth of uses. The last code of this theme, *availability of resources*, captures the perception that a tool was selected because information for its use was online. For example, a student said, "R had many features as well that were easily researchable." This suggested the perception that professors care about the students' ability to locate information and learn how to best use a tool through out-of-class resources.

Actions Augmented Using Computation

Actions augmented using computation captures the perception that computation and computational tools were used because of the tasks that can be completed and processes that can be improved upon with computation. The student responses that evidenced this perception documented actions made possible and easier through computation and specific tools. This theme was identified more frequently in response to the general question (55%) than the tool specific question (34%). In total, this theme has four codes (see Table 1).

The first code, *ease of calculation*, captures the perception that computation allowed for efficient and accurate analysis, particularly in comparison to doing calculations by hand. *Ease of calculation* was the most common perception evidenced in the general question (cited by 34% of students). One student said, "[Computation is] useful for solving stats problems quicker and more accurately than solving by hand." Going a step further, many students who evidenced a perception that *ease of calculation* was a part of their professors' motivation, appreciated this benefit. For example, a student stated, "Computation is a very useful and efficient tool for statistics and statistical analysis. Not including [computation] would prove a detriment."

Beyond calculations, computation's use was perceived to be motivated by the augmentation of exploration, visualization, and collaboration. *Exploration of parameters and data* captures the perception that computation allowed for quantitative manipulation of data and experimentation with varying parameters. For example, a student claimed, "Computation was used to demonstrate how different variables impact distributions. This can easily be done with computation." *Use for visualization* captures the perception that computation allowed for the creation of graphs and figures which allowed students to qualitatively see something important. One student said, "[R helped] with visualizing distributions through plotting data." The final code of this theme, *collaboration*, captures the perception that the ability to work together and easily share or export data, was also a factor in their professors' consideration. One such student stated, "R is…easy to setup & collaborate on through notebooks, which makes it ideal for a group project."

Longer-Term Benefits of Computation

Longer-term benefits of using computation captures the perception that computation and computational tools were used as a mechanism for delving deeper into the material or as a steppingstone for something students may need later in life. We use "longer-term" in the sense that the perceived reasons for using computation have an impact that extends beyond its immediate application (i.e., one assignment). Once again, this theme was more common in responses to the general question (77%) than the tool specific question (40%). In total, this theme has three codes (see Table 1).

Our first code, *conceptual understanding*, captures the perception that computation allows for better comprehension of course concepts. One student said, "[Computation] allows for greater understanding and practice of the material." Analogously, another student said, "[computation] allows us to think more broadly about the concepts." For these students, computation was perceived to be a part of how their professor was improving their teaching. As such, computation's use in their course was perceived to be motivated by the longer-term benefit of computation's influence on learning and understanding of the course's content. For the general question, Minitab users' responses were most frequently coded for *conceptual understanding* (50%), and R users were the least frequent (18%).

Use for applications captures the perception that computation allows students to gain authentic experience with statistical problems and see the applications of their learning. For these students, computation allowed them to use pre-existing data sets or generate data for applying statistical concepts in an authentic way. In one instance, a student claimed, "[Computation was used] to assist us in applying what we learn to real world examples of raw data." For students who expressed this perception, computation was a way for their professors to give them "real" experience using statistics.

Finally, *career readiness* captures the perception that exposure to computation was useful for preparing students for future academic or professional settings. Students who evidenced this code focused on the idea that computation will be used in their careers, rather than focusing on the general benefit of computation in their current course. One student said, "in real life computation is more likely to be used in the statistics field so by giving us experience with it we are more prepared." Another student's response, to the tool specific question, was coded for *career readiness* because they claimed, "[R was used] to help us when modeling statistical information in our careers and in academic pursuits." These responses shared a perception that their professors were focused on the use of computation in the field of mathematics or statistics and, generally, that computational skills will be needed later in life. Compared to the Minitab/Python users (31%), the R users most frequently evidenced this perception (51%).

Conclusions

In this study, we identified 14 perceptions our students held about their professors' implementation of computation and computational tools in their undergraduate mathematics course. While there are several reasons why a professor may use computation or a specific tool, this work explores the different perceptions students hold of their professors' goals. The 14 perceptions were further clustered into three main themes. The first theme, consideration of a tool's features, centered on the affordances of different attributes of computation or of a specific computational tool. Several codes in this theme align with the criteria used by the statistics instructors in Johnson and Berenson (2019) to identify the best computational tool for introductory statistics courses. For example, Johnson and Berenson considered the criteria of the availability of the tool and the cost. Similarly, our students perceived *ease of access* as a part of their professor's decision to use computation or specific computational tools. Furthermore, Johnson and Berenson's criteria included whether a tool was user friendly and had features that were simple to use (e.g., simplicity in data importing). Likewise, our students expressed the perception that *ease of use* was a part of their professor's implementation of specific tools.

The second theme we identified, actions augmented using computation, centered on the tasks that can be completed with the use of computation. Again, this theme appears to align with real considerations when integrating computation into mathematics courses. For example, Bray and Tangney (2017) categorized the use of technology in mathematics education research as either transforming or enhancing a professor's course. In our theme, the codes of *ease of calculation* and *use for visualization* capture ways in which our students perceived computation to be about enhancing their work. Similarly, *exploration of parameters and data* described students' perceptions of activities that might not be possible without computation and, thus, were transformed by its inclusion in their course.

The last theme, longer-term benefits of computation, focused on the affordances of using computation that temporally extends beyond its in-the-moment use. Once again, this perception can be supported by the field's conceptualization of computation. The first code we identified, *conceptual understanding*, is grounded both by the influence computation has on students' mathematical thinking (Wilensky, 1995) and the learning gains associated with the use of computation (Basturk, 2005). Relatedly, *use of applications* is firmly established in the calls made by introduction to statistics course materials (e.g., GAISE; Carver et al., 2016). Finally, Nolan and Temple Lang (2010) made theoretical claims about the use of computation for analyzing real/complex data and the importance of preparing students for the evolving landscape of tools used by statisticians. This supports our students' perceptions of *career readiness*.

This study is suggestive of several avenues of future work. Foremost, while it was beyond the scope of this research report, the data collected from our survey offers the opportunity to compare, quantitatively, how students' perceptions differed based on the tool used in their course, their background experiences, and their professor. For example, Minitab users simultaneously perceived *ease of use* and *conceptual understanding* most frequently, but R users' perceptions more frequently aligned with *use for applications*. This emergent result warrants further inquiry. Additionally, several studies have identified a difference between professors' intentions and students' perceptions (e.g., Lew et al., 2016). As such, our identified themes offer a framework to compare professors' motivations behind their use of computation, generally, and a given tool, specifically, to how their students responded to our survey. While many of the perceptions we identified are grounded in the literature, it remains an open question whether they align with the professor's goals or are a product of a broader narrative.

"When I Write in English, It Doesn't Touch My Heart": Bilingual Graduate Students' Language Switching in Mathematical Understanding

Anna Mikulo
University of Oklahoma

Miloš Savić
University of Oklahoma

Bilingual students are an integral part of the mathematical graduate education system, so understanding their perspective on learning mathematics is important to ensure they are provided proper support. While many students learn undergraduate mathematics in English, some graduate students' first exposure happens at the upper undergraduate or graduate level, introducing additional challenges. The purpose of this study is to discover reasons for bilingual graduate students' language switching when understanding and experiencing mathematics. All four bilingual participants were in a math PhD program and acquired their undergraduate degrees outside of the United States in their respective languages. The results revealed that students switch languages not only between reading textbooks or during lectures, but also when working on solving mathematical problems and internalizing difficult concepts.

Keywords: code switching, graduate students, bilingualism

Bilingualism is a complex concept that does not have a universal definition. Although a consistent component of the term is the use of two or more languages, there are slight differences in definitions seen in the literature. Grojean (1997) defined bilingualism as "the ability to produce meaningful utterances in two (or more) languages" (p. 164) and bilinguals as "people who use two (or more) languages (or dialects) in their everyday lives" (p. 164). On the other hand, Planas and Setati (2009) added a focus on comprehension of language describing a bilingual as "someone who has acquired or learned to speak and understand the world by means of two languages, though the contents of her/his understanding may not be the same depending on the language that s/he uses" (p. 38). This highlights a potential discrepancy between using or speaking a language and the application of that language in different settings.

The science and engineering fields, many of whom utilize mathematics, report an increase in foreign-born students. In 2017, almost 60% of the workforce in computer science and mathematics were foreign-born (National Science Board, n.d.). Because of the almost universal use of English in higher level mathematics, many of these students need to shift their mathematical thinking from their native language to find success in advanced education programs. This exploratory study seeks to understand the language shifts of students with a bachelor's degree in mathematics achieved predominantly in their native language. Therefore, our research question is: For those students, what are the reasons behind switching languages when seeking help in understanding mathematical concepts?

Literature Review

Analogous to the myriads of definitions of bilingual people, language switching, or code switching, has been defined in numerous ways (Green & Wei, 2014; Hofweber et al., 2020; Moschkovich, 2007). Zeller (2020) claimed that code switching "ranges from inserting single words into the main language of discourse to alternating languages for larger segments of a discourse and can occur at various syntactic positions and with various word classes" (p.1). Alternatively, Bosma and Blom (2019) adopted a definition of code switching as an "ability of a bilingual to alternate effortlessly between two languages" (p. 1432). Both definitions have one

common element – code switching is a dynamic process of integrating one language into another and should not be regarded as a lack of language proficiency in any of the languages, but rather as a sign of bilingual competence (Bosma & Blom, 2019). When considering code switching, the asymmetry between language switching sometimes corresponds to the notion of minority-majority language pair, where the majority language is used by most inhabitants of the country (Bosma & Blom, 2019).

Despite the existent notion and practice of language switching, the approach in classrooms mathematics bilingual students follow may be more intuitive. In a report by Clarkson (2005), eighty Vietnamese students were studied while solving mathematical problems in English and 51% described switching to Vietnamese for at least one problem, which supports the use of code-switching as one of the strategies for problem solving. Bernardo (1999) discovered that the success of Filipino-English students in solving word problems in Filipino was higher than in English due to a better comprehension of the stated problem. According to Bernardo and Calleja (2005), during their study of eighty-five Filipino fifth graders, when mathematical problems were presented in English, students reverted to their native language for several reasons. One reason was the social aspect of the classroom which allowed students to seek help from other classmates in Filipino (Bernardo & Calleja, 2005). Another circumstance of language switching occurred when students perceived a problem to be too hard, whether it was a written word problem in English or what may be regarded as straight processing of algorithms or counting. Students were less likely to produce solutions when the problems were presented in their non-dominant language (English) and were more successful in applying appropriate arithmetic procedures to problems written in their dominant language (Filipino).

The research shows that bilingual students tend to use more advanced strategies for solving complicated mathematical problems in their native language (Domínguez, 2011). According to Domínguez (2011), "if bilinguals are strategic language users, they may also be strategic problem solvers, especially if learning to problem solve is viewed as a communication-based experience" (p. 309). While many bilingual students use their native language outside of school, different language of instruction might provide additional cognitive costs which could result in lower accuracy and processing speed (Saalbach et al., 2013). Domínguez argued that integrating students' everyday experiences into mathematical problems could blend two languages together, which was an approach that has been posited for equitable mathematics education (Adiredja et al., 2020). Participants tended to have more discussions, arguments, and risk taking along with mutual learning, which appeared during solving problems in Spanish, their native language, while reverting to traditional approaches when working on problems in English.

The findings from the Dominguez study were further supported by Ní Ríordáin and Flanagan (2020). Two undergraduate Irish-English students, whose dominant language was Irish, chose to interact in English, as it was the dominant language of instruction in their university. This reflects the impact of the social context on students' choice of language. That social context was also apparent in the study of Catalan-Spanish speaking students (Planas and Setati, 2009), where students used Catalan in a socialization setting while briefly addressing the whole group and Spanish when acting like mathematical learners in their small groups (Planas & Setati, 2009). Other studies (e.g., Planas and Civil, 2013) showed that students' overall demeanor changed to more relaxed when using their home language in mathematical explanations. In contrast, when using their non-native language, students' presentation style changed to less natural and non-engaging.

According to Ní Ríordáin and Flanagan (2020), alternate use of two languages is not only a demonstration of proficiency of the languages but of the social circumstances of the languages in use. The dependence of bilingualism's expression on the immediate surrounding makes this process a highly socially contingent phenomenon. In academic settings, the shift to a common, or a higher status, language may occur more often as it pertains to students' perception of access to social goods, while lower status language may bear the perception of being related to segregation and marginalization (Ní Ríordáin & Flanagan, 2020). It is crucial to note that in these settings, the social process is integrated in social interaction where issues of identity and power are structural (Ní Ríordáin & Flanagan, 2020), so the freedom of expressing oneself is often constrained by a social aspect or the surroundings.

The reviewed literature demonstrates the occurrence and reasons for language switching in mathematics, and it describes reasons and effects of language switching. However, to our knowledge, examining language switching among mathematics graduate students has not been investigated. With that, we hope our findings will contribute to the evolving literature and bring awareness to the experiences and learning approaches of bilingual graduate students in mathematics.

Methods

The aim of this exploratory study is to acquire insights on reasons behind bilingual graduate students' language switching when working on mathematical problems. To achieve that, four graduate students were recruited from a central, high-research, U.S. university's doctoral program. All participants were approached in person and a set of qualifying pre-screening questions was asked. Among ten reached graduate students, four agreed to participate in this study that earned their bachelor's degrees outside of the United States (Table 1).

Table 1: Participants and Backgrounds

Participants	Bachelor's Degree	Master's Degree
Bach	Vietnam	U.S.
Ergun	Turkey	Turkey
Maria	Colombia	U.S.
Miguel	Mexico	Mexico

The semi-structured interviews were video- and audio-recorded in a seminar room ranging between thirty and sixty minutes. Open-ended interview questions were developed with a purpose to learn each student's educational background along with their mathematics-related studying and learning practices. For example, participants were asked, "Can you describe your transition to all-English lectures?" or "Did you ever use online or offline resources in your native language to understand some mathematical concepts better?". Additional follow up and clarifying questions were posed.

Once data was collected, the interviews were transcribed. Since the study is exploratory and no known coding scheme was used, all transcripts were coded using a hypothesis coding approach (Saldaña, 2013). The hypotheses were "developed from a theory/prediction about what will be found in the data before they have collected or analyzed" (Saldaña, 2013, p. 147) and additional codes were identified and classified as "other". The coding was done individually by interviewers, compared, and finalized based on mutual agreement: "[they] made no attempt to

develop a numerical reliability rating, because our goal was consensus, with each point of difference being debated and clarified until the group agreed on appropriate usage of the set of codes" (Harry et al., 2005, p. 6).

Results

During the interview analysis, and after the original hypotheses, the research team discovered three main categories of language switching: external factors (during lectures and reading textbooks); internal processes (processing mathematical information and solving problems); and social influences (driven by social or environmental factors).

External Factors

As all four participants earned their undergraduate degrees outside of the United States, their initial learning of mathematics primarily happened in their native language until higher mathematical content was introduced. This equipped them with the ability to understand mathematics in multiple languages, widening their pool of resources. For example, Ergun's current interest is p-adic groups, so he discovered a Turkish professor's work on that topic in a Turkish mathematical digital magazine, explaining the concept clearly. Miguel has searched for recent Spanish dissertations written on topics of interest to receive the most recent information available in his own language. Although helpful, online sources are generally not frequently used by the participants because of the lack of these resources online. Maria stated that finding advanced math-related resources online in Spanish was not easy compared to those in English and Ergun stopped consulting Turkish resources altogether due to their scarce numbers. Similarly, Bach found it disadvantageous to consider online sources in Vietnamese because questions he might seek answers for are already stated in English:

> And I am Googling something like that... Becauseif you look at the words in the textbook, you will type that in English, right? You don't type it in Vietnamese. So, you type that and it will show many English textbooks so that's... Obviously, I have to look at English only.

While most online resources were deemed insufficient, in some situations, participants were able to find complement material to available resources including books and hand-written notes in their native language. For example, Miguel kept Spanish copies of "Topological Groups" and "Introduction to Topological Transformation Groups" as well as Spivak's Calculus, and Maria continuously referenced a Spanish copy of Munkres' "Topology" textbook. Similarly, personally written notes in participants' native language were regarded as a valuable resource. Both Maria and Miguel tend to consult their own previously taken notes in Spanish due to familiarity with notations or simply because the content of those notes was once challenging. Interestingly, Maria reports that the frequency with which she refers to her old notes changed as she learned more mathematics in English throughout her academic career, identifying her knowledge replacement in a new language.

The externally influenced language shifts during lectures were beyond the control of our participants, but they seem to have had a positive impact. During Bach's senior year of undergraduate study, mathematical lectures were held primarily in English, which provided early exposure to mathematics in English. Likewise, Miguel's early introduction to mathematics in English happened during conferences:

> Some people came to the National University of Mexico, they did their lecture, and it's, in some sense, I believe a really safe environment because it's not like they're going to question you if you understood the material or not. So, that helped a lot, I think.

The notion of gradually easing into learning mathematics in English appears to have a positive effect on Bach and Miguel's perception of language switching in a math setting. Beyond lectures, textbooks written in English were often used during undergraduate education. Bach shared that the number of comparable mathematical textbooks written in Vietnamese was scarce, so while some texts were recommended by his professors, he often searched for relevant English literature on his own. The practice of favoring English texts also influenced Maria's undergraduate experience, where the textbooks were in English or Portuguese, but the proofs were still expected to be written in Spanish, even if she referenced the non-Spanish textbook.

Internal Processes

The translation is not foreign for mathematical graduate students and, rather, at some stages of their academic careers, is integral. Translation can be considered as an internal factor of language switching controlled by the student compared to external factors which are outside of participants' control. Bach shares his communication experience while using internal translation for double switching between receiving information in English, generating a response in Vietnamese, and translating it back to English: "So, before we actually speak that one, we think about it in Vietnamese and we translate words by word, word by word," which is not applicable solely to verbal communication, but to written, too. Maria shared that, when solving math problems stated in English, she began by "thinking in Spanish and then trying to write it down in English when I first came here," but then by "one semester after my first semester I started to think more in English". For Ergun, reading math problems is not the challenge, "the difficulty starts from generating arguments. And so, to attack the problems... my brain automatically goes to Turkish." This presents a vivid example of an internal language switch, where participants unintentionally default to their native language for response creation or problem solving due to sufficient mathematical knowledge acquired in their native language.

The notion of mental internalization and translation we label as "inner voice", which entailed mental work participants conducted while learning or solving mathematics. For instance, as Ergun worked on a math problem stated in English, he wrote questions and keywords to himself in Turkish:

> Yeah, I have some English statement, mathematical, maybe proposition. So, now, I'm working on some bilinear forms. So, I kind of check myself and I see that these questions… I'm asking lots of questions to myself, and writing lots of keywords, and it's kind of a puzzle and makes sense after some point if I work on it in one hour or two hours. But if I get some new good proposition, write in English. But then, still the teaching part is always Turkish to internalize, to understand some deep, deepness... To have some deepness still. My voice, inner voice is Turkish.

There is a strong connection of Ergun's mathematical work to his language, as he shared:

> So, some writings are Turkish, and some write things are English, and it's a mixture… When I write in English, it doesn't touch my heart. So, if I write in Turkish, I feel much more at home and just... I get more motivation... The pop-up questions are much more fruitful for me. Sometimes English is mechanical. I don't know. Maybe it's a linguistic issue. I mean, the words always trigger something, and they are connected to each other.

> And, in my native language, it's connecting very quickly in my mind, in brain, but English words is much more slow works for me.

It is prominent that Ergun's linguistic attachment to his native language plays a significant role in solving mathematical problems. While participants' current lectures are purely in English, there are times, like with Ergun, their notetaking is still in their native language. For example, Maria finds herself jotting down quick notes in Spanish to provide herself a gist of presented material. The language switch during note taking emphasizes the connection of our participants to their native language, as it is an important aspect of their identities.

The thought process around problem solving in different languages is unique and intriguing. As it can be observed, Ergun integrates Turkish and English as his problem-solving strategy where the translation process is no longer obvious but, rather, fluid and continuous. Ergun has a well-established practice that intertwines the language of the problem and language of mental processing. However, Maria shared a different experience: "when I translated from Spanish, there is where I have those problems. Worse. They are, like, worse if I translate. No, I need to think in English and try to write it down in English." This indicates that language switching when solving problems for some students is not a helpful strategy.

While language can be tied to previous experience, it can also serve as a helpful resource. Maria described a time during her topology class where a notion of universal set was introduced. At first, she encountered difficulties with conceptualizing the definition, so the professor provided an alternative name – ambient set. Since Maria took topology class in Colombia, she immediately recalled the familiar Spanish word "ambiente" which triggered previously acquired knowledge about ambient sets. Similarly, while working with his advisor, Miguel encountered concepts stated in Spanish and struggled to understand their differentiation. When he attended to his professor, he was given English alternative definitions of these concepts that immediately distinguished them from one another.

Social Influences

Another type of language switching identified seemed to be dictated by social norms and a strive to learn English. For example, Maria shared her early attempts to write proofs in English, saying: "When I was finishing my undergrad, I was... trying to write down the statements of the homework and try to write down the proofs in English… it's easier in English to find a master's, with a scholarship of course." The described strive to improve proof-writing in English was driven by a notion of socially accepted high status of the English language in a mathematical setting. Similarly, Ergun stated that, "Mostly I gave up to look up Turkish resource maybe at the beginning, after one year in my master's program, because I was feeling that I need to learn to read English, just need to improve myself more." The idea of integration is perceived by participants to relate to improvement of their English skills, which is what Bach shared about:

> Later I figured out that this is not convenient to just use Vietnamese. So, in general, I want to improve my English, so I stop thinking as Vietnamese. So, then I stopped using... Googling or finding this term in Vietnamese… I will say I preferred English. Yeah, because now I am in a completely 100% English program, so I have to do more with English. So, instead of using these sources in Vietnamese, I just start reading English.

The data shows that our participants view English as either higher status language or majority language (Bosma & Blom, 2019), which could skew their perception of their native language's importance or relevance.

Discussion

Our goal in this paper was to learn why bilingual graduate students shift between languages when working through mathematical problems to further understand how language and problem solving intertwines as well as to highlight potential hurdles bilinguals might face during their graduate careers. Another objective of this study was to determine what impact transitioning from (mostly) non-English lectures to purely English mathematical courses had on our participants.

In the light of our research question, we conducted four semi-structured interviews with mathematics graduate students who earned their bachelor's and, sometimes, master's degrees outside of the United States with the primary language of instruction being not English. During their bachelor's or master's experience, all participants consulted English advanced mathematics textbooks based on professor's reference and for the expansion of available information and resources. We also found that our participants' personal notes taken in their native language served as a valuable resource as they contained familiar mathematical notation and content viewed as challenging in the past. Even though online resources were not indicated to be in the highest demand, two graduate students used queries in their native language to widen the pool of information or simply because they prefer a particular non-English author. We also discovered that internal language switching while solving math problems was not uncommon among our participants, as some switch to their native language when producing mathematical arguments which enhances their understanding and success in proving problems.

To our knowledge, there are no studies done with bilingual graduate students pursuing a PhD in mathematics on language (code) switching, so we strive to contribute our results to the currently growing literature. Almost all, if not every, department of mathematics have graduate students with similar backgrounds as our participants, and while carrying multiple languages for these students can be a tool for studying mathematics, lack of certain vocabulary in their second language can impose difficulties during their studies. We believe it is important to be aware of additional support graduate students might need to succeed in graduate programs, even if it is a simple recognition and understanding of potential language barriers.

While participants were representing four different continents and three different languages, our results were limited to a small number of perspectives. A broader study to include experiences of those from other countries and continents would gain insight into the global needs of different students.

Implications and Future Research

The results of our findings reveal a potential need to improve integration of bilingual students into English-led courses. This may lead to professors and educators being more mindful of a language gap in not only mathematical domain, but also in everyday language. As the results showed, some students found success in intertwining both their native language and English, while others were convinced switching to English was the best choice for them. Instructors should encourage graduate students to practice different problem-solving techniques which could involve language switching. Future work in this area should consider increasing participants' pool to diversify participants' experience, which would enhance the knowledge and awareness of various graduate students' practices and difficulties and could more broadly be done for other domains of graduate programs. Also, interviewing participants in their native language could reveal more insights to the researcher while circumventing a language barrier.

Inquiry into Suitability of a Qualitative Framework about Scaffolding Moves to Support Mathematical Modeling for the Purpose of Quantitative Analysis

Alex White
Texas State University

Andrew Baas
Texas State University

An important goal in research on mathematical modeling is to understand the influence of teacher scaffolding moves on students' model construction. This paper validates the use case of two common frameworks (one for scaffolding and one for student modeling processes) with STEM undergraduates. Study I investigated whether variability in scaffolding strategies could predict variability in participants' modeling processes. Findings suggested that the initial assumption—that scaffolding moves articulated by the framework are clearly aligned with specific modeling processes—was not supported. Study II further explored how scaffolding moves related to distinct stages of model construction and sought to improve cohesion of the categories of scaffolding moves. Our results challenge simplistic expectations about the relationship between scaffolding strategies and learner engagement, highlighting the need for more nuanced approaches to using these frameworks. The studies also demonstrate the importance of qualitative follow-up to refine our understanding of how scaffolding supports complex model construction processes.

Keywords: mathematical modeling, mixed methods, scaffolding

For STEM majors, mathematical modeling (hereafter: modeling) is a major instructional goal because it can authentically promote interaction between scientific and mathematical knowledge domains (Hallström & Schönborn, 2019). For research with a focus on blending knowledge (Hu & Rebello, 2013), a cognitive approach to studying students' engagement in mathematical modeling is often adopted (Kaiser, 2017). Over several decades, this has led to a fairly stable *descriptive* account of the processes attendant to modeling – called a mathematical modeling cycle (MMC) (Blum & Leiß, 2007) - which has, in turn, motivated research agendas like articulating features of learning environments that elicit those processes (Hankeln, 2020; Maaß, 2010) and improving modeling competence (Ärlebäck & Albarracín, 2019; Durandt et al., 2021). Naturally, that work has extended to understanding what teachers can do to support students' progress in constructing models. However, the descriptive accounts of student engagement are not predictive. On its own, an MMC does not indicate how an individual might engage in a specific task (Ärlebäck & Bergsten, 2010; Czocher, 2016) and it leaves out the role of the teacher. Separately, there are frameworks that describe teacher knowledge (e.g., Greefrath et al., 2021) and frameworks that hypothesize potential teacher moves that would be supportive of students' engagement in modeling (e.g., Stender & Kaiser, 2015).

Ideally, scaffolding moves would be linked to student engagement in modeling. To date, the existence and extent of these associations have not been systematically explored despite their heavy usage for describing student modeling engagement and teacher scaffolding moves separately. In this paper, we investigate whether a qualitative framework describing scaffolding moves aligns functionally with a framework describing engagement in modeling and justify modifications needed to use the frameworks to carry out studies capable of predicting which moves promote which processes. We report a pair of mixed methods studies that interrogate the utility and promise of two frameworks by addressing the following questions: (1) Are the descriptive categories of the frameworks naïvely associated? (2) Do theoretically similar codes

from the scaffolding moves framework function similarly? (3) What other considerations are there for using these frameworks to study the influence of scaffolding on modeling processes?

Theoretical and Analytic Frameworks

We conceive of a laboratory-based learning environment as a task-modeler-interviewer triad (Koichu & Harel, 2007), and in this study we focus on the modeler-interviewer interactions. We are interested in particular interactions that serve as *scaffolding* for the modeler's *engagement* in modeling. This means we required a framework for engagement, a framework for scaffolding, and a means for relating the two. To describe participant engagement in mathematical modeling, the field uses a mathematical modeling cycle (MMC) (Blum & Leiß, 2007). The cycle decomposes the mathematical modeling process into six sub-processes which connect stages of model construction: a modeler conceives a real-world problem, *understanding* it as a (mental) situation model, *simplifies* it to an idealized real model, *mathematizes* that to produce an externalized mathematical model, *works mathematically* to obtain a mathematical result, which is then *interpreted* in terms of the real-world context to yield real results, and then *validated* against the real-world situation.

Sub-Processes	Definition	Connects Stages
Understanding	Forming an initial idea about what the problem is asking for	real world → situation model
Simplifying & Structuring	Identify (un)important real-world entities and relationships	situation model → real model
Mathematizing	Represent idealized version of the real-world problem using mathematical conventions	real model → mathematical model
Working Mathematically	Analyze or solve mathematical problem	mathematical model → mathematical results
Interpreting	Re-contextualize mathematical results	mathematical results → real results
Validating	Verify results against constraints	real results → real situation

Table 1 Stages and processes of model construction from Blum and Leiß (2007)

Scaffolding is proffered support that aids a student "when performing a task that the student might otherwise not be able to accomplish" (van de Pol et al., 2010, p. 274); we focus on *contingent* scaffolding in-the-moment rather than longer-term scaffolding processes like fading and transfer of responsibility. In the context of modeling, an interviewer needs to provide that support contingent to the modeler's current mathematical reasoning and progress in model construction/evaluation. Stender (2016) developed a framework for scaffolding during modeling that aims to describe moves an educator can make to respond to students' reasoning and further their progress through the modeling cycle that retain student autonomy. Among the categories of moves in the framework are those labeled "B3" – these classify contingent moves targeting the cognitive dimensions of modeling (as opposed to moves that target affective factors). For example, the code B3.6 Prompt to Include Aspects labels moves in which the modeler is asked or encouraged to include something from the real-world she has not yet included in her model, for example posing the question "Do you think maybe there should be another [separate] population, like people who are recovered?" during a disease transmission task when the modeler was struggling with two meanings for the idea of "healthy people." Due to space constraints, it is not possible to include in this manuscript the 26 B3 codes and 6 MMC codes we used, along with rules and examples. The codebooks are available in the following publications: the MMC

codebook was originally published in Czocher (2016) and the B3 codebook was originally published in German in Stender (2016).

Methods

Our interrogation of the analytic frameworks spans multiple mixed methods studies (Creswell, 2014). We used cognitive task-based interviews to generate data, cluster analyses and logistic regression to develop variables and explore associations among them, and then followed with interpretive methods to validate, refute, and explain patterns in the results.

Data were generated through a set of individual, task-based clinical interviews (Clement, 2000; Maher & Sigley, 2014) with 24 undergraduate STEM majors at a large southern university in the US who were studying differential equations. Each participant worked on between four and eleven modeling tasks across 10 hour-long sessions. The modeling tasks were based on canonical problems from differential equations and dynamical systems that call on feedback loops (e.g., disease transmission; predator-prey). Of the 11 tasks, the final six were open problem statements and contained only contingent scaffolding provided by the interviewer. The interviewer accepted all student productions as provisionally correct (Goldin, 2000) and attempted to make sense of why the participant reasoned as they did. The interviewer intervened in the participants' modeling process if the participant requested help, if it seemed that the participant got stuck, or to generate and test conjectures about the participants' ways of reasoning about the mathematical or real-world aspects of the task. Interviewer turns were formulated so they could map to the scaffolding moves framework.

In this report, we consider only the tasks without embedded scaffolding to isolate the influence of contingent scaffolding on participants' modeling processes. The dataset for this study comprised 52 events completed by 22 (distinct) participants working on six modeling tasks. Qualitative analysis proceeded with deductive coding procedures (Saldana, 2016), using the pre-defined, published codes for engaging in mathematical modeling processes (MMC codes), model construction stages (Stage codes), and contingent scaffolding moves for modeling (B3 codes). Due to the complexity of the codebooks, total duration of the 52 events, and planned quantitative models, our primary concerns about reliability were the chance of missing codable segments and consistent application of the codebooks across participants and tasks. Thus, two analysts independently coded each event. Pairs met regularly to reconcile codebook application to their assigned events and to resolve disagreements based solely on code definitions. In total there were 3,478 instances across 26 B3 codes and 5,596 instances across 6 MMC codes. Due to the interview protocol, *understanding* (233) and *working mathematically* (261) processes were rarely elicited compared to the others, and so were excluded from further analysis.

Study I: Are the Two Frameworks Naïvely Associated?

By meaningful association between frameworks, we mean that variability across the set of MMC codes should be accounted for by variability across B3 codes, when aggregated across the events. At each instance of a B3 move and for each MMC process, we determined if the target process was observed within a two-minute window subsequent to the B3 move. If the process was observed at least once in the window, we said the B3 move was taken up by the participant. Combining results across events, we estimated the probability of uptake for each process and set of B3 codes. To account for variation in base rate of occurrence of MMC codes, we estimated a base probability under the null or no effect model, where the null assumption is that MMC codes are uniformly distributed across the interview sessions. Under the null model, we let X_k be the number of instances of MMC code k in a given two-minute window. Then X_k follows a binomial

distribution with size equal to the total number of instances of code k and probability equal to 2 divided by the total combined time of the sessions. The base probability is $p_{b_k} = P(X_k > 0)$. We then normalized the probability of uptake, by computing an odds ratio:

$$OR = \frac{(p/(1-p)}{(p_{b_k}/(1-p_{b_k})}$$

If the uptake probability equals the expected value under the null model, then $OR = 1$, and indicates the contingent scaffolding move is not associated with an increased uptake of process k. On the other hand, $OR > 1$ indicates that the contingent scaffolding move promotes process k. The results table was a daunting $18 \times 4 = 72$ rows long without clear patterns emerging. While the reader might be muttering "no duh," we note that this initial analysis was necessary for exploring whether each B3 category had a cohesive nature with respect to the MMC's. There were some pairs of B3 and MMC codes with a strong association, for example, B3.11u Attention to Units was often followed by *validating* (OR = 1.463), but in general, the B3 codes were not clearly tied to specific phases of modeling, which washed out any aggregate impact of scaffolding moves on participant modeling processes. We took this result as evidence against the naïve hypothesis that the scaffolding moves framework was aligned with the modeling processes framework. We determined that the hypothesis rested on an implicit assumption that, in the aggregate, each B3 code would contain scaffolding moves that were largely homogenous with respect to the modeling process induced in the participants. This called for qualitative follow-up.

Upon inspecting the instances of B3 codes, some of the codes seemed to operate in a general descriptive way, supporting a wide range of participant modeling activities. Such B3 codes had very high usage and because the data corpus was quite large, we had opportunities to see more specific usage patterns arise. For example, the code B3.12 Interviewer Explaining or Instructing had 254 instances, but the nature of what was being explained or instructed was not uniform across all of the instances. An inductive coding process within B3.12 yielded 6 subcodes (instructing real world, instructing mathematics, instructing modeling, considering alignment between model and reality, explaining distinctions and similarities between scenarios, explaining meaning of representations). We carried out a similar process for 3 other B3 codes. This yielded a new total of 47 B3 codes. Again, inspecting instances of B3 codes, most of the B3 categories did not correspond to a single aspect of model construction. This explained our results from Study I. If the categories of scaffolding moves are not homogenous with respect to what aspects of model construction they are targeting, then we ought not expect a consistent response from the modeler in terms of what process is elicited. Thus, we further hypothesized that the proportion of uptake of scaffolding moves depended on which stage of model construction the B3 codes referred to. Our next step was to examine the extent to which each B3 code could be said to refer to a single stage of model construction or a Profile of stages.

Study II: How Does the Scaffolding Framework Connect to Model Construction?

Our next step was to explore the distribution of B3 codes across model construction stages. We conducted a deductive qualitative coding procedure inspired by Çakmak Gürel (2023) and Tropper et al. (2015) that mapped each instance of a scaffolding move to (1) the stages of model construction presented in the modeling cycle it referred to (see Table 1, third column) or (2) to no stage. For example, the move "Let's work on just the susceptible and infectious. And we'll pick back up the removed later" used with a participant who was working on modeling disease transmission was coded as B3.23 Narrowing Scope because the interviewer suggested the participant to ignore the removed population. Because the move referred to the distinct

populations identified by the participant (susceptible, infectious, recovered), we inferred it to refer to the Real Model stage of the MMC. For example, the code B3.24 Documenting Writing was an interviewer move that merely sought to clarify what the participant wrote down (e.g., Does that say "x" or "α"?) and was not coded as referring to a stage of model construction.

This qualitative analysis along with descriptive statistics enabled us to examine the characteristics of the B3 scaffolding moves in two ways. First, for each scaffolding move, independently from the B3 code it is assigned to, reflects a combination of model construction stages it refers to. These combinations can be aggregated across B3 codes to give a sense of the relative frequency each stage is referred to within a given B3 code. For example, the proportion of B3 instances referring to both the Real Model and the Math Model was 39.31%. Second, each B3 code can be said to have a *profile* for the stages of model construction its instances refer to. For example, the code B3.7 Encourage to Make Assumptions or Simplify contained instances that typically referred to Real stages of model construction. We noticed that some profiles referred to stages of model construction associated with the Real World (i.e., situation model (SM), real model (RM), and real results (RR)) others referred only to stages of model construction associated with the Math World (i.e., mathematical model (MM) and mathematical results (MR)), and some profiles referred to both. Hence, we used the analysis of B3 code instances in terms of model construction stage to collapse to four broad categories: Real (scaffolding move refers to situation and/or real model), Math (scaffolding move refers to mathematical model), Both (scaffolding move refers to both Real and Math), and Neither (scaffolding move refers to neither Math nor Real). To fully characterize the differences in uptake of MMC codes according to whether each B3 category contained instances that primarily referred to Real, Math, Both, or Neither stages of model construction, we developed a set of regression models. For each process we fit a mixed logistic regression model with a participant random effect, u_i, to account for dependence (Agresti, 2012):

$$\log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 \text{Real} + \beta_2 \text{Math} + \beta_3 \text{Both} + u_i$$

To test our hypothesis that the induced MMC fingerprint would depend only on the stage profile of the B3 codes (i.e., that in the aggregate, the B3 codes have clear associations with sets of elicited modeling processes) we conducted a two-step cluster analysis. We first clustered the B3 code instances based on their Stage profiles. Then, within each Stage Profile cluster, we clustered the B3 codes according to the MMC processes elicited by the codes in that sub-cluster.

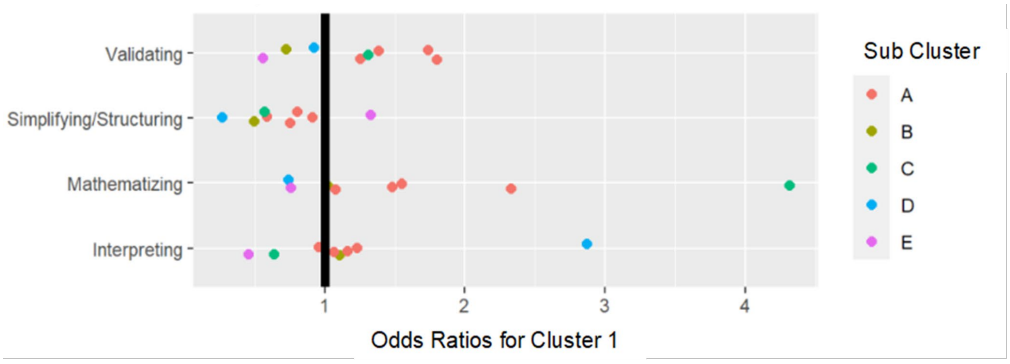

Figure 1 Sample of odds ratios for Cluster 1, from the two-step cluster analysis. Each dot represents a B3 code category. Cluster 1 contains B3 codes whose instances tend to target Both mathematical and real-world stages of model construction. Subcluster 1-A tended to promote validating, mathematizing, and interpreting while suppressing simplifying/structuring.

We refer to the elicited MMC processes as the induced MMC Fingerprint associated with a given B3 code's Stage Profile.

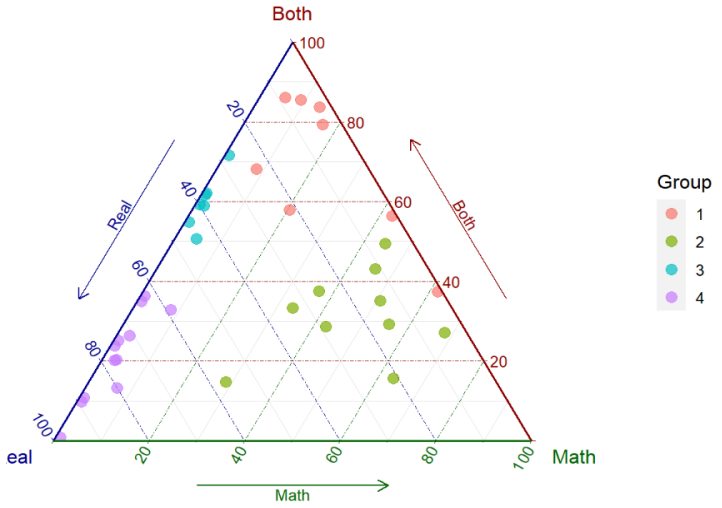

Figure 2 Ternary graph depicting clusters of B3 codes according to Stage Profile. Colors are re-used and do not indicate the same cluster membership as the colors in Figure 2. Figure 1 contains only codes from Group 1 in Figure 2.

The result was four clusters each containing between three and five sub-clusters. Odds greater than 1 indicated that, in the aggregate, moves in the given B3 code elicit the given modeling process at a higher rate than the null model would predict (see Figure 2 for Cluster 1 results). For example, the code B3.14 Suggestion for action, related to content (next mathematical step or analysis) strongly promotes validating ($\text{odds} = 2.21$) while the code B3.11p suppresses simplifying/structuring ($\text{odds} = 0.14$). We observed good separation between the clusters based on Stage profile, as illustrated in the ternary graph in Figure 1. Each point within the ternary graph can be thought of as a triple corresponding to a Stage profile (% Real, % Math, % Both). For example, the apex which is labeled Both corresponds to a (fictional) B3 code whose moves were always classified as Both and never classified as either Real (only) or Math (only) and the Cluster 3 codes tend to contain moves that do not refer to Math (only).

This seemed a good sign and so we qualitatively characterized all clusters and all 16 subclusters (impossible to report here and it would bore the reader if we did). We found that while quantitative analysis grouped B3 codes together based on the similarity of their profiles of model construction stage, moves within each cluster induced dissimilar MMC fingerprints and moves within the subclusters were often difficult to characterize. This suggested we should further analyze the similarities and differences of B3 codes within each Stage Profile cluster as well as examine the expression of B3 moves within each B3 code to explain each cluster's capacity to elicit (or suppress) multiple modeling processes. For example, both B3.22 Modify Scenario and B3.23 Narrowing Scope are B3 moves which were grouped into the same Stage Profile, and both moves elicit the *simplifying/structuring* and *mathematizing* modeling processes. Thus, while Study II did indicate that the modeling processes elicited by the various scaffolding moves depended, at least in part, on the Stage the moves in the category tended to target, the grouping criteria Real/Math/Both/Neither was too coarse to facilitate theory-driven interpretations for many of the sub-clusters. We discuss the next steps in the discussion, next.

Discussion

Our investigations confirmed that the MMC Fingerprint induced by categories of scaffolding moves does depend on model construction Stage. This finding partially supports previous assertions (see, for example Schukajlow et al., 2015; Stender & Kaiser, 2015) that successful scaffolding depends on which stage or phase of the modeling cycle a move is relevant to. However, Stender and Kaiser (2015)'s assertion implies that the key to understanding successful scaffolding lies in diagnosing which phase of the modeling cycle the modeler is *in* and conditioning the contingent facilitator response on that information. In contrast, we observed that many of the interviewer's scaffolding moves -- when contingent to the modeler's mathematical reasoning and accounted for what had been produced so far by the modeler – may or may not be related to the stage or phase of modeling cycle the modeler finds themselves in by the time the interviewer intervenes.

Our analysis challenges two other naïve expectations about associating interviewer moves and modeler engagement through the modeling cycle. First, one might expect that if the interviewer provides scaffolding for phase N of the modeling cycle that the modeler would respond by progressing to phase $N + 1$. That does not seem to be the case. For example, there were sub-clusters whose MMC Fingerprints were characterized by *interpreting* that followed from interviewer moves that focused on the situation model. Underlying the first expectation is a deeper assumption that the appropriate thing to do if a modeler needs scaffolding for stage M of model construction that the proffered support should target stage M. This also seems not to be the case. Our analysis of uptake of scaffolding moves was based on the antecedents to participants' elicited modeling processes. The moves were contingent to the participants' in-the-moment needs and often targeted Stages of model construction that did not correspond to the contemporaneous stage that the participant was in. Thus, paralleling well-known results that students' routes through modeling cycles are nonlinear and idiosyncratic (Ärlebäck & Bergsten, 2010; Borromeo Ferri, 2006; Czocher, 2016), it seems that one should also not expect that promoting student progress in their model construction would be as simple as targeting specific stages or phases of the cycle.

The quantitative analysis established associations between scaffolding moves and the modeling processes they elicited. Some interviewer moves that mapped to the same sub-cluster elicited very similar MMC fingerprints suggesting that the moves either functioned similarly or co-occurred frequently enough that their MMC uptake was similar. We also found that interpreting these associations was complicated by a lack of theoretical coherence within some clusters. In particular, moves that seemed similar based on the code descriptions or move expression may not have similar Stage profiles and therefore did not cluster together. This observation knocked down a third naïve hypothesis that moves that are behaviorally described similarly would have a similar impact on modeling processes. Additionally, our results suggest that the number of B3 codes could be streamlined by examining co-occurrences of similarly functioning code categories. As our investigation has laid the groundwork for the two-step clustering approach, future work can examine the uptake resulting from a streamlined B3 codebook. This next step would bring the goal of estimating the likelihood that a given scaffolding move would induce a particular modeling process within reach.

How Course Coordinator Values and Practices Align With the Needs of Instructors

Debra Carney
Colorado School of Mines

Rebecca Swanson
Colorado School of Mines

Megan Sanders
Colorado School of Mines

Chris Rasmussen
San Diego State University

Course coordination in high enrollment undergraduate mathematics classes in the United States is a common practice that seeks to provide consistency in learning opportunities for students while balancing instructional support and pedagogical autonomy. In this study we investigate how the needs of instructors who teach in a coordinated course align with the values and practices of course coordinators. Analysis of 44 survey responses from both coordinators and instructors who teach in a coordinated course identified several coordinator actions and corresponding orientations that align with instructor needs as well as actions that instructors find valuable but that are not frequently occurring. These findings are significant because they can lead to better articulation of the knowledge, skills, and dispositions needed to be an effective course coordinator, which could then lead to the design of professional development aimed at helping coordinators be better able to meet the needs of their co-instructors.

Keywords: Coordination, orientation, calculus, professional development

It is common in the United States for high enrollment undergraduate mathematics courses required of most STEM majors to consist of multiple sections taught by several different instructors and for those sections to be coordinated. Coordination typically consists of uniform course elements (e.g., common text, exams) and regular instructor interactions around issues of instruction to support each other in delivering high quality courses. A key characteristic of effective course coordination is the delicate balance between enacting policies and practices that provide consistency across sections while at the same time maintaining instructor pedagogical autonomy (Rasmussen et al., 2015; Rasmussen et al., 2021). This can be challenging given the increasingly wide variation in who teaches calculus and their sometimes-contingent status.

While previous studies have documented the different elements of course coordination and the different roles that course coordinators play (e.g., Adeyemi et al., 2023; Rasmussen et al., 2015), what is currently missing from the literature is a close investigation of how the values and practices of course coordinators align with (or do not align with) the needs of instructors who teach in a coordinated course, particularly given the change in who is teaching these courses and the variation in their background and experiences. The goal of this study is to begin to fill this gap, and we address the following two research questions:

- What are the needs and experiences of coordinated faculty?
- To what extent do the values and practices of coordinators, coordinated contingent faculty, and coordinated permanent faculty align with one another?

Insight into the needs of the varied instructors who teach calculus and the extent to which the values and practices of coordinators meet these needs is significant because it can lead to better articulation of the knowledge, skills, and dispositions needed to be an effective course coordinator, which could then lead to the design of professional development aimed at helping coordinators be better able to meet the needs of their co-instructors.

Theoretical Background

Central to our research goal is the need for insight into the practices and values of course coordinators. An overarching construct that encompasses both what coordinators do (i.e., their practice) and what they value is that of *orientation*. A person's orientation to a particular task or job not only provides a sense of direction for what one does but also reflects what that person deems important (Schoenfeld, 2010). As such, the orientation that a coordinator takes to their role shapes what their goals are and how they interact with their colleagues. In the context of classroom teaching, an orientation is a disposition or tendency one takes toward some aspect of their job as a teacher (Thompson et al., 1994; Philipp, 2007).

The work of Martinez et al. (2022) provides a comprehensive analysis of course coordinator orientations that we heavily draw upon in this study. Their analysis revealed two overarching course coordinator orientations. They refer to these two orientations as a Resource-Managerial orientation and a Humanistic-Growth orientation. A Resource-Managerial orientation refers to values and practices that leverage the knowledge, experience, and logistical management skills of the coordinator to facilitate consistency across multiple sections and different instructors. They identified the following five themes that characterize a Resource-Managerial orientation: a) draws on knowledge of the course, department, and institution, b) demonstrates experience teaching and knowledge of teaching the course, c) provides material related to content and curriculum, d) communicates clearly, and e) exhibits strong administrative skills. In contrast to a Resource-Managerial orientation, a Humanistic-Growth orientation refers to values and practices that facilitate the personal and professional growth of the instructors teaching in the coordinated course. A Humanistic-Growth orientation is manifested in the following five themes: a) attends to student experience, b) concerned about others, c) takes action to build community, d) attentive to instructor differences, and e) provides instructor support.

Part of the significance of this work is that the two orientations offer different but complementary approaches to professional development. More specifically, Martinez et al. (2022) argue that a Humanistic-Growth orientation outlines how course coordinators can provide professional learning for instructors in a way that is flexible, attentive to individual differences, and builds community. On the other hand, a Resource-Managerial orientation is a leadership approach that can promote instructional innovation by offering instructional materials, insights and knowledge about student difficulties, and relevant department and institutional policies. As such, the job of a coordinator is (or can be) complex and multi-faceted.

In this study we further this line of inquiry into course coordinator orientations by investigating the extent to which course coordinator orientations align with the needs and experiences of the coordinated faculty at one institution. This particular institution is an ideal case for such analysis as it has a long history of coordination and a growing number of teaching-focused faculty that serve as course coordinators.

Methods

Top Applied University (TAU) is a public engineering school with just under 6,000 undergraduate students, all of whom complete Calculus I, II, and III and at least one additional math course. Coordinated courses within the department are typically structured in sections of about 40 students, which are taught by a mix of adjunct faculty, Postdoctoral Teaching Fellows, and Graduate Teaching Fellows and are coordinated by a Teaching Faculty member. At TAU, Teaching Faculty are largely comparable to Tenured/Tenure-Track Faculty (T/TT) in how they are viewed and in how they can participate on campus but are generally only evaluated on teaching and service. Teaching Faculty are eligible for promotion but not tenure at TAU.

Currently, the department is almost evenly split between Teaching Faculty and Tenured/Tenure-Track Faculty. For this study's purposes and given the context at TAU, we define adjunct faculty, Postdoctoral Teaching Fellows, and Graduate Teaching Fellows as contingent faculty. We define Teaching Faculty and Tenured/Tenure-Track Faculty as permanent faculty given their nearly identical status to that of Tenured/Tenure-Track Faculty.

We developed a survey with two versions, one for coordinators and one for coordinated faculty, both of which focused on actions that coordinators take in their roles that could contribute to an effective and supportive environment for coordinated instructors. Of the 12 total invited coordinators, 11 responded (91.7% response rate), and of the 47 invited coordinated instructors, 32 responded (68.1% response rate). Among the coordinated faculty, 19 (59.3%) were contingent instructors and 13 (40.6%) were permanent faculty. We based the actions on previous research (Martinez et al., 2022; Rasmussen et al., 2015), and feedback from department faculty. The finalized 14 coordinator actions for these surveys is listed in Table 1:

Table 1. Coordinator actions organized by HG (Humanistic-Growth) and RM (Resource-Managerial)

HG1	The coordinator attended to student experience.	RM1	The coordinator provided clear, consistent information about what content was covered.
HG2	The coordinator provided opportunities for professional development.	RM2	The coordinator provided common written homework.
HG3	The coordinator made me feel welcome in the department.	RM3	The coordinator maintained common online homework.
HG4	The coordinator valued my input and feedback in the course.	RM4	The coordinator provided course content materials.
HG5	The coordinator allowed for some degree of instructional autonomy.	RM5	The coordinator exhibited strong administrative skills.
HG6	The coordinator provided regular meetings throughout the semester to ask questions about teaching the course and students.	RM6	The coordinator maintained a common Canvas course or Canvas Blueprint for the course.
HG7	The coordinator demonstrated knowledge of pedagogical and evidence-based practices.	RM7	The coordinator provided guidance on how to evaluate exams.

For each action, we asked participants to identify how frequently they implemented those actions (coordinators) or how often those actions occurred in their coordination experiences (coordinated instructors) and how important these actions were for the role (coordinators) and to have a positive experience in a coordinated setting (coordinated instructors). Both sets of questions were asked on a three-point scale.

We also asked both groups two open-ended questions: what worked well about their experience in coordinated courses and what challenges they encountered in coordinated courses. The first two authors used thematic analysis (Braun &Clarke, 2006): they read through and considered patterns in the responses, taking an inductive approach to identifying themes. They each reviewed the entire set of responses, coding responses with one or more themes. Finally, they met to discuss the coding and reconcile any differences until complete agreement was reached.

Results

We averaged the ratings on the three-point survey questions to create heat map visualizations to compare perceptions of frequency/importance of each action among the groups of participants: coordinators, coordinated permanent faculty, and coordinated contingent faculty (see Figure 1).

Humanistic-Growth
IMPORTANCE
Ranges: ≤2.0, 2.01-2.5, 2.51-3.0

	Coordinator	Contingent	Permanent
1. Attends to student experience	2.64	2.53	2.69
2. Provides PD opportunities	1.45	2.16	1.62
3. Makes me feel welcome	2.45	2.68	2.31
4. Values my input	2.55	2.74	2.38
5. Allows for instructional autonomy	2.00	2.58	2.23
6. Provides regular meetings	2.27	2.11	1.85
7. Demonstrates pedagogical knowledge	2.00	2.42	1.62

Humanistic-Growth
FREQUENCY

	Coordinator	Contingent	Permanent
1. Attends to student experience	3.00	2.74	2.46
2. Provides PD opportunities	1.82	2.00	1.62
3. Makes me feel welcome	2.82	2.95	2.92
4. Values my input	2.91	2.79	2.85
5. Allows for instructional autonomy	2.45	2.89	2.69
6. Provides regular meetings	2.55	2.47	2.23
7. Demonstrates pedagogical knowledge	2.27	2.68	2.38

Resource-Managerial
IMPORTANCE

	Coordinator	Contingent	Permanent
1. Provides consistent info about content	2.91	2.95	2.92
2. Provides common written HW	2.82	2.74	2.85
3. Maintains common online HW	2.64	2.63	2.58
4. Provides course materials	3.00	2.68	2.69
5. Exhibits strong administrative skills	3.00	2.95	3.00
6. Maintains a common Canvas course	2.82	2.74	2.77
7. Provides guidance on evaluating exams	2.55	2.63	1.75

Resource-Managerial
FREQUENCY

	Coordinator	Contingent	Permanent
1. Provides consistent info about content	3.00	2.89	2.85
2. Provides common written HW	3.00	2.89	3.00
3. Maintains common online HW	2.73	2.84	2.54
4. Provides course materials	3.00	2.84	2.92
5. Exhibits strong administrative skills	3.00	2.95	2.69
6. Maintains a common Canvas course	2.82	2.79	2.85
7. Provides guidance on evaluating exams	2.91	2.84	2.50

Figure 1. Average perceived importance and frequency of different coordinators actions by faculty group. Scores of 1 = Not important/In few coordination experiences, 2 = Somewhat important/About half of coordination experiences, 3 = Very important/In most or all coordination experiences

We first consider research question 1: What are the experiences and the needs of coordinated faculty? We use the ratings about the frequency of coordinator actions to explore coordinated instructors' experiences and the ratings about importance of these actions to examine coordinated instructors' needs. We also use coded responses to the open-ended questions.

What are the Experiences of Coordinated Faculty?

Finding 1a: **Coordinated faculty agree that most coordination actions are occurring frequently and more consistently agree about the frequency of Resource-Managerial actions as opposed to Humanistic-Growth actions.** In looking at the two frequency heat maps on the right of Figure 1, 71% (10 of 14) actions have averages of at least 2.50 for both coordinated contingent and coordinated permanent faculty, suggesting general agreement that many actions are occurring most or all of the time. The four actions that coordinated faculty feel are happening less often are all in the Humanistic-Growth category: 'attends to student experience' (HG1), 'provides PD opportunities' (HG2), 'provides regular meetings' (HG6), and 'demonstrates pedagogical knowledge' (HG7). We observe that there is much more variability in the HG frequency table compared to the RM frequency table. Additionally, faculty commented more frequently about Resource-Managerial actions compared to Humanistic-Growth actions when asked about what is working well for coordination.

What are the Needs of Coordinated Faculty?

Finding 1b: Coordinated faculty believe that nearly all Resource-Managerial actions are important and report them as more important than Humanistic-Growth actions, although most Humanistic-Growth actions are rated as at least somewhat important. The importance heat map averages for RM statements for coordinated faculty are all 2.58 or above (see bottom left heat map) apart from 'provides guidance on exams' (RM 7) for permanent faculty (average 1.75). By comparison, if we look at the heat map averages for HG statements for coordinated faculty (see upper left heat map in Figure 1), only one Humanistic-Growth action, 'attends to student experience' (HG1), was rated as important by both coordinated contingent and coordinated permanent faculty with an average of 2.53 and 2.69 respectively. Additionally, about half or more of all coordinated faculty in each group rated each of the RM and HG coordination actions as at least somewhat important. This suggests that even though there may be differences in importance ratings between RM and HG actions, all coordination actions have some value to many faculty.

Finding 1c: Coordinated contingent faculty have different needs from the coordinated permanent faculty, primarily with respect to Humanistic-Growth actions. Most differences in needs between coordinated contingent and coordinated permanent faculty were with the HG actions, with coordinated contingent faculty rating all HG actions, except 'attends to student experience' (HG1), as more important than the coordinated permanent faculty did (see upper left heat map in Figure 1). It could be that these actions provide a greater benefit to contingent than permanent faculty due to the nature of their employment. All these actions focus on helping instructors feel included and supported in growth, something that permanent faculty may already get elsewhere, but what contingent faculty are primarily obtaining through their coordinated experience.

Another difference between coordinated contingent and permanent faculty had to do with the need for consistency across sections. In responses to the open-ended question about challenges with coordination, 64% (9 of 14) of coordinated contingent faculty expressed concerns about providing a consistent experience for students compared to only 22% (2 of 9) of coordinated permanent faculty. We believe there is a good reason more contingent faculty brought up the consistency issue. Namely, for coordinated contingent faculty members, teaching is the entirety of their job, so consistency issues over which they have little to no control can cause anxiety over whether they are adequately performing the position requirements.

We next consider research question 2: To what extent do the values and experiences of coordinated faculty align with what coordinators value and practice? To answer this question, we focus our attention on all three columns of the heat maps shown in Figure 1 and the responses to the open-ended questions for both coordinated faculty and coordinators.

Alignment between coordinators and coordinated faculty.

Finding 2a: The needs of coordinated permanent faculty generally align with the values of coordinators, with a few exceptions. By examining columns one and three on the left two heat maps, we can see that for most coordination actions, the importance averages are similar for coordinators and coordinated permanent faculty. This is perhaps unsurprising, because the coordinators are all permanent faculty, although neither group was a subset of the other when considering survey respondents. In Finding 1c, we addressed the ways in which coordinated contingent faculty importance ratings aligned with those of coordinated permanent faculty in RM categories as well as the ways they did not align in HG categories. The alignment of coordinators with coordinated permanent faculty means that there is also alignment between coordinators and

coordinated contingent faculty in importance for RM actions and more misalignment between coordinators and coordinated contingent faculty in importance for HG actions. We believe that those actions for which coordinators and coordinated permanent faculty did not align in terms of importance reflect a lack of clarity around expectations for the coordinator role.

Alignment between needs and experiences.

Finding 2b: Most of the needs of the coordinated faculty (related to the RM and HG actions) are being met by the coordinator practices. We can compare the importance ratings of the coordinated faculty to the experience ratings of the three groups (which are generally aligned) as a measure of how these needs are being met. For RM actions, the needs of coordinated faculty are mostly being met in their coordination experiences. It is interesting to note that for (RM5) 'exhibits strong administrative skills' the coordinated permanent faculty unanimously report it as 'very important' with a 3.0 importance rating, yet only 69% (9 of 13) report the action as always happening in their coordination experiences.

In looking at the ratings of importance and experience for HG actions, there are only two actions for which the frequency rating was lower than the importance rating. We highlight 'provides PD opportunities' (HG2) for coordinated contingent faculty (2.16 importance, 2.0 experience). While this is not a large difference, we have previously discussed the importance of this action to some contingent faculty. The following was expressed by one of the coordinators in the open-ended questions and relates to the lack of clarity around professional development: "It is also challenging to gauge how involved I need to be with each individual coordinated instructor and what my role is helping/mentoring/evaluating them. It would be nice to have some more clarity about what, exactly, my role is for them as professionals."

Discussion

We first consider the question, "How are the needs of coordinated faculty being met?" The results show that RM actions were valued more than HG actions in general by coordinated faculty (Finding 1b) and there are different needs for the coordinated contingent faculty and coordinated permanent faculty (Finding 1c). About half or more of all coordinated faculty in each group rated each of the RM and HG coordination actions as at least somewhat important (Finding 1b). Additionally, given the concern that coordinated contingent faculty had around consistency, it seems that coordinated faculty in general need a coordinator who performs all coordination actions while also addressing consistency concerns across sections. We also observed that some needs were clearly not being met (Finding 2b), which suggests a need to revisit the coordinator's duties and expectations list adopted by the department. Furthermore, our data supports Martinez et al.'s (2022) thesis that RM actions serve as a baseline for coordinator expectations and that HG actions are advanced practices.

We next consider the question, "How should the coordinator role be defined so it meets the needs of coordinated faculty while also supporting coordinators?" Our findings indicate that in addition to ensuring that coordinators perform RM actions, it is also valuable to support coordinators in performing HG actions. Given that almost all of the coordinated courses at TAU utilize a mix of contingent and permanent faculty, each coordinator action is valuable to at least some cohort of coordinated faculty. The three HG actions that were not rated as 'very important' were still rated as 'somewhat important' by contingent faculty (Finding 1b) while coordinators viewed these actions as either unimportant (HG2, HG7) or only somewhat important (HG6). The data suggests that coordinated contingent faculty view coordinators as mentors, whereas coordinator actions are not always fulfilling that role.

We hypothesize that the variations in which actions a coordinator chooses to perform may occur because the coordinator is unsure of the required list of duties, does not have time to attend to some actions, or is not sure how to perform some of the actions. Additionally, some coordinators may not believe HG actions should be part of the job. While we do not know the exact reasons, we conjecture that all the above are factors to at least some coordinators. To help coordinators appreciate the value of HG actions, we believe that greater uptake would occur if we were able to demonstrate improved student learning and increased sense of belonging of contingent faculty when coordinators embrace an HG orientation and attend to HG actions.

Conclusion

TAU is not unique in employing both contingent faculty and permanent faculty to teach in coordinated courses, although the ratios and types of contingent faculty may vary at other institutions. Findings suggest two needs for coordination more broadly. First and foremost, there is a need for our professional societies to provide guidance on what the role of a course coordinator should be and to provide recognition for this challenging and important role. Identifying evidence-based coordination best practices would support departments and institutions in defining the coordinator role more locally. Coordinators have both direct and indirect impact on all the students enrolled in coordinated courses and therefore have the potential to make a significant impact on student learning (Bressoud et al., 2015; Rasmussen et al., 2019).

In addition to identifying the coordinator role and best practices, there is also a national need to provide professional development for coordinators to develop both the dispositions and skills necessary to be effective in their roles. The different needs of coordinated faculty pose a particular challenge for coordinators. While many coordinators may feel more comfortable performing RM actions, the differing values for and uncertainty around HG actions imply that coordinators may need more support in performing these actions. Our professional societies could also lead this charge by providing workshops, materials, or even certification for coordinators. Given the impact a coordinator has on instruction and student learning, it is imperative for departments and professional societies to provide guidance on the role, identify best practices, develop professional development programs, and to provide recognition for coordinators.

Acknowledgements

We want to thank all the coordinators and coordinated faculty who participated in this study. We especially appreciate the current and former adjunct faculty in our department who were able to find time to complete the survey.

Innovation Configuration Maps: A Tool for Guiding Team-Based Change Work in Higher Education

Mary E. Pilgrim
San Diego State University

Amelia Stone-Johnstone
California State University Fullerton

DAT Grant Project Team

The Department Action Team (DAT) model supports groups of individuals in creating sustainable improvements to education within their department. A DAT, consisting of department members and external facilitators, works collaboratively towards a shared goal. Using innovation configuration (IC) maps we study three DATs, exploring members' perspectives about their goals, work, and the process of actualizing goals. We examine the degree to which these groups perceived their alignment with the DAT model, and close with a discussion of how IC maps can be used as a tool to assess the alignment of team-based change work to change models.

Keywords: innovation configuration maps, department change, principles for change.

Meaningful and lasting change is a complex process that goes beyond the efforts of a single individual (Fisher & Henderson, 2018) and can often call into question strongly held beliefs and ingrained practices. Because deep-rooted institutional structures and cultural norms complicate educational transformation (Austin, 2011; Kezar et al., 2015), effective and lasting change must involve stakeholders collectively developing and working towards a shared vision to support and assess innovation efforts to improve STEM education (Henderson et al. 2011; Palmer & Giering, 2023). The Departmental Action Team (DAT) model is such a model that engages multiple stakeholders, taking into account both context and culture to enact and sustain change at the department-level (Reinholz et al., 2019).

The work presented in this paper was part of a larger project aimed to develop collaborative teams (DATs) to work on a local problem in undergraduate STEM education[1]. As part of this work, Innovation Configuration (IC) maps in the form of a survey were developed to support DAT members to come together on the key characteristics of the DAT model. Assessing each DAT's alignment with the DAT model is essential for evaluating their change efforts. In this manuscript we explore the work of three STEM DATs and use IC maps to answer the following question: *What are DAT members' perceptions of alignment with the DAT model?*

Theoretical Framework: The Department Action Team Model and Guiding Principles

A DAT is a type of working group typically consisting of 4-8 department members (e.g., faculty, non-tenure track faculty, students, staff) and 1-2 external facilitators. External facilitators are typically individuals trained in group facilitation and may be part of an institution's Teaching and Learning Center. DATs work to make sustainable change by addressing an educational problem of broad-scale importance. Past DATs have focused on developing program-level outcomes, assessments, and studying student experiences for program improvements. A DAT's goal is developed through a shared visioning process (Reinholz et al., 2021), and the DAT meets regularly to enact a project related to the identified goal. The work of the DAT is guided by six core principles which reflect a synthesis of research grounded in organizational change and higher education literature (Quan et al., 2019, p. 010141-2):

[1] Go to https://dat-project.org/ for more information about the DAT project.

1. Students are partners in the educational process (P1).
2. Work focuses on achieving collective positive outcomes (P2).
3. Data collection, analysis, and interpretation inform decision-making (P3).
4. Collaboration among group members is enjoyable, productive, and rewarding (P4).
5. Continuous improvement is an upheld practice (P5).
6. Work is grounded in a commitment to equity, inclusion, and social justice (P6).

Although Quan et al. note that "fostering departmental change requires more than principles alone" (e.g., readiness, resources, etc.; p. 010141-18), they acknowledge that when coupled with an effective model, such as the DAT model, a change initiative can be more effective. External facilitators use these principles to guide a DAT in their work as well as formatively assess a department's shift in culture (Ngai et al., 2023; Reinholz et al., 2019).

Innovation Configuration Maps as an Analytical Framework

An IC map is an instrument intended to document and potentially quantify particular aspects of a change effort. Specifically, an IC map illustrates "different ways of getting from A to B" by summarizing "in words of the different ways the key components of an innovation can be made operational" (Hall & George, 2000, p. 3). In this manuscript we focus on an IC map of the six core principles of the DAT model. Each principle makes up a component of the IC map, and each component has variations that illustrate how that principle may manifest in a DAT. These variations illustrate degrees of alignment with the DAT model. For example, the P1 component is illustrated with its five variations in Figure 1[2]. Variations of P1 that are aligned with the DAT model are listed first and are black, ■. The ideal manifestation of P1 is the first option, and the second is an acceptable variation that is still in alignment with P1. Those below are partially aligned (gray, ■) or unaligned (red, ■).

P1 - Students are partners in the educational process

■ The DAT has student members. Student members participate meaningfully and see themselves as partners.

■ The DAT has student members that contribute to decision making to an extent, and see themselves as partners in the DAT some of the time.

■ The DAT seeks input from students to inform its work.

■ The DAT has student members, but they do not see themselves as partners in the DAT.

■ The DAT does not have student members, and the DAT does not seek input from students to inform its work.

If you have additional comments, please explain:

Figure 1. Principle 1 and its corresponding variations.

Methods

This study focuses on the participant perspectives from three STEM DATs: Herbs, Summoning, and Prophecy (all pseudonyms). Data collection occurred during the last phase of the Herbs and Summoning DAT work as external facilitation began to diminish, and immediately after the Prophecy DAT concluded their work. Thus, we deemed them as well-positioned to pilot the DAT Core Principles IC Map, which has gone through subsequent revisions. The current version can be found in *Facilitating change in higher education: The Departmental Action Team mode* (Ngai et al., 2020). Twenty-nine DAT members were invited to

[2] All principles and their corresponding variations can be found in this document: https://tinyurl.com/3zaphsbm.

participate, and 19 responses were received. Respondents included department members as well as facilitators, many of whom were involved in the development of the IC Maps.

We used a Google form to administer the IC Map as a survey and synthesized perspectives from DAT members to establish a holistic picture of the level to which the DAT was embodying each of the six principles. First, DAT members were asked open-response questions about their DAT's goals and the DAT experience, and then multiple-choice questions about the six principles followed where respondents were prompted to choose variations of each principle that matched their DAT's implementation. Following each multiple-choice prompt, respondents were also asked if they had additional comments, which were provided as open responses. The survey ended with two closed-form responses about department structures, however, the focus of this manuscript is on how the DAT engaged with the six core principles.

Participants' responses were categorized (aligned, partially aligned, unaligned) by the authors based on the variation selected for each core principle. Responses from facilitators triangulate and add context to broader results.

Results

In the following sections we describe three DATs (Herbs, Summoning, and Prophecy) and how they focused their work based on their survey responses. We discuss members' perspectives of how their respective DAT's work aligned with the six principles.

Herbs

The Herbs DAT assembled for about two academic years with the primary aim to assess the alignment between the department's desired student outcomes and the skill development from targeted coursework for undergraduate majors. At any given time, the Herbs DAT was composed of up to seven members: up to four faculty members, one graduate student, one undergraduate student, and up to two facilitators, with members cycling on or off the DAT due to other obligations. Seven Herbs DAT members responded to the IC map survey: one student, three faculty members, and three facilitators.

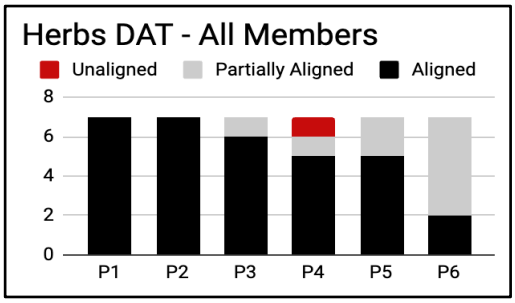

Figure 2. Herbs DAT responses to IC map.

The Herbs DAT members were in complete agreement with regard to alignment with P1 and P2 (Figure 2). Although in agreement on P2, there was some tension, with a facilitator noting that there were times when a couple of DAT members had "outsized influence" on the work. For the most part members were also in agreement with regard to their use of data (P3). The one dissenting respondent, a facilitator, commented that "data comes from their choice of assessments. [It is] unclear whether they will engage in pure bias prediction activity. [Institutional Research] and course data has not been included."

While five of the seven respondents characterized Herbs' collaboration (P4) as ideal, a few members noticed certain areas that did not align with the DAT model. One member indicated

that they perceived the group collaboration to be overall positive, but questioned whether the DAT would actualize their goals. One facilitator chose an unaligned option, noting that there were some members with "lower attendance." However, another facilitator highlighted the DAT's success in fostering collaborative learning about assessment.

For P5, two members selected a partially aligned statement expressing concern with specific details of how and when assessments would be conducted and how results would impact future work. Two faculty expressed uncertainty about lasting impact, with one indicating it would be dependent on whether faculty continue the work, and another noting the need for establishment of an ongoing committee if the work was to continue.

Regarding P6, the DAT respondents were mostly in agreement that their work was partially aligned with a commitment to equity, inclusion, and social justice, with two members feeling that the work was aligned. For example, one facilitator acknowledged the diversity in the membership of the Herbs DAT but expressed some reservation about the degree to which Herbs' work was grounded in equity, inclusion, and social justice. They explained, "I wouldn't say inclusion is routinely considered, but they have done so unprompted."

Summoning

The Summoning DAT operated as a DAT for about two years, honing on the issue of cultivating community among the undergraduate majors. Summoning began their work with six members: three faculty members, two graduate students, and one facilitator. The membership expanded to include up to two undergraduate students and two external facilitators. Six of the ten Summoning members completed the IC map survey, including three facilitators, one faculty member, and two students.

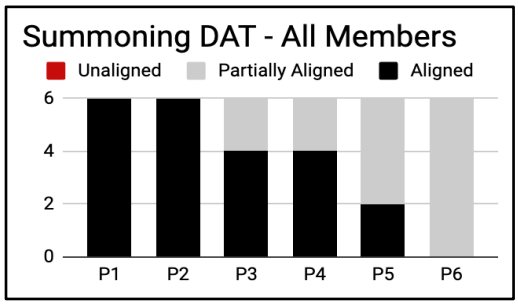

Figure 3. Summoning DAT responses to IC map.

The Summoning DAT was in agreement with perceived alignment with P1 (Figure 3). Summoning members saw the value that students brought, noting that they were "driving forces" for change and "accomplishments would not have come to fruition without them." One student member expressed that they were able to develop communication skills and a sense of belonging:

> I have been able to work with my professors in the DAT and meet with some amazing people, learn how to communicate effectively and hear so many different ideas. I really was able to learn the beauty of collaboration from a socially diverse group.

One facilitator responded, "this is the DAT that showed me how friendly and supportive a group can be toward its undergraduates."

The DAT members also were in agreement about alignment with P2. While the DAT felt that their work was primarily consensus-driven, some members felt that there were some instances when work was driven by a few more vocal members - thus categorized as aligned, but not ideal.

Disagreement among members crops up more with regard to P3 and P4, with four members perceiving their work as aligned with the DAT model and two members selecting partial

alignment. Members who felt that they were aligned with P3 noted that they used student survey data, department statistics, and faculty and student opinion polls, noting specifically that their work was "motivated by student voices". The two respondents who perceived the work as partially aligned, one of whom was a facilitator, did not elaborate on their selection. There was however further elaboration with regard to the partial alignment characterization of P4. Two DAT facilitators chose partial alignment here, with one adding "they have been stronger as a group around their process skills, than in executing projects that will be big/structural/sustainable." While the group collaborated well, it struggled to achieve its goals.

Four respondents' selections were coded as partially aligned with P5; these respondents acknowledged that change may occur, but two of them did not believe that Summoning considered nor developed an assessment to guide the change, and the other two did not believe the group planned for sustainability.

The IC map prompt for P6 asked respondents to measure the extent to which their work is grounded in equity, inclusion, and social justice with choices pertaining to both 1) the group composition and 2) the DAT's work. All six respondents indicated the DAT partially aligned with the ideal of P6. One facilitator stated,

> [The group was diverse] in role and gender. They have considered how language and scheduling impact [undergraduates] vs. other roles in the department. They have considered issues of [universal design for learning] and accessibility, but they didn't apply these strongly to event planning. They struggled over how to advertise inclusively for various reasons. One member requested inclusion be put in the agenda, once.

One member stated, "We lack diversity in our membership, but I think it is something that we realize and we are trying to think about it with respect to our goals." So, while there was agreement regarding group composition, there was some tension around whether or not DAT work was grounded in P6.

Prophecy

The Prophecy DAT was made up of four faculty members, one graduate student, and two external facilitators. Membership remained unchanged for the Prophecy DAT during its one-year tenure. Of the seven DAT members, three faculty members, one graduate student, and two facilitators responded to the IC map survey. Responses on the IC map survey indicated that the Prophecy DAT struggled in identifying a singular goal for their work.

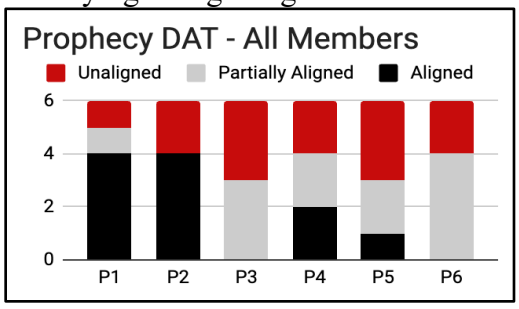

Figure 4. Prophecy DAT responses to IC map.

Figure 4 illustrates the mixed perceptions Prophecy DAT members had with regard to the six principles. Although P1 and P2 had some agreement of perceived alignment, there were still notable differences. For instance, the graduate student member stated finding it "difficult to contribute [her] opinion." Other DAT members felt that their student member was valued and

had meaningful participation opportunities. Further, both facilitators and the graduate student stated that having an undergraduate student on the DAT would have been valuable.

The divide with P2 was between department DAT members and facilitators. The facilitators did not see the work as having a meaningful positive outcome. In contrast, the department DAT members selected statements coded as aligned with P2. These selections seem to contradict these members' statements that they had difficulty identifying a goal.

None of the Prophecy DAT members selected choices coded as aligned with P3. A facilitator pointed out that data was examined early on when the DAT was looking into doing work associated with Prophecy majors and research experiences. However, the facilitator also stated in their response that when they brought up the need to examine data connected to Prophecy's final goal, some DAT members pushed back, telling the facilitator "this is not an education research project." This indicates that in addition to not coalescing around a distinct goal, these DAT members did not recognize data's role in decision-making and their change efforts more broadly.

P4 and P5 had the least agreement among DAT members, with members' responses ranging from aligned to unaligned. While some found the meetings generally enjoyable, some were frustrated with the presence of facilitators, with one member stating that they felt like the facilitators were trying to "move in a direction" that was different from what the department DAT members wanted. There was a lack of agreement regarding sustainability (P5), most members viewed the work as a temporary "fix". One department DAT member noted that faculty are already overburdened with service, so the DAT work was not a priority and "a permanent DAT would be unwelcome both for the DAT members and for other department members."

The department DAT members were in agreement regarding P6, with all members selecting the partial alignment option, "The group exhibits diversity within its membership. The group can consider how decisions impact diverse populations when prompted." One pointed out that diversity was a challenge as members of the Prophecy Department were predominantly White and male. However, another DAT member felt that their group "could have been more diverse". The student member noted the lack of diversity, being the only student and female member, apart from facilitators. One department DAT member felt that the DAT did "indeed frequently consider the effects of [their] work on the diversity of our major population". However, a facilitator DAT member, in contrast, selected the unaligned option and added a note in their open response that they did not see any commitment by the DAT to equity, inclusion, or social justice.

Discussion

Responses to the IC Map survey yielded varied perceptions of alignment with the Core Principles of the DAT model. However, across all three DATs, P6 was the principle where most respondents did not perceive alignment with the DAT model. Historically, oppression and power imbalance have been prevalent in academic structures and across roles. Deep change work must attend to academic systems, structures, and roles (e.g., Fisher & Henderson, 2018; Henderson et al., 2011; Kellam et al., 2020; Malachowski et al., 2020; Reinholz & Apkarian, 2018), with consideration given to understanding how change impacts marginalized groups. A DAT could attend to this in several ways, including recruiting diverse (e.g., in role, background, gender, race, etc.) members when establishing a DAT, soliciting input and feedback from a diversity of stakeholders, and critically attending to issues of equity, inclusion, and social justice as it pertains to the DAT's overall goals. While Herbs and Summoning exhibited diversity in their membership, external facilitators noted the lack of a grounding or execution of DAT work attending to equity, inclusion, and social justice. Department DAT members of Prophecy, on the

other hand, acknowledged a lack of diversity in their membership. Further a facilitator questioned Prophecy's commitment to these principles in their DAT work altogether.

DAT Goals correlated with the enactment of six principles

We noticed a relationship between clearly articulated goals agreed upon by all members and better alignment with the principles. Summoning and Herbs were exemplars of how clear goals were associated with (perceived) alignment with the six principles. In contrast, Prophecy struggled to identify and state a goal and achieve alignment with the principles. This association may occur when a clearly articulated goal facilitates a DAT's embodiment of the six principles. For instance, a goal can guide a DAT's approach to stakeholder input, data collection, and feedback, which are necessary for informing their work.

Herbs. The work of the Herbs DAT focused on student outcomes and skill development in targeted coursework. They believed that including a student voice (P1) was crucial to achieving their student-centered goal. In addition, Herbs' clearly articulated goal may have better positioned them to focus on achieving positive outcomes as a collective (P2). Short-term success was perceived, but the long process to actualizing the stated goals raised concerns about the DAT's productivity (P4) and sustainability of efforts (P5). Ultimately, members acknowledged that institutionalization was necessary for long-term sustainability. Overall, the Herbs DAT mostly agreed on alignment (or in some cases partially aligned) with the six principles and considered themselves successful in pursuing their goal.

Summoning. Summoning aimed to foster community among undergraduate students in their program. To incorporate the student voice, which was crucial in discussing student community aspects, Summoning recruited and actively engaged student members in their DAT work (P1). Both department DAT members and facilitators emphasized the value of the student voice, and targeted data sources that would help them capture it (P3). Although Summoning focused on collectively achieving positive outcomes (P2) and collaborated in a rewarding way (P4), they struggled to have a clear assessment plan to guide ongoing work and change efforts (P5) focused on the undergraduate student community in their program.

Prophecy. Unlike Herbs and Summoning, Prophecy struggled to define a clear goal and also struggled with uncertainty about which student voices should be heard and debates over student inclusion (P1). The absence of a focus hindered discussions on data-driven decision-making (P3). Furthermore, some department members felt that facilitators were steering the work in a direction not chosen by the DAT members, causing collaboration difficulties (P4). Overall, this lack of clarity made it hard for the Prophecy DAT to focus their meetings and work in a meaningful way, which negatively impacted long-term efforts and sustainability (thus Prophecy's lack of alignment with P5). It is possible that for the Prophecy DAT the absence of a clear goal contributed to varying perceptions of alignment with the six principles.

Conclusion

The DAT model provides a framework for anyone wishing to pursue department-level change with the IC Map acting as a research-based tool for professional development facilitators or teams engaged in change work. The six core principles of the DAT model can guide teams to actualize sustainable and meaningful change within their communities. DAT facilitators and team members can use the IC Map to regularly evaluate the alignment of their work with the six core principles and make adjustments as needed. However, the analysis of the three DATs underscores the need for clearly articulated goals towards pursuing sustainable departmental change.

Equity Does as Equity Feels: Perspectives on Equity and Active Learning in Collaborative, Problem-solving Courses at an HSI

Jocelyn Rios
University of Northern Colorado

Guadalupe I. Lozano
University of Arizona

In this study, we explore notions of HSI servingness and equity in practice as perceived by instructors, facilitators, and students in active learning collaborative, precalculus and calculus problem-solving courses. These courses were part of a grant-funded, scholars program for minoritized student populations. While program outcomes on student achievement, engagement and confidence (discussed elsewhere) are promising, our intent here is to identify and characterize how equity was understood and experienced in practice by those taking and facilitating the courses. Our analysis suggests that instructors and students agree on the learning themes where equity played a role within these active learning courses, but differ in their conceptions of equity within these themes, and in how they saw equity being enacted in practice.

Keywords: active learning, precalculus, calculus workshops, equity, HSI servingness

Purpose of the Study

As Hispanic/Latine populations grow, more universities are being designated as Hispanic-Serving Institutions (HSIs). Yet, Latine representation in STEM remains stagnant, urging HSIs to prioritize making mathematics learning more equitable for Latine and other minoritized students (e.g., Lozano et al., 2018). One popular response approach is scaling student-centered, evidence-based practices, like active learning (Theobald et al., 2020). But how does equity take form in active learning spaces? And to what extent does it serve minoritized populations?

As active learning uptake increases (Patrick, 2020), more needs to be learned about how it is experienced and enacted in practice to promote equity, particularly in gateway mathematics courses. One approach to do this is learning how different stakeholders—researchers, institutions, instructors, and students—understand equity and perceive it in practice. While equity can mean enhancing student achievement and learning, it is also tied to enriching students' experiences, affirming their identities and values, and promoting human flourishing.

In this paper, we seek to understand equity in practice from the perspective of different stakeholders, in the context of active learning, problem-solving (PS) courses (henceforth, PS courses) intended to support the transition to the university for particular minoritized populations. We analyze how facilitators and students conceptualized and experienced equity in the (precalculus and calculus) PS courses at a 4-year HSI.

The PS courses centered in this study serve to support an NSF-funded PS Scholar program designed to enhance equity in the transition to the university. As such, the program ran at three sites, including two 2-year HSIs. This paper focuses on the experience in the PS courses at the 4-year HSI. While results on the program's impact on student achievement, engagement and confidence have been preliminarily reported elsewhere and are promising, we focus here on qualitatively understanding how equity was seen and felt in the PS courses. We address two research questions: (RQ1) *In what ways did facilitators see students as equitably supported (or not) in the PS courses and what conception(s) of equity underlie their perspectives?* (RQ2) *In what ways did students see themselves equitably supported (or not) in the PS courses and what conception(s) of equity underlie their perspectives?*

Relevant Literature

Active learning practices have been shown to improve outcomes for traditionally minoritized populations by reducing achievement gaps (Laursen et al., 2014; Theobald et al., 2020). Successful examples include the Emerging Scholars Program (ESP) calculus workshops, inspired by Uri Triesman's work with Black and Latine students at UC Berkeley (Hsu et al., 2011). These workshops, now implemented across the U.S., support minoritized students by creating small, diverse classrooms where students work collaboratively on rich mathematical problems, just as in the PS Scholar program grounding this study. Research indicates that these workshops can lead to improved course grades and increased persistence in STEM (Duncan & Dick, 2006; Moreno & Muller, 1999). One qualitative study by Oppland-Cordell and Martin (2015) highlights the positive impact the workshop had on Latine students' mathematical and racial identities. However, McNeilly (2021) notes a need for deeper understanding of how students experience these active learning workshops and how different practices promote equity.

In everyday classrooms, active learning practices are not always inherently equitable (e.g., Johnson et al., 2020; Reinholz et al., 2022; Rios, 2023). For instance, Rios (2024) demonstrates how multilingual students of color at HSIs were often positioned in deficit ways during group work, while Leyva et al. (in press) demonstrate that group work could either support or hinder Latine students' access to supportive, "racially-affirming communities" (p. 1). Additionally, there are varying perspectives among mathematics instructors on the role of equity within active learning. Bennet et al. (2022) found that instructors often view equitable teaching as a subset of active learning, yet Williams et al. (2022) reported that instructors did not explicitly address equity in their understanding of active learning. Moreover, research also suggests varying perspectives on the relevance of social identities, like race, when conceptualizing equity (Garcia et al., 2020). Some studies suggest that color-neutral instructor attitudes are linked to less effective equitable practices (Aragón et al., 2017; Garcia et al., 2020). Addressing these gaps, our study explores how students and instructors perceive and enact equity in active learning classrooms, focusing on critical notions of equity that center the whole learner.

Theoretical Framing

Several theoretical frameworks distinguish between critical notions of equity—centering identity, cultural capital, and lived experiences—and equity in academic achievement. Gutiérrez's (2007) equity framework in mathematics education, for example, comprises two axes: the dominant axis, which focuses on access and achievement, and the critical axis, which emphasizes identity and empowerment. The dominant axis conceptualizes equity as granting access to resources—such as quality teaching, instructional materials, and a supportive classroom environment—to ensure student learning and achievement (Gutiérrez, 2011; Rubel, 2017). The critical axis highlights the importance of considering students' identities and the power dynamics within the classroom. It acknowledges that students' cultural, racial/ethnic, gender, and linguistic identities play an important role in their educational experiences. Gutierrez (2007) argues that to champion equity, classrooms must increase access *and* create spaces that affirm and empower students' identities, allowing thriving without sacrificing who students are.

In the context of HSIs, Garcia (2017) introduces a framework describing four institutional identities HSIs may embody in serving students. In alignment with Gutiérrez's (2007), Garcia's framework is built upon two key dimensions. The *outcomes* dimension captures Latine retention and graduation rates. The *culture* dimension reflects how the campus environment affirms Latine students' identities and enhances their educational experiences. Garcia's term, *servingness*—an

institutional commitment to advancing both of these dimensions—connotes the embodiment of support for Latine student flourishing alongside academic achievement (e.g., Garcia, 2017).

We argue that the alignment between Gutierrez's and Garcia's frameworks suggests that when equity beliefs and practices include aspects of both the dominant and critical axis, the classroom environment mirrors and supports an institutional identity of HSI servingness.

Methods

The PS courses centered in this paper were taught at a large, urban 4-year HSI in the Southwestern U.S. They were open to all students concurrently enrolled in main precalculus or calculus course, including student participants in the NSF-funded PS Scholars program grounding this study (see Study Purpose). PS Scholars participants at the 4-year HSI included 2-year HSI transfer students and students with STEM majors belonging to certain specific minoritized populations: first-generation students, Latine women, and Veteran students.

The PS courses were interactive, co-curricular problem-solving courses utilizing evidence-based practices, including active and collaborative learning. Students met once a week and worked collaboratively (in groups of 3-4 students) directly on whiteboards for the two-hour class period, discussing and eventually co-solving 3-4 challenging problems shared with the class a week prior to each course meeting. Students were expected to think about/sketch ideas for solving each problem ahead of class. During class, instructors and facilitators actively listened, observed, asked questions and offered as-needed feedback as students worked on the boards.

The participants in this study were ten course facilitators (faculty, graduate and undergraduate student teaching assistants) and nine students enrolled in the program. Nine of the facilitators were either inferred as being white or self-identified as white during the interview. In contrast, student participants self-identified as being Mexican, Mexican American, or Hispanic (five), and African American (one). Three other students self-identified as White. Semi-structured interviews were conducted using two different interview protocols–one for facilitators and one for students. The protocols focused on understanding participants' takeaways from the course, and perspectives on equity. Interviews were recorded and lasted approximately one hour.

Transcripts were analyzed using thematic analysis (Braun & Clark, 2022), read multiple times, then coded in two rounds using deductive and inductive coding schemes (Fereday & Muir-Cochrane, 2006). The first round of coding was deductive and yielded two principal codes developed based on Gutiérrez's (2007) notion of dominant and critical equity. This first round served to parse out our understanding of the various meanings of equity discussed by students and instructors. The second round of coding was inductive and focused on analyzing the data to identify emergent codes. Specifically, we were interested in developing codes that captured the course features and teaching practices students and instructors identified as relating to equity (both dominant and critical). Using an iterative open coding scheme, emergent codes were identified and refined. Once the final codes were developed and defined, the data was carefully re-coded to ensure consistency and accuracy. The final stage of analysis organized the data into a content log based on three organizational categories: (1) student vs. facilitator data, (2) dominant vs. critical equity notions (3) equity themes tied to course features and teaching practices.

Findings

We identified three themes surrounding student and instructor perceptions of equitable support in the co-curricular courses: (1) access to facilitator support, (2) engaging with problems geared towards critical thinking, and (3) collaborating with others in groups. However, our analysis reveals differences in whether students and instructors felt that the practices described

by each theme were, in fact, equitable, as well as differences in their underlying conceptions of equity (i.e., equity understood from the dominant or critical axis). For example, while both facilitators and students felt that theme (1), access to facilitator support, enhanced student learning, students expressed wishing they could interact with faculty who shared their cultural and language identities. Similarly, while both students and facilitators appreciated the rich problem sets in the course (theme 2), one student expressed wanting the problem contexts to be more relevant to everyday life.

In this paper, we focus on exploring theme (3), group work (Figure 1). Facilitators' perceptions about equity in group work were primarily aligned with dominant conception of equity, that is with notions of equity tied to access and achievement. Most Facilitators did not

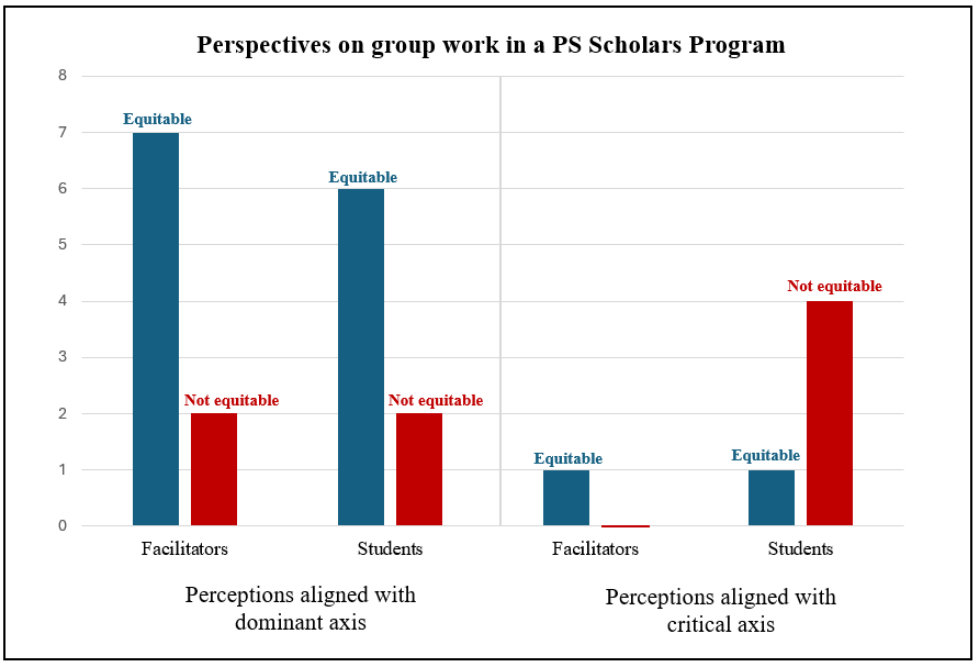

Figure 1. Number of facilitators and students who discussed group work as equitable (or not equitable). The left shows examples coded as aligning with the dominant axis, the right shows examples coded as aligning with critical.

perceive group work as connected to critical dimensions of equity. In contrast, students' perceptions of equity in group work aligned both with dominant and critical notions of equity, hence touching on aspects of what Garcia calls a Latine-serving HSI identity. While both students and facilitators saw group work as largely supporting equity in access and achievement in alignment with Garcia's Latine-producing HSI identity (blue bars vs. red bars, Figure 1, left), students also saw group work as undermining critical dimensions of equity (hence servingness), including identity and power (blue bars vs. red bars, Figure 1, right). We expound on the facilitator and student perspectives underlying these findings next, parsing them out in terms of Gutierrez's framework of dominant and critical equity. We come back to both Gutierrez's and Garcia's frameworks in the discussion.

Dominant Notions of Equity

Most facilitators and students perceived group work as aligned with equity in access and achievement and as mostly supporting (rather than undermining) equity in access and achievement (blue bars, Figure 1, left). Two facilitators and two students also perceived aspects of group work as undermining equity in access and achievement (red bars, Figure 1, left).

Facilitator Perspectives: *Group Work as Equitable*. Most facilitators viewed group work as a "key feature" of the course that supported equity. When discussing this, facilitators made arguments related to access and achievement. For example, they felt that group work gave students access to peers with different ideas and ways of thinking about mathematics, which supported their learning and success in the course. Several facilitators also mentioned group work naturally facilitated participation among students. One instructor noted that students "worked together beautifully" and that it was easier for them to "make mistakes" among peers than "in front of the whole class." Instructors also felt the challenging problems encouraged equitable participation. James explained, "everyone is struggling together," so there no dominant voice over the group work.

Facilitators also shared two practices they often used to ensure participation during group work was equitable: (1) monitoring student participation and stepping in as needed to ensure all were "actively participating," and (2) "mixing up" the groups frequently to ensure that "stronger" and "weaker students" worked together and helped each other learn. Some instructors described the utility of using colored markers to see that everyone was participating; others shared ways of bringing all students to actively participate by asking directed questions like "How would you explain that?" This was seen as helping everyone learn, by everyone sharing what they knew.

Several instructors commented on how regrouping allowed "students that did well" to share their knowledge with different student cohorts and benefit most of the class. Garrett sensed some students disliked regrouping, but felt it amplified students' access to knowledge and learning:

> For equity, one of the most important things was to make sure the groups were different every time so they all had access. /…/ I don't think students loved randomized groups, there was pushback on that. /…/ Of course, students who speak Portuguese will naturally gravitate to students who speak Portuguese or we have a lot of students from China who tend to stick together because they have a very shared experience and they can help each other survive through the process.

Garret acknowledges that students may naturally gravitate toward peers who share aspects of their identity, but believes promoting equity involves focusing on students' mathematical backgrounds to ensure equal access to learning.

Facilitator Perspectives: *Group Work as Not Equitable.* Two instructors raised concerns group work did not equitably support all students. James and Ashley observed that some students were "resistant" to group work. Despite the strategies used, "weaker" students at risk of failing tended to "hide in the background," showed less progress, and were reluctant to participate. James noted some students prefer to "lead" while others "follow," and the followers often fall into hard to break habits, likening it to an elastic band that wants to snap back to their "comfort zone". Other instructors perceived some students put minimal effort and let those who seemed more capable do the work. Overall, instructors felt all students gained something from group work, with James commenting that "just being there was enough" to support their learning.

Student Perspectives: *Group Work as Equitable*. Several students noted that group work equitably supported them in the course by enhancing their access to learning opportunities. They explained that collaborating in groups improved their understanding of mathematics by exposing them to different ways of thinking about and solving problems. For these students, the advantages of group work align with the dominant axis of equity. Alberto commented:

> To work in a collaborative setting is being able to get different perspectives. Since not every professor teaches the same way, each student will understand it differently. Having your peers explain it in different ways, that was really helpful.

Another student, Lucía, notices the presence of Hispanic peers yet seems to value the benefits of group work in terms of seeing different mathematical backgrounds:

> We were a pretty diverse set of individuals and we were mostly made up of Hispanic students, so it was nice being able to share ideas and different ways of learning things.

Student Perspectives: *Group Work as Not Equitable.* Two students felt that aspects of group work did not equitably support their access to learning and achievement. For example, Chantel described the problems she was expected to collaborate on as feeling "like a different language." She did not feel like she "understood" enough math or had the confidence to engage with problems, especially in front of peers. Chantel shared that if the goal of the course was to help students "get better at math", it was "helping her [group members] get greater at math" while she felt that she could not take "advantage" of the course.

Critical Notions of Equity

All but one facilitator perceived group work as neither supporting nor hindering critical dimensions of equity. Students, however, talked about identity and power when addressing group work, and saw this practice as mostly undermining critical dimensions of equity (Figure 1, left).

Facilitator Perspectives: *Group Work as Equitable.* One facilitator, Hannah, provided examples of equitable teaching practices related to group work, which suggest a conception of equity that also considers identity and power. Hannah described "intentionally" grouping women together and Veteran students together. Hannah worried that female students might feel "super overwhelmed and walked over" in groups with only men. Additionally, coming from a military family, Hannah recognized "nontraditional students" may not "relate" to "students in their 20s". Thus, having another Veteran student to work with would help them feel "validated".

By and large, facilitators did not seem to consider students' racial identities in their decisions or perspectives toward equity during group work. We see this in Garrett's quote described above. Similarly, Tamra commented there "was a relatively diverse ethnic group in the class," but added, "I don't feel like any of those differences [impacted] how well [students] participated in the classroom and how effective the classroom was for them."

Student Perspectives: *Group Work as Equitable.* For Stacie, group work affirmed her identity as a Veteran, in alignment with critical dimensions of equity—she felt "engaged and connected," less isolated when tackling problems by having other Veteran students in her group. Stacie appreciated sharing military collaborative practices with her group and felt her instructor, raised by military parents, created a space that felt "comfortable" and supportive for Veteran students.

Student Perspectives*: Group Work as Not Equitable.* Other students, primarily of color, felt group work interfered with supporting identity and power in the classroom. Several students felt the course lacked opportunities to meaningfully connect with peers who shared their cultural backgrounds. Anisia, for example, valued connecting with other peers from Mexico who understood her culture, language, and music, but struggled to "find [her] community" in class. She suggests group work can be challenging for connecting with peers when you are "forced to discuss math".

Other students, like Chantel, a first-generation "African American student" studying STEM, felt disempowered during group work. Raised by a single mother who was "always afraid of math" and with "parents who could not afford tutoring" Chantel felt overwhelmed and "dumb" when working with peers who appeared more confident and knowledgeable:

> When it comes to doing math in front of other people who seem to have it all together, like they really understand it conceptually, it makes me not want to do it because I feel dumb /…/ even if I think I have the right answer, I don't have the confidence to believe in myself.

Chantel shared that "where I come from, like my background, I think that was a hard factor for me in that class".

Similarly, Mateo noted "power dynamics" between "minority students" and "white students", who have had more "exposure" to advanced math courses at "wealthy high schools". He shared:

> Even though we are HSI, I feel like most Hispanics come in with the idea that there's definitely a power difference. If you go into a classroom, who is most likely to speak up is white students /…/ I feel like that's something that's kind of hindering this process of making everyone feel like they're part of the classroom.

Mateo wished that facilitators in the course would have focused on "trying to get rid of that power dynamic and making sure everyone's on the same playing field".

Discussion

Facilitators and students identified three themes that felt relevant to equity in the courses (facilitator support, rich problems, group work). These have been noted as core pillars of active learning and IBL (Apkarian et al., 2024; Laursen & Rasmussen, 2019). Focusing on equity in practice, however, our findings suggest differences in how facilitators and students viewed equity within these themes. Facilitators tended to focus on dominant notions of equity that center access and achievement. In contrast, students expressed a more holistic view of equity aligned with access and achievement as well as identity and power. Facilitators and students primarily agreed that the courses supported dominant notions of equity, which is consistent with traditional active learning design and measures of active learning success. Students' reflections on critical dimensions of equity—like identity and power—suggest the PS courses (which preceded the HSI designation by several years) embodied a Latine-producing HSI identity (Garcia, 2017) not quite yet fully embracing *servingness*. In other words, instructor and student perceptions suggest more can be done to embrace servingness at the classroom level in active learning PS courses, in ways that center identities, values, and lived experiences of all students.

The field's emphasis on dominant dimensions of equity when it comes to active learning may have prevented some instructors from thinking more critically about why students might choose not to participate or may not have access to participation. Rubel (2017) reports that the myth of meritocracy, feelings of "I can't relate", and colorblindness were three reasons White school teachers struggled to engage with critical equity-oriented practices. These reasons also emerged as themes in our data. For example, the perception that students who do not participate simply need to put in more effort aligns with ideas of meritocracy. These suggest an area for professional development (PD) to better support HSI faculty in cultivating equitable practices. Such PD could include facilitating conversations about the role of identity in students' STEM experiences (Adiredja et al., in press) and designing and implementing place-based, culturally responsive curriculum (Lozano, 2023).

We close by noting that, historically, much of the work on calculus workshops has used quantitative methods to assess normative outcomes as measures of success (McNeilly, 2021). While we are not questioning the impact of these programs, our work suggests that focusing exclusively on dominant understandings of equity—aligned with access and achievement—may overlook how equity is intended, perceived, and felt by minoritized students in the classroom, and shortchange opportunities for instructors to learn about and enact critical equity practices.

Coordinate Representation of Vectors and Matrix Representations of Linear Transformations in a DGS Assisted Linear Algebra Learning Environment: The Case of Polynomial Vector Space

Günhan Caglayan
New Jersey City University

The contributed report highlights the understanding of matrix representations of linear transformations mapping finite-dimensional polynomial vector spaces among university mathematics majors within a dynamic geometry software (DGS)-assisted linear algebra learning environment. Through an analysis of data from in-depth qualitative interviews, framed by the theories of representations in linear algebra (Dorier & Sierpinska, 2001; Hillel, 2000) and the concreteness principle (Harel, 2000), the findings reveal a range of innovative and creative ways in which the students integrated visual and analytical approaches to understand, produce, and interpret matrix representations of linear transformations. The results contribute new insights into the pedagogy of university-level linear algebra, highlighting the growing understanding of the role of visualization in the teaching and learning of the subject. The study also adds to the increasing body of evidence supporting the importance of visualization in linear algebra education.

Keywords: matrix representation; linear transformation; polynomial vector space; differential operator; dynamic geometry software

Researchers widely focused on the pedagogy of linear algebra (Dogan-Dunlap, 2010; Dorier, 1991, 1995, 1998; Dreyfus, Hillel & Sierpinska, 1998; Gueudet-Chartier, 2006; Harel, 1987, 1989, 1990; Parraguez & Oktac, 2010; Pavlopoulou, 1993; Robert & Robinet, 1989; Rogalski, 1994; Sierpinska, 1995, 2000; Sierpinska, Dreyfus & Hillel, 1999; Sinclair & Gol Tabaghi, 2010; Thomas & Stewart, 2011; Zandieh, Wawro & Rasmussen, 2017) along with representations in R^n and the multi-representational aspect of linear algebra (Dorier, Sierpinska, 2001; Hillel, 1997, 2000). Harel and Kaput (1991), and Harel (1990) formulated the concreteness principle, as a fundamental approach for the teaching and learning of linear algebra. He recommends MATLAB as a tool that would help students visualize vectors and matrices as concrete mathematical objects, in accordance with the concreteness principle. Aligned with the concreteness principle (Harel, 2000) and in search for a desirable matrix representation for a linear transformation as brought forward in Hillel (2000), this study focuses on linear algebra students' understandings of the matrix representations of linear transformations mapping finite dimensional polynomial vector spaces in a dynamic environment.

Representations in Linear Algebra

Describing linear algebra as an explosive compound of systems of representation, Dorier and Sierpinska (2001) classifies the representations used in linear algebra as the graphical, the tabular, and the symbolic representations (p. 270). Hillel (2000) views basis-dependent representations in linear algebra as the major cause of difficulties for students of introductory linear algebra courses. Basis-dependent representations are not unique; these representations are contingent upon the particular basis or bases used. The two major challenges for linear algebra students are the understanding of such basis-dependent structures along with the understanding of representational invariants, that is, the understanding of what stays invariant irrespective of the bases that are being employed in representing linear algebraic structures (p.199). In general,

when representing linear transformations like matrices, students often have difficulties in interpreting the columns of these matrix representations. A matrix representation itself is used to represent a linear transformation, yet, students are tempted to think of columns of this matrix as the images of the corresponding basis vectors under the linear transformation: "It stems from thinking that the columns of the matrix representation of an operator are, so to speak, images of the basis vectors, not representations of these images relative to a basis" (p.203-204). In their exploration of linear transformations, the mathematics majors in this study creatively and innovatively integrated visual and analytic approaches to construct meaningful matrix representations. Thus, the study is framed within the guiding theoretical perspectives of the concreteness principle (Harel, 2000) and the multi-representational context of linear algebra (Dorier & Sierpinska, 2001; Hillel, 2000).

Table 1. Interview tasks: Find the matrix A' for $T: \mathbb{P}_n \to \mathbb{P}_m$ relative to the bases B and B'.

Task 1	♦Multiplication by x Operator $\begin{cases} T: \mathbb{P}_2 \to \mathbb{P}_3 \\ p \mapsto xp \end{cases}$	$\mathcal{B} = \{1, x, x^2\}; \mathcal{B}' = \{1, x, x^2, x^3\}$
Task 2	♦Multiplication by x^2 Operator $\begin{cases} T: \mathbb{P}_2 \to \mathbb{P}_3 \\ p \mapsto x^2 p \end{cases}$	$\mathcal{B} = \{1, x, x^2\}; \mathcal{B}' = \{1, x, x^2, x^3, x^4\}$
Task 3	♦Differential Operator $\begin{cases} D_x: \mathbb{P}_2 \to \mathbb{P}_1 \\ p \mapsto p' \end{cases}$	$\mathcal{B} = \{1, x, x^2\}; \mathcal{B}' = \{1, x\}$
		$\mathcal{B} = \{1 + x, x - x^2, x + x^2\}; \mathcal{B}' = \{1 - x, 1 + x\}$
Task 4	♦Differential Operator $D_x: \mathbb{P}_3 \to \mathbb{P}_2$	$\mathcal{B} = \{1 + x^2, x - x^3, 1 - x^2, x + x^3\}; \mathcal{B}' = \{1 + x, x - x^2, x + x^2\}$
Task 5	♦Integral operator $\begin{cases} J: \mathbb{P}_2 \to \mathbb{P}_3 \\ x^k \mapsto \int_0^x t^k dt \end{cases}$	$\mathcal{B} = \{1 - x, x - x^2, 1 - x + x^2\}; \mathcal{B}' = \{1, x, x^2, x^3\}$
		$\mathcal{B} = \{1 + x, x - x^2, x + x^2\}; \mathcal{B}' = \{1, x, x^2, x^3\}$
		$\mathcal{B} = \{1, x, x^2\}; \mathcal{B}' = \{1 + x^2, x - x^3, 1 - x^2, x + x^3\}$
Task 6	♦Integral operator $\begin{cases} J: \mathbb{P}_3 \to \mathbb{P}_4 \\ x^k \mapsto \int_0^x t^k dt \end{cases}$	$\mathcal{B} = \{1, x, x^2, x^3\}; \mathcal{B}' = \{1, x, x^2, x^3, x^4\}$
		$\mathcal{B} = \{1 + x, x - x^2, x + x^2, x^3\}; \mathcal{B}' = \{1, x, x^2, x^3, x^4\}$
Sample Interview Outline: Is T/D/J a linear transformation? What does it mean for T/D/J to be a linear transformation? What is the standard matrix representation? Is it possible to have a square matrix as the matrix representation of T/D/J? Is it possible to use non-standard bases in the expression of the matrix representation of T/D/J? How would you multiply/differentiate/integrate a polynomial using the matrix representation of T/D/J? How would you compare the two approaches? How does the matrix representation you proposed act on the polynomial on the DGS ? How would you distinguish between the actual object from its representation?		

Context and Method

Qualitative-descriptive interview data were collected at a U.S. university as part of a research project aimed at enhancing math and math education majors' understanding of advanced mathematics, with a particular focus on the connections between geometry and linear algebra using DGS-MATLAB technology. The qualitative interviews followed a semi-structured interview model (Kvale, 2007), where the interviewer used follow-up probes and questions to delve deeper into the interviewees' responses. Sixteen math majors participated and answered a series of questions centered around matrix representations (see Table 1). The tasks were designed to be explored through both visual and analytic approaches, in line with the study's theoretical

framework. Although optional, the math majors were eager and enthusiastic about using MATLAB/DGS, primarily to check their work, visualize analytic solutions, test conjectures, and provide examples or counterexamples.

The analysis of the videotaped interviews, along with MATLAB-DGS inscriptions, was conducted using thematic analysis (Boyatzis, 1998) and the VA (visual-analytic) strategy coordination method (Zazkis, Dubinsky, & Dautermann, 1996). This methodology was employed to describe the innovative and creative ways in which participants coordinated visual and analytic approaches to make sense of matrix representations of linear transformations. After transcribing the interview videos, the author reviewed the videos and original transcripts line by line, using thematic analysis in coordination with the interview analysis method described by Zazkis et al. (1996), to identify the strategies (visual and analytic) employed by students in exploring matrix representations. The final stage of data analysis involved a comprehensive review of the entire dataset multiple times, following the constant comparative methodology (Glaser & Strauss, 1967).

Results

This section considers the polynomial multiplication operator (Tasks 1-2), the differential operator (Tasks 3-4), and the integral operator (Tasks 5-6). In each task, students were asked to find the matrix representation A' for the given linear transformation T relative to bases $\mathcal{B}$ and $\mathcal{B}'$. The analysis that follows focuses primarily on student-generated approaches and strategies.

```
>> t1=[0;0;1;0;0];t2=[0;0;0;1;0];
>> t3=[0;0;0;0;1]; A=[t1 t2 t3]

A =

     0     0     0
     0     0     0
     1     0     0
     0     1     0
     0     0     1
```

```

>> w=A*p

w =

     0
     0
     2
    -3
     1
```

Figure 1. S1's analytic-arithmetic representation for Task 2.

The Polynomial Multiplication Operator

Most of the research participants thought of Tasks 1-2 illustrating standard matrices of linear transformations that act as a polynomial-multiplication operator as straightforward and sufficed with the analytic representation by expressing $T(\mathbf{e}_1), T(\mathbf{e}_2), T(\mathbf{e}_3)$ in terms of $\mathbf{w}_1, \mathbf{w}_2, \mathbf{w}_3$ accompanied by the MATLAB verification process in obtaining the matrix representations. S1, for instance, first expressed the image vectors $T(1) = x, T(x) = x^2, T(x^2) = x^3$ in terms of the vectors of the standard basis $\mathcal{B}'$ of the codomain vector space $\mathbb{P}_3$ as $T(1) = 0\mathbf{w}_1 + 1\mathbf{w}_2 + 0\mathbf{w}_3 + 0\mathbf{w}_4, T(x) = 0\mathbf{w}_1 + 0\mathbf{w}_2 + 1\mathbf{w}_3 + 0\mathbf{w}_4, T(x^2) = 0\mathbf{w}_1 + 0\mathbf{w}_2 + 0\mathbf{w}_3 + 1\mathbf{w}_4$. She then wrote the 4×1 coordinate matrices $[T(\mathbf{e}_1)]_{\mathcal{B}'}, [T(\mathbf{e}_2)]_{\mathcal{B}'}, [T(\mathbf{e}_3)]_{\mathcal{B}'}$ using the coefficients in each linear combination in the previous step. Upon juxtaposing these coordinate matrices she obtained the desired 3×4 matrix $A = [[T(\mathbf{e}_1)]_{\mathcal{B}'} \quad [T(\mathbf{e}_2)]_{\mathcal{B}'} \quad [T(\mathbf{e}_3)]_{\mathcal{B}'}]$. To illustrate how the multiplication-by-x-operator works via the matrix representation, S1 first converted the polynomial $\mathbf{p} = 2 - 3x + x^2$ to its column vector representation $[\mathbf{p}]_{\mathcal{B}} = [2 \quad -3 \quad 1]^T$ relative to the standard basis $\mathcal{B}$ of the domain vector space $\mathbb{P}_2$. Upon applying the matrix A on $[\mathbf{p}]_{\mathcal{B}}$, she obtained $A[\mathbf{p}]_{\mathcal{B}} = [T(\mathbf{p})]_{\mathcal{B}'}$. Finally, she retrieved the image polynomial $T(\mathbf{p})$ from its coordinate representation $[T(\mathbf{p})]_{\mathcal{B}'}$ via the linear combination expression $T(\mathbf{p}) = 0\mathbf{w}_1 + 2\mathbf{w}_2 - 3\mathbf{w}_3 + 1\mathbf{w}_4 = 2x - 3x^2 + x^3$. S1's approach for the other warm-up example was similar, as illustrated in Figure 1.

The Elementary Differentiation Operator

Interviews on differential operators (Tasks 3-4) began with the warm-up activity in which math majors explored the standard matrix of the differential operator $D_x: \mathbb{P}_2 \longrightarrow \mathbb{P}_1$. The common approach was the analytic one: (i) Math majors first determined the 3 image vectors $D_x(1), D_x(x), D_x(x^2)$ by applying the linear transformation D_x to each vector of the standard basis $\mathcal{B} = \{\mathbf{e}_1 = 1, \mathbf{e}_2 = x, \mathbf{e}_3 = x^2\}$ of the domain vector space $\mathbb{P}_2$; (ii) They then expressed each image vector $D_x(1) = 0, D_x(x) = 1, D_x(x^2) = 2x$ in terms of the vectors of the basis $\mathcal{B}' = \{\mathbf{w}_1 = 1, \mathbf{w}_2 = x\}$ of the codomain vector space $\mathbb{P}_1$ as $D_x(1) = 0\mathbf{w}_1 + 0\mathbf{w}_2, D_x(x) = 1\mathbf{w}_1 + 0\mathbf{w}_2, D_x(x^2) = 0\mathbf{w}_1 + 2\mathbf{w}_2$; (iii) They then wrote three 2×1 coordinate matrices $[D_x(\mathbf{e}_1)]_{\mathcal{B}'} = [0 \quad 0]^T, [D_x(\mathbf{e}_2)]_{\mathcal{B}'} = [1 \quad 0]^T, [D_x(\mathbf{e}_3)]_{\mathcal{B}'} = [0 \quad 2]^T$ using the coefficients in each linear combination in the previous step; (iv) Finally, they combined the coordinate matrices from the previous step to form the sought 2×3 matrix $A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix}$.

Students then switched to the MATLAB approach to visualize what has been analyzed, and to use the 2×3 matrix A to evaluate $D_x(\mathbf{v})$ where $\mathbf{v} = 2 - 3x + x^2$. For that purpose, the common approach was to enter the 2×3 matrix A and the vector $\mathbf{v}$ by typing **D1=[0;0]; D2=[1;0]; D3=[0;2]; A=[D1 D2 D3]** and **v=[2;-3;5]**, respectively. Finally, typing **w=A*v** resulted in a column vector with components -3 and 10 (fig.2a). S2, for instance, stopped at this stage and remarked that the vector's components were the same as the coordinates because she was dealing with standard basis representations. Although several students stopped at this stage; some others further indicated that $[-3 \quad 10]^T$ was the coordinates of the vector sought, and that the additional step of moving back from coordinate vector representation $[-3 \quad 10]^T$ to the vector itself was necessary, whereby deduced the answer as $\mathbf{w} = -3 + 10x \in \mathbb{P}_1$. Students who felt the need to take this additional step of mapping the coordinate representation back to the actual vector itself could be thought of as being aware of the distinction between the components of a vector and the coordinates relative to the standard basis, even though the same set of numbers were used to express them (Hillel, 2000, p.201).

In another task, students were asked to determine the matrix representation of the differential operator $D_x: \mathbb{P}_3 \longrightarrow \mathbb{P}_2$ using the nonstandard bases $\mathcal{B} = \{\mathbf{v}_1 = 1 + x^2, \mathbf{v}_2 = x - x^3, \mathbf{v}_3 = 1 - x^2, \mathbf{v}_4 = x + x^3\}$ and $\mathcal{B}' = \{\mathbf{w}_1 = 1 + x, \mathbf{w}_2 = x - x^2, \mathbf{w}_3 = x + x^2\}$. Unlike the previous task in which students had begun with the analytic approach, in this task all students began with a visual approach primarily for the purpose of verifying that the given sets $\mathcal{B}$ and $\mathcal{B}'$ were indeed bases for $\mathbb{P}_3$ and $\mathbb{P}_2$, respectively (fig.2b-e). One group of students verified this via the traditional rref procedure on MATLAB (fig.2b,d). Those who embraced the DGS approach created sliders in an attempt to demonstrate that any polynomial of degree ≤ 3 (or degree ≤ 2) could be written as a linear combination of the basis vectors of the set $\mathcal{B}$ (or $\mathcal{B}'$), respectively (fig.2c,e). Upon establishing $\mathcal{B}$ and $\mathcal{B}'$ as bases, students switched to the analytic procedure in order to obtain the matrix representation of the differential operator. S3 expressed each image vector $D_x(1 + x^2) = 2x, D_x(x - x^3) = 1 - 3x^2, D_x(1 - x^2) = -2x, D_x(x + x^3) = 1 + 3x^2$ in terms of the vectors of the basis $\mathcal{B}' = \{\mathbf{w}_1 = 1 + x, \mathbf{w}_2 = x - x^2, \mathbf{w}_3 = x + x^2\}$ of the codomain vector space $\mathbb{P}_2$ as $D_x(\mathbf{v}_1) = 0\mathbf{w}_1 + 1\mathbf{w}_2 + 1\mathbf{w}_3, D_x(\mathbf{v}_2) = 1\mathbf{w}_1 + 1\mathbf{w}_2 - 2\mathbf{w}_3, D_x(\mathbf{v}_3) = 0\mathbf{w}_1 - \mathbf{w}_2 - \mathbf{w}_3, D_x(\mathbf{v}_4) = 1\mathbf{w}_1 - 2\mathbf{w}_2 + 1\mathbf{w}_3$. In the third stage, S3 wrote the corresponding 3×1 coordinate matrices $[D_x(\mathbf{v}_1)]_{\mathcal{B}'} = [0 \quad 1 \quad 1]^T, [D_x(\mathbf{v}_2)]_{\mathcal{B}'} = [1 \quad 1 \quad -2]^T, [D_x(\mathbf{v}_3)]_{\mathcal{B}'} = [0 \quad -1 \quad -1]^T, [D_x(\mathbf{v}_4)]_{\mathcal{B}'} = [1 \quad -2 \quad 1]^T$ using the previously determined coefficients in each linear combination from the second stage. Finally, he obtained the matrix representation of

the differential operator by juxtaposing the four column vectors from the third stage as the 3×4 matrix $A = [[D_x(\mathbf{v}_1)]_{\mathcal{B}'} \quad [D_x(\mathbf{v}_2)]_{\mathcal{B}'} \quad [D_x(\mathbf{v}_3)]_{\mathcal{B}'} \quad [D_x(\mathbf{v}_4)]_{\mathcal{B}'}] = \begin{bmatrix} 0 & 1 & 0 & 1 \\ 1 & 1 & -1 & -2 \\ 1 & -2 & -1 & 1 \end{bmatrix}$.

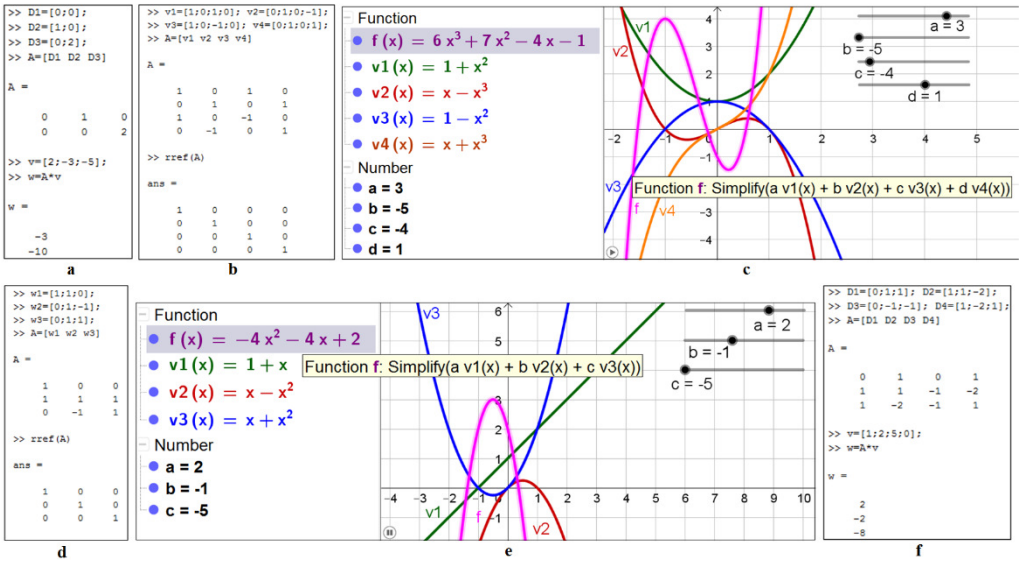

Figure 2. Analytic and visual approaches.

The interviewer then asked the research participants to evaluate the derivative of the cubic polynomial $\mathbf{v} = 6 + 2x - 4x^2 - 2x^3$ via the two approaches and then to compare the two answers. Using the power rule, students easily determined the derivative of the cubic polynomial as $D_x(\mathbf{v}) = 2 - 8x - 6x^2$. In an attempt to see how the matrix approach works, S4 first expressed the cubic polynomial $\mathbf{v}$ in terms of the vectors of the basis $\mathcal{B} = \{\mathbf{v}_1 = 1 + x^2, \mathbf{v}_2 = x - x^3, \mathbf{v}_3 = 1 - x^2, \mathbf{v}_4 = x + x^3\}$ of the domain vector space $\mathbb{P}_3$ simply as $\mathbf{v} = 6 + 2x - 4x^2 - 2x^3 = 1\mathbf{v}_1 + 2\mathbf{v}_2 + 5\mathbf{v}_3 + 0\mathbf{v}_4$; then obtained the coordinate vector representation of the cubic polynomial as $[\mathbf{v}]_{\mathcal{B}} = [1 \quad 2 \quad 5 \quad 0]^T$. She then switched to MATLAB and followed a procedure similar to S2's (fig.2a) and determined the matrix applied coordinate vector $A[\mathbf{v}]_{\mathcal{B}} = [2 \quad -2 \quad -8]^T$ as shown (fig.2f). Upon the interviewer's probing whether she would want to stop or continue, S4 responded that she should continue, explaining that what she had was not the vector itself but its image, specifically its coordinate vector representation according to the basis B prime. She added that she still needed to find the vector itself, or the image polynomial. Using the linear combination analytic approach, she determined the image polynomial as $2\mathbf{w}_1 - 2\mathbf{w}_2 - 8\mathbf{w}_3 = 2(1 + x) - 2(x - x^2) - 8(x + x^2) = 2 - 8x - 6x^2$.

In another task of determining the matrix representation of the differential operator $D_x: \mathbb{P}_2 \longrightarrow \mathbb{P}_1$ using the nonstandard bases $\mathcal{B} = \{\mathbf{v}_1 = 1 + x^2, \mathbf{v}_2 = x - x^2, \mathbf{v}_3 = x + x^2\}$ and $\mathcal{B}' = \{\mathbf{w}_1 = 1 - x, \mathbf{w}_2 = 1 + x\}$, upon establishing the basisness of $\mathcal{B}$ and $\mathcal{B}'$ in a similar manner as in the previous task via DGS-MATLAB approach, S5 first obtained the matrix representation of the differential operator as a 2×3 matrix D via the analytic-arithmetic procedure in a manner similar to S4's, then demonstrated how this matrix representation actually acts on the coordinate representation $[\mathbf{v}]_{\mathcal{B}}$ of the previously explored polynomial $\mathbf{v} = 2 - 3x + 5x^2$ in the DGS. Upon graphing all the key actors (fig.3a-c); S5 concluded her exploration by verifying that the image polynomial (fig.3d) obtained both ways coincide via the linear combination syntax in a similar manner as before.

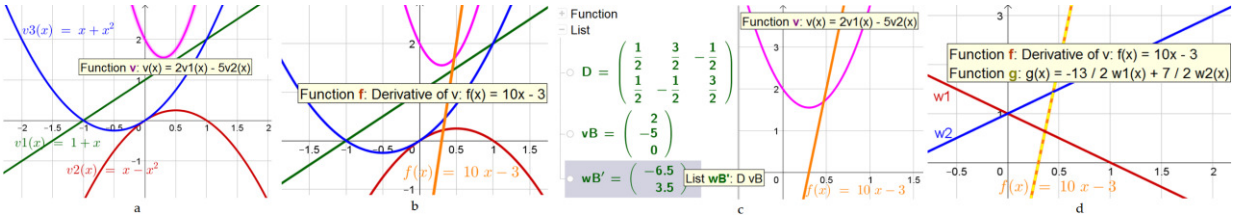

Figure 3. S5's visual approach for Task 3.

The Elementary Integral Operator

In the previous tasks on the elementary differential operator $D_x: \mathbb{P}_n \longrightarrow \mathbb{P}_{n-1}$, math majors made use of both analytic and visual approaches by involving DGS and MATLAB in their explorations. Such a visual-analytic coordination proved to be the case in the investigation of the integral operator mapping polynomials vector spaces as well. In the task of finding the matrix representation of the integral operator $T: \mathbb{P}_2 \longrightarrow \mathbb{P}_3$ defined by the equation $T(x^k) = \int_0^x t^k dt$ using a nonstandard basis $\mathcal{B} = \{\mathbf{v}_1 = 1 + x, \mathbf{v}_2 = x - x^2, \mathbf{v}_3 = x + x^2\}$ for $\mathbb{P}_2$ and the standard basis $\mathcal{B}'$ for $\mathbb{P}_3$, S6 first analytically verified that $\mathcal{B} = \{\mathbf{v}_1 = 1 + x, \mathbf{v}_2 = x - x^2, \mathbf{v}_3 = x + x^2\}$ was actually a basis for $\mathbb{P}_2$ via the straightforward rref procedure. She then applied the analytic procedure via which she obtained the coordinate vector representations $[T(\mathbf{v}_1)]_{\mathcal{B}'} = [0 \quad 1 \quad 1/2 \quad 0], [T(\mathbf{v}_2)]_{\mathcal{B}'} = [0 \quad 0 \quad 1/2 \quad -1/3], [T(\mathbf{v}_3)]_{\mathcal{B}'} = [0 \quad 0 \quad 1/2 \quad 1/3]$; then switched to the MATLAB approach by introducing the three 4×1 coordinate matrices by typing **T1=[0;1;1/2;0]; T2=[0;0;1/2;-1/3]; T3=[0;0;1/2;1/3]**. She then thought aloud and stated that because $\mathcal{B}' = \{1, x, x^2, x^3\}$ for $\mathbb{P}_3$ was a standard basis, she could simply combine the three 4×1 column vectors to form the desired matrix representation via the syntax **A=[T1 T2 T3]**.

To test her visualization, she first obtained the coordinate vector representation $[\mathbf{v}]_{\mathcal{B}} = [1 \quad -1 \quad -1]^T$ of the polynomial $\mathbf{v} = 1 - x$ relative to the basis $\mathcal{B} = \{\mathbf{v}_1 = 1 + x, \mathbf{v}_2 = x - x^2, \mathbf{v}_3 = x + x^2\}$ in the domain vector space $\mathbb{P}_2$. Then she applied the matrix A to $[\mathbf{v}]_{\mathcal{B}} = [1 \quad -1 \quad -1]^T$, resulting in $A[\mathbf{v}]_{\mathcal{B}} = [\mathbf{w}]_{\mathcal{B}'} = [0 \quad 1 \quad -1/2 \quad 0]^T$ (fig.4a). She interpreted this as the coordinate vector representation of the polynomial $\mathbf{w} = x - (1/2)x^2$ relative to the standard basis for the codomain vector space $\mathbb{P}_3$. She concluded by indicating that the real things are related to each other via integration, that is, the fact that the integral of $\mathbf{v}$ polynomial would result in the $\mathbf{w}$ polynomial under the T operator. In a similar task of finding the matrix representation of the integral operator $T: \mathbb{P}_3 \longrightarrow \mathbb{P}_4$ defined by the equation $T(x^k) = \int_0^x t^k dt$ using a nonstandard basis $\mathcal{B} = \{\mathbf{v}_1 = 1 + x, \mathbf{v}_2 = x - x^2, \mathbf{v}_3 = x + x^2, \mathbf{v}_4 = x^3\}$ for $\mathbb{P}_3$ and the standard basis $\mathcal{B}' = \{\mathbf{w}_1 = 1, \mathbf{w}_2 = x, \mathbf{w}_3 = x^2, \mathbf{w}_4 = x^3, \mathbf{w}_5 = x^4\}$ for $\mathbb{P}_4$, S7 followed almost the same approach as S6 with the slight difference in her concluding steps where she demonstrated the action of the matrix representation on the polynomial $\mathbf{v} = 2 - x + 3x^2 + 4x^3$ with the coordinate vector representation $[\mathbf{v}]_{\mathcal{B}}$ (fig.4b).

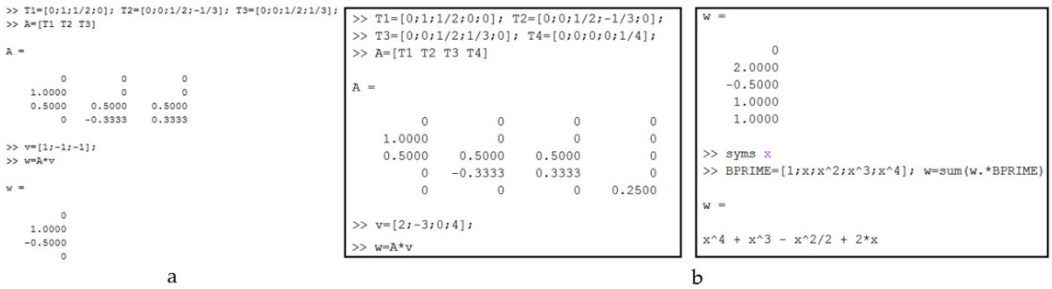

Figure 4. Students' MATLAB approach for Task 5.

In another version of the same task for finding the matrix representation of the integral operator $T: \mathbb{P}_2 \longrightarrow \mathbb{P}_3$ defined by the equation $T(x^k) = \int_0^x t^k dt$ using the standard bases $\mathcal{B} = \{\mathbf{v}_1 = 1, \mathbf{v}_2 = x, \mathbf{v}_3 = x^2\}$ and $\mathcal{B}' = \{\mathbf{w}_1 = 1, \mathbf{w}_2 = x, \mathbf{w}_3 = x^2, \mathbf{w}_4 = x^3\}$, all math majors embraced a straightforward step-by-step approach similar to the integral operator one previously analyzed. Upon exploring the matrix representation both analytically and in MATLAB in a similar manner as before, math majors came up with the matrix representation A; they also felt the need to explore the integral operator and its representation further with the DGS. For that purpose, S8 entered the basis vectors of $\mathcal{B}$ as functions by respectively typing **v1(x)=1; v2(x)=x; v3(x)=x^2**; in the DGS. S8 referred to $\mathbf{v}_1$, $\mathbf{v}_2$, and $\mathbf{v}_3$ as a constant, a line with positive slope, and a parabola, respectively. Upon the interviewer's probing how she would visualize the vector $\mathbf{v}$ whose coordinates relative to the basis is given by $[4 \quad 0 \quad -3]^T$, she entered the desired vector by typing the linear combination syntax **v=4v1-0v2-3v3**, whose graph S8 referred to as an upside-down parabola (fig.5a). She then typed the command **f=integral(v)**, resulting in the curve with purple color (fig.5b). Next, she focused on the representations. S8 introduced the matrix A of the integral operator T which she had previously obtained algebraically by typing the syntax **A={{0,0,0}, {1,0,0}, {0,1/2,0}, {0,0,1/3}}**. She then entered the coordinate representation of vector $\mathbf{v}$ relative to the standard basis $\mathcal{B} = \{1, x, x^2\}$ for $\mathbb{P}_2$ using the syntax **vB = {{4}, {0}, {-3}}**. Next, she typed **wB'= A*vB** and explained that wB' represented the coordinate representation of the sought vector relative to the standard basis $\mathcal{B}' = \{1, x, x^2, x^3\}$ for $\mathbb{P}_3$ which should coincide with the graph of the purple curve when plotted (fig.5c). In the last step of her visualization, she entered the sought vector by paying close attention to its coordinate representation by typing **g=0*1+4*x+0*x^2-1*x^3** and commenting that the two graphs should match, a result she indicated she was expecting (fig.5d).

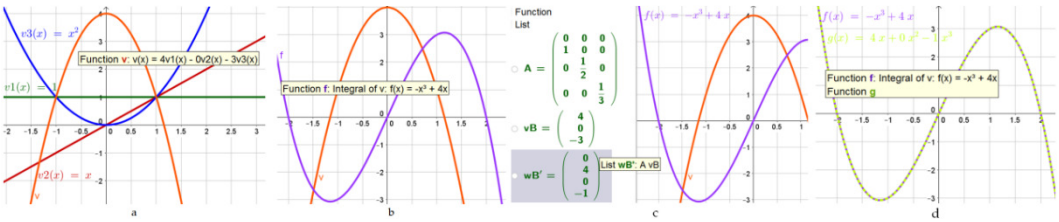

Figure 5. S8's visual approach for Task 6.

Conclusion

The findings highlighted in the present report are in agreement with Hillel's (2000) observations regarding the importance of correctly finding a matrix representation of a linear transformation relative to a basis; the report's findings are also in agreement in that math majors were also "able to think about matrix representations of linear operators as objects of inquiry in their own right" (p.199). Furthermore, math majors demonstrated representational creativity which enabled them "consider the general conditions under which a linear operator can have a particularly desirable representation" (p.199). In order to help linear algebra students understand how objects and their representations interact in analogy, a CAS such as MATLAB or DGS such as GeoGebra could be very beneficial. This has a pedagogical implication that aligns with the Linear Algebra Study Group (LACSG) recommendation for use of technology and computer software: "Faculty should be encouraged to utilize technology in the first linear algebra course" (Carlson, Johnson, Lay & Porter, 1993, p.45). Because basis-dependent representations are not unique, generating object-representation analogy maps in a DGS-MATLAB facilitated learning environment could help linear algebra learners make sense of what stays invariant.

Student Explanation Strategies in Postsecondary Mathematics and Statistics Education: A Scoping Review

Huixin Gao
University of Auckland

Tanya Evans
University of Auckland

Anna Fergusson
University of Auckland

This scoping review examines the use of student explanation strategies in postsecondary mathematics and statistics education. We analyzed 46 peer-reviewed articles published between 2014 and 2024, categorizing student explanations into three main types: self-explanation, peer explanation and explanation to fictitious others. The review synthesizes the theoretical underpinnings of these strategies, drawing on the retrieval practice hypothesis, generative learning hypothesis, and social presence hypothesis. Our findings indicate that while self-explanation and explaining to fictitious others foster individual cognitive processes enhancing generative thinking, peer explanation have the potential to combine these benefits with collaborative learning. However, explanation to fictitious others have the potential to mitigate some of the negative impacts that may occur in peer explanation, such as more knowledgeable students dominating peer discussions. The efficacy of the methods varies based on implementation, duration, and context. This scoping review contributes to the growing body of literature on generative learning strategies in postsecondary education and provides insights for optimizing the integration of student explanation techniques in within mathematics and statistics.

Keywords: Student explanation, Self-explanation, Peer explanation, Peer instruction, Explanation to fictitious others

Introduction

In mathematics and statistics education, explanations serve as a critical tool for conveying complex concepts and fostering deep understanding (Rittle-Johnson & Loehr, 2017). These explanations can be broadly categorized into two types: teacher explanations and student explanations.

Teacher explanations traditionally dominate both face-to-face and online video-based instruction in postsecondary education, often criticized for fostering student passivity. In response, recent research has increasingly explored strategies to reduce the reliance on teacher-centered methods, particularly following Freeman et al.'s (2014) meta-analysis, which found that active learning significantly boosts student performance in Science, Technology, Engineering, Mathematics (STEM) fields. From a cognitive perspective, meaningful learning and long-term knowledge retention are shown to require active engagement in the process of knowledge generation and construction, rather than passive consumption (Fiorella & Mayer, 2014; Freeman et al., 2014; Rittle-Johnson et al., 2017)

Student explanations, on the other hand, involve learners articulating their understanding of concepts, processes, or problem-solving steps, either to themselves or others. Hodds et al. (2014) demonstrated that prompting undergraduate students to elucidate mathematical concepts enhances their focus on analyzing and explicating the learning content, thereby facilitating improved learning outcomes. In general, there is a consensus that student explanations play a crucial role in shaping understanding and engagement (Bisra et al., 2018; Fiorella & Mayer, 2014; Rittle-Johnson et al., 2017).

Despite the recognized importance of student explanations, current research still exhibits several gaps in integrating their theoretical bases. Additionally, the specifics of implementation

processes of student explanations in mathematics and statistics remain relatively vague. This investigation aims to contribute to the growing body of literature on generative learning strategies in postsecondary educational contexts, by categorizing the literature about student explanation in mathematics and statistics education at the tertiary level.

Theoretical grounding

The cognitive processes underlying student explanation can be understood through the lens of Human Cognitive Architecture (Atkinson & Shiffrin, 1968). This model posits that information processing occurs in stages: from sensory memory (visual, auditory, and tactile inputs) to working memory (where information is manipulated) and finally to long-term memory (where knowledge is stored and retrieved). These processes are fundamental to understanding how student explanations facilitate learning in mathematics and statistics education.

The retrieval practice hypothesis, proposed by Roediger & Karpicke (2006), aligns with the role of long-term memory in this cognitive model (Karpicke & Roediger, 2008). It posits that the act of explanation enhances learning through active retrieval of previously acquired knowledge. In mathematics and statistics education, this can be applied by encouraging students to explain complex formulas (Lyle et al., 2020), statistical concepts (Hun Lim et al., 2015), or problem-solving procedures without referring to notes or textbooks (May, 2022). This process strengthens memory traces and improves long-term memory, as demonstrated by Lachner et al. (2020, 2021).

The generative learning hypothesis (Lachner et al., 2018) relates to both working memory and long-term memory processes. It suggests that student explanation involves complex cognitive processes beyond mere retrieval. In higher-level mathematics and statistics courses, this can be implemented by having students create explanations that connect different mathematical concepts or apply statistical principles to novel problems. This approach emphasizes active knowledge construction and the development of meaningful connections between concepts, engaging both working memory for immediate processing and long-term memory for knowledge integration (Fiorella & Mayer, 2014).

The social presence hypothesis (Short et al., 1976) also involves working memory and long-term memory processes, but through an interpersonal dimension. In mathematics and statistics education, this can be applied through peer teaching activities or group problem-solving sessions. This theory suggests that anticipating an audience's knowledge leads to continuous adjustment of explanatory content, enhancing learning (Mills et al., 2020). Empirical evidence shows that learners engaged in student-to-student explanation reported higher levels of social presence (Nasir et al., 2023), motivation (Morris et al., 2023), and increased mental effort (Alegre et al., 2019), indicating enhanced engagement of working memory and potential for long-term memory consolidation.

These three hypotheses collectively offer a comprehensive framework for understanding the efficacy of student explanation in mathematics and statistics education, highlighting the interplay between sensory input, cognitive processing, and social factors in enhancing learning outcomes.

Methods

The approach for the scoping review is underpinned by Arksey & O'Malley's (2005) five-stage framework, which adopts a rigorous process of transparency, enabling replication of the search strategy and increasing the reliability of the study findings. The five stages of the framework are: (1) identifying the initial research questions; (2) identifying relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing and reporting the results. These stages were utilized in this review of the student explanation literature.

Identifying the initial research questions

The focus of our review was to examine the specifics of the use of student explanation in mathematics and statistics postsecondary education, thus we proposed the following research question:

How can literature on student explanation strategies in postsecondary mathematics and statistics education be categorized to reveal current research patterns and trends?

Identifying relevant studies

All publications included in this review were published in English and indexed in Eric, Scopus, or Web of Science databases. Additionally, we utilized websites (i.e., Google Scholar and Research Rabbit https://www.researchrabbit.ai/) and conducted citation searches to ensure comprehensive coverage. The linked descriptive key search terms that were developed to guide the search are outlined in Table 1. Research prior to the past decade, when educational reforms have incorporated principles of active learning into higher education curricula, is unlikely to reflect these specific teaching techniques in higher education. Therefore, the time period 2014 to 2024 was considered appropriate. The search strategy's exclusive focus on the term 'explanation' may have inadvertently excluded relevant studies that incorporated explanatory activities as intervention components but utilized different terminology in their documentation. A full list of inclusion and exclusion criteria is outlined in Table 2.

Table 1. Search string

Structured combination of keywords, phrases, and Boolean operators
(“Higher Education” OR “Postsecondary” OR “Tertiary Education” OR “Undergraduate” OR “College”) AND (“Mathematics” OR “Statistics” OR “Science education” OR “Engineering science” OR “STEM”) AND (“Learning by explaining” OR “Explaining-based learning” OR “Explanation-driven learning” OR "Self-explanation" OR "Self-explaining" OR “Learning by teaching” OR “Learning-by-teaching” OR “Team-based-explanation” OR “Peer tutoring” OR “Peer instruction” OR “Peer assist” OR “Peer-led” OR “Explanation to fictitious others” OR “ Non-interactive learning”)

Table 2. Inclusion and exclusion criteria

Criterion	Inclusion	Exclusion
Time period	2014 to 2024	Studies outside these dates
Language	English	Non-English studies
Type of article	Original research, published in a peer review journal	Articles that were not peer-reviewed or published elsewhere

Literature focus	Articles where the overwhelming theme relates to student explanation	Articles that made a passing or token reference to student explanation
Population and sample	Undergraduate or college students enrolled in a recognized program of study	All other students not enrolled in undergraduate study

Study selection and data charting

The process of study selection followed the Preferred Reporting of Items of Systematic Reviews and Meta-Analyses (PRISMA) protocol (Moher et al., 2009). We implemented a search strategy across Eric, Scopus, and Web of Science databases, which yielded 759 initial results. After removing duplicates and screening titles and abstracts, 102 publications progressed to the full-text evaluation stage. Based on our predefined criteria, we excluded 56 publications. Ultimately, 46 studies were included in the final analysis (the full list is available at figshare: https://doi.org/10.17608/k6.auckland.28202357). Summaries were developed of each study related to the author, year, location of study, study design, study methods, and sample size, and a brief comment on the limitations and recommendations of the individual selected study.

Findings

Based on the analysis and synthesis of the results of selected literature, the student explanation strategies can be categorized into three broad types: self-explanation, peer explanation and explanation to fictitious others. Of the 46 studies reviewed, 15 focus on self-explanation (12 on mathematics, 3 on statistics), 26 discuss peer explanation (9 on STEM, 14 on mathematics, and 3 on statistics), while 5 mainly focus on explanation to fictitious others (3 on STEM, 2 on mathematics).

Self-explanation, peer explanation, and explanation to fictitious others

Self-Explanation (SE) is a cognitive process wherein individuals elucidate to themselves the meaning of new information, often integrating it with existing cognitive schema (Bichler et al., 2022). This strategy facilitates learners' active participation in knowledge construction (Hall & Vance, 2010). SE are generated for the learner, not intended to teach the content to other people (Rittle-Johnson et al., 2017). Specifically, these methods can be broadly categorized into three main forms: written (e.g., documenting explanations on paper or in digital text boxes) (Salle, 2020), oral (e.g., recording verbal explanations via audio devices or self-narration) (Hodds et al., 2014), and gestural (e.g., conveying information through body language) (Salle, 2020).

The 15 SE studies we reviewed primarily explore the efficacy of SE. These studies examined various aspects, including promoting learning outcomes (e.g., Atisso et al., 2023; Rittle-Johnson & Loehr, 2017; Ryan & Koppenhofer, 2022), self-explanation for proof comprehension (Hodds et al., 2014; Maarif et al., 2020; Wirth et al., 2024), the impact of self-explanation quality on learning (Bichler et al., 2022), types of self-explanation and their impact on learning (Salle, 2020), and influence on cognition (Hadfield, 2021; Miller-Cotto & Auxter, 2021).

As postsecondary education has evolved, peer tutoring and cooperative learning approaches have been increasingly integrated with explanatory techniques in university settings (Naughton et al., 2021; Pollock et al., 2023). This study employs the term "Peer Explanation" (PE) to refer specifically to the explanatory process within peer instruction at undergraduate and postgraduate levels. PE focuses on explanatory interactions among students, emphasizing the impact of collaborative dynamics on the quality and effectiveness of explanations. At the same time, PE seems to include the process of SE, since students convey their own understanding to their peers. Unlike the independent cognitive process of SE, PE requires real-time bi-directional or multi-directional communication, demanding immediate question-and-answer interactions between the explainer and the audience, where listeners can raise questions, request clarification, or seek additional information (Maxwell & Wiles, 2022). PE typically involves a formalized process where students engage in mutual explanation within learning groups of at least three participants. In classroom settings, PE typically operates in pairs or fixed groups (3-5 members), with clearly defined roles (explainer and listeners) and structured time allocations and rotation mechanisms.

The 26 PE studies we reviewed examine various aspects, including impact on learning motivation (Mayerhofer et al., 2023), improvement of academic achievement (e.g., Biju, 2019; Corbo & Sasaki, 2021; Han & Thiel, 2022; Kishbaugh et al., 2018; Maxwell & Wiles, 2022; Morales et al., 2014; Nasir et al., 2023), effect of mixed-gender activities (Dumitru et al., 2022; Powell et al., 2023), cognitive development (Kustina & Meredith, 2023), the relationship with self-work during lectures (Leitner & Gabel, 2024), and the development of self-efficacy (Mills et al., 2020; Morris et al., 2023; Naughton et al., 2021). Advantages and Disadvantages of Online PE (Campbell, 2019).

With technological advances transforming postsecondary education, innovative methods for capturing student explanations through audio and video recordings have emerged. These developments have given rise to a new learning activity known as Explanation to Fictitious Others (EFO) (Lachner et al., 2018). EFO refers to students generating explanations and then explaining them to non-present, fictitious others via video, audio or text. While EFO also involves student-generated explanations, it differs from SE in that the explanatory content must be recorded through media tools (video, audio, or text), making it available for sharing and self-refinement (Hoogerheide et al., 2016). Generally, it includes three stages (Fiorella & Mayer, 2014): first, students prepare their explanations; second, they have to explain the subject matter to potential others either orally or in writing; third, students answer subsequent questions in interactive settings or receive feedback from an instructor. EFO triggers distinct cognitive processes that are essential for students' knowledge acquisition (Lachner et al., 2018).

The 5 EFO studies we reviewed mainly focus on comparing the effects of explaining through writing and explaining via video (Hoogerheide et al., 2016; Lachner et al., 2018), the impact of EFO on learning achievements and students' self-perceptions (Fiorella & Mayer, 2014; Hoogerheide et al., 2014), the effects of the timing of EFO implementation on students (Lachner et al., 2020), and the impact of EFO on students' problem-solving performance (Hoogerheide et al., 2019). EFO typically yields the most significant results when students record videos explaining problems (Hoogerheide et al., 2016, 2019).

Theoretical underpinnings of SE, PE and EFO

The Retrieval Practice Hypothesis and Generative Learning Hypothesis provide theoretical support for the efficacy of SE and EFO in enhancing students' long-term memory through retrieval and more advanced generative learning mechanisms such as organization and integration (Lachner et al., 2021). This is particularly evident in the learning performance of

students with different levels of prior knowledge (Hodds et al., 2014; Maarif et al., 2020; Ryan & Koppenhofer, 2022; Leppink et al., 2012). Low prior knowledge students perform worse on challenging questions due to insufficient knowledge reserves, which hinders their working memory. Therefore, PE can offer a useful knowledge link to address this disparity. Because of differences in students' knowledge, PE could be beneficial to further balance their learning. The Social Presence Hypothesis provides additional theoretical support for PE. The students' interactions and discussions with each other are able to some extent promote their cognitive thinking and build their understanding (Mills et al., 2020; Morris et al., 2023). This collaborative aspect of PE could help bridge the gap between students with different levels of prior knowledge, facilitating a more balanced learning environment where students can benefit from each other's strengths and compensate for individual weaknesses.

However, PE may also have limitations. Students with lower levels of understanding might unintentionally reinforce each other's misconceptions, leading to the spread of incorrect information (Kishbaugh et al., 2018). Additionally, the quality of explanations can vary significantly, as not all students possess the ability to clearly articulate complex concepts (Bichler et al., 2022). Without proper guidance and oversight from the instructor, peer-led discussions may sometimes fail to address critical gaps in understanding, potentially hindering overall learning outcomes (Smith et al., 2009). Furthermore, students who are more confident or knowledgeable may dominate the discussion, limiting the contributions of others and reducing the collaborative benefits intended by peer explanation (Mills et al., 2020).

Thus, EFO, by eliminating real-time peer interactions, mitigates some of the potential negative effects that the presence of peers can have in peer explanations. Although the target audience for the explanation is non-present fictitious others, it still involves the stages of preparation and explanation. In the preparing stages, EFO encourages learners to engage in a multi-faceted cognitive process that seems to differ to SE. With the expectation to teach others, this process involves selecting salient information to be conveyed, organizing it into a coherent mental representation, and integrating it with existing knowledge structures. This aligns with the teaching expectancy effect, as described by Fiorella and Mayer (2013), which posits that anticipation of teaching enhances one's own learning.

The explanation stage leverages the power of perspective-taking. Learners, when constructing explanations for their imagined audience, are compelled to consider diverse viewpoints. This cognitive exercise not only enhances the quality of their explanations but also reinforces their own understanding. As Hoogerheide et al. (2016) suggest, the belief that one's explanations may influence others can serve as a potent catalyst for self-directed learning. Moreover, the concept of non-present others in EFO serves a dual purpose. It heightens learners' awareness of their potential audience, thereby increasing their level of arousal and engagement (Hoogerheide et al., 2019). This heightened state of cognitive alertness may contribute to more effective information processing and retention.

Conclusions

This scoping literature review synthesizes the theoretical underpinnings of student explanation and categorizes student explanations into three main types: SE PE, and EFO. While SE and EFO foster individual cognitive processes that support effective generative thinking, PE combines these benefits with collaborative learning. However, EFO have the potential to mitigate some of the negative impacts that may occur in PE, such as more knowledgeable students dominating peer discussions. The retrieval practice, generative learning, and social presence hypotheses underpin the effectiveness of these approaches. However, the varying

efficacy of SE, PE and EFO warrants further exploration, as current research reports mixed outcomes depending on factors such as implementation, duration, and context. Future research should focus on consolidating findings through systematic or integrative reviews to better understand and compare the impact of SE, PE and EFO on student learning outcomes.

The Impact of Questions on Students' Independent Reading of Mathematics

Depy Makri
Loughborough University, UK

Ian Jones
Loughborough University, UK

This study contributes to research on the impact of questions on students' reading of mathematics and informs design considerations for questions included in workbooks. We used eye-tracking complemented by open-text questions. Participants were engineering and science students from the first to the third year of their studies. We considered proceduralness, conceptualness, and difficulty as dimensions of the workbook questions. We found that what we call a 'conceptual question' triggered more attention to the explanation than the example part of the workbook text, but so did what we call the 'procedural question'. In addition, relative question difficulty may have influenced our results. An implication of our findings is the need to investigate the interrelations of the conceptualness and proceduralness of mathematical questions while also considering the role of questions' relative difficulty.

Keywords: Reading Attention, Questions, Conceptual Knowledge, Eye-Tracking

Questions are used for both assessment and as learning tools, with one aim being to help students attend to important content and prepare for exams (Quiroz et al., 2022) . Educators often develop mathematical questions integrated within worksheets or workbooks, which can be studied independently, with expectations that tertiary students should develop as autonomous learners. However, students have been observed engaging only minimally with the content of mathematical texts (St Clair-Thompson, Graham, & Marsham, 2018). Therefore, research is needed that investigates the impact of questions on independent reading in undergraduate mathematics, specifically regarding questions' effectiveness in directing attention to particular parts of a mathematical text.

In this paper we report outcomes from a study that aimed to provide evidence of variations in where students direct their attention while reading mathematics with the goal of answering questions. Our specific focus is on comparing the impact of questions targeting explanations versus those targeting examples. Findings may enhance our understanding of how different question types influence students' reading of mathematics.

Literature Review

We provide a theoretical framing for the study by synthesizing the educational psychology literature on relevance manipulation and the mathematics education literature on conceptual and procedural knowledge. We also draw on the educational assessment literature to consider the relative difficulty of mathematics questions.

Relevance Manipulation

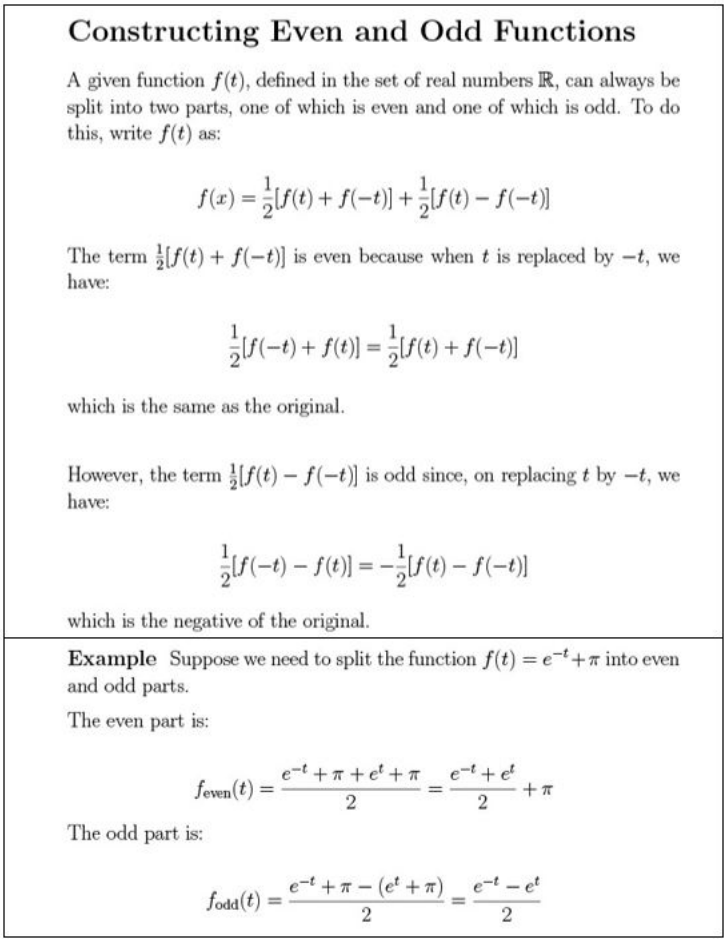
The directive to read with a specific purpose acts as a form of relevance manipulation (McCrudden & Schraw, 2007). Relevance is the degree to which a text segment is germane to a reader's goals. Authors assign importance to text segments according to the degree to which they are essential to understanding the ideas intended to be communicated in the text (McCrudden & Schraw, 2007). However, readers often prioritize relevance over importance (McCrudden & Schraw, 2007; Pichert & Anderson, 1977). Even when in-text cues indicate importance, readers

are more likely to focus on and recognize the significance of text segments that align with their perceived relevance (Sperber, 1995).

Relevance has been associated with optimal cognitive efficiency in processing the information presented in the text (Sperber, 1995). Moreover, questions can be designed to evoke particular kinds of reflection. For example, the Cognitive Reflection Test (CRT) (Frederick, 2005) comprises three questions that activate what are called System 1 cognitive processes, which are fast and generate intuitive answers with little conscious deliberation. To answer the questions correctly, these processes must be overridden by what are called System 2 cognitive processes, which are slower and more reflective. Accordingly, we are interested in how questions can be utilized as an integral part of mathematical texts to facilitate reading through relevance manipulation and to instigate cognitive reflection.

Mathematics Questions

We consider three dimensions of questions from the assessment literature and the mathematics education literature.



Difficulty. Some questions are more difficult to answer than others due to various factors including requisite background knowledge, length or complexity of the question, whether it is open or closed, use of context, and so on (Holmes et al., 2017). In the assessment literature, difficulty, and its converse facility, are typically measured in terms of the proportion of accurate responses by a sample of students (Bond & Fox, 2007). Questions of different difficulty have been found to impact student reading comprehension differently in other subjects (Cerdán et al., 2009), and this might be expected to be the case for mathematics too (e.g. Engelbrecht , Bergsten & Kågesten, 2009).

Conceptualness. Some questions, often used in research studies or to generate discussion in lectures, are intended to assess conceptual knowledge. Well-known examples include carefully designed and validated multiple-choice items such as those in Epstein's (2007) Calculus Concept Inventory. Conceptual knowledge has been defined in terms of understanding a domain's definitions, representations, rules and categories, as well as comprehending underlying principles and the connections between them (Crooks & Alibali, 2014). We might expect what we call here *conceptual questions* to direct students' attention to explanatory parts of a text.

Proceduralness. Routine questions, such as those that appear in common mathematics examinations and tests, are often considered to be procedural (Sangwin & Jones, 2017). Such questions tend to be closed and require students to apply one or more steps to produce a number or transformed expression or equation. We might expect what we call here *procedural questions* to direct students' attention to worked examples within a text.

The Study

We conducted a study designed to identify variations in students' attention while reading mathematics with the goal of answering questions, specifically comparing the impact of a question focusing on the explanatory part versus one targeting the example part of a text. In particular, we were interested in whether answering a conceptual question results paying greater attention to the explanation part of reading material, and whether answering a procedural question results in greater attention to the example part. Seeking differences in how conceptual or procedural questions drive attention can shed light on how question types might affect the depth of their comprehension of mathematical ideas.

Constructing Even and Odd Functions

A given function $f(t)$, defined in the set of real numbers $\mathbb{R}$, can always be split into two parts, one of which is even and one of which is odd. To do this, write $f(t)$ as:

$$f(x) = \frac{1}{2}[f(t) + f(-t)] + \frac{1}{2}[f(t) - f(-t)]$$

The term $\frac{1}{2}[f(t) + f(-t)]$ is even because when t is replaced by $-t$, we have:

$$\frac{1}{2}[f(-t) + f(t)] = \frac{1}{2}[f(t) + f(-t)]$$

which is the same as the original.

However, the term $\frac{1}{2}[f(t) - f(-t)]$ is odd since, on replacing t by $-t$, we have:

$$\frac{1}{2}[f(-t) - f(t)] = -\frac{1}{2}[f(t) - f(-t)]$$

which is the negative of the original.

Example Suppose we need to split the function $f(t) = e^{-t} + \pi$ into even and odd parts.

The even part is:

$$f_{\text{even}}(t) = \frac{e^{-t} + \pi + e^{t} + \pi}{2} = \frac{e^{-t} + e^{t}}{2} + \pi$$

The odd part is:

$$f_{\text{odd}}(t) = \frac{e^{-t} + \pi - (e^{t} + \pi)}{2} = \frac{e^{-t} - e^{t}}{2}$$

Figure 1. The reading text: explanation on the top and example on the bottom.

Methods

Participants. We recruited 45 engineering and science students from various year levels through flyers, announcements, and class presentations. Participants received a £10 voucher as a gesture of gratitude for their contribution.

Materials. For the reading material, we adapted page 12 from *Helping Engineers Learn Mathematics* (HELM) Workbook 6, as shown in Figure 1. The HELM series, available online, was developed from 2002 to 2005 by a consortium of five UK universities led by Loughborough University and have been widely adopted. The page we used comprises two parts. The first introduces and explains the concept that every function can be written as the sum of two components: one symmetrical to the *y*-axis (the even part) and one symmetrical to the origin (the odd part). The second part illustrates how we can find the odd and the even part of a function. We call these the *explanation text* and *example text* respectively.

The first author developed two questions as shown in Figure 2. The conceptual question was intended to relate to the ideas presented in the explanation text, and the procedural question was intended to relate to the example text. We then developed two visual stimuli for eye-tracking. Both contained explanations and example texts. On the right of this text, one of the mathematical questions was presented.

Conceptual Question

Suppose $f_{even}(t)$, and $f_{odd}(t)$ are respectively the even and the odd part of a function $f(t)$ defined in the set of real numbers.

If $f_{even}(\pi) = f_{odd}(\pi) = 2023$, then $f(-\pi) = 0$.

a) Correct

b) Wrong

Procedural Question

To find the odd part of the function $f(t) = t^3 + 3^t$, we write:

$$f_{\text{odd}}(t) = \frac{1}{2}\left(t^3 + 3^t - \left((-t)^3 + 3^{-t}\right)\right) = \frac{1}{2}\left(t^3 + t^3 + 3^t - 3^{-t}\right)$$

Therefore:

$$f_{\text{odd}}(t) = \frac{1}{2}\left(3^t - 3^{-t}\right) + t^3$$

a) Correct

b) Wrong

Figure 2. The conceptual and procedural questions

Eye-tracking measures. Eye-tracking determines gaze point coordinates and eye movement velocity when a person views a visual stimulus (Bojko, 2013), which are then classified into fixations and saccades. Fixations are continuous low-velocity data points, while saccades are high-velocity sequences of eye movements between fixations. Researchers define regions of a visual stimulus to obtain eye-tracking metrics that address their research questions. These regions are called Areas of Interest (AOIs). The interpretation of these metrics is based on the Eye-Mind Assumption (EMA), which posits that eye movements and visual focus are aligned with attention and cognitive focus (Just & Carpenter, 1980).

Here, we used as our metric fixation counts, where a high fixation count serves as a proxy for increased attention directed towards an AOI (Skaramagkas et al., 2023; Strohmaier et al., 2020). We defined two AOIs: one for the explanation text and one for the example text (Figure 1).

Open-text questions. The post-eye-tracking questions included "Did you find the questions you had to answer complex or difficult?" and "Were the questions anyhow unexpected to you?"

Procedure. The study followed a within-subjects experimental design. Participants were randomly allocated into two groups. The participants in one group encountered first the visual stimulus with the procedural question, and then the visual stimulus containing the conceptual question. For the other group the sequence was reversed, i.e. conceptual then procedural question. Participants completed the eye-tracking and then the open-text questions one by one in an eye-tracking lab where the researcher unobtrusively observed through a second screen behind the participant.

Results

The distributions of fixation counts across question type (conceptual, procedural) and text type (example, explanation) are shown in Figure 3. As can be seen the data are skewed, with some participants not looking at some text types at all for a given question type (zero fixation counts), and a few participants with much higher fixation counts than most.

Overall, the conceptual question resulted in higher fixation counts than the procedural question, and this was the case for both the explanation and the example text. For the explanation text the median fixation count when participants were shown the conceptual question was 57, and when shown the procedural question the median was 24. For the example text these medians were 16.5 for the conceptual question and just 3 for the procedural question. Therefore, the conceptual question resulted in more attention in general than the procedural question.

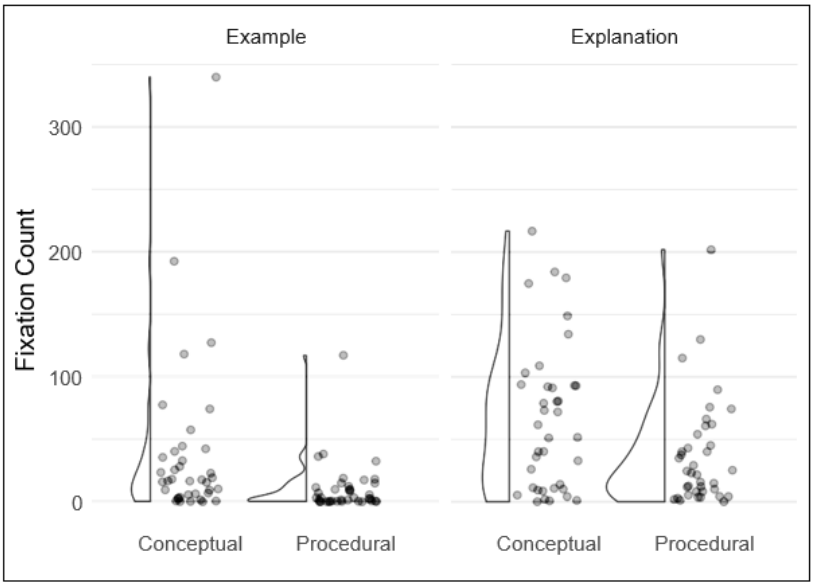


Figure 3. Jitter and raincloud plots of fixation counts. Each point shows the mean fixation count for each participant within each question type (conceptual, procedural) for each text type (example, explanation). The raincloud represent the density of points along the fixation count axis.

These medians also show that the conceptual question followed the pattern we expected: higher fixation counts for the explanation text than the example text, and a paired Wilcoxon test revealed that this difference was significant, $W = 558.5$, $p = .002$. In other words, when presented with the conceptual question the participants paid more attention to the explanation text than the example text. However, the medians also contradicted our expectations for the procedural question that participants would pay more attention to the example than the explanation text. In fact, they paid more attention to the explanation text, and the difference was again significant, $W = 649.5$, $p < .001$. Therefore, for both question types, fixation counts were higher for the explanation text than the example text.

This greater attention on the explanation text might reflect that it is larger than the example text, as shown in Figure 1. We therefore considered the ratio of the median fixation counts. For the conceptual question the ratio of median fixation counts for the explanation to example texts was 3.5, and for the procedural question it was 8.0. Therefore, the procedural question resulted in attention being paid to the explanation rather than the example text relatively more than the conceptual question, again contradicting our expectations.

Discussion

We conducted an eye-tracker experimental study in order to understand how relevance manipulation might be productively applied to independent study materials. Specifically, we investigated how what we called conceptual and procedural questions might direct attention to the explanation and example parts of a mathematical text.

The conceptual question was associated with higher fixation counts on the explanation text than on the example text as we expected. However, many participants still paid reasonable attention to the example text when presented with the conceptual question. Part of the reason for this may be that participants were looking for a comparison example to help them answer the question. Some of the responses to the open-text questions supported this, with one participant stating, “There was not an example to compare with” and another stating “No example given for a case like that”.

We were surprised that the procedural question was also associated with higher fixation counts on the explanation text than the example text. We wonder if part of the reason is that the true-false format may have resulted in participants attempting to validate the question with reference to the explanation text. In other words, what we intended as a question requiring calculation may not have been perceived as such by the students. Some participants' open-text comments supported this, for example "I was expecting something to work out, not just mental thinking" and "There was no calculation".

Another consideration is the relative difficulty of the two questions. The participants in our study were more successful with the procedural question (51% answered correctly) than the conceptual question (21% answered correctly). There may be something more inherently difficult about conceptual questions and, as discussed earlier, this may arise due to procedural questions being more common in tests and exams. Consistent with this one participant commented "I have not encountered a question like this".

It is possible that the unfamiliarity some participants stated, which, as aforementioned, may have contributed to the question's perceived difficulty, also reduced their appreciation of the relevance of the explanation text. The conceptual question required participants to combine pieces of information from the explanation text and make inferences based on these, rather than directly referring to any single text segment that is immediately recognizable as corresponding. Some participants did not recognize any relevance in the specific parts of the explanation text that we intended as pertinent. Evidence of this appears in some participants' open-text comments, such as "The text did not mention such a scenario", and "Nothing similar in the text". Therefore, the ability to appreciate relevance when reading, particularly for answering conceptual questions, may need to be cultivated in undergraduate students.

Our findings also bring forward the complexity of designing questions to function as conceptual or procedural and the confounding role of difficulty. In a follow up study, we are using the method of comparative judgement (Jones & Davies, 2023) to investigate whether the conceptualness or proceduralness of a question are independent or belong to the same spectrum. We are also investigating the extent to which the relative difficulty of a question relates to conceptualness and proceduralness. This will enable us to better interpret the results reported here, and also to conduct future studies to investigate further the role of relevance manipulation in the design of mathematical texts and questions for students.

Pre-Service Teachers' Strategic Noticing During Modeling Through Centers of Focus

Sindura Kularajan
Utah State University

Tye Campbell
Utah State University

Lily Roth
Utah State University

Mathematical modeling tasks require modelers to consider both real-world conditions and mathematical properties while constructing models that represent the given real-world phenomenon. While the field is matured with research on the processes involved in constructing models, little research has explored what modelers center their focus on (i.e., notice) while solving modeling problems and how those centers of focus inform the strategies for solving modeling tasks. Through analyzing data from two pairs of undergraduate pre-service teachers' work on modeling tasks, we found three cases in which PSTs' centers of focus informed their strategies for model construction. In this report, we illustrate two of those cases and discuss implications for research and instruction on modeling.

Keywords: modeling-oriented noticing, mathematical modeling, strategic noticing

To enhance student experiences in mathematical modeling, the mathematical modeling education community has undertaken numerous research programs. For example, scholars have conducted research on student thinking in modeling (e.g., Borromeo-Ferri, 2010), teacher knowledge for modeling (e.g., Greenfrath et al., 2022), scaffolding strategies that advance students in their modeling process (e.g., Czocher et al., 2024) and designing modeling tasks and learning environments through employing theoretical frameworks (e.g., Lesh and Doerr, 2003). The majority of these works have been built on a simplified framework of the modeling process, commonly referred to as modeling cycles or modeling process diagrams (e.g., Blum and Leiß, 2007; Niss 2010). From the cognitive perspective of modeling, a modeling cycle usually consists of a real-world domain, a mathematical domain, and modeling competencies that are unique to solving modeling tasks (usually depicted as transition phases from one domain to another or within domains). Examples of micro-level modeling competencies include systematizing, mathematizing, validating, interpreting, and understanding the situation (e.g., Blum and Leiß, 2007). Examples of global competencies include metacognition, reflection, and anticipation (e.g., Stillman, 2011). In some modeling cycles, there is a clear separation between the real-world domain and the mathematical domain (e.g., Niss, 2010), while in others, these domains are interwoven (e.g., Czocher, 2018). Regardless of the extent to which the real-world domain and the mathematical domain are integrated, Stillman and Brown (2014) argue, the identification of the two domains as distinct is based on the epistemological foundation that real-world and the mathematical world "co-construct each other" (Doerr and Pratt, 2008, p. 260). This separation between the two domains, is at the "heart of modeling" (Stillman and Brown, 2014, p. 3). This is because the modeler has to *notice*—a global competency—both real-world conditions and mathematical elements and transition between these domains simultaneously (Blum, 2011) to construct a model that is viable to represent the experienced phenomena. However, little research has been conducted on how modelers' noticings of real-world and mathematical properties enable or constrain their modeling process. Knowing what students notice and how they attend to what they notice is instrumental for designing modeling tasks that can elicit certain modeling competencies and for contingent scaffolding—skills necessary for teaching modeling. In light of this, the objective of this paper is to shed light on learners' modeling-oriented noticing as they constructed models to represent real-world situations.

Background and Theoretical Framework

Noticing refers to intentionally focusing on particular phenomena so as to inform one's decision-making in the future (Mason, 2008). Noticing became popularized within the field of education through the domain of "teacher noticing" (Jacobs et al., 2010; Sherin & van Es, 2005). Teachers notice phenomena in their classroom, and these noticings inform their decision-making. There are three elements of teacher noticing: attending, interpreting, and deciding how to respond (Jacobs et al., 2010). First, teachers attend to aspects of students' mathematical strategies and interpret students' mathematical understanding based on those "attendings." Then, teachers make decisions about how to respond to students based on their interpretation of students' mathematical understanding. Scholars have explored *what* teachers notice, *how* they notice, and productive ways to notice. Within the field of mathematical modeling, among other competencies required for teaching modeling (For example, see Borromeo Ferri and Blum, 2011), modeling-specific noticing has been explored as an avenue to support students' learning of modeling. For example, Alwast and Vorhölter (2022) conceptualized teacher noticing within modeling as teachers' skills in perceiving, interpreting, and decision making based on students' difficulties, metacognitive strategies, and approaches to solving modeling task (pp. 167-268). On the other hand, Glabraith (2015) identified three classes of modeling specific noticing: Noticing as a mathematician (determining the situations that can be modelled using mathematics), noticing as an educator (designing tasks that support modeling competencies), and noticing as a student mentor (noticing students' in-the-moment modeling-oriented thinking) (p. 11).

Recently, scholars have expanded the noticing literature to examine how and what students notice to inform their mathematical thinking (Campbell & Yeo, 2023; Hohensee, 2016; Lobato et al., 2012; Lobato et al., 2013). In this study, we build upon recent literature on students' modeling-oriented noticing (Galbraith et al., 2017), that extends Galbraith's (2015) classes of modeling-specific noticing to also include *noticing as a student*. Here, the focus is on the specificities of what students notice as relevant in order to progress in constructing models of real-world situations. Galbraith et al. (2017) included modeling-oriented noticing as a component of anticipatory metacognition, a global modeling competency, which "shifts the emphasis towards reflection that points forward to actions not yet undertaken (p. 84)." The authors argue that successful modeling not only requires 'noticing' but also discerning the relevance of what has been observed (p. 85). Therefore, the authors defined a new construct, productive modelling-oriented noticing as, "the process of modelers noticing in a productive manner what is important and what is not in order to generate strategies" for successfully carrying out a modeling activity (p.84). Within modeling-oriented student noticing, Galbraith et al. (2017) proposed two ways in which noticing can be expressed: strategic noticing and explanatory noticing. We interpret strategic noticing as noticing the steps required, including macro and micro-level steps, to achieve modelers' modeling goals (e.g., decision to include air-resistance to model the speed of a falling ball). We interpret explanatory noticing as noticing that serves as an explanation of their approach to solving the task (e.g., because air-resistance can slow the speed of a ball). Since the strategies generated inform modelers' next steps, it can be said that *strategic noticing* is a key driver of modelers' progress through the modeling process.

The cognitive processes of sorting relevant information from competing information are not new; it has long been used to study how individuals construct knowledge (e.g., Piaget, 1952). Typically, what surfaces as relevant from the rest are shaped by the goals the learners set for themselves (Simon et al., 2004; von Glasersfeld, 1995). Lobato et al., (2012) refer to these significant aspects of noticing as 'centers of focus,' defining them as "features, regularities,

properties, or conceptual objects to which individual students pay attention" (p.439). Within a mathematical modeling context, where the modeler is required to transition between the real-world and mathematical domains simultaneously, either the real-world conditions, the mathematical elements, or both become the centers of focus that inform the modelers' strategies. Therefore, in this report, we address the following research question: *How do real-world and mathematical centers of focus inform modelers' strategic noticing*?

Methods

Data were collected by conducting task-based interviews (Goldin, 1997) with two pairs of undergraduate pre-service teachers (PST) enrolled in a public university in the western United States. The first pair consisted of Gwen and Arya and the second pair consisted of Luna and Sahana, with all names being pseudonyms. We chose to conduct the interviews in pairs to create an environment conducive to observing PSTs' modeling-oriented noticing due to their communication with each other as they co-constructed mathematical models. Each pair participated in 8 interview sessions. In the first 7 sessions, the PSTs worked on 11 mathematical modeling tasks, which were adapted from prior literature. These tasks were selected due to their heterogeneity of modeling characteristics (see Maaß, 2010) and their appeal to socio-justice and environmental issues. The last session was used for reflection and member-checking. In this paper, we report on Luna's and Sahana's work on the tasks shown in Table 1.

Table 1. Tasks from which findings are reported

Tasks	**Description (abridged versions)**
Hospital Task (Zbiek and Connor, 2006)	Boise (Idaho), Helena (Montana), and Salt Lake City (Utah) are three large cities in the northwestern part of the United States. The map shows the locations of the three cities as well as other large cities in the area. Suppose you are hired to determine the best location for the hospital. Where would you locate the hospital?
Piano Tuners Task	How many piano tuners are there in the city of New York?

The interviews were conducted in a laboratory setting where a video camera was placed to record PSTs' written work and gestures. The PSTs were given freedom to interpret the tasks in any way they chose, and they were not given any time restrictions for completing the tasks. The interviewer's questioning mainly focused on unpacking PSTs' reasoning and uncovering the aspects of PSTs' modeling-oriented noticing. For example, to evoke justification of their strategies, the interviewer asked questions such as "why was it important to consider this?" "why did you make that assumption?," and "how reasonable is the assumption that you made?." The interviewer maintained an ongoing research journal where she recorded her reflections and possible conjectures of PSTs' reasoning at the end of each interview.

Since the overarching goal of the study was to investigate PSTs' modeling-oriented noticing, we used an a priori framework for our initial coding. Two members of the research team coded the videos for strategic noticing (Galbraith et al., 2017), where the unit of analysis was chunks of text that discuss a single idea. Table 2 provides a list of indicators that were developed using techniques from constant comparison methodology (Strauss and Corbin, 1990) to identify PSTs' strategic noticing. The research team met and discussed any discrepancies in the coding until we reached complete agreement.

Finally, each instance of the strategic noticing was coded for real-world and mathematical centers of focus. If the strategic noticing was explicitly grounded in real-world considerations, it was coded as real-world. If the strategic noticing was based on information given in the task,

simplification for mathematical convenience, mathematical strategies (i.e., writing an equation, finding a quantity to proceed), and mathematical properties, those instances were coded as mathematical center of focus. The explanations and justifications the PSTs provided for their strategies were used to determine the centers of focus.

Table 2. Indicators for strategic noticing

Indicator	**Definition**
I1: Taking stock	PSTs review key points through *reiterating*, *underlining/circling/highlighting,* or *recalling* previously provided information from the modeling task.
I2: Researching information	PSTs search and gather relevant data and information through technology.
I3: Identifying parameters	PSTs identify specific parameters or variables necessary to progress
I4: Identifying the need to make assumptions	PSTs acknowledge and express the need for making assumptions to progress.
I5: Simplifying the situation	PSTs simplify complex situations, making model progression possible. Examples include making necessary assumptions, prioritizing and sorting the most critical assumptions from less important ones, rounding values and/or purely guessing the values of a parameter.
I6: Proposing strategies and considerations	PSTs brainstorm and consider various approaches, strategies, and factors for developing and solving the model. This phase often involves uncertainty or hesitation by students as they deliberate on an approach to adopt.
I7: Implementation of a strategy	PSTs execute the planned steps or approach for constructing a model by breaking the problem into smaller steps, assigning known values to parameters, and making decisions for choosing certain computations. This phase typically involves greater certainty in the adopted approach and less hedging or hesitation.
I8: Verifying/ validating the model or approach	PSTs check the accuracy, reliability, and effectiveness of the implemented model or approach. This includes ensuring that the model's outcomes align with expected results, testing against known data or information, and validating assumptions and calculations.
I9: Noticing patterns and characteristics of the model	PSTs observe and recognize patterns, mathematical properties, or features inherent in the model. Examples include identifying relationships between variables, observing trends in data, or noticing underlying principles that affect the model's behavior

Findings

We present our findings through three cases: (1) Noticing of mathematical elements foregrounded; (2) Noticing of real-world conditions foregrounded; and (3) Noticing of both mathematical elements and real-world conditions foregrounded. In case 1, PSTs' strategic noticing was informed primarily through mathematical elements as their centers of focus. In case 2, PSTs' strategic noticing was informed through real-world conditions as their centers of focus. That is, the centers of focus driving each strategy were grounded in real-world conditions. In case 3, PSTs strategic noticing was informed either by real-world conditions, or mathematical

elements, or both. Due to space constraints, we illustrate two of the cases below. In our illustrations, we identify the strategic noticing (I#), and the centers of focus for each strategic noticing (R for real-world, M for mathematical elements). Concluding each case, we describe how the students' centers of focus informed their modeling strategy.

Case 2: Noticing of Real-World Conditions Foregrounded

We illustrate this case using Luna and Sahana's work on the hospital task. After reading the task, Luna suggested that she wanted to connect the three cities and make a triangle and proposed that the hospital would be somewhere within the triangle (I6, R). She made this proposal because she wanted to speculate which other cities would also use the hospital, justifying her strategy based on real-world considerations. Luna justified her strategy as:

> Luna: If it's the three points, it's the areas surrounding it. A lot of areas in Utah especially that's shown here, has a high population. Montana's a bit more spread out. People from Wyoming might be coming, depending on where it is. Northeastern Idaho is the more populated area of Idaho…So I'm just thinking this is (referring to her triangle), it just gets a rough estimate of where there's more people and who all is going to that hospital.

Next, Sahana expressed her dilemma in choosing a hospital location near the I-15 freeway (I6, I1, R) for better accessibility versus choosing a location based on the population in the major cities and surrounding areas (I6, R) because she stated more population implies more use of the hospital. Luna suggested that Salt Lake and Boise are more concentrated therefore it would make sense to put the hospital closer to Boise and Salt Lake area, for example either in Idaho Falls or Pocatello, rather than closer to Helena (I6, R), once again prioritizing real-world conditions.

The interviewer gave additional information regarding the population of each city. The data given was consistent with PSTs' conception of the population of the three cities. The PSTs decided that the hospital should be placed either at Pocatello or Rexburg (I6, R) because the two cities are closer to Salt Lake City and are on the highway, therefore easily accessible, justifying their proposal through real-world conditions.

Based on her personal experience living in Pocatello, Luna suggested Pocatello as a great place for hospital (I6, R) because it is the junction for many other popular highways (such as I-86 interchange). Sahana concurred as well. Both PSTs agreed that Pocatello was the next best city for a hospital after Salt Lake City and drew a star on the map to finalize their solution. Furthermore, the PSTs agreed that Pocatello was a good city for a hospital as evidenced in the exchange below:

> *Luna:* We want to go where there's a higher concentration of people because that makes it more accessible if there's more people. Pocatello has, it's just where all of the major roads or highways and interstates combine. And so it's just a good meeting spot.
>
> *Sahana:* …Yeah. Realistically Pocatello is a better place to be equipped for building a hospital, funding a hospital, maintaining a hospital.
>
> *Luna:* Yeah. Staff in the hospital. Yeah.
>
> *Sahana:* Relative to main roads. Real world ability.
>
> *Luna:* It's like the ability to support or community's ability to support… a hospital. To be able to staff it and maintain it. And it has to be in a place that it's also going to draw people to want to work there…
>
> *Sahana:* And live there.

In this vignette, we presented six instances of strategic noticing, all of which were informed by PSTs real-world considerations as their centers of focus. That is, the PSTs approached the modeling task by strategically by prioritizing only real-world conditions (over mathematical

elements) by attending to the following: the population of each city, highway accessibility, the city's capacity to fund and maintain a hospital, and its ability to attract people to relocate for work.

Case 3: Noticing of Mathematical and Real-World Elements Foregrounded

To illustrate this case, we use Luna and Sahana's work from the Piano Tuners task. After reading the task, Sahana said that they need to make assumptions (I4, **M**) because "we don't know anything, so we literally, we're going to fill it," addressing the scope of the task. The PSTs suggested that they need to identify the number of people in New York city (NYC), and how many of those people have pianos (I3, **M**). They further proposed that whether a person plays a piano or not would not affect their model (I5, I6**, R**) because "some people will just get it tuned", "some people play the piano and don't get it tuned", and that "some people get it tuned way after they should have. It's not a consistent amount of time." Here, the PSTs were justifying their approach through real-world considerations. The PSTs researched the population of New York as 8.468 million, which they approximated to 8.5 (I5, **M**).

Next, Luna suggested that there were not very many pianos in NYC that need tuning (I6**, R**) because NYC apartments are small. Luna further suggested that that there are probably more electric keyboards as they are easier to move into smaller apartments, justifying her approach through real-world considerations. Therefore, the PSTs assumed that there were 956,000 pianos in total (those that need tuning and those that do not) (I5, **R, M**). Sahana commented that 956,000 seemed like a lot of pianos but expressed that she can commit to it (I7, **R**) since "they (NYC) do music-y things", have "big college that does music stuff", and that there is Broadway, where her commitment was informed through her noticing of real-world considerations.

Next, The PSTs wanted to determine "how many of them [pianos] need to actually be tuned?" (I3**, R, M**). Here, the PSTs decision to consider only a portion of the pianos as needing to be tuned was informed through their real-world knowledge and their mathematical goal towards estimating the number of piano tuners. The PSTs assumed "one third of all pianos are classic, regular, pianos [that need tuning]" (I5, **R, M**) and evaluated the number of piano tuners that need tuning as $315,480$. The PSTs proceeded with determining "how many pianos can a tuner tune in a year?" (I3, **M**). To accomplish this, Sahana simplified the situation (I5, **M**) by assuming that all pianos need to be tuned once a year. She commented on the reasonableness of the assumption as "I don't think they actually do, but we're just going to do it for our sake," indicating her decision was driven primarily for mathematizing purposes. Sahana proposed that a piano tuner can tune a piano in 30 mins (I6**, R**). This decision was based on two real-world considerations: "piano tuners are insanely good. They can do it really quick" and "you have to factor in travel time." Next, the PSTs assumed (I5**, R**) that a piano tuner's work week consists of 5, 8-hour workdays. The PSTs justified their assumption as, "he's a busy piano tuner, got to put food in the table." Given these conditions, the PSTs computed the number of pianos tuned by a piano tuner during a week as 80 (see Figure 1).

Having determined the number of pianos tuned in a week, the PSTs proceeded with considering the number of piano tuners tuned in a year (I3, **M, R**). While the PSTs assumed that there were 54 weeks in a year (I5**, R**), Luna then brought up that the piano tuners will not be working all 54 weeks (I6**, R**) because piano tuners are "probably not going to work on Christmas." The PSTs decided that there 52 working weeks within a year (I7, **R**). Under these assumptions, the PSTs found that a piano tuner can tune 4,160 pianos in a year (see Figure 1). Finally, Luna proposed (I5**, M**) taking "how many pianos there are (315,480), and divide[ing] it by 4,160 (i.e. number of pianos needing tuning per year) [to] give the total number of piano

tuners". The result was 75.8, which the PSTs approximated to 76 (**I5, R**) because the PSTs argued that there can't be partial piano tuners. However, the PSTs proposed (**I6, R**) that 75.8 could be accounted for by the fact that some piano tuners may work part-time.

In this vignette, we presented 20 instances of strategic noticing. In particular, to find the number of piano tuners in NYC, the PSTs noticed that the following parameters first need to be determined: the population of NYC, the number of pianos in NYC, the number of pianos need tuning, and how many pianos can a piano tuner tune in a year. Each of these parameters were consequences of the PSTs considering both mathematical centers of focus (building on prior quantities to arrive at the final quantity) and real-world centers of focus (piano tuners do not work during Christmas). As illustrated in the vignette above, there were some strategies, where the centers of focus were both math and real-world elements which primarily served the PSTs to consider a new quantity as a result of a real-world constraint (for example only considering a subset of the number of pianos because not all pianos need to be tuned).

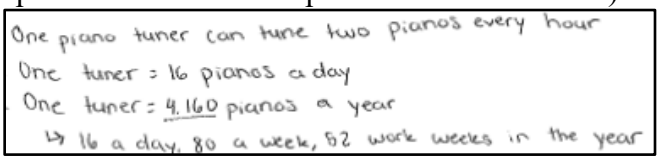

Figure 1. Luna and Sahana's work for the piano tuners task

Discussion

Our paper has three primary contributions. First, we contribute to the existing research on PSTs and modeling by positioning PSTs as *learners of modeling* through a novel cognitive lens, rather than focusing solely on typical modeling competencies. Second, our findings have important implications for design and implementation of modeling tasks. For example, in the piano tuners task, the PSTs considered both real-world conditions and mathematical strategies when developing a model for the situation, at times alternatively and at times simultaneously. The characteristics of PSTs' centers of focus may be attributed to the nature of the piano tuners task, which was open ended, artificial, and therefore allowed for more creativity. In contrast, in the more realistic hospital task, the PSTs prioritized real-world conditions over the use of mathematical strategies (e.g., measuring distance proportional to population size). This may be attributed to PSTs' local knowledge about the cities and the surrounding areas. Therefore, we ask: *How real do we want modeling tasks to be if we want student to develop certain modeling competencies such as using mathematical approaches to solving a modeling task*? Finally, our study contributes theoretically and methodologically to existing frameworks on *noticing*. Theoretically, we build on noticing as a teacher competency to also include *noticing as a student* specific to modeling. Our findings can be used to make inferences about what students attend to, how they interpret those attendings, and what decision they make based on their interpretations depending on students' centers of focus. For example, when the center of focus is real-world conditions, students attend to the real-world conditions that may affect the model (*attending*), analyze the perceived information based on personal or real-world experience (*interpreting*), and place emphasis on the significance of the real-world conditions over mathematical strategies in model development (*responding*). Methodologically, we generated a list of indicators that can be used to identify strategic noticing (Galbraith et al., 2017). Research within the cognitive perspective of modeling has largely stagnated over the last decade, where the emphasis is placed on phases of the modeling process (such as those depicted in the modeling cycles). Following Galbraith et al (2017), we see our work as advancing the modeling field in a newer direction through introducing a fresh perspective for analyzing student thinking in modeling.

EHR #2000602, 2000644, 2000527, 2000566

This study compares mathematical knowledge for teaching college algebra at community colleges between instructors and math majors without teaching experience, aiming to show that the instrument assesses more than mathematical knowledge. We used an instrument designed to assess knowledge used in doing two tasks of teaching across three function types taught in college algebra, linear, rational, and exponential functions. The Multiple Indicators and Multiple Causes (MIMIC) model was applied to 416 community college mathematics instructors and 85 college students to estimate mean difference in the knowledge between the groups. The higher scores in the MKT-CCA suggests that instructors possess higher MKT than the students. As such, this instrument can be used to identify areas for focused faculty development.

Keywords: mathematical knowledge for teaching, college algebra, teaching experience, MIMIC

Our research group has been working on the development of an instrument to assess mathematical knowledge for teaching college algebra at community colleges. To measure this knowledge, we use an instrument organized by two tasks of teaching (understanding student work and choosing problems) with three function types (linear, exponential, and rational). An earlier study (Mesa et al., 2024) provided evidence supporting the validity of the inferences that can be made about instructors' knowledge, particularly, regarding its teaching-related features. The instrument provides a measure that differentiates the knowledge among community college instructors and the measure is correlated with both experience in teaching advanced college algebra and the frequency of doing a specific task of teaching-- choosing problems, a unique task teachers engage in on a routine basis.

To further support that the instrument assesses knowledge of teaching and not just mathematics, we compared the performance of two groups: math major students, who may have content knowledge but lack teaching experience, and community college instructors, who can reasonably be assumed to have both content knowledge and teaching experience. The analysis can further give evidence that the instrument is a viable tool for measuring this knowledge across the combined groups and to understand the characteristics of the knowledge it assesses. Specifically, we test whether the instrument can reliably differentiate knowledge levels between students and instructors, and whether instructors, those with teaching experience in the subject matter, perform better on the measured knowledge than students, those without such experience.

After confirming the instrument's ability to distinguish knowledge levels among both groups, we compare their knowledge on a common scale. The significant difference in knowledge between instructors and students who lack teaching or tutoring experience provides additional evidence that our instrument measures an aspect of knowledge related to teaching. This led us to pursue the following question: How does the measured mathematical knowledge for teaching college algebra differ between community college instructors and college students who are majoring in mathematics?

Theoretical background and literature review

Central to the conceptualization of the instrument used in our work is that mathematical knowledge for teaching can best be elicited through the mathematical work embedded in activities that teachers do when they teach, and that are directly related to how they organize instruction (the interactions between content, students, and teachers) (Cohen et al, 2003). Herbst and colleagues developed an instrument measuring teachers' mathematical knowledge, structured by the types of work teachers do across different instructional situations (Herbst & Kosko, 2014; Ko et al., 2016). The data collected from their instrument have provided evidence that, at least in the context of teaching of high school geometry, it is possible to differentiate two distinct dimensions of the knowledge: one related to knowledge needed to choose givens for a geometry problem and another related to understanding students' work (Ko & Herbst, 2020).

The distinction of knowledge by different tasks of teaching is grounded on the concept of instructional exchange, which describes how knowledge is "transacted" in classrooms and the role of the teacher managing the exchange (Herbst & Chazan, 2011). Two key tasks – providing students with activities that would enable and support mathematical work and interpreting the work to assess student learning – represent a teacher's role in managing the exchanges. To manage this exchange effectively, teachers need to draw on their mathematical knowledge to make decisions guided by the instructional goals. By focusing on these instructional exchanges, Herbst and colleagues provide a unique lens for examining teachers' mathematical knowledge in key tasks of teaching that are applicable to any teacher, subject matter, and context.

As our instrument is grounded on specific activities that the instructors are expected to do as they teach, we ascertain this knowledge is unique to those who teach the specific content. Consequently, people who presumably know the content (because they took the courses and have been using that content for other more advanced math courses) but who do not have teaching experience with the content would not perform well on an instrument assessing such mathematical knowledge for teaching, particularly in the context of community college algebra instruction.

Research on mathematical knowledge for teaching has consistently documented that as teachers teach more advanced mathematical courses (e.g., middle teachers with experience with high school mathematics; community college teachers teaching courses beyond calculus), they perform better on instruments measuring mathematical knowledge for teaching than those teachers with experience only on the mathematical content assessed by the instruments (Ko et al., 2021; Hill, 2007). Thus, we hypothesized that people who knew the content, but had not taken too many advanced mathematical courses, would not perform well on an instrument assessing such mathematical knowledge for teaching community college algebra. Consequently, we anticipated that a sample of people who could be seen as having the knowledge of the mathematical content that the instrument assesses but without teaching experience on that content and without knowledge of more advanced mathematics, would score lower on our instrument compared to instructors teaching the content in community colleges.

Methods

For the comparison, we chose undergraduate mathematics majors and a sample of community college instructors. The student sample was recruited from 47 large, public, and four-year colleges across all states that offered a mathematics degree and that had a high percentage of admitted students. Students were eligible for participating in the project if they had no tutoring or teaching experience beyond middle school. Of the 191 eligible students, 149 started the questionnaire and 110 completed the instrument. Out of 110 participants, 85 students' responses were used in the analysis after confirming their eligibility for participation. The majority (57%) were between 18 and 22 years old, 51% identified as male and 42% as female, and a minority (13%) identified as Hispanic or Latino, while the majority (76%) identified as White. All the participating students indicated that they took a calculus course, and 80% of the students indicated that they took a college algebra course. The instructor sample was recruited from two-year degree granting institutions in the United States by inspecting community college websites and then sending direct invitations to instructors for participation in this project. Among the respondents, 556 instructors from 314 institutions participated in the project. Among the 556, 416 instructors completed the instrument, and their responses were used in the analysis. Of the 416 instructors, 48% identified as male and 46% as female; in terms of race, 76% identified as White, 11% as Asian, 4% as Black, 2% as mixed, and 4% chose Other. Seventy-eight percent of the participants said they held full-time positions; 9% were on tenure track. The average number of years of teaching experience was close to 17 years (mean = 16.76, SD = 9 years; range: 1.5 to 47 years). The majority (68%) held a master's degree and 20% held PhDs in mathematics, mathematics education or another mathematics-related field (about 5% were PhD in Mathematics Education).

For this study, we used items of the MKT-CCA instrument designed to measure mathematical knowledge for teaching used in two tasks of teaching (understanding student work, choosing problems) college algebra in three function types (linear, exponential, rational) (Mesa, Ko, Boeck, et al., 2023). The instructors and students completed the exact same items. Following the prior studies that validated the instrument regarding the dimensionality of the measured MKT (Mesa, Duranczyk, et al., 2024; Mesa, Ko, et al., 2024), we used a unidimensional model estimating the amount of MKT-CCA as a single score. However, given the error correlations among the testlet sub-items that have the same stem and the possibility of the effect of different item formats (multiple choice or testlet), we used only multiple-choice items (19 items) in this study. A sample item is presented in Figure 1.

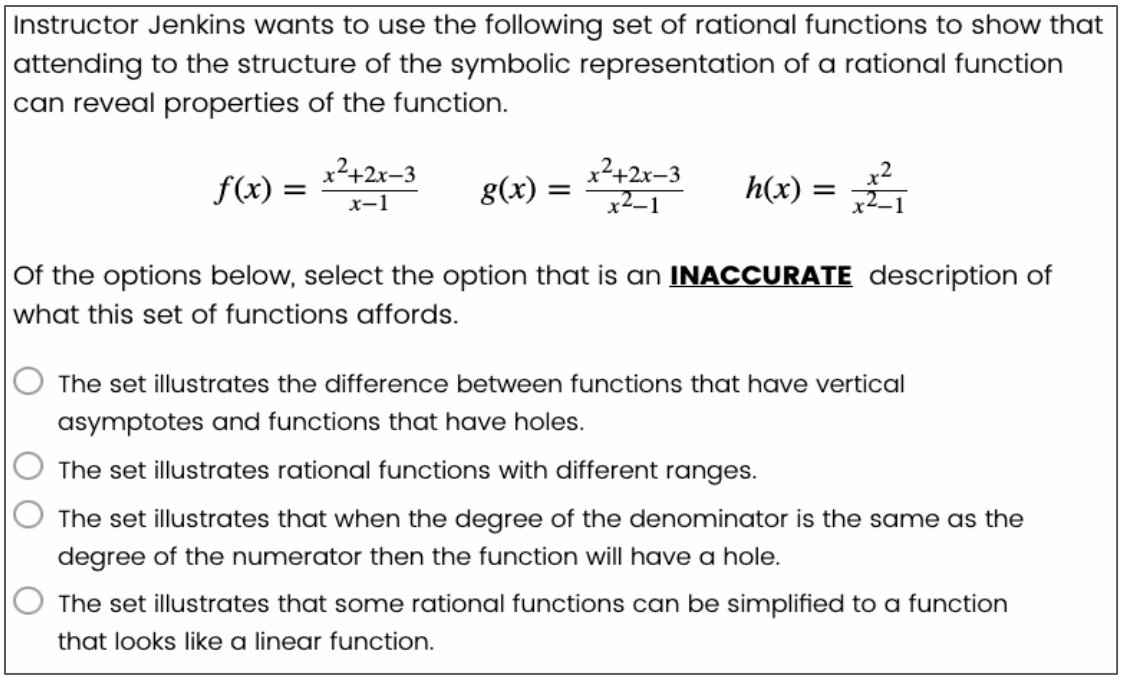

Figure 1. A sample MKT-CCA item involving Choosing problems in Rational function

To compare MKT-CCA scores between instructor and student groups, we applied the Multiple Indicator Multiple Cause (MIMIC) model that compares latent mean between the groups while detecting item bias. Specifically, in this model, we estimated the effect of the group variable on MKT-CCA while estimating the unidimensional MKT-CCA score for both instructors and students. The group variable indicated whether a sample is from a group of instructor (0) or student (1).

Results

Establishing unidimensional construct MKT-CCA

A one-parameter (1PL) and two-parameter (2PL) item factor analysis was conducted on the 19 items using the weighted least squares with mean and variance adjusted (WLSMV) estimator for the whole sample, including instructors and students. Both models fit the data well. In the 1PL model, factor loadings of all 19 items were set to be the same, while in the 2PL, they were freely estimated. The fit indices for 1PL and 2PL were as follows: 1PL (RMSEA=0.038, CFI=0.941, TLI=0.941l) and 2PL (RMSEA=0.011, CFI=0.996, TLI= 0.995). In all models, factor mean and variance was set to 0 and 1, respectively. All the analyses were performed using Mplus v.7.4 (Muthén & Muthén, 1998–2015). All item loadings were significant and greater than 0.3. A comparison of the 1PL and 2PL models using DIFFTEST suggested that 2PL is significantly better than 1PL (DIFFTEST(18) = 71.016, $p<0.001$), indicating that item discriminations are significantly different across different items. Consequently, in the subsequent analyses, we used a 2PL approach.

Comparing MKT-CCA scores between instructor and student groups

The MIMIC model fits the data well (RMSEA=0.021, CFI=0.979, TLI=0.977) and the result suggests that being in the student group has a significantly negative effect on MKT-CCA. Specifically, on average, the student group scored 0.40 standardized deviations lower on the

MKT-CCA than the instructor group. This effect size can be considered as medium according to Cohen's criterion (small, medium, and large for values of 0.20, 0.50, 0.80) (Cohen, 1988). The estimated model diagram is presented with standardized estimates in Figure 2.

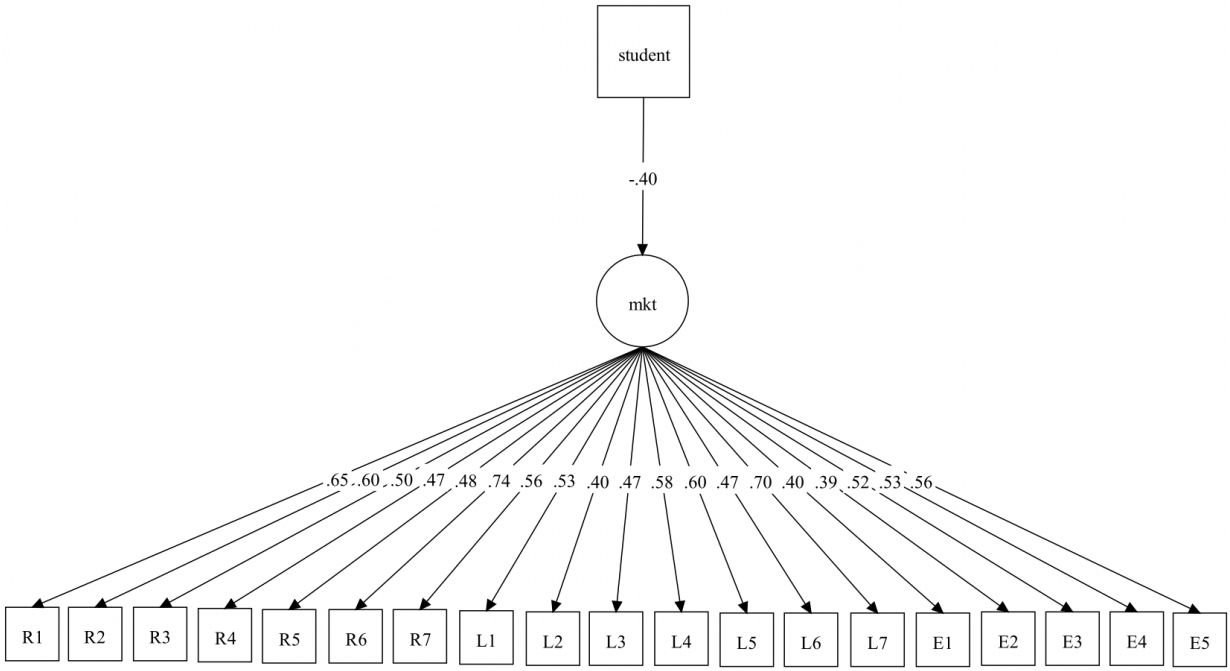

Figure 2. MIMIC model with student group indicator (standardized & significant estimates)

Identifying differential item functioning (DIF) items

Next, we used the MIMIC model to identify potentially biased items across the two groups in how each item measures the MKT-CCA. The difference in MKT-CCA score should stem from the differences in their MKT-CCA, not from items favoring one group over the other. In other words, items with significantly different item intercepts, even after adjusting for latent mean differences, indicate bias that may not relate to the knowledge commonly measured by the 19 items. We tested whether the two groups responded similarly to each item measuring MKT-CCA while controlling for their MKT-CCA. Those items showing differences after adjusting for latent mean differences are considered differential item functioning (DIF) items (Kaplan, 2008). This analysis showed that instructors are more likely to answer correctly than students for two items Item L7 and Item R1 after controlling for their MKT-CCA. Item L7 is an item about choosing problems in linear functions. The stem of the item stated a professor's intended goal for the students and asked participants to choose the option that presents a form of linear equation that will enable his or her students to achieve the learning goal. The correct answer is one form of a linear equation that is not as commonly introduced in textbooks as other forms like slope-intercept or point-slope form. The form is more likely to be found in advanced mathematics courses or specialized texts dealing with analytic geometry. Thus, students might be less familiar with the form than instructors, who have more experience teaching various courses related to algebra, and it might have caused students to score lower than instructors at the same level of MKT-CCA. Item R1 provides an example of incorrect student work and asks the respondent to select the option that is likely to be produced by the student who solved the problem. To choose the correct answer, the participant must be able to identify the error the student made in the

example and choose the option that shows the same error. Thus, familiarity with similar kinds of errors or experience in seeing the error would help a participant in choosing the correct answer. As instructors have more experience in analyzing a variety of student errors, the experience may benefit them in getting a correct answer, even if their mathematical knowledge level is the same as a student's.

We conducted an adjusted MIMIC model that allows estimating the effects of the two items, which are suggested to have DIF, on MKT to account for group differences in the measurement of biased items. Specifically, we regressed MKT-CCA on the group indicator while also adding suggested regression paths from the group indicator to each of the two items. This approach allowed us to estimate the mean difference while also determining the remaining item variance explained by the group indicator. The estimated diagram with significant effects is presented in Figure 3.

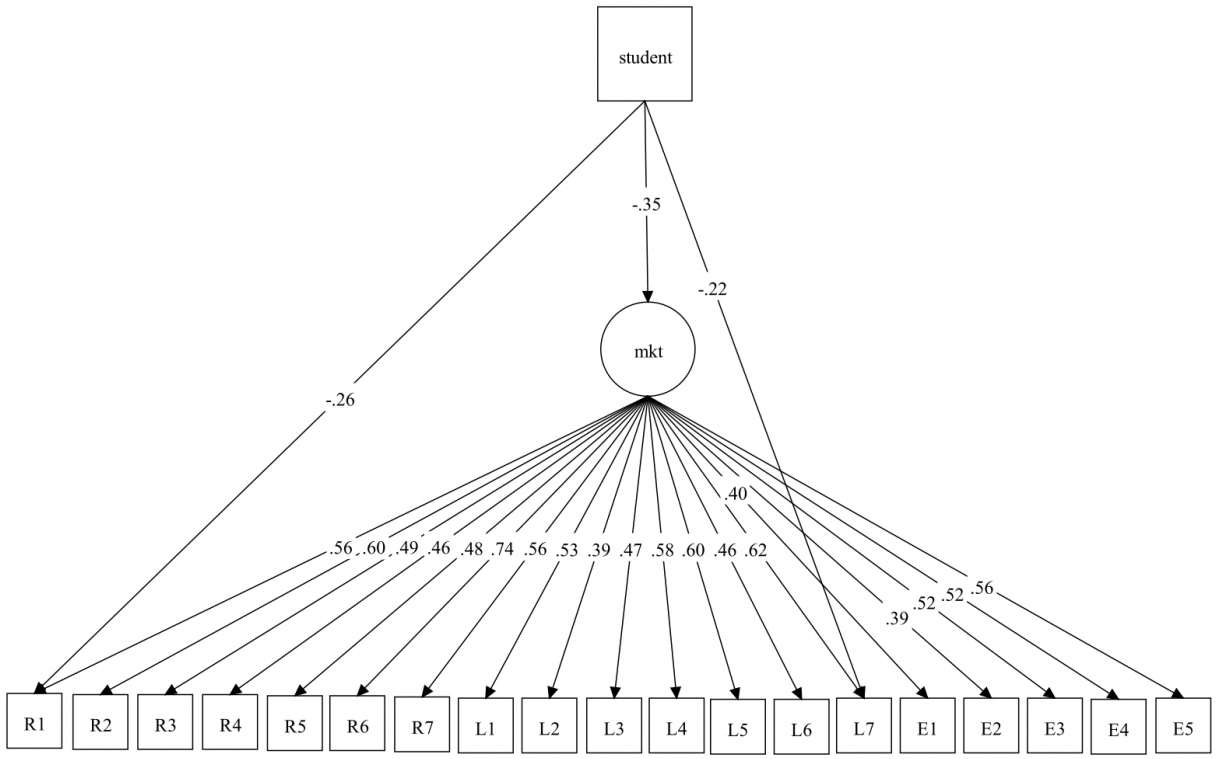

Figure 3. Adjusted MIMIC model with student group indicator and DIF effects (standardized & significant estimates)

The adjusted MIMIC model yielded improved fit statistics (RMSEA=0.012, CFI=0.993, TLI=0.993). As expected, considering the direction of DIF items, the estimated difference in MKT-CCA between instructors and students remained positive and significant (standardized beta=-0.35). This indicates that instructors tend to possess higher MKT-CCA than students, after controlling for DIF items.

Discussion

This study examined the differences in performance on developed instruments consisting of 19 items designed to measure mathematical knowledge for teaching college algebra in community colleges between community college mathematics instructors and college students.

We hypothesized that students would score lower because the participants in the student sample included in this study did not have teaching or tutoring experience. The results confirmed this hypothesis – estimated MKT-CCA was lower for students, and this pattern was consistent across all items. Our hypothesis was based on the characteristics of the knowledge construct we intended to measure through our instrument. As our instrument items were designed to capture the mathematical knowledge used in teaching mathematics, higher scores for instructors with teaching experience imply that the knowledge measured by our instrument is related to teaching. However, it remains unclear whether the instructors' higher scores are due to knowledge acquired from teaching experience or from taking more advanced mathematics courses. Future analysis could examine item-by-item response patterns among instructors and identify qualitative features of the items significantly affected by teaching experience versus those affected by advanced mathematics coursework.

In this study, we applied a MIMIC model rather than multiple group models given that it had a lower sample size requirement, and it is suggested to be an efficient way of comparing latent constructs with adjusting item intercept bias (Diemer, 2023). However, as we did not apply a measurement invariance model that tested the extent to which each of the different components of item estimates across groups, including invariance in factor structure and item discrimination, there is a possibility that we are missing some differences in how each item works for the groups regarding the strength in discriminating the knowledge. In a future study, we will apply a full measurement invariance model and test equal factor loadings for the groups and examine whether the model provides the same result.

By providing a tool that can be used for both instructor and student (including graduate students interested in teaching) populations, our study contributes to the field in identifying potential areas for interventions, training, and curriculum development to enhance not only current community college instructors' mathematical knowledge for teaching college algebra, but also that of students, who might eventually be interested in teaching mathematics at the community college or possibly at other post-secondary institutions.

Symbolic Forms for Inverse Relationships? Calling for Clarification on the Construct

Elizabeth Roan
Indiana University

Jennifer A. Czocher
Texas State University

Symbolic forms is a theoretical construct that has been used to study the meanings students have for symbols. One promising application of symbolic forms is to describe how students construct mathematical equations to represent real-world relationships, a skill needed across STEM disciplines. As more scholars use symbolic forms as an analytic tool across multiple contexts, they make adaptions to the theoretical construct by expanding existing lists of symbolic forms. In this paper, we continue this line of work by documenting undergraduate STEM majors' symbolic forms corresponding to inverse relationships that arose as they modeled dynamic scenarios. We end the discussion with theoretical considerations researchers must make to continue to use symbolic forms to describe students' equation construction.

Keywords: symbolic forms, inverse, differential equations, representations

Scholars across multiple disciplines are investigating how students understand and use symbols in a variety of contexts including chemistry (Becker & Towns, 2012; Rodriguez et al., 2018), physics (Dreyfus et al., 2017; Meredith & Marrongelle, 2008), and mathematics (Dorko & Speer, 2015; Jones, 2013). One thing these scholars have in common is their use of Sherin's (2001) theoretical construct of symbolic forms to operationalize how students understand patterns and meanings of symbols. One promising line of inquiry using symbolic forms is to describe students' construction of mathematical equations intended as representations of real-world scenarios (Schermerhorn & Thompson 2023; Roan & Czocher, 2024), a key skill needed across STEM disciplines. To work towards a fuller description of how students coordinate their knowledge of real-world relationships with symbolic forms to create mathematical equations, we used symbolic forms as a malleable tool of inquiry (see Moore et al., 2024). That is, we used symbolic forms to describe students' construction of equations to represent a predator-prey scenario and disease transmission scenario (Roan & Czocher, in press). That work allowed us to describe how students utilized symbol templates related to the mathematical concept of inverse, a type of mathematical concept that is important not only to modeling but to mathematics as a whole. We end the paper with theoretical considerations researchers must face to move forward in using symbolic forms as a theoretical construct to describe equation construction.

Theoretical Background and Literature Review

Symbolic forms (Sherin, 2001) are a theoretical construct used to describe how students think about equations. Symbolic forms are thought of as a blend (see Schermerhorn & Thompson, 2023) of two components: a symbol template and the associated conceptual schema. The symbol template is the pattern of the symbols. The conceptual schema associated with the symbol template is the idea being expressed by the symbols (Sherin, 2001). For example, a common symbol template used in mathematics is ■ + ■. A conceptual schema associated with the symbol template ■ + ■ is *a whole comprised of two parts* (Sherin, 2001). Conceptual schema are intended to be "relatively simple structures, involving only a few entities and a small number of simple relations among those entities" (Sherin, 2001, p. 491). The term conceptual schema is akin to diSessa's (1993) *phenomenological primitives* (p-prims), that is "elements of intuitive knowledge" like "increased effort begets greater results" (diSessa, 2018, p. 69). Further work has

described the conceptual schema as the "underlying mathematical justification of the symbol template" (Schermerhorn & Thompson, 2023, p. 12). Conceptual schema correspond to the students understanding of relationships and structures (Sherin, 2001), thus conceptual schema may not align to normative characterizations of structures. At the heart of the theoretical construct is the hypothesis that "students learn to express a moderately large vocabulary of simple ideas in equations and to read these same ideas out of equations", where the "elements" of the vocabulary are symbolic forms (Sherin, 2001, p. 482). Researchers who use symbolic forms as a theoretical construct typically provide undergraduate students with pre-existing mathematical equations and ask them to interpret those mathematical equations. For example, Becker and Towns (2012) used symbolic forms to document how students understand mathematical equations in different physical chemistry contests like thermodynamics. Their findings indicate that students start to make sense of unfamiliar mathematical equations using heuristics that can be described by symbolic forms. In their study, the symbolic forms originally found in Sherin (2001) were sufficient to describe the students' reasoning. In other cases, researchers adapt the theory to include novel symbol template – conceptual schema pairs. For example, Dreyfus et al. (2017) investigated two students' sense-making while working on a quantum mechanics task. They used symbolic forms as an analytic tool to describe how the students made sense of the task. In doing so, they observed students using a symbol template – conceptual schema pair they called an eigenvector-eigenvalue symbolic form. Scholars have also used symbolic forms, commonly together with conceptual blending, to describe students' construction of mathematical equations (Ryan & Schermerhorn, 2020; Schermerhorn & Thompson, 2019, 2023). Schermerhorn and Thompson (2019) described how undergraduate physics students constructed a differential length vector for a spherical coordinate system. Part of this work was to add new symbolic forms to the list, and another part was to describe how students coordinated concepts from physics with symbolic forms to create their mathematical equations. They were able to identify what concept, like direction, motivated the student's use of a symbolic form, like parts-of-a-whole.

We situate our work within a similar line of inquiry as Schermerhorn and Thompson (2023); our work focuses on students' construction of differential equations that represent canonical scenarios students tend to encounter when in a differential equations class such as a predator prey scenario or a disease transmission scenario. A key mathematical relationship underlying those two scenarios is *inverse*. This is, because the predator – prey and disease transmission scenarios afford students the opportunity to think of flux to and from different populations (predator-prey) and/or sub-populations (disease transmission), students must coordinate their understanding of *additive inverse* with symbolic forms to create their models. To work towards a fuller description of how students coordinate their understandings of real-world relationships with symbolic forms to create mathematical models, we answer the research question: *what symbolic forms do STEM undergraduates use to represent inverse relationships between quantities that form their models for dynamic scenarios?* To answer this question, we share examples symbolic template conceptual schema pairs our participants used when representing scenarios that mathematically called for an additive inverse.

Methodology

The data for this paper draws from a larger dissertation study designed to characterize the cognitive obstacles students encounter while creating mathematical equations that represent dynamic scenarios. In this paper, we report on eleven participants' work on two modeling tasks: predator-prey and a disease transmission (Roan, 2024). The participants were high achieving

undergraduate STEM majors who self-reported familiarity with mathematical concepts like instantaneous rates of change and who had taken or were enrolled in a differential equations course. The data were collected via task-based interviews conducted and recorded using Zoom. Images of the participants' written work were collected at the end of each session. In both tasks, participants were asked to create a (system of) differential equation(s) that would model the given dynamic scenario. In the predator-prey task, participants were asked to model the species dynamics between cats and birds in a back-yard habitat. In the disease transmission task, participants were asked to model how quickly a disease, like tuberculosis, spread through a community of infected (sick) or susceptible (healthy) individuals.

The goal of data analysis was to document distinct symbolic forms participants utilized while creating their models. We documented the symbolic forms by identifying the symbol template and identifying the conceptual schema associated with the symbol template. Identifying the use of a symbol template is straight forward, identifying the conceptual schema associated with the template was more inductive. This analysis was aided by the interview protocol, that guided the interviewer to ask the participant to explain why they chose a symbol template. For example, when a participant wrote down a mathematical equation like $C(t) \times B(t)$, the interviewer would ask "why did you decide to use × here?". We then used this information to infer what simple mathematical relationship (i.e., conceptual schema) the participant was trying to express using the symbol template. In instances where participants did not explicitly express their reason for using a symbol template, we inferred what simple mathematical relationship they were trying to represent using the participants' explanations of what the mathematical equation represented. We matched the symbolic forms our participants used when creating their models to clearly analogous symbolic forms documented in prior literature (see Brahmia, 2019; Dorko & Speer, 2015; Dreyfus et al., 2017; Jones, 2013; Pina et al., 2023; Riihiluoma et al., 2023; Schermerhorn & Thompson, 2023; Serbin & Uscanga, 2023). For example, our participants used the symbolic forms extensive – extensive, intensive – extensive, base $\pm$ change, and more, all of which are documented in Sherin's (2001) initial list of symbolic forms. We do not provide evidence of this use and instead focus on providing more details about the [potential] symbolic forms our participants utilized when creating models of dynamic scenarios that focus on representing inverse relationships. That is, we focus on the instances where our participants used symbol template – conceptual schema pairs that depict inverse relationships that did not have clear analogous symbolic forms from the literature. That is, the conceptual schema and symbolic template have not been reported together as a symbolic form previously. In this report, we show data excerpts from Ivory, Yixli, and Rillir, whose work was selected because they concisely explicated their reasoning with symbol templates. Ivory and Yixli were physics majors, and Rillir was an electrical engineering major.

Results

In the following section, we describe three symbol template – conceptual schema pairs our participants utilized when representing relationships that mathematically called for an additive inverse. We note here that, from the researcher's perspective, these relationships called for an additive inverse. We report the conceptual schema, the underlying mathematical justification, our participants associated with the symbol templates they chose to use, which might not align with the researcher's perspective. For each pair, we will provide the symbol template, our inferred conceptual schema, and evidence of that inferred conceptual schema. Additionally, we will state which task the symbol template – conceptual schema pair was utilized for, as not all pairs were utilized across all tasks. An overview of our findings can be seen in Table 1.

Table 1 An overview of symbolic forms

Symbol Template	Conceptual Schema	Task Scenario
$x = \frac{1}{y}$	Quantity y is inversely related to quantity x.	Disease Transmission
$x = -y$	Flux in equals the flux out	Disease Transmission
$x = 1 - y$	Quantity x is the percent complement of quantity y.	Predator - Prey Disease Transmission

Inverse

Ivory (physics) was working on the disease transmission task. She had established that the instantaneous rate of change of the sick population would be represented by the symbol $\frac{dS}{dt}$ and the instantaneous rate of change of the healthy population would be represented by the symbol $\frac{dH}{dt}$. Ivory sought to create a mathematical equation that would represent the relationship between the instantaneous rate of change of the sick and healthy populations. To meet her goal, Ivory wrote down $\frac{dS}{dt} = 1 \Big/ \frac{dh}{dt}$. When explaining her model, Ivory stated

> Ivory: You could also do one over $\frac{dh}{dt}$, I think. [LAUGHS] Because you're either sick or not sick. So the inverse of sick people would be the healthy people. And the-- the inverse of healthy people would be the sick people.

A few moments later, when asked about her model she explained again that she had written $\frac{dS}{dt} = 1 \Big/ \frac{dh}{dt}$ because "it's just, you're either healthy or you're sick." We infer from Ivory's explanation that she envisioned that the entire population could be split into two subpopulations: the sick and the healthy. Further, if a person is sick, then they cannot be healthy; thus her logic goes, the sick population and the healthy population are inversely related.

The conceptual schema, the intuitive mathematical relationship being represented, is: one quantity is inversely related to another quantity. The symbol she associated with this symbol template was $x = \frac{1}{y}$. Mathematically, we would anticipate that the conceptual schema associated with such a symbol template would be something like one quantity is inversely proportional to another quantity. However, it is not the case that Ivory attended to proportionality when writing down her mathematical equation, leading us to believe that Ivory's conceptual schema paired with the symbol template $x = \frac{1}{y}$ is novel, though nonnormative. In fact, Ivory edited her mathematical representation and changed the symbol template multiple times before settling on a normatively correct mathematical representation for an SI model, $\frac{dS}{dt} = -\frac{dH}{dt}$. We will discuss the ramification of her edits in the discussion.

Additive Inverse

Like Ivory, Yixli (physics) was also working on the disease transmission task. He had previously created a mathematical equation that represented the change in the infected population, which he labeled as ΔI. A full breakdown of Yixli's model is given below in Table 2.

Table 2 A breakdown of Yixli's mathematical equation for the change in the infected population

Quantity	Symbol / Equation
Infected people	$I(t)$
Susceptible people	$S(t)$
Possible Encounters	$I(t) \times S(t)$
Exposures per Possible Encounter	α
New infection per exposure	τ
Change in the infected population	$I(t) \times S(t) \times \alpha \times \tau$

Yixli sought to create a mathematical equation that would represent the instantaneous rate of change of the susceptible population. To meet his goal, Yixli wrote $\Delta S = -I(t) \times S(t) \times \alpha \times \tau$. When explaining his model, Yixli explained that

> Yixli: OK, so I think this will just be inverted? [writes $-\tau \times \alpha \times S(t) \times I(t) = \Delta S$]. And that's it. You know, because if we're- if we gain two on the-the infection, then we lose two on the susceptible. Um, so it's just going to be the negative reciprocal. Not negative reciprocal, but, you know, um, this is going to be the negative of- of- of the rate of the infection.

We infer from Yixli's explanation that he envisioned that flux out of the susceptible population is equal in magnitude to the flux into the infected. That is, the conceptual schema being represented here is: flux in equals the flux out. The associated symbol template to this conceptual schema is $x = -y$. We used Yixli as an example because of his well-worded explanation, but many of our participants used this symbolic form during the disease transmission task.

Percent Complement

Rillir was working on the predator-prey task. He had previously created a mathematical representation for the number of interactions between a cat and a bird that do not result in death. The quantities and their corresponding symbols within his mathematical equation are shown in Table 3.

Table 3 A breakdown of Rillir's mathematical representation for the number of interactions between a cat and a bird that do not result in death.

Quantity	Symbol/Equation
Bird population	$B(t)$
Cat population	$C(t)$
Total possible interactions between species	$B(t) \times C(t)$
Percent of possible interactions that happen	α
Percent of actual interactions that do not result in death	β
Number of interactions between a cat and a bird that do not result in death	$B(t) \times C(t) \times \alpha \times \beta$

Rillir sought to create a mathematical equation representing the number of interactions between a cat and a bird that result in death. To meet his goal, Rillir wrote down $100 - \beta = G$, explaining that "since it's a β. Since it's a percent. You can do $100 - \beta$". He then replaced β with G in his mathematical representation so that $B(t) \times C(t) \times \alpha \times G$ represented the number of interactions between a cat and a bird that do result in a death. We infer from Rillir's

explanation that he thought that since there are two outcomes of an interaction, death and not death, the percentage of interactions that do result in death must be the percent complement of the percentage of interactions that do not result in death. That is, the conceptual schema being presented here is: one quantity is the percent complement of the other. The associated symbol template to this conceptual schema is $1 - x = y \; or \; 100 - x = y$, depending on whether the percentage is in decimal form or not. One other participant used this conceptual schema-symbolic template pair, and they also explained their mathematical representation in a similar way to Rillir.

Discussion

In this paper, we have presented three conceptual schema–symbol template pairs our participants utilized while modeling dynamic scenarios that have some connection to the idea of *inverse*. The pairs were observable because the dynamic scenarios the participants modeled lent themselves to consider flux within a population and between populations. Our work expands what is known about how students use of symbolic forms to represent inverses and also has implications for studying students' mathematical equation construction using symbolic forms.

Serbin and Uscanga (2023) used the symbolic form construct to discuss how pre-service mathematics teachers reasoned about additive, multiplicative, and compositional cancellation. The symbolic form construct focused their analysis on what kinds of symbolic templates (i.e., templates with or without explicit depictions of inverse or identity) their participants used when thinking of cancellation operations. We infer that Serbin and Uscanga's descriptions align with two of the three ways students' reason about inverses across contexts described by Cook et al. (2023): inverse as an undoing and inverse as a manipulated element. By studying students' construction of mathematical equations that represent dynamic scenarios, we have described three conceptual schema–symbol template pairs that align with the third way of reasoning Cook et al. (2023) described: inverse as a coordination of the binary operation, identity, and set. Our efforts add to the growing list of symbolic forms and further test the symbolic form construct in a new area and adding to its applicability in more contexts.

However, we have rhetorically referred to these as conceptual schema – symbol template pairs because there are alternative interpretations of each of these pairs that brings to light considerations for using symbolic forms to describe equation construction. First, we proffer alternative interpretations of each example and second, raise the difficulties of making inferences based on student reasoning.

First, Ivory used the conceptual schema "quantity y is inversely related to quantity x." paired with the symbol template $x = \frac{1}{y}$. She, in that moment, justified using symbol template $x = \frac{1}{y}$ using the mathematical idea of inverse. When students create mathematical equations to represent real-world relationships, the "underlying mathematical justification" (Schermerhorn & Thompson) for the symbol template may not be mathematically accurate. In prior literature, researchers have discussed how the conceptual schema might not accurately depict the phenomena of interest (see Schermerhorn & Thompson, 2023) but the schema and template still aligned mathematically. This raises the question, do cases where the conceptual schema and the symbol template do not mathematically align belong on the growing list of symbolic forms seen across contexts? We assert that they should belong on the list, because these cases are informative about what underlying justifications students associate with the symbol templates. Further, these indicate places where students might need support to disentangle nonnormative conceptual schema with symbol templates. Ivory later edited her model because she realized that

her mathematical equation was incorrect and that the conceptual schema she had associated with the symbol template $x = \frac{1}{y}$ did not match the relationship between her quantities as well as she originally thought. When students make edits to their mathematical equations the conceptual schema may change. When that change occurs, researchers must consider if theoretically that is that another instance of a symbolic form or a different manifestation of the same symbolic form.

Second, we consider Yixli's use of the conceptual schema *flux in equals the flux out* along with the symbol template $x = -y$. An alternative interpretation of Yixli's example is that he used the symbolic form Sherin (2001) called competing terms, where the conceptual schema was *influences in competition*, and the symbol template was $\blacksquare \pm \ldots \pm \blacksquare$. In Yixli's case, he simply had one term that was doing the influencing. From our perspective, this interpretation overlooks that Yixli created a mathematical equation that simultaneously described a positive influence on one quantity and a negative influence on another, a key aspect of the justification Yixli gave for using that symbol template. Thus, his conceptual schema was distinct from *influences in competition* since, from his perspective, no influences were competing.

Lastly, we consider Rillir's use of the conceptual schema *quantity x is the percent complement of quantity y*, along with the symbol template $x = 1 - y$. In our interpretation, the $1 - y$ or $100 - y$ is like an operator, a thing done to a percentage to get its complement. This aligns with other explanations of symbolic forms such as in Jones (2013), who described the parts of an integral as operators that acted on an original function. An alternative interpretation of Rillir's example is that he instead activated the whole - part symbolic form (Sherin, 2001) where the conceptual schema is taking away a part of an original whole and the symbol template is $[\blacksquare - \blacksquare]$. Sherin (2001) described this symbolic form as "a new net amount is produced by taking away a piece of an original whole" (p. 534). It is unclear the extent to which Rillir and other participants saw the 1 or 100 in the symbol template as a whole that the percentage is being taken from rather than an operator that does something to the percentage. When cases like this occur, researchers must decide if theoretically this is an instance of a singular symbolic form or an instance where the student is using a few symbolic forms waring a trench coat. Researchers need to take into consideration the loss or gain in explanatory power when making that decision. We infer the theoretical consideration is directly linked to the grainsize of students' justifications. Thus, researchers must consider the theoretical construct's ability explicate differing grain sizes of the mathematical justifications underlaying students' choice in symbol template. We acknowledge some of our difficulty classifying our participants symbol template – conceptual schema pairs as symbolic forms may lie with the interview protocol. However, our limitations to making more definitive claims have brought to the forefront important theoretical considerations. That is, the three examples reported in our paper bring to light considerations research must address if work is to move forward in using symbolic forms to describe students' construction of mathematical equations.

Graduate Student Instructors' Mathematical Knowledge for Teaching Inverse Functions and Their Goals for Student Learning

Erin Wood
University of Georgia

The mathematical meanings that instructors hold necessarily impact the ways that they teach and their goals for student learning. This study examined five graduate student instructors' (GSIs') mathematical meanings related to inverse function with the goal of exploring links between their meanings and the meanings they hoped for their students to construct. I found that the GSIs had multiple meanings for inverse functions that were evoked in different contexts, and that they had trouble drawing connections between these meanings when asked about relationships between them. Similarly, their goals for student learning did not include connections between meanings and were additionally constrained by factors such as the departmental curriculum used and the need to adhere to mathematical convention that students were accustomed to.

Keywords: Mathematical Knowledge for Teaching, Inverse Functions, Graduate Student Instructors

Researchers and teacher educators have long called for more attention to the mathematical meanings that teachers hold (Thompson & Thompson, 1996), arguing that without a coherent web of strong mathematical meanings, teachers are not best positioned to effectively work to foster strong understandings in their students (Tallman, 2021; Thompson, 2013). Graduate student instructors (GSIs) teach large numbers of undergraduate students in introductory math courses every semester (Blair et al., 2018), and often have little to no training (Belnap & Allred, 2009; Lewis & Tucker, 2009). Although there has been a tacit assumption that the mathematical content they teach is unproblematic for GSIs (e.g., Ellis, 2014) recent research focused on GSIs' mathematical meanings calls this into question and indicates a need for more attention to GSIs' mathematical meanings (Musgrave & Carlson, 2017; Rocha, 2022).

This proposal reports on a study designed to investigate the mathematical meanings related to inverse functions held by GSIs teaching Precalculus, and to gain insight into aspects of their mathematical knowledge for teaching (MKT) in this context. It is well known that students generally struggle with inverse functions (e.g. Bayazit & Gray, 2004; Brown & Reynolds, 2007; Engelke et al., 2005; Even, 1992; Paoletti et al., 2018; Vidakovic, 1996), but less is known about how teachers understand these ideas, especially at the postsecondary level. The broad goals of the study were to answer the questions:

1) What are graduate student instructors' meanings for inverse functions?
2) How do these meanings impact their goals for student learning related to inverse function?

Literature Review and Background

The knowledge required for teaching has been studied for several decades, beginning with quantitative analyses of teachers' education and their students' achievement (e.g., Ferguson & Womack, 1993; Guyton & Farokhi, 1987; Monk, 1994). When these studies began to shed doubt on the assumption that teachers with more mathematical knowledge would have higher student achievement, mathematics education researchers sought new methods for investigating the link

between teacher knowledge and student outcomes. Several frameworks for conceptualizing mathematical knowledge for teaching (MKT) have been proposed, with some focusing on measuring and categorizing that knowledge (e.g., Ball et al., 2008) and others working to provide explanatory mechanisms for how MKT might be developed (e.g., Silverman & Thompson, 2008). I draw on Silverman and Thompson's conceptualization of MKT for this proposal, as it focuses specifically on the mathematical meanings that teachers hold with respect to a given concept.

Silverman and Thompson's (2008) framework for mathematical knowledge for teaching is based in a constructivist perspective, where "knowledge" and "meaning" are thought of differently than how they are generally used elsewhere. Rather than knowledge referring to things that someone believes to be true, it instead refers to assimilation to a scheme, which entails assigning meaning to the object of assimilation by fitting it into an already developed cognitive structure and includes inferences based on this meaning (Thompson, 2013). These related inferences are critical in understanding someone's meanings, because they establish what it is that particular knowledge will allow someone to do. Silverman and Thompson (2008) argued that the first step in developing MKT is to first have a strong personal understanding of the mathematical concept. This understanding includes relationships between the concept in question and other content knowledge, creating a web of connections between seemingly disparate mathematical topics. Next, a teacher must transform this knowledge into knowledge with pedagogical power by understanding how students conceptualizing mathematical ideas in a similar way to the teacher will enable them to learn related ideas, and by imagining the actions that the teacher might engage in to help support students in developing this understanding. Silverman and Thompson (2008) claimed that this transformation of knowledge into knowledge with pedagogical power requires a teacher to consciously reflect on their understanding, and to reflect on how students might develop compatible understandings.

The productivity of instructor's mathematical meanings can be defined by how productive these meanings would be for students' long-term learning if they were to also hold those meanings (Byerley & Thompson, 2017). From this perspective, meanings that help a student to answer questions about the given topic correctly but that are not easily built upon to develop future mathematical ideas are less productive than meanings that provide a foundation for further learning. In addition, the purpose of knowledge is to help the knower maintain a state of equilibrium as they engage with the world (von Glasersfeld, 1995), and so meanings that are useful in a wider variety of contexts can be considered to be more productive than those that are useful only in limited contexts (Byerley & Thompson, 2017). Similarly, those meanings that provide important foundations for reconciling future perturbations that occur and engender learning are considered to be more productive.

Methods

This study was conducted at a large public university in the southeastern United States, and five graduate student instructors participated. The GSIs ranged from second to sixth year mathematics PhD students and had all taught Precalculus for at least one semester prior to the commencement of the study. At this university, inverse functions are taught in Precalculus as a prelude to exponential and logarithmic functions. Students are expected to determine whether a function is one-to-one algebraically and by examining the graph of a function, and they are presented with the standard composition definition of inverse functions. Students learn to find the inverse of a given function algebraically by switching x and y and solving for y (the "switch and solve" technique), and graphically by reflecting over the line $y=x$.

I conducted a series of clinical interviews (Clement, 2000) with participants individually. The first two interviews focused on the GSIs' goals for student learning in relation to inverse function, and the remaining interviews were task-based interviews aimed at developing models of the GSIs' mathematical meanings for inverse functions (Steffe & Thompson, 2000). The GSIs participated in between 6 and 9 interviews each, with the number of interviews determined by how long it took to develop stable models of each participant's mathematical meanings. I engaged in ongoing analysis between each task-based interview to develop and refine my models for how my participants understood inverse functions and developed tasks for future interviews to test these hypotheses. I then compared the goals that participants had for the meanings their students would construct to the models of my participants' own meanings that I developed to look for areas of agreement or disagreement.

Results

Throughout the task-based clinical interviews, it was clear that the GSIs held meanings that allowed them to productively engage with inverse function tasks. However, most of them drew on meanings that were disparate (from my perspective) to solve different types of tasks, and they often had trouble describing coherence or connections between their different meanings. Isabelle, a sixth year graduate student, consistently thought of inverse functions as functions that describe the same invariant relationship from two perspectives. With this meaning, one function is viewed as giving one quantity (Q_1) in terms of another quantity (Q_2), while the inverse function describes the same relationship between Q_1 and Q_2 but instead gives Q_2 in terms of Q_1. She described this as being one of the big ideas that she wanted students to understand about inverse functions, saying,

> So let's say if we have cosine theta is *a*, we can have cosine inverse *a* is theta. And what it tells us is this is theta, uh, *a*, 1, right? [pointing at the triangle in Figure 1] So both of them tell me the same story. So I have the same, uh, object or same thing in the real life and I can say that in a different way. And I can use whichever I want to use or whichever is useful for me in that situation.

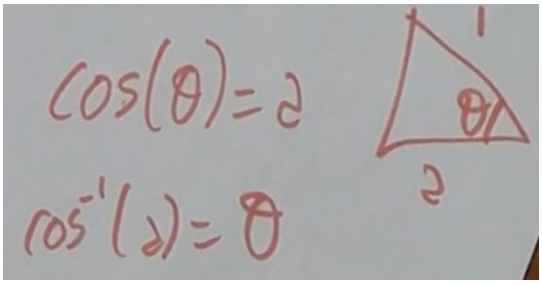

Figure 1. Isabelle 's work while discussing intended student meanings for inverse function.

At other times throughout the interview sequence, Isabelle also talked about wanting students to understand that inverse functions undo the original functions via function composition, and to think about inverse functions involving inverse operations from the operations in the original function. I was curious about the extent to which these two meanings were related for her, because she talked about undoing and composition in relation to algebraically defined functions without context, whereas she discussed the invariant relationship meaning when discussing trigonometric functions or functions with a real-world context. As an example of the latter, when presented with the following task (Figure 2), Isabelle almost immediately identified that the two graphs could be thought of as representing the same glass, and that they could be seen as inverse

functions. To explore the connections between her meanings for inverse functions, I asked her to clarify how a student might understand how these two ways of thinking about inverse functions might be related in this context.

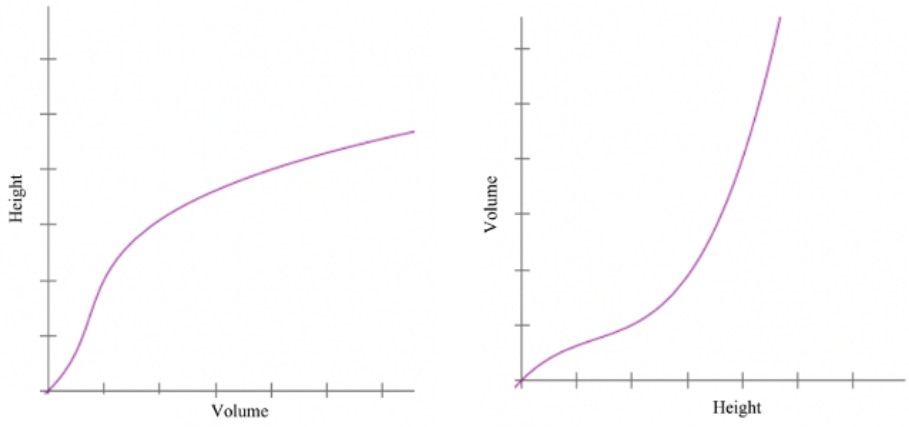

Figure 2. A task used in Isabelle 's interview.

Interviewer: What about if a student was like, "I thought inverse functions, like, undo each other, um, but these are just, like, kind of representing the same relationship. How do, how do I, like, make sense of that?" How would you respond?

Isabelle : For the undoing thing, I would say they are undoing in algebraic way.

Interviewer: Okay, what do you mean by that?

Isabelle : Like, when I'm adding two, for one of them, I'm subtracting two for the other one.

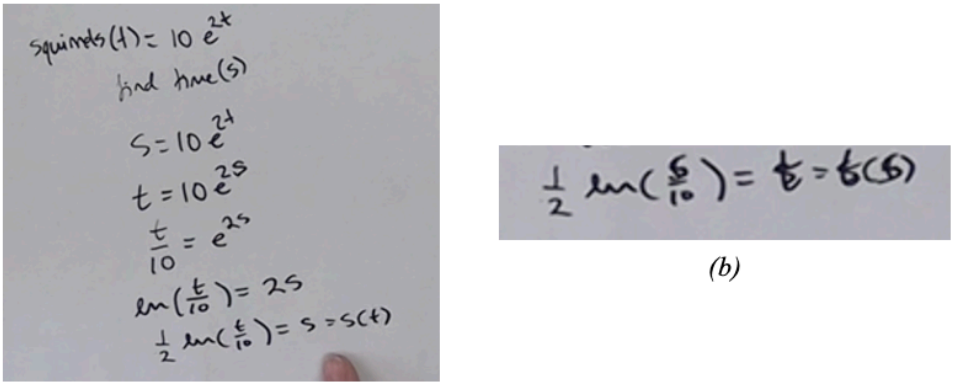
Interviewer: Okay.

Isabelle : But they represent the same thing in the real life. They represent the same glass.

She continued to describe how undoing can be seen algebraically when finding the inverse of a function, and I pushed her to explain conceptually how a student might connect the idea of undoing with the physical context of the glass.

Interviewer: If we're thinking about, like, the relationship between volume and height, or height and volume, is there a way of thinking about the undoing, in terms of, like, that relationship?

Isabelle : No, because I feel like they are doing the same thing. Like, again, I will just look at one part here [pointing to one graph], or here [pointing to the corresponding section on the other graph], and for both parts, when I look at, like, volume and height, let me say it like this, when I think, this is the height, this is the volume, this is the height, this is the volume here, so they give me this [pointing to her drawing of the associated glass]. They give me the same object. So because of that, in the real life explanation, there is no undoing. Because height is going, well, let's say, two units, but volume is going eight units in both of them. So, no. There is no undoing part.



I interpreted this to mean that Isabelle thought about composition and "undoing" in the context of algebraically defined functions, but that these meanings were not explicitly related to her meaning for inverse functions in real-world contexts (i.e., a function and its inverse capturing an invariant relationship). When I asked whether she wanted students to see these different ways of thinking as related, she did not express a desire for them to make any connections. While I

have only presented an example of a lack of connections in one participant's meanings due to space constraints, other GSIs demonstrated similar differing meanings for inverse functions across various contexts, and these inconsistencies were reflected in the lack of specific connections between the ideas that they wanted students to develop.

However, the GSIs' teaching goals were not only constrained by their personal mathematical meanings, but also by their perceived constraints due to the curriculum used and mathematical convention that they perceived their students to be accustomed to. All the participants explicitly described a disconnect between finding the inverse of a given function in a real-world context and solving the same type of problems without context. When finding the inverse of a function expressed algebraically, participants generally used the "switch and solve" technique. When solving problems in context, however, participants did not swap the variables and instead simply solved for the other quantity in the problem.

One participant, Nadia, described a problem that she used in her class, in which the population of squirrels in someone's backyard was growing according to the relationship $S = 10e^{2t}$ where S represented the number of squirrels and t represented time. Students were tasked with finding a function that would represent the time elapsed as a function of the population of squirrels in the yard. When doing this problem in an interview, Nadia first employed the switch and solve technique and ended up with a function that was again in terms of t (see Figure 3a). Once she finished, she perceived that her solution no longer accurately described the original relationship and switched the variables again to fix it (Figure 3b), stating "if it were *x*'s and *y*'s, it would have worked out with inputs and outputs. Um, but I shouldn't have switched these because I wanted to keep time and squirrels different." To her, the "switch and solve" technique was appropriate to use when dealing with x and y because it maintained the convention that x is the input of a function and y is the output of a function, but was not appropriate to use when the variables in a function represented real-world quantities. When I questioned how she helped students understand when to swap variables versus when to leave them, she stated,

> I think it would have confused them more if I had talked about that, because then it would be like, why are *x*'s and *y*'s special where we want to switch them? And, and I mean, the answer to that is just because it would be more confusing for the students to be trying to graph, like, if you were, if you had a function *x* with *y* as the variable, and you were trying to graph that on your regular plane, that would just be more confusing for the students. As opposed to saying *y*'s are on the *y* axis, *x*'s are on the *x* axis.

(a) (b)

Figure 3. Nadia's work for the squirrel population problem.

Another participant that identified the same disconnect discussed that he would prefer to approach the topic differently than the given curriculum did in order to address the perceived disconnect. Jake reflected on how he would prefer to teach students to find the inverse of a given function, saying he would like them to solve for *x* in terms of *y* instead of swapping the variables. He noted that,

> Somehow that makes more conceptual sense to me, because *y*, kind of, you know, in this sort of picture [pointing to Figure 4], it's like, the *x*'s lived over here [pointing to the circled *x*], the *y*'s lived over here [pointing to the circled *y*], and then there is the function, which takes you from there to there [motioning from left to right]. And so this is a recipe which tells you, given an *x*, how do you get a *y*? So it's like, how do you go this way? And if you solve for *x* in terms of *y*, that's telling you given a *y*, how do you get an *x*?

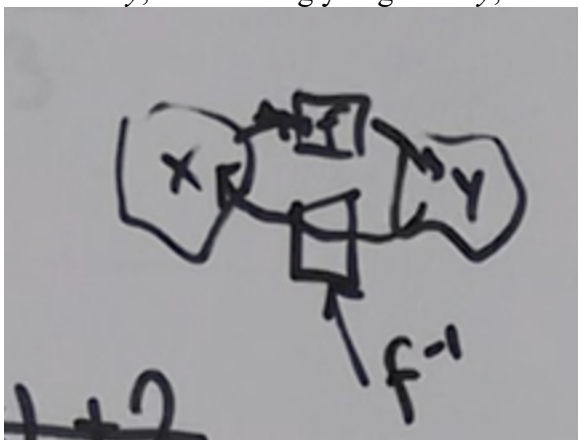


Figure 4. Jake's function diagram.

He went on to describe why he does not teach in this way, saying,

> I've tried that in like once or twice and I think that it's another inertia momentum thing where, you know, just solving, they're just so used to solving for *y*. Yeah, ideally, I would not do the swap. But, yeah, why do they do the swap in the process? I think it's just somehow to make it, um, yeah, because, like, they look at this kind of thing [pointing to the equation $y = 3x + 2$] and they're, like, not sure what to solve for somehow. Um, so once you make the swap, then it becomes clear. Like, uh, I wanted *y* equals some stuff, and now I don't have that situation anymore, so now I have to do algebra to get, you know, *y* equals some stuff in the process.

I interpreted this to mean that Jake prioritized maintaining the procedural habits that his students were accustomed to over teaching in a way that aligned with his personal meanings for inverse functions. He had tried to teach using his own meanings in the past, but was, in his opinion, unsuccessful, which could indicate that he had not transformed his personal meanings into meanings that were pedagogically useful in this context. While he had an image for the meanings he wished for his students to construct, he did not know how to support them in constructing these meanings. Nadia and Jake both compromised the coherence of their instruction to maintain habits that students were used to (such as graphing *x* on the horizontal axis and always solving equations for *y*), instead of working to help their students construct mathematical meanings that were compatible with their own.

Discussion and Conclusion

Through this study, I sought to investigate the coherence of participants' meanings for

inverse functions because, in accordance with my theoretical perspective, coherence in an instructor's mathematical meanings is a necessary condition for them to be able to intentionally design instruction to support students in constructing powerful, coherent meanings. I found that the meanings for inverse functions that the GSIs' drew on in different contexts were distinct from each other, and that they struggled to draw connections between these differing meanings. Some, like Isabelle , did not have a desire to draw these connections, while others actively searched for ways to connect their meanings during our interviews. One participant expressed her frustration when trying to understand how a function and its inverse can simultaneously represent the same quantitative relationship and can be seen as undoing one another, saying "I feel like I'm so close to getting this right. Um, like this connection between what we saw here, that like, it's, it's really the same relationship, and it being some inversion of the relationship. It's still not there." She sought to reconcile these ideas over the course of the interview sequence, and wanted to find a way to help her students understand the ideas as compatible as well.

The curriculum that the GSIs used in their courses centers actions for students to do, rather than meanings for them to construct. If student meanings for inverse function are limited to actions such as "I should compose functions to show that they are inverses", "I switch x and y and solve for y to find an inverse function", and "I reflect the graph over $y=x$", then each of these meanings is only useful in very specific contexts. If the productivity of meanings is determined by the range of situations that they allow a learner to handle, then these meanings are extremely limited. As the GSIs pointed out, the "switch and solve" technique has the potential to be conceptually limiting for students. The GSIs themselves understood why the technique works in some cases but not others, but had not operationalized these understandings in ways that made them useful pedagogically. Jake and Nadia, along with other participants, described their reasons for teaching this technique despite its limitations, which centered around wanting to match what students had seen in previous classes, wanting to align with the textbook and course materials, and not wanting to confuse students by altering the convention that x is always an input and y is always an output. These are all entirely valid reasons and underscore that shifting to teaching for mathematical meanings is incredibly difficult at the level of the individual instructor, and requires a broader scale effort at the level of course coordinators and curriculum designers.

It should not come as a surprise that the GSIs struggled to describe central meanings behind the concept of inverse functions when the curriculum they use has no such underpinnings. It would be unreasonable to expect GSIs to come into their graduate programs with fully developed sophisticated understandings of all the mathematical ideas they will teach, and often the materials that they are given to teach offer them no opportunities to further develop their understandings. While this study uncovered worrisome findings about GSIs' mathematical knowledge for teaching, I do not intend for it to be a critique of the GSIs, but instead of the systems within which they are expected to operate. The GSIs in this study are clearly mathematically capable and yet they hold limited meanings for these mathematical concepts and meanings that are not pedagogically powerful. This is an indication that they have not had opportunities that would lead them to develop stronger mathematical meanings, not that they are incapable of it. This has implications for both professional development programs for GSIs and curriculum design, as developing stronger meanings in GSIs will be of limited value if they are still constrained by action-focused curriculum. Future research should investigate how to help GSIs develop more coherent meanings, and how to help them transform their meanings into meanings that are pedagogically useful.

Developmental Mathematics Student Motivation: A Mixed-Methods Study

Katherine J. Burke
Temple University

Failure and attrition are unfortunately common experiences for developmental mathematics students. These students also frequently experience course repetition and redundancy, though these phenomena are less well-understood. In this mixed-methods study, I aimed to investigate how developmental math students' attitudes and motivation are impacted by their experiences with relearning and course repetition. Additionally, I aimed to describe how these experiences influence shifts in motivation, resulting in changes to academic behaviors and, thus, performance. Quantitative analyses, though statistically insignificant, warrant future inquiry regarding the attitudinal impact of course repetition. Qualitative analyses reveal how students' particular aims and learning histories meaningfully mediate shifts in their motivation. The results of this study demonstrate the salience of investigating how *repetition impacts students' motivation, as well as the utility of theories of motivation in the study of developmental math students' perceptions.*

Keywords: Developmental math, motivation, student perceptions

Developmental mathematics education is a unique and complex system at the threshold of postsecondary mathematics education. Courses in this system–typically focused on algebraic topics–aim to ready underprepared students for college-level coursework through remediation and reinforcement of their mathematical knowledge and skills. Discussions regarding the high rates of failure and attrition documented in developmental mathematics education tend to seek remedies and improvements, rather than to more deeply understand the mechanisms and consequences of the outcomes themselves. For instance, the related phenomena of *course repetition*—when a student retakes a course that they previously withdrew from or failed—and *redundancy*—when a college student takes a course at the same or lower level than what they completed in high school—are common, though research is limited regarding these experiences (Ngo, 2020). Bicak and colleagues (2023) found that two-year to four-year institution transfer students who experienced math course repetition had worse outcomes–including lower cumulative GPA, lower rates of degree attainment, and longer time for degree completion–than students who did not experience course repetition. Ngo (2020) found that nearly 40% of community college developmental math students were in a redundant math course. Lastly, Ngo and Velasquez (2023) found that 48% of community college students experienced a math trap, which is "when students never go beyond their highest level of math in high school" (p. 1637). These findings, situated in the context of community colleges and within the broader scope of postsecondary math programs, warrant further inquiry into the influence of course repetition and redundancy with a specific focus on developmental math, its students, and their learning experience.

Ngo (2020) pondered the "psychic costs to redundant math experiences," speculating "implications for college persistence, degree attainment, and STEM participation" (p. 223). Pursuing this line of inquiry, I am interested in unpacking the influence course repetition has on students' attitudes and motivation, which impacts their performance via their academic behaviors. Research documenting developmental math students' perspectives is limited, despite

it yielding rich insight into the learning experience of these students. I use mixed methods to conduct this study and am guided by theories of motivation.

Theoretical Perspective

Amman (2022) defined *relearning* as "the experience of trying to learn content one has learned (or attempted to learn) before" (p. 1). Given the algebraic content of developmental math courses, it is likely that most students have taken an algebra course during their 6-12 math education. Additionally, as a student experiences course repetition, they are further engaging in relearning. Amman's research demonstrated how students' perceptions of relearning meaningfully shaped their learning in their developmental math classes. In this study, relearning is used to frame the unique context of developmental math students' learning experiences.

To guide my inquiry regarding students' motivation, I used Eccles and Wigfield's (2020) expectancy-value theory (EVT) as a foundational theoretical framework. Specifically, I was interested in students' academic self-concept, subjective task values (i.e., relative cost value), and expectation of success as psychological determinants of motivation (PDM), that is, as proximal influences on their "task and activity choice, performance, and engagement" (Eccles & Wigfield, 2020, p. 3). I am interested in leveraging the relearning framework and EVT together because they both acknowledge the salient accumulation of values and perceptions across time.

This mixed-methods study was guided by the following questions:

1. What is the relationship between measures of motivation and degrees of relearning?
2. Why do shifts in students' motivation occur and how do these shifts relate to experiences with relearning or course repetition?

In quantitatively addressing the first question, I hypothesize that positive measures of motivation would negatively correlate with degrees of relearning (e.g., students with more relearning experiences are less likely to agree with positively oriented motivation statements), while negative measures of motivation would positively correlate with degrees of relearning. In qualitatively addressing the second question, other theories of motivation—such as implicit theory (e.g., Yeager & Dweck, 2012), attributional theory (e.g., Graham, 2020), and control-value theory (e.g., Pekrun, 2019)—meaningfully informed my analysis of the interviews.

Methods

Data Collection

For this explanatory sequential mixed-methods (quan → QUAL) study, I conducted two phases of data collection in three consecutive semesters (Spring 2024 and Summer Sessions I and II) at Temple University, a large, urban research university on the East Coast. Because I was interested in students' degree of relearning—reflecting the extent of a student's experience with relearning, repetition, or redundancy—I sought participants enrolled in Temple University's second level developmental mathematics course, College Algebra.

The first phase of data collection involved a quantitative survey instrument with Likert-type items that measured students' mathematical PDM—that is, their academic self-concept (ASC) on a six-point scale, valuation of relative cost (RC; specifically, effort, emotional, and opportunity costs) on a six-point scale, and expectancies of success (ES) on a five-point scale. These scales were adapted from Marsh and O'Neill's (1984) Academic Self-Description Questionnaire III, Gaspard et al.'s (2014) expectancy-value instrument, and Pintrich and DeGroot's (1990) Motivated Strategies for Learning Questionnaire, respectively. The survey had 30 items, 10 ASC items that alternated between positive and negative orientation, 11 negatively oriented RC items, and 9 positively oriented ES items.

The results from the survey were used to identify participants of interest for the second phase of data collection, which involved a semi-structured interview focused on students' prior and current math learning experiences. Across the three semesters of data collection, 32 students consented and completed the survey, and 4 students took part in the interviews (Table 1).

Table 1. Interview Participants

Participant	Year of Study	Degree of Relearning
Samantha (she/her)	Second year[1]	First enrollment in College Algebra
Aniya (she/her)	First year	First enrollment in College Algebra
		One prior enrollment in Intermediate Algebra
Victoria (they/them)	Third year	Third enrollment in College Algebra
		Two prior enrollments in Intermediate Algebra
Robin (he/him)	First year transfer[2]	First enrollment in College Algebra
		One prior enrollment in Intermediate Algebra

[1] Samantha was a junior by credits.
[2] Robin was a sophomore by credits.

Data Analysis

I used R to conduct cluster and correlational analyses to probe the relation between degree of relearning and student motivation from the survey responses. Specifically, I conducted hierarchical clustering using Gower distance and found Spearman's correlations since I was analyzing Likert-type, ordinal data (Islam, 2023). I conducted a cluster analysis to group the participants according to the orientation and degree of their PDM. To analyze the interview data, I first conducted a thematic analysis of each participant's interview, and then conducted a cross-case comparison of these results to draw conclusions regarding the influence of relearning and course repetition on students' attitudes. During the thematic coding, I looked for descriptions of motivated behavior, that is, when participants explained why they behaved in a certain way. It was in this portion of data analysis that I leveraged different theories of motivation to generate a comprehensive understanding of each participants' experience.

Results

Quantitative. Five clusters emerged from the hierarchical cluster analysis. There were strong, statistically significant positive correlations between participants' cluster and their responses on the positive motivation items (ASC: ρ=0.72; ES: ρ=0.70) and strong, statistically significant negative correlations between participants' cluster and their responses on the negative motivation items (ASC: ρ=-0.79; Effort: ρ=-0.87; Emotional: ρ=-0.74; Opportunity: ρ=-0.77). The cluster analysis discerned two clusters of increasingly negative PDM (clust –1, clust –2) and three clusters of increasingly positive PDM (clust 1, clust 2, clust 3); Samantha was in clust –2, Aniya and Victoria were in clust –1, and Robin was in clust 1. There was a significant, moderate negative correlation between the participants' clusters and their degrees of relearning (ρ=-0.35, p=0.051). In terms of the correlations between participants' degrees of relearning and their responses to the motivation items, there were weak negative correlations for positive motivation items (ASC: ρ=-0.21; ES: ρ=-0.05) and moderate, statistically significant positive correlations for negative motivation items (ASC: ρ=0.38, p=0.034; Effort: ρ=0.36, p=0.046; Emotional: ρ=0.21; Opportunity: ρ=0.42, p=0.018).

Qualitative. All four of the interview participants are pursuing STEM majors: Samantha, Aniya, and Victoria need to pass College Algebra as a prerequisite for their major courses, while Robin needs to complete the calculus sequence for his engineering major.

Samantha. When I spoke with Samantha at the end of the spring 2024 semester, she described herself as never having had a good relationship with math and as being "very grade-motivated, extrinsically motivated." That said, in high school, Samantha successfully completed AP Statistics, which she viewed as one of her few positive math experiences. Samantha traced the shift in her feelings toward math back to elementary school when she struggled to learn fractions, saying:

> Everyone was like, 'Oh, you're just not that good at math,' and then I was like, 'Oh, I'm not good at math—why am I gonna try?' So, it was always just the thing where I'd get to math class be like, 'Oh, here we go.'

Thus, Samantha internalized others' conception of her (lack of) math ability and concluded that it was therefore not worth trying. The last part of Samantha's explanation demonstrates her negative fixed mindset regarding her math ability that she brings with her into the classroom.

Samantha's responses also demonstrate the dependency of her motivation on her grades. When asked to describe a time when she felt good in College Algebra, Samantha replied, "On the first quiz, the first quiz I got 100, and I was the only person in the class to get 100. But it's been downhill since then." She went on to say:

> I did well on the first quiz, and then as soon as I tried on the second quiz and didn't do as well, I was so disengaged in class. [...] There's been a lot of times where I've put effort in—like, trying to do the homework, trying to understand—and then I get an average grade back and I feel like I put above average work into this class, which is very frustrating.

This response underscores Samantha's belief in the reciprocity of effort and performance.

Aniya. When I spoke with Aniya at the end of the spring 2024 semester, she identified a drastic shift in her relationship with math that occurred in College Algebra. When reflecting on her prior math experiences, Aniya described herself as being "really good" at math and "extremely confident" in her skills. Therefore, she was surprised when she tested into Intermediate Algebra— Temple University's first level developmental course—because she was "used to a higher math," leading to her having a negative attitude. As a result, Aniya explained that she wasn't paying attention or engaging in class, and therefore initially performed poorly. However, due to this outcome and her instructor's support, Aniya "switched it and turned it positive" by engaging in class, acknowledging that she could use a "refresher." Ultimately, Aniya described Intermediate Algebra as a positive experience that meaningfully reinforced the strength of her mathematical understanding. This positive shift demonstrates Aniya's resilient and positive malleable mindset regarding her math ability.

Aniya's confidence and positive perception of her own math ability shifted toward the negative in College Algebra when she was accused of cheating on the first exam. Following this incident, Aniya said she "completely checked out," explaining that she was disheartened by the nature of the accusation, which, at its core, questioned her mathematical knowledge. When discussing how her survey responses would have "absolutely" been different if she had taken the survey prior to the spring semester, Aniya reflected:

> It is absolutely saddening to me, if I'm being completely honest, because I really used to enjoy math and it was one of my favorite subjects. [...] And, honestly, I can say now that if I could choose to never take a math course again, I would.

While reflecting on her new feeling of annoyance and inadequacy when doing math, Aniya stated, "Now, I don't feel smart anymore when it comes to math."

Victoria. When I spoke with Victoria at the end of summer 2024 session I, they described themselves as an overall anxious learner with particularly inhibiting test-taking anxiety. When asked how they felt about their math skills upon entering college, they said:

> I wasn't terribly excited about it—just because I know math isn't my strong suit—but I didn't expect it to be as hard as it is; I didn't expect to have to take Intermediate Algebra for two semesters, and then this being my third attempt at College Algebra.

The reality of repeating these courses multiple times weighed heavily on Victoria. They later affirmed that their survey responses would have been different prior to the current term, noting, "my answers kind of just progressively went down the more like times I took it." Specifically, they tied the connectedness of their PDM and course repetitions to their STEM major, saying:

> I guess it [(my survey responses)] kind of goes down more because I'm a STEM major. I feel like a lot of stuff I have to do is math stuff and it's like I don't really understand math a lot. Like, I'm doing a bit better, but I'm still having the same issues that I was having, like, not understanding them. It kind of makes me base my self-worth and academics on my math class and I'm not doing good, so it's like my [survey] answers are poorer.

When discussing their current attempt at College Algebra, Victoria described defeating anxiety about the ramifications of not passing including having to reluctantly change major or dropping out of college, "I don't want to have to drop out and then be like, 'Oh my God, I had to drop out because I couldn't pass College Algebra.' So, it's a lot mentally riding on me passing this time."

Robin. When I spoke with Robin at the end of summer 2024 session I, he brought a unique perspective as a non-traditionally aged student, returning to college after over a decade in the workforce to complete his degree, advance at his career, and continue to support his family. As such, Robin's motivations extend beyond academic credit. Prior to enrolling at Temple University, Robin pursued a degree at another local university, completing up through Calculus I after having taken it twice. He noted that he felt frustrated and disinterested in learning math at his previous institution.

After receiving a low score on the placement exam, Robin reported that he "didn't feel confident at all about his math skills" and explained that he was presently enrolled in College Algebra because he "needed to get caught up" to swiftly advance through his engineering math coursework. Speaking of his placement in Intermediate Algebra, Robin explained:

> I'm willing to just start over because I don't want to get to this level and then be stuck because I don't remember any of the basics. It was no big deal for me to just pay the extra money to start over and, you know, learn properly again.

Thus, looking to the future, Robin is motivated to shore up his mathematical fundamentals, knowing he will have to complete the calculus sequence. Furthermore, Robin noted his awareness of his academic financials, explaining his prior reluctance to complete his degree:

> I don't want anything that's going to stress me out: I don't get that [concept], so I have to take [the class] twice. Now, it's wasted money because I have to take it twice or because I failed.

Thus, reflecting on the past, Robin describes his academic behaviors as being motivated by a desire to avoid (the financial consequences of) repeating classes again.

Discussion

Quantitative

In exploring the relationship between measures of motivation and degrees of relearning, I hypothesized that students' motivation would decrease as their degree of relearning increased. Though not all the correlations were statistically significant, the directionality of the negative correlations between the positively oriented motivation items and degrees of relearning and of the positive correlations between the negatively oriented motivation items and degrees of relearning support this hypothesis.

There are two notable limitations to these findings. First, while the survey items used had strong internal validity (Cronbach's alpha = 0.966), the survey's external validity—for measuring the EVT constructs of ASC, RC, and ES in college math students—is questionable given its construction from different extant instruments. Second, this study's sample size is quite small (n=32), further limiting the validity of these analyses. That said, given the limited research focused on understanding the impact course repetition has on students, their non-cognitive factors, and their learning, these results warrant further study.

Qualitative

The conversations I had with my four participants underscored the unique and individual nature of student motivation and its sensitivity to individuals' particular aims and learning histories. For instance, Samantha and Aniya reacted completely differently in response to poor grades, which can be understood by leveraging attribution theory, implicit theory, and control-value theory. On the one hand, Samantha described feeling the demotivating negative emotions of frustration and helplessness when her "above average effort" yielded average grades. In this response, Samantha also expressed her belief that her other classes were "arguably harder" than College Algebra and reported exerting more effort and receiving higher grades in those other classes. Given Samantha's negative and fixed view of her math ability and her grade-based extrinsic motivation, it is likely that this experience, in some way, confirmed the notion that her effort could not compensate for her perceived lack of math ability. On the other hand, Aniya appeared to feel *motivating* negative emotions when she initially received poor grades in Intermediate Algebra, which prompted her to modify her behaviors to be more engaged in class. Implicit theory suggests that Aniya's malleable view of her math ability attributed to her response. While this has less to do with these students' experiences with relearning, the differences between Samantha and Aniya's responses underscore the salience of students' motivational characteristics to their course engagement and performance, as well as the importance of the perspectives they bring with them into the classroom.

Focusing on the influence of relearning and course repetition experiences specifically, Robin and Victoria's responses demonstrate how such experiences influence shifts in motivation. On the one hand, Robin's prior experience with course repetition—and desire to avoid its financial consequences—motivates his current approach to learning math. Specifically, knowing he has to complete the calculus sequence, Robin demonstrates diligence in solidifying his mathematical foundation. On the other hand, reflecting on their second attempt at College Algebra following their two enrollments in Intermediate Algebra, Victoria described being very conscious of their course repetitions, which prompted an adjustment of their behaviors in an effort to avoid future repetitions: "I realized that I can't be anxious to ask for help. Like, I'd rather ask for help than fail my class." Therefore, Robin and Victoria demonstrated how experiences with course repetition can serve as motivators, prompting positive behavioral changes. However, overall, Victoria's experience with multiple course repetitions appears to inhibit, more so than help, their

attitude, motivation, and academic behaviors. Specifically, Victoria described relating their course repetitions to their self-worth via their STEM major because their success on their third attempt at College Algebra would dictate the future of their academic trajectory. This generated a lot of anxiety for Victoria, which increased their test anxiety and likely impacted their memory and performance by depleting their cognitive resources (Ashcraft, 2002; Meinhardt & Pekrun, 2002). Relatedly, Victoria described struggling to remain optimistic about their likelihood of success and ability to continue their desired academic path. Therefore, Victoria's experience demonstrates how experiences with course repetition can accumulate and negatively impact students' attitudes and motivation, underscoring the importance of this investigation.

Lastly, Aniya's experience (i.e., positive prior math attitudes and outlooks, and then a hard shift during a developmental math course) might provide insight into the development of math traps, when students do not go beyond their highest-level high school math course. Though this is not to say that Aniya is or will get stuck in a math trap, it is important to highlight that Aniya proudly described passing Calculus "with flying colors" in high school and that, before College Algebra, she was extremely confident in her math abilities. When discussing her developmental math courses, she described two instances where her prior, more advanced mathematical knowledge caused her instructor to question the strategies she used. While one experience she described fondly as positive reinforcer of her math ability, the other (when she was accused of cheating) left her reluctant to engage with math in the future. I see Aniya's experience as a cautionary example of the negative consequences of redundant math.

This study is a first step in documenting the motivational, non-cognitive impact of course repetition. By capturing the perspective of students, we can better understand *why* and *how* developmental math courses suffer from high rates of failure and attrition. Future research warranted by this study includes a semester-long study of how course retakers' motivation shifts over the course of a semester.

Applying to graduate school in mathematics requires both a desire to attend graduate school, but also an understanding of the application process. The more students know about the process, the more successful they are in their pursuit of admission to a graduate program. We examined mathematics majors' knowledge of both graduate school and the graduate school application process as part of a larger study examining barriers to students applying to graduate school in mathematics. We also examined the impact of mentors on student interest in graduate school and whether having a mentor has an impact on student knowledge of graduate school. We frame and explain our results using the theory of social capital.

Keywords: Mentors, Graduate School Applications, Social Capital

In 2023, approximately 3.1 million students were enrolled in graduate-level programs and 15.2 million enrolled in undergraduate programs in the US (National Student Clearinghouse Research Center, 2024). A fraction of those 15.2 million will decide to apply to graduate or professional programs in the next few years. There are a variety of reasons for attending graduate school including increasing earning power, career options, depth and breadth of disciplinary knowledge, obtaining more satisfaction with their career and accomplishments, increasing self-esteem, access to professional leadership opportunities, being assigned more responsibilities, and intrinsic motivation for the challenge. However, Estien et al., (2023) points out that before students enter graduate school, they must overcome the obstacle of applying.

Researchers have investigated the graduate/professional admissions process in several disciplines (e.g., Chari & Potvin [Physics], 2019; Hadinger [Medical School], 2017; Landrum [Psychology], 2010; Sylvan et al. [Speech-language Pathology], 2020). Estien et al. (2023) states that researchers have found "several factors that shaped students' experiences applying to graduate school including: financial constraints (Hadinger, 2017; Sylvan et al., 2020); concerns regarding the use of admissions criteria such as the Graduate Record Examination (GRE) scores (Sylvan et al., 2020); a lack of support, guidance, and advising from faculty members (Hadinger, 2017; Sylvan et al., 2020); and a lack of transparency due to variation in admissions requirements across graduate programs (Sylvan et al., 2020)." (p. 56). Furthermore, the National Academies of Science, Engineering and Medicine (NASEM) argues that mentorship is one way to enhance students' graduate school aspirations (2019) and has multiple benefits for students like higher GPAs, completing more coursework each semester, stronger self-esteem and academic self-efficacy, higher career goals, less stress, better psychological health, improved attitudes, and better discipline-based skills (Luna & Prieto, 2009). We add to this by examining what mathematics majors know about the graduate school application process through the lens of the theory of Social Capital and assess the impact of mentoring on undergraduate mathematics students' knowledge of the application process. Specifically, we seek to answer the following:

1. *What do undergraduate mathematics majors know about applying to graduate school and about graduate school itself?*

2. *Is there a difference in students' knowledge between students who do and do not have a mentor?*

Literature Review

Poock & Love (2001) identify extensive literature examining variables that influence students' choice of colleges at the undergraduate level. These studies focus on which students go to college, the process of students' choosing which colleges to apply to and which colleges they attend, but not on the application process at the undergraduate level. Similar to the limited research on the application process at the undergraduate level, there is also meager literature on students' choice of graduate school. Kallio (1995) called for further investigations into why students apply and choose to enroll (or not) in graduate school once admitted, but there is still scant literature on the application process at all levels. There is specifically little information known about students' application to and knowledge of the application process for graduate or professional school.

Chari & Potvin (2019) is the first study investigating undergraduate students' perceptions about graduate admissions in physics. Their sample of 802 physics juniors and seniors ranked letters of recommendation, prior research experience, GPA or grades in physics and mathematics classes, reputation of recommender, and prior research publications as the top five most important admission criteria respectively when applying to graduate school. They compared these rankings to physics faculty's top five most important admission criteria from a prior study (Potvin, et al., 2017): GPA or grades in physics and mathematics classes, letters of recommendation, undergraduate courses taken, GRE physics subject test, and prior research experience. They found that there were statistically significant differences between faculty and student perceptions on prior research experiences, reputation of recommenders, prior research publications, personal statements, and familiarity with the department.

Landrum (2010) surveyed 348 students about whether they planned to apply to graduate school and knew about the application process and found that personal belief in how well they would do academically, on their preparation for graduate school, and available opportunities beyond the classroom were important factors in students' decision to apply. In addition, Sanders & Landrum (2012) surveyed undergraduate psychology majors assessing their understanding of the application process for graduate or professional school. Of the 134 students that responded, research experience, letters of recommendation, and GPA were rated as the most important components of an application for graduate school. Finally, Oakes et al. (1999) implemented a successful seminar series at Purdue University that consisted of seminars on graduate school, the General and Engineering GRE, and applying for fellowships. They found that students' understanding about graduate school increased substantially after participating in the seminars.

There is also little research on how academic advisors influence students' decisions to apply and attend graduate school. However, mentorship is a key aspect that has shown substantial impact on students' post-graduate pathways (Luna & Prieto, 2009). The literature documents different aspects of mentoring (or mentorship) that plays an important role in students' graduate school plans like faculty mentoring through research experiences (Adedokun et al., 2013; Eagan et al., 2013; Merolla and Serpe, 2013; Park et al.,2022; Pender et al., 2010), graduate school preparation programs (e.g., McNair Program [Renbarger & Beaujean, 2020] and EMERGE [Peteet & Lige , 2016]), mentoring programs (Meza et al., 2018), classroom experiences (Park et al., 2022), and faculty interactions (Espino, 2014; Hanson, et al., 2016).

Theoretical Background

We apply the theory of social capital to explore the impact of mentors on the graduate school application process. Coleman (1988) defines social capital by its function and states that it is a "variety of different entities all sharing two elements in common: they all consist of some aspect of social structures, and they facilitate actions of actors, whether persons or corporate actors, within the social structure" (p. S98). Furthermore, Coleman (1988) clarifies that "an important form of social capital is the potential for information that inheres in social relations" (p. S104). Knowledge is an essential resource necessary to apply to graduate school since students need to know it exists, why they would want to apply, and what is required to apply. In this paper, we focus on the relationships that undergraduate students have with their mentors that can provide multiple forms of resources to them because of social capital that are useful for applying to graduate school in mathematics. This social capital could be in the form of information on the graduate school application process or access to letters of recommendation. We add to the body of literature by examining what information undergraduate mathematics majors know about the graduate school application process primarily as a result of mentoring.

Methods

Instrument Development

The research team created a survey based partially on a survey developed and used to determine undergraduate physics majors' interest in graduate school and how important they believed different aspects of the application process were (Chari & Potvin, 2019).[1] Nineteen of our survey items were adapted from that instrument. A notable difference in our survey was that we provided an opportunity for participants to express their lack of knowledge about different parts of the application process. The final survey had 57 items separated into four categories: (a) knowledge about different aspects of the application process, (b) barriers to applying, (c) interest in graduate school and what students want in programs they apply to, and (d) demographic questions. Most items were Likert scale or multiple choice, though four were open-ended and some multiple-choice items allowed participants to type in a text response.

Data Collection

The research team sent the survey to department chairs and undergraduate program directors at all undergraduate mathematics programs at U.S. colleges and universities with at least 1000 students total ($N = 985$). Initial emails were sent in Fall 2022 through Spring 2023 with follow-up emails sent to encourage a greater response rate. The research team also posted the survey on social media, listservs, and in newsletters for several professional organizations in mathematics.

Data Analysis

We received 1090 responses from students at 181 colleges and universities, with 519 complete responses. Participants could skip part of an item and still have their response marked as complete. Thus, the *N*s for different items are not always equal. Descriptive statistics and Chi-squared tests of association were run in IBM SPSS. To address our research questions, we analyzed responses for five survey items, where two of those items had 8 and 6 subitems respectively.

[1] The full survey is available at this link: https://researchrepository.wvu.edu/faculty_publications/3291/

Results

Knowledge of Applying to Graduate School

Table 1 provides the overall participant knowledge of the application process for graduate school in mathematics.

Table 1. Reponses to "Please rate your familiarity with the following concepts about graduate school application process."

Sub-Item	*N*	Never heard this before	May have heard this before	Definitely heard this before
Requires a minimum GPA	586	5%	21.8%	73.2%
Requires transcripts	585	1.4%	7.5%	91.1%
Requires letters of recommendation	585	4.1%	12.1%	83.8%
Letters of recommendation should be from mathematicians	585	19.8%	35.2%	45%
Programs require application fees	585	8.2%	25.3%	66.5%
Some programs offer ways to reduce or eliminate application fees	585	26.7%	31.8%	41.5%
Often requires a personal statement	584	15.8%	23.1%	61.1%
Some doctoral programs do not require applicants to get a master's degree first	585	30.3%	18.8%	50.9%

The participants who responded "Definitely heard this before" to the sub-item asking about a minimum GPA for graduate school were then asked: "You have indicated that you heard that you need a minimum GPA to have a competitive graduate school application. What is that GPA?" The average of the responses to this follow up question was a GPA of 3.3.

There was a wide range of responses from participants depending on the sub-item. For some sub-items such as "applying to graduate school requires transcripts" nearly all participants chose the option "definitely heard of before". For other sub-items including "the availability of application fee waivers" participants were less certain that they had "heard of this before". Overall, most participants had heard of most of the sub-items in this item.

Knowledge of Graduate School

Table 2 provides the overall participant knowledge of graduate school in mathematics.

Table 2. Reponses to "Please rate your familiarity with the following concepts about graduate school in mathematics".

Sub-Item	*N*	Never heard this before	May have heard this before	Definitely heard this before
A master's degree usually takes 2 years to complete	586	3.6%	21.1%	75.3%
A doctorate usually takes between 5 to 7 years to complete	583	8.4%	25.9%	75.7%
Math graduate programs usually provide some sort of funding	584	18.2%	31.3%	50.5%
Students in doctoral programs with funding usually have tuition waivers	584	38.3%	24%	37.7%
Funded graduate students must maintain some minimum overall GPA to keep their funding	583	18.5%	40.8%	40.7%
Graduate students in some programs are unionized and are protected under a collective bargaining agreement	584	69%	13.2%	17.8%

In comparison to the previous item, participants were less likely to have heard information about graduate school itself than they were to have heard about the graduate school application process. Participants mostly knew the length of graduate school but knew less about graduate school funding structures.

Mathematical Mentors

We asked participants "Do you have someone you consider a mathematical mentor? (This is someone who has not necessarily been formally assigned to you by your institution but gives you advice on how to advance your career in mathematics.)" Of 584 participants, 327 (56%) said they had someone they consider a mathematical mentor. We used a Chi-squared test of homogeneity to see if there was an association between interest in graduate school and having a mentor.

Table 3. Reponses to "Which of the following describes your interest in graduate school in mathematics?" for Students With and Without Mentors.

Option	Mentor	No Mentor	*N*
Not interested in attending graduate school in mathematics	46 (52.3%)	42 (47.7%)	88

Interested in earning a master's degree only	54 (54%)	46 (46%)	100
Interested in earning a master's or attending a post baccalaureate program then earning a doctorate	76 (52.4%)	69 (47.6%)	145
Interested in earning a doctorate without earning a masters or attending a post baccalaureate program first	107 (70.4%)	45 (29.6%)	152
Not sure	43 (44.3%)	54 (55.7%)	97

There was an association in which participants with mentors were more likely to say they were interested in earning a PhD than their peers without mentors $\chi 2(4, N = 582) = 19.56$, $p = < .001$ ($V = .18$). This result had a small effect size. In addition, we ran a Chi-squared test of independence and found that participants with mentors were more likely to say they knew about the following aspects of graduate school and the graduate school application process (Table 4).

Table 4. Results for Chi-Squared on Student Knowledge For all tests df = 2.

Sub-Item	Mentor	Never heard this before	May have heard this before	Definitely heard this before	*N*	Values	*p*-value	*w*
Letters of recommendation should be from mathematicians	Yes	54	86	183	585	38.82	< .001	.26
	No	59	120	80				
Often requires a personal statement	Yes	44	65	216	584	8.77	.012	.12
	No	48	70	141				
Some doctoral programs do not require applicants to get a master's degree first	Yes	85	59	182	585	7.91	.019	.11
	No	92	51	116				
Math graduate programs usually provide some sort of funding	Yes	57	82	186	584	15.41	< .001	.16
	No	49	101	109				
Students in doctoral programs with funding usually have tuition waivers	Yes	109	80	134	584	7.95	.019	.12
	No	115	60	84				

There were no associations ($p > .05$) for all other sub-items in Tables 1 and 2 that were not reported in Table 4. For the five sub-items in Table 4, participants with mentors were more likely to respond that they had "definitely heard this before". The effect size is small for all sub-items

(all *w*'s between 0.1 and 0.3), but the effect size for "letters of recommendation should be from mathematicians" is approaching the upper bound for a small effect size.

Discussion

Overall, we found significant variability in student knowledge of applying to graduate school and graduate school itself. Some sub-items, such as the requirement for transcripts, were nearly universally known by our participants. Other sub-items including "students in doctoral programs usually have tuition waivers" were largely unknown to our participants. Some programmatic requirements and structures were more common to be well known, including the length of degree programs and parts of the application. However, the financial aspects of graduate school including funding and tuition waivers were less well known. This is problematic for students from low-income backgrounds, because they may believe they cannot afford to apply to or attend graduate school even though they may know how to apply.

Almost half of our participants did not have someone they considered a mathematical mentor. We found that students who had mentors were more likely to state that they were interested in directly earning a PhD in mathematics compared to their peers without a mentor. Since students who want to go to graduate school may be more likely to seek a mentor, we cannot say this association is necessarily causation. Still, participants with mentors were more likely to know more about specific aspects of the application process and graduate school than their peers without mentors. They were more likely to know about the norms in applying to graduate school in mathematics such as letters of recommendation should be from mathematicians and that you can be admitted to a doctoral program directly after undergraduate school. They were also more likely to know about norms in graduate student funding, including that mathematics graduate students are usually funded and receive tuition waivers. All these factors are items that faculty mentors, mathematicians with advanced degrees, are knowledgeable about given their own experiences in graduate school. The results of our study show that the social capital that mentors can and do provide benefit students seeking to apply to graduate school, especially through access to knowledge about the application process.

That said, there were a few aspects of the application process and graduate school that were not well known by our participants and having a mentor was not associated with increased knowledge for these. The two we believed were most important are the availability of application fee waivers and the graduate school GPA requirement to maintain funding. It is the case that not all programs may have something in place like fee waivers, so this piece of information may not be as readily available to mentors. In a previous study on this data set, we found that minoritized students were more likely to view application fees as a barrier to applying to graduate school (McEldowney et al., 2024). Therefore, mentors not knowing about or talking to students about application fee waivers is especially problematic for marginalized students. In addition, giving mentees an advanced warning of graduate school GPA requirements could help ensure that more students succeed after being admitted to graduate school.

An important consideration for these results is sampling bias. While we attempted to obtain a representative sample, participants were students who chose to take a relatively long survey. Thus, we can reasonably assume that the average mathematics major knows less about graduate school than our results indicate.

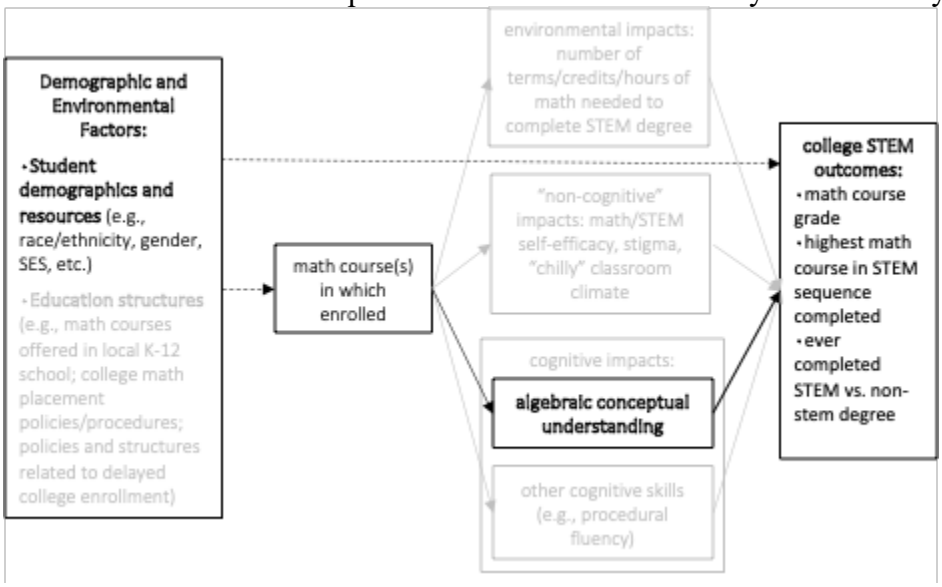
Algebra has been found to be a barrier to college and STEM-major completion, and a contributing factor to unequal access to STEM fields. Conceptual understanding has often been discussed as an important component of mathematics learning; yet more marginalized students often have less access to rich mathematics instruction and to algebra learning opportunities. However, to date no research has investigated the relationship between conceptual understanding and math or STEM outcomes in college. In this research, we explore the predictive validity of the recently validated Algebra Concept Inventory (ACI) to determine whether college students' ACI scores predict math course grades, STEM-major math course completion, and STEM vs. non-STEM degree attainment as well as whether ACI score explains outcome differences by race/ethnicity/gender.

Keywords: Algebra, conceptual understanding, college students, STEM majors, equity



Students' prior mathematical preparation (e.g., Cohen & Kelly, 2020; Minaya, 2021) and their college performance (Chen & Soldner, 2013) influence whether they enroll in or persist in STEM degrees. Algebra serves as both a barrier to college degree completion (e.g., Bailey et al., 2010; Ganga & Mazzariello, 2018) and a requirement for earning a STEM degree (Bahr et al., 2017; Sithole et al., 2017). However, there is no large-scale research on whether algebraic conceptual understanding influences STEM degree completion. Algebraic conceptual understanding may also represent an equity issue, as research indicates that marginalized students have fewer opportunities for rich instructional experiences to develop higher-level skills, such as conceptual understanding (Schoenfeld, 2022; Yeh et al., 2020). Marginalized students are also less likely to enroll in and complete STEM degrees (e.g., Black et al., 2021; Hatfield et al., 2022; Wright et al., 2023).

Prior research on persistence in STEM degrees has explored various predictors, including environmental impacts from course sequences (e.g., Ryu et al., 2022), college math placement policies (e.g., Ngo et al., 2018), and general cognitive skills (Park et al., 2021). Yet, there is limited exploration of whether specific measures of conceptual understanding predict STEM outcomes. Existing models of STEM major retention that do include academic factors tend to use more diffuse assessments of general knowledge, such as GPA or standardized test scores (e.g., Alkhasawneh & Hargraves, 2014; Gipson, 2016; Wolniak, 2016). Additionally, models including specific math course completion as predictors may obscure the separate impact of different factors that are difficult to distinguish because they are correlated with course enrollment and completion (e.g., Crisp et al., 2009; Larnell, 2016; Quarles & Davis, 2017).

Our research is distinguished by a college STEM major retention model that includes algebraic conceptual understanding as a core factor (Figure 1). We use scores on the validated Algebra Concept Inventory (ACI; Wladis et al., 2024a) as a measure of algebraic conceptual

understanding to explore the following research questions:

- Can ACI scores predict: a) students' grades in a student's current mathematics course? b) whether they ever completed core math courses required for STEM majors? c) whether they ever completed a STEM vs. non-STEM degree?
- To what extent do ACI scores explain differences in outcomes by race/ethnicity or gender?

Notes: Grey arrows represent relationships that have been tested in other research. Thick black arrow at far right represents main relationship tested in this research. Thin black arrow represents fixed effects by course (controlled for in all analyses). Dotted black arrows represent control variables included in analyses that use controls.

Figure 1. Model of STEM Major Access and Retention as it Relates to College Math Course Placement

Algebraic Conceptual Understanding

Conceptual understanding is crucial in mathematics (Booth, 2011; Richland et al., 2012), though it is frequently neglected in algebra instruction. This is especially important for STEM students, who should be able to flexibly apply their algebraic knowledge in unfamiliar situations (Quarles & Davis, 2017). Access to effective and meaningful mathematics instruction is an equity concern since marginalized students often face fewer chances to develop advanced mathematical skills (e.g., Schoenfeld, 2022), and this access gap may significantly influence STEM degree progression and completion.

Algebraic conceptual understanding as measured by the ACI refers to understanding of mathematical concepts, which is defined as including mathematical reasoning about concepts. In the ACI, concepts are defined as well-defined mathematical processes, objects, or ideas accepted by the mathematical community (Sfard, 1991). The ACI emphasizes algebraic concepts that are accessible to students beginning in elementary algebra such as equivalence, syntactic structure, algebraic properties, functions/variation, and variable.

Below we present an ACI item as an illustrative example:

In the expression $-2x^3 + 5$*, which part is being cubed (or raised to the third power)?*

a. $-2x$
b. $2x$
c. x

Students conceptualizing the normative structure of the syntax of the expression would most likely choose C, the correct answer. Alternatively, students who choose incorrect options A or B

typically extract the structure of the syntax from non-mathematically salient features drawn from instructional experiences, like spacing, or how often instructors treat substrings of the form ax for some number a as a unified subexpression during transformation. These students may conceptualize the meaning and structure of algebraic syntax differently than those who link it to normative operational precedence (for more details, see Wladis et al., 2024b, 2024c).

The ACI's 402 multiple-choice items were developed and previously validated through a cyclical process using the Evidence-Centered Assessment Design (ECD) Framework (Mislevy & Riconscente, 2005) (see details in Wladis, et al., 2024a). The ACI is the first large-scale assessment to undergo mixed-methods validation for measuring algebraic conceptual understanding in college students, particularly for students across course levels. It was validated for use with students starting in elementary algebra. In this study we use previously collected ACI scores to explore the relationship between algebraic conceptual understanding and college outcomes such as math course grade, completion of STEM-major math courses, and STEM vs. non-STEM degree completion.

Method

Participants and Data Collection

The participants in this study were students enrolled in mathematics courses at the largest community college in the City University of New York (CUNY) between spring 2019 and summer 2023. The participants were enrolled in a wide range of math courses, from elementary algebra to advanced topics such as calculus, linear algebra, and differential equations. Data obtained from CUNY's Institutional Research (IR) Offices included detailed information on each student's course enrollment and grades, demographic characteristics (e.g., gender and race/ethnicity), academic background (e.g., G.P.A., credits earned, and major), as well as socio-economic status, which was approximated using household income data from the American Community Survey based on students' home zip codes. Institutional records were combined with the existing ACI dataset to explore relationships between students' algebraic conceptual understanding and their academic outcomes.

The ACI dataset included student scores generated during the creation and validation of the ACI. A total of 402 unique items were developed and tested; this study analyzes data from 6,582 students who took the inventory for whom CUNY then also provided additional administrative data. Math courses in which students were enrolled included elementary algebra, intermediate algebra, mathematics for elementary educators I and II, quantitative reasoning, various levels of statistics, mathematics for liberal arts majors, mathematics for health science majors, discrete mathematics, precalculus, Calculus I, II and III, advanced calculus, linear algebra, abstract algebra, and differential equations. For more information on the initial data collection and validation of the ACI see Wladis, et al. (2024a).

Data Analysis

A student's score on the ACI was the primary independent variable of interest. ACI scores are based on multiple test forms designed through common-item random groups equating design, where each student was given a different subset of approximately 25 of the 402 items. Analysis has demonstrated excellent reliability and validity for the inventory (Wladis et al., 2024a). Given its wide coverage of algebra concepts and limited prerequisite knowledge, the ACI is well-suited for investigating whether algebraic conceptual understanding is a predictor of math outcomes and STEM degree progress or attainment for students enrolled in a wide range of math courses.

ACI scores were generated using two-parameter logic (2PL) item-response-theory (IRT) models, which account for differences in item difficulty and discrimination. The models produced scores (θ values) representing how many standard deviations a student's performance was above or below the mean compared to others in the sample. For students who took the ACI more than once in a term (due to multiple math course enrollments), the mean ACI score for that term was used in the analysis.

Dependent variables included in this study are course grade (converted to GPA scale), successful course completion (defined as earning a grade of C or better), and STEM or non-STEM degree attainment during the study period. Control variables included gender, race/ethnicity, age, GPA, credits earned, and median income of home zip code. Missing data were minimal, affecting less than 2% of the dataset, so we used listwise deletion for these cases. We categorized math courses by their relevance to typical STEM major required math course sequences and by prerequisites. Fixed effects were added to account for the specific course taken, and/or course level or sequence.

We primarily employed fixed-effects linear and logistic regression models to predict math course grades and STEM degree attainment. For binary outcomes, both logistic and linear probability models were used, with linear models reported for easier interpretation. For mediation analysis, we used the KHB decomposition method (Kohler et al., 2011), to decompose disparities in ACI scores into "indirect" and "direct" components related to race/ethnicity and gender.

To address differences between the full student population, and students for whom we had ACI scores, we used entropy balancing (Hainmueller, 2012) to reweight data and improve covariate balance. This allowed ACI-taking to be independent of measured background characteristics. This step was important since students who consented to take the ACI may have been more likely to be higher-achieving, with better math self-efficacy and performance. They were more likely to be Asian, female, and slightly older, with fewer credits earned. Despite these differences, we maintained a wide representation of gender, GPA, and racial/ethnic groups. Entropy balancing resulted in a weighted dataset that closely reflected the full population of students enrolled in math courses, ensuring that our analysis would allow for inferences across the general population.

Results and Discussion

One goal of our analysis was to determine if ACI scores would predict course completion and STEM degree attainment. A one standard deviation (SD) increase in ACI score on average correlated with a 0.4 increase in grade points (scale 1-4) in the math course in which a student was enrolled ($p < 0.001$) (Table 1). This was reduced but remained highly significant ($p < 0.001$) in full models with covariates. For individual courses, ACI scores significantly predicted grades in most math classes, especially those that rely heavily on algebra: intermediate/college algebra[1], precalculus, and Calculus I ($p < 0.001$). ACI scores also significantly predicted course completion (if attempted) for each of the five core STEM major mathematics requirements, in base and full models ($\alpha = 0.001$ level for all except full model predicting Calculus II completion, where $\alpha = 0.008$). These differences were not due to correlations between ACI

[1] We were unable to include elementary algebra courses in this analysis due to small *n*; very few had grades beyond pass/fail designations.

score and currently enrolled course level, because all models included fixed effects for course level.

Table 1. ACI Score as Predictor of Math Course Grade, Completion of Core Math Courses for STEM Major, Completion of STEM vs. Non-STEM Major.

As a Predictor of Math Course Grade (Grade Scale: 1-4)								
	Base models				Full models[a]

Notes: Multi-Level Weighted Regression, fixed effects by course (first row) or separate models by courses (listed in first column), random effects by instructor, math course grade as dependent variable, ACI score as independent variable; *Sig. levels*: *** $\alpha = 0.001$, ** $\alpha = 0.01$, * $\alpha = 0.05$, . $\alpha = 0.10$

[a]Full models include control variables: GPA at start of term, number of prior credits earned by start of term, race/ethnicity, gender, age, and median household income of zip code

We also found that for students who completed a two- or four-year degree during the study period and who were in the same level mathematics course when taking the ACI, that those with

higher ACI scores were significantly more likely to graduate with a STEM degree. In fact, the ACI score predicted STEM degree completion more strongly than course grade alone. For every one standard deviation increase in ACI score, students were 5.1 percentage points more likely to complete a STEM degree when accounting for fixed effects for course level. In models with both ACI score and course grade, one standard deviation increase in ACI score and one letter grade increase corresponded to 4.0 and 1.8 percentage point increases in STEM degree completion, respectively; this illustrates the predictive power of ACI scores above and beyond the information provided by course grades.

Another goal of our analysis was to determine the extent to which ACI scores explain differences in outcomes by race/ethnicity and gender. For race/ethnicity, we found direct and indirect discrepancies related to course grades highly significant in both base and full models with controls (Table 2).

Table 2. ACI Score as Mediator Between Underrepresented Minority Status (URM)[a] or Gender and Math Course Grade

	Base models				Full models			
underrepresented minority status	Coef.	SE	*p*	sig.	Coef.	SE	*p*	sig.
total discrepancy (total "effect")	-0.65	0.05	0.000	***	-0.42	0.06	0.000	***
direct discrepancy (direct "effect")	-0.54	0.05	0.000	***	-0.36	0.06	0.000	***
indirect discrepancy (indirect "effect")	-0.11	0.01	0.000	***	-0.06	0.01	0.000	***
female gender	Coef.	SE	*p*	sig.	Coef.	SE	*p*	sig.
total discrepancy (total "effect")	0.24	0.04	0.000	***	0.23	0.05	0.000	***
direct discrepancy (direct "effect")	0.29	0.04	0.000	***	0.26	0.05	0.000	***
indirect discrepancy (indirect "effect")	-0.04	0.01	0.000	***	-0.03	0.01	0.001	**

Notes: Mediation using the KHB Method: Mediation of the Relationship Between Underrepresented Minority Status or Gender and Math Course Grade by ACI Score, fixed-effects by course sequence number, clustering by instructor; *Significance levels*: *** $\alpha = 0.001$, ** $\alpha = 0.01$, * $\alpha = 0.05$, . $\alpha = 0.10$

[a]Underrepresented minority indicates students of color who have been traditionally underrepresented in STEM fields, and includes Black, Hispanic, and American Indian/Native Alaskan students (vs. White and Asian/Pacific Islander students)

In Table 2 we see that ACI score accounts for 17% of the difference in course grades by race/ethnicity in base models and 13% in full models. We also found direct and indirect discrepancies related to STEM-major-math-course-sequence completion highly significant in base and full models (except full models for elementary algebra). ACI scores explain about 16-18% of the difference for intermediate/college algebra through Calculus I in base models and 7-11% in full models. Finally, for race/ethnicity, neither the total nor direct discrepancy related to STEM-vs.-non-STEM-degree completion is significant in base or full models, while the indirect discrepancy is significant. Interestingly, after accounting for the indirect relationship of ACI score as an explanatory variable for differences in STEM vs. non-STEM major attainment by race/ethnicity, underrepresented minorities are ***more*** likely to complete a STEM vs. non-STEM degree (although not statistically significantly so). Thus, ACI score explains 100% of the total discrepancy in STEM vs. non-STEM degree attainment by race/ethnicity.

For gender, exploring mediation models shows different trends for course completion. While both direct and indirect discrepancies are highly significant in base and full models, the direction of the relationship is different. Despite having lower ACI scores, women on average earn higher

grades in mathematics courses. Thus, considering a mediation model that includes ACI scores reveals a suppressor "effect" where women earn even higher grades than men with equivalent ACI scores. Looking at STEM-major-math-course-sequence completion, the models suggest a suppressor "effect" (significant for all courses except elementary algebra and Calculus II full models), where women are on average more likely to complete core mathematics course requirements for STEM majors, even though they score on average lower on the ACI. Finally, concerning degree attainment, exploring mediation models for gender shows the total, direct, and indirect discrepancies are all statistically significant, with ACI score explaining about 10% of the total discrepancy in base and full models (or 10% of differences in STEM vs. non-STEM degree attainment by gender).

Implications and Conclusion

This study found that ACI scores predict math course grades, successful completion of core math courses required for STEM majors, and STEM vs. non-STEM degree attainment. Notably, the ACI score was predictive of STEM degree completion even when controlling for course grades, showing a predictive strength comparable to or even stronger than the predictive power of course grades. In particular, a one-standard-deviation increase in ACI score was associated with a one-third to one-half letter grade improvement in courses such as algebra and calculus, an 8-16% increase in the probability of completing core math courses, and a 4-5% increase in STEM degree attainment.

While this study included a broad range of students, we note that those who completed the ACI differed slightly from the overall student population enrolled in math courses. Despite this, there was still strong representation across racial/ethnic groups, genders, GPA bands, and course levels. CUNY, where the study was conducted, is more diverse than the average U.S. college, with higher proportions of racial/ethnic minorities, first-generation students, lower SES students, and those requiring developmental coursework. While the findings may be generalizable to a national student population, CUNY's unique diversity makes it a valuable setting for studying the relationship between algebraic conceptual understanding and college math/STEM outcomes for groups that have been traditionally underrepresented in math and STEM.

These results suggest that algebraic conceptual understanding, as measured by the ACI, plays a crucial role in college math and STEM outcomes. The findings support calls to better integrate algebraic conceptual understanding into K-12 and higher education teaching and curricula. Moreover, the study highlights equity concerns, as ACI scores explained significant portions of racial/ethnic and gender disparities in math course grades, core course completion, and STEM degree attainment. Women, despite having lower ACI scores, were more likely to succeed in math courses, which may be related to other factors like dedicating more time to their studies (Wladis et al., 2021; 2024d; 2024e).

This research provides evidence that race/ethnicity and gender differences in access to high-quality K-12 math instruction likely contribute to disparities in STEM outcomes. Future research should investigate how improving algebraic conceptual understanding may enhance college math performance and STEM degree attainment, particularly for groups that have been traditionally marginalized and underrepresented in math/STEM. This study provides some of the first large-scale quantitative evidence linking algebraic conceptual understanding to STEM success, showing the need for targeted interventions to improve math outcomes and equity in STEM.

Texas State University

This study explores Transition-to-Proof (TTP) students' proof comprehension by analyzing written responses to proof intention and validation tasks. We examined students' use of set-based reasoning as they completed these tasks. Our analysis of 28 students' written work found that students used set-based tools for logic to support their reasoning. We also found that their explanations in their responses included discussion of the overall structure, individual lines or components, the mathematical veracity of the claim, and a walk through of the proof-text. We concluded that in these tasks students leveraged set-based reasoning for logic to make sense of the context and claim of the proof, supporting them in their overall proof comprehension.

Keywords: Transition to Proof, Set-Based Reasoning, Proof Comprehension

Reading, writing, and validating proofs are fundamental skills for participation in higher mathematics, so it is vital for undergraduate students to acquire these skills to learn and communicate within advanced mathematics (Tall et al., 2012). Because of this, understanding transition to proof (TTP) students' comprehension of proof, and providing interventions that meaningfully increase proof comprehension for students has been a focus within undergraduate mathematics research (Alcock & Weber, 2005; Selden & Selden, 2003; Dawkins & Zazkis, 2021; Hodds et al., 2014). These studies have demonstrated that interventions can improve students' performance on proof comprehension tasks.

Our study explicitly builds on the work seeking to improve students' proof comprehension by strengthening set-based reasoning for logic within conditional proofs (Dawkins et al., 2023; Dawkins & Roh, 2024). These works have provided evidence of components students deem important in proofs via validation tasks, along with presenting a variety of interventions tailored to this population of TTP students.

Building on the work of Dawkins et al. (2024), we explore how set-based reasoning for logic was evidenced in a class of students' written work on proof intention and validation tasks. While this study shares similarities with existing research on proof validation and set-based reasoning for logic within proof, we focus on analyzing the written artifacts of a TTP class rather than individual interviews or group discussions. In this study, we sought to answer the question: In what ways is set-based reasoning present in transition to proof students' proving activities?

Theoretical Framework and Related Literature

As we focused on student attention in their justifications surrounding proof validity and intention, we adapted existing research in the field and identified three key constructs for this study: *Overall Structure*, *Line-by-Line*, and *Mathematical Veracity*. *Overall Structure* refers to the structure or form of a proof (Selden & Selden, 1995, 2003; Tucci et al., 2023); Mejia-Ramos et al. (2012) emphasize this as a component of holistic proof comprehension. We take *Line-by-Line* to mean student attention related to local aspects of the proof text within their justifications surrounding proof activities, including meanings of terms and individual lines within the proof.

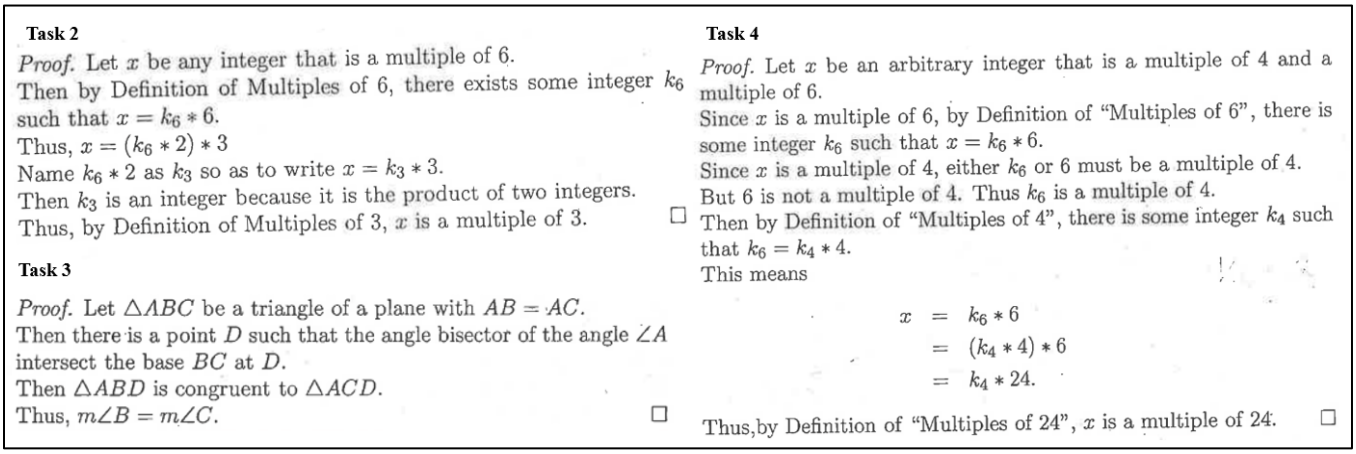
This includes what the existing literature has described as surface features (Selden & Selden, 2003), warrants between lines of a proof-text (Alcock & Weber, 2005), and comprehension of local aspects of a proof (Mejia-Ramos et al., 2012). By *Mathematical Veracity*, we refer to the degree to which students consider a mathematical statement to be proven as true. This concept is characterized by Tucci et al. (2023) as the alignment of the theorem, the proof, and the students' own understanding.

Proof Validation and Intention

Proof comprehension is complex (Mejia-Ramos et al., 2012), so we focus on two task types that provide connected but distinct insights into proof comprehension: Proof Validation and Proof Intention. Proof Validation, determining if a proof text is valid or invalid (e.g., Alcock & Weber, 2005), is a core component of proof comprehension. However, students may not necessarily consider what the proof intends to establish, or determine the Proof Intention (e.g., Roh & Lee, 2024; Tucci et al., 2023). As such, a validation task might overlook the importance of intention unless it specifically asks the student to articulate what the proof sets out to prove. Understanding proof intention involves recognizing the overall structure of the proof and how each part (line-by-line) contributes to what the proof is trying to establish (mathematical veracity). Because of this interrelated nature, both proof validation and proof intention are valuable for gaining insights into how students comprehend proofs.

Set-Based Reasoning for Logic

Finally, this work builds on prior work about set-based reasoning. Set-based reasoning is an approach to logic leveraging sets and set relations as a core tool (Hub & Dawkins, 2018) that has been applied to logic instruction in the TTP environment. To provide context for students' demonstrated proficiency in set-based reasoning, we adopted the codebook and approach of Dawkins et al. (2024), considering normativity and internal consistency of student work in tasks using multiple logical registers (diagrams, set relations, conditionals, etc.). We also developed a new coding set related to student annotations present in the margins, including their logic or set-based understandings of a proof task, detailed in the methodology section.



Methodology

Data Collection

This study is part of a more extensive project (NSF DUE #2141925) aiming at curriculum development for transition-to-proof courses at the undergraduate level. The larger project intends to implement a series of interventions, including set-based reasoning for logic, to support novice provers in their proof comprehension. This paper specifically analyzed part of the data collected from the project's second phase, which implemented the RAMP curricular materials in the classroom at a large Southwestern university.

In order to focus on students' use of set-based reasoning in proof comprehension, we chose tasks in homework and exams that contained problems centered on set-based reasoning, proof validation, and proof intention. We considered the written work of 28 students, and this analysis focused on the midterm, which was the first formal assessment that included proof tasks in the course. The midterm included three multipart tasks that asked for both proof intention and proof validation for provided proof texts with varied contexts and varied normative sufficiency (See Figure 1 below). This midterm occurred in week 7, after one unit of set-based reasoning for logic (weeks 1-3) and one unit of introduction to conditional proofs (weeks 4-6). To provide

context for the set-based reasoning of students, we also analyzed two preceding homework assignments from week 4 and week 6.

Task 2

Proof. Let x be any integer that is a multiple of 6.
Then by Definition of Multiples of 6, there exists some integer k_6 such that $x = k_6 * 6$.
Thus, $x = (k_6 * 2) * 3$
Name $k_6 * 2$ as k_3 so as to write $x = k_3 * 3$.
Then k_3 is an integer because it is the product of two integers.
Thus, by Definition of Multiples of 3, x is a multiple of 3. □

Task 3

Proof. Let $\triangle ABC$ be a triangle of a plane with $AB = AC$.
Then there is a point D such that the angle bisector of the angle $\angle A$ intersect the base BC at D.
Then $\triangle ABD$ is congruent to $\triangle ACD$.
Thus, $m\angle B = m\angle C$. □

Task 4

Proof. Let x be an arbitrary integer that is a multiple of 4 and a multiple of 6.
Since x is a multiple of 6, by Definition of "Multiples of 6", there is some integer k_6 such that $x = k_6 * 6$.
Since x is a multiple of 4, either k_6 or 6 must be a multiple of 4.
But 6 is not a multiple of 4. Thus k_6 is a multiple of 4.
Then by Definition of "Multiples of 4", there is some integer k_4 such that $k_6 = k_4 * 4$.
This means

$$\begin{aligned} x &= k_6 * 6 \\ &= (k_4 * 4) * 6 \\ &= k_4 * 24. \end{aligned}$$

Thus,by Definition of "Multiples of 24", x is a multiple of 24. □

Figure 1: Proof Texts Responded to in Midterm Tasks

Data Analysis

We began by developing an initial codebook for attention in proof validation explanations based on the existing literature. The next phase of the data analysis was to refine and finalize the codebooks by adding new codes for the data that did not fit into the initial codebook and grouping the codes into four categories. Through this process, we developed a new code for proof validation emergent from our data*, walk-through*, which will be detailed in the results section. In the final phase, we finalized the codebook (see Table 1).

Table 1: Finalized codebook for student explanation in verification/intention tasks

Code	Definition
Line-by-line	Discussion of strengths or weaknesses in the line-by-line argument (e.g., use of definitions, logical or mathematical steps, or arguments or reasoning connecting individual lines of the proof) or show overall concern for the process of the proof argument
Overall Structure	Discussion of the structure or framework of the proof, including explicit attention to the first and last lines of the proof as significant and explicitly stating proof structure (i.e., direct proof, proof by contradiction)
Mathematical Veracity	Discussion of the mathematical correctness of the statement being proven or provides a counterexample demonstrating mathematical falsehood
Walk-through	Evaluation includes a retelling of the proof logic, without other comment or evaluation, a walk-through of the steps taken by the proof-text author

In our initial pass of the data, we also noticed that many students had used the margins of the midterm exam to make notes about the proof validation tasks. We developed a codebook for these notes using open and axial coding (Strauss & Corbin, 1998), as seen in Table 2.

Results

Through this study, we characterized student comprehension of proof-text tasks by considering the written explanations they provided in their responses. We also saw students engage with set-based reasoning in support of their proof comprehension in these tasks. We

reflect on the apparent effectiveness of the approaches and variation in methods between the three different presented tasks.

Table 2: Margin Evidence Codebook

Code	Definition
Logical Statements	Annotations that are related to logical reasoning (i.e., logic statement types, generating a conditional statement, or identifying logical equivalence of multiple statements)
Set Based Reasoning	Annotations related to sets and set-based reasoning (i.e., definitions of sets, Euler diagrams, relations between sets)
Examples	Concrete examples or cases considered, such as diagram drawings or arithmetic with example values
Truth Value	Explicit annotation of provided potential conditional as mathematically true or false

Attention in Proof Comprehension

Through iterative refinement of our codebook, we identified four components of the proof text that students attended to when explaining their reasoning in these tasks. These categories are based on student written responses to the prompt "Evaluate if the proof-text properly proves what it attempts to prove. Explain why or why not." These categories are not mutually exclusive; students' written responses often contain multiple parts or arguments, so they often attend to multiple components in the same response.

Overall structure. Many responses contained explicit references to the overall structure of the proof-text. For example, some responses referenced common types of proofs (e.g., proof by contrapositive), content recently introduced in the course. For example, Bailey wrote,

> The proof-text properly proves that for any integer x, if x is a multiple of 6, then x is a multiple of 3. This is a direct proof. (iii) is the contrapositive of the direct proof and would result in the same truth table. However, the proof text does not use the contrapositive format.

Others showed awareness of the overall structure by commenting on the first and last lines of the proof, a technique introduced in a prior curricular activity. In Task 2, Adam wrote:

> The proof text is attempting to prove that for all integers x, if x is a multiple of 6, then x is a multiple of 3. The proof text does indeed prove this properly, as it starts by establishing that x is any integer that is a multiple of 6, breaks it down with the prime factorization, and ultimately concludes with x being shown to be a multiple of 3.

These were not isolated instances. In Task 2, 15/26 responded to the overall structure in their response. This was not consistent across all three tasks, however. 8/26 cited the overall structure in their written explanation for Task 3, and 10/25 cited it in Task 4.

Line-by-line. Students also provided arguments based on surface features or individual components of the proof, which we coded as line-by-line arguments. For example, Tucker's response to Task 3 reads,

> The proof-text does not properly prove what it attempts to because there is a gap in justification between line 2 and line 3. The proof-text does not point out the consequence of the angle bisector and quickly jumps to line (3).

Arguments in this category were cited as justification for the proof's validity. For example, Evan's response to Task 2 cited the internal components of the proof as the reason the proof

proves what it attempts to, saying: "Yes, because it logically states and justifies each step using either algebra or a definition that ultimately arrives at the desired conclusion."

Overall, 13/26 responses to Task 2, 19/26 to Task 3, and 10/25 to Task 4 included a line-by-line argument. Some responses included both line-by-line and overall structure components; 14/77 responses were coded as both. This shows that students attending to overall structure do not necessarily cease to use line-by-line reasoning in their validation explanations.

Mathematical veracity. Some explanations demonstrated attention to the correctness of the statement being proven, which we called mathematical veracity of their answer a claim. For example, John response reads:

> The proof tries to prove that multiples of 4 and 6 are always multiples of 24 but doesn't do it properly because they neglected the case where multiples of 4 and 6 are also every other multiple of 12 as well.

In Tasks 2 and 3, with 2/26 and 1/26 responses coded as attending to mathematical veracity, and in Task 4 8/25 responses cited mathematical veracity. This is not surprising; compared to the previous two categories, mathematical veracity doesn't directly connect to a recent curricular activity. Fewer responses coded as citing mathematical veracity likely do not have to do with what students think is important but rather what recent course activities have primed them to include in responses to proof-text tasks.

Walk-through. While most student explanations analyzed contained arguments we expected to see based on previous literature, we also noticed a new focus. Some responses included a retelling of the proof itself, or a walk-through of the reasoning of the proof as justification for the proof properly proving what it set out to prove. For example, Ben's response to Task 3 contains a walk-through of the proof-text:

> The proof-text attempt to prove that for any triangle ABC, if $AB = AC$, then $m\angle B = m\angle C$. The prove does not fully prove the prove properly. The statement "Then triangle ABD is congruent to triangle ACD" is not properly justified. The proof start state how the point D from the angle bisector creates line AD. Then, since $AB = AC$, $\angle CAD$, and $\angle DAB$ are equivalent by definition of angle bisector, and $AD = AD$ triangle ABD is congruent to triangle ACD. The proof is mostly correct and just would benefit from some clarity.

In most cases the walk-through was included along with another category of explanation. Walk-through was the only code applied to a written response only 4/19 of the times it was used.

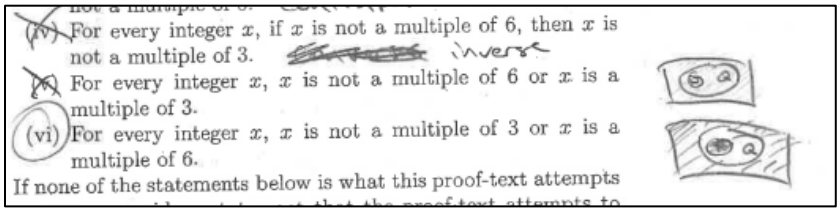


Figure 2: Example of student set-based margin annotations

Engagement in Set-Based Reasoning

In the process of our analysis, we observed margin annotations present (see Figure 2) on all three tasks, including a variety of annotations, some of which were set-based reasoning tools that had been presented earlier in the course. We had observed general proficiency, though not without error, with set-based reasoning for logic in the work of this same class on prior homework assignments, using the same approach and codebook as Dawkins et al. (2024), but

due to space constraints, we focus only on the set-based tools students used on these midterm tasks. However, it was because of this context that we attended to these margin annotations.

Evidence of set-based reasoning in proof comprehension contexts. Since the midterm questions did not require students to show their work in the question stem, we can conclude that these annotations were added because they were of value to the student in their problem-solving process on the task. Based on these observations, we developed the codebook in Table 3. These margin annotations demonstrate that students found set-based tools for logic useful as they solved proof intention and verification tasks (see Table 2).

Table 3. Number rates of occurrence in margins of midterm tasks

Task	Set-based	Logic	Example	Truth
2	12/26	14/26	1/26	1/26
3	4/26	6/26	21/26	2/26
4	3/25	12/25	4/25	1/25

The margin work also indicated attention to the logical reasoning skills previously introduced as part of the RAMP curriculum, showing student uptake of those concepts and skills. This is unsurprising, as these concepts were freshly introduced and directly associated with proofs in the way they were presented. However, this is also some indication of adoption, as students found these concepts valuable enough to make personal notes to support their proof comprehension on these tasks.

Diversity of use amongst tasks. The margin annotations were not uniformly present across the three tasks, as evidenced in Table 3. Two components likely contributed to this. First, the mathematical context of the task seemed to be associated with the margin notes used; specifically, the use of examples was much higher on Task 3, the only geometry-based task. It seems likely to us that students could run examples of the divisibility context in their mind's eye but that the more spatially challenging context of geometry led to the higher use of examples as a written aid. Also, set-based tools appeared at a much higher frequency on Task 2 than on Tasks 3 and 4. However, all students who used set-based tools on Task 3 or Task 4 had also used them on Task 2. This suggests that because of the similar setups of these three problems, some students used set-based tools to help them conceptualize the first task but then transferred their conclusions to the next two questions that were of a similar form, without a need to reconstruct the annotations they had previously made. Also, the question directly preceding Task 2 on the assessment asked about equivalent sets; it is possible that this prior task primed set-based thinking in the students. However, we posit that the students would not have used set-based annotations if they found them fully irrelevant to the task at hand.

Our analysis of the students' work on these tasks, in light of our observations of their work on prior set-based homework, suggests that while set-based reasoning might not be trivial to the students, it was accessible to them. In particular, the students' use of set diagrams, notations, and terminologies in their margin scratch work indicates that students found this set-based reasoning approach beneficial for reading and comprehension of proof texts on these types of tasks.

Normative Proof Validation

While we avoid making statistical claims past describing the proportion of the responses that fit in each category, as this was not a representative sample, we did see patterns in response categories of attention, margin note types, and the normativity of the response to the question of

the proof text's properness, which we considered a proof validation task. These observations, we believe, provide insights as to how these techniques connect to proof comprehension broadly.

Overall structure and mathematical veracity in validation explanations. Student attention to overall structure in their explanation of reasoning did not consistently co-occur with a normative evaluation of the proof text in these three tasks. In Task 2, all 15 responses citing overall structure correctly validated the proof as proper, and 8/9 overall structure responses validated the proof as proper in Task 3. However, Task 4 tells a different story. 9/10 responses coded for overall structure declared the proof "proper" even though its claim is mathematically false. This suggests that the responses that attended to overall structure, while relatively successful at the proof intention component of the task, were not consistently normatively validating the conditional they successfully identified.

In Task 4, many responses that correctly identified the proof as improper were coded as mathematical veracity, (see Table 1 for definition). For example, John responded:

> The proof tries to prove that multiples of 4 and 6 are always multiples of 24 but doesn't do it properly because they neglected the case where multiples of 4 and 6 are also every other multiple of 12 as well.

In Task 4, 8/25 responses cited mathematical veracity, among which 7/8 correctly declared the proof improper in proving what it attempts to prove. While attention to overall structure in the response seemed to help students complete proof intention tasks normatively, mathematical veracity most frequently co-occurred with a normative declaration of a proof as invalid.

Conclusion/Discussion

Through our analysis of these two interrelated proof comprehension task types, proof intention and proof validation, we found evidence of students' use of set-based reasoning tools from their TTP course. Students used overall structure arguments in their explanations of proof validation and included components of set-based reasoning and logical structures in their margin work on the tasks. Because margin work was not a required or graded component of the assessment, we take this to mean that the students found these tools relevant to the presented proof comprehension tasks. It is worth noting that these set-based tools were not self-emergent; the intention of the course was to teach intro to proofs using set-based reasoning for logic.

Many of the aspects of proof we saw students attend to were consistent with those described in prior work, including student focus on proof structures (Selden & Selden, 2003; Tucci et al., 2023), surface feature or line-by-line reading (Selden & Selden, 2003; Dawkins & Zazkis, 2021), and a focus on mathematical veracity of the claim made (Tucci et al., 2023). This demonstrates that these categories continue to be evidenced in full class as demonstrated on written proof comprehension tasks. However, we did observe a new component included in the written explanations, that of a walk-through of the proof text. Though this was a small set of tasks, it does seem from these written responses that walk-through occurs as a way for students to say it's right because it's right, since among these artifacts, a claim of improperness tended to include identifying a failure within the proof, leading to a code of line-by-line instead. It is also possible that this retelling action is a byproduct of the novelty of the context and the task; students may be retelling themselves the argument of the proof as they work to explain their reasoning. However, this is a conjecture, and so we believe that more investigation into this novel code of walk-through as an explanation is warranted.

The Impact of an Upper Division Inquiry-Oriented Content Course on Prospective Teachers: Embracing a Critical Stance

Ruo Ning (Nancy) Qiu
San Diego State University

Chris Rasmussen
San Diego State University

Debra Carney
Colorado School of Mines

Nicholas Fortune
Western Kentucky University

In this study, we analyze interviews with prospective secondary school teachers focused on how an upper division inquiry-oriented content course influenced their beliefs about learning and teaching mathematics. In particular, we examine how students describe their experiences in this course and the extent to which (and why) students see themselves using an inquiry-oriented instructional approach in their future teaching. Using thematic analysis, we found that the ways prospective teachers described their experiences in the course aligned closely with the four pillars of Inquiry-Based Mathematics Education, and the course empowered students to embrace a critical stance to self-reflect on their experiences and to raise their awareness of their agency to change things (for the better) through their own actions and future forms of instruction.

Keywords: critical stance, inquiry, prospective teachers, beliefs about teaching

The relevance and usefulness of upper division mathematics courses for prospective secondary school mathematics teachers has long been of concern (Begle, 1972; Klein, 1932; 2016; Wasserman et al., 2019). A number of studies document that teachers find their advanced mathematics courses have little relevance to their future professional life (e.g., Cofer, 2015; Wasserman, 2017, Zazkis & Leikin, 2010). One approach to addressing this issue, and the one taken in our larger study, is to redesign upper division math content courses to make intentionally strong connections to high school mathematics content and teaching.

A recent issue of *ZDM Mathematics Education* has made progress on the discontinuity (Klein, 1932) between university and secondary school by examining how the intersectional nature of mathematics educational content might be addressed in a wide range of university courses in order to prepare better secondary mathematics teachers (Wasserman et al., 2023). For example, Buchbinder and McCrone (2023) focused on bridging the disciplinary practice of proving and the teaching of secondary mathematics. In another paper in this special issue, one that is related to our larger project, Apkarian and colleagues (2023) investigated the impact of an upper division mathematics course on prospective teachers' knowledge of rate of change and their shifting beliefs about mathematics learning and teaching. In other related prior work that investigated the impact of this same course, Goodchild and colleagues (2021) took a community of practice perspective to document the adoption by these prospective teachers of a *critical stance* toward learning and teaching mathematics. In this report, we further this line of inquiry by examining prospective secondary school teacher experiences in an inquiry-oriented upper division math course and the extent to which they see themselves enacting an inquiry-oriented instructional approach in their future teaching. In particular, we address the following two research questions: *(1) How do students describe their experiences in an upper division math course and how are these experiences similar to or different from their previous college and high school math experiences?* and *(2) To what extent do students see their future selves using an*

inquiry-oriented instructional approach and what are their reasons for doing so (or not doing so)?

The work reported here is part of a larger NSF-funded project that is investigating the impact of an upper division mathematics course, Inquiry-Oriented Dynamical Systems and Modeling (IODSM), on prospective teachers' knowledge of content connected to high school mathematics, the ways in which they engage in the eight Standards for Mathematical Practice (Common Core State Standards Initiative, 2010), their beliefs about learning and teaching mathematics, and contributions to their emerging professional practices.

Theoretical Framework

As alluded to in the introduction, two central and related ideas to our line of investigation are inquiry-oriented instruction and critical stance. The upper division math course that we are redesigning for prospective teachers embraces and reflects the four pillars of inquiry-based mathematics education (IBME): (1) Students engage deeply with coherent and meaningful mathematical tasks, (2) Students collaboratively process mathematical ideas, (3) Instructors inquire into student thinking, and (4) Instructors foster equity in their design and facilitation choices (Laursen & Rasmussen, 2019). Our creation of coherent and meaningful tasks where students reinvent mathematics is guided by the instructional design theory of Realistic Mathematics Education (Freudenthal, 1991; Gravemeijer, 1999) and our perspective on the ways in which students and instructors inquire into others' thinking and reasoning is informed by the constructs of social and sociomathematical norms (Yackel & Cobb, 1996). In particular, the instructor sought to create a classroom environment that nurtured the following social norms: students routinely explain their thinking, however tentative, students listen to and try to make sense of others' reasoning, and indicate agreement or disagreement with reasons. In terms of sociomathematical norms, the instructor sought to foster student explanations grounded in mathematical relationships and meaning, as opposed to procedural accounts of their solution.

For his part, the instructor sought to foster the two student pillars by valuing and bringing out student ideas and then leveraging those ideas to move forward the mathematical agenda (Kuster et al., 2018; Rasmussen & Marrongelle, 2006). The instructor's attention to equity included specific teaching choices such as attending to group composition, explicitly crediting ideas to student authors to foster intellectual ownership, and regularly collecting and leveraging student reflections on each class session. Another choice made by the instructor was to assign rotating group roles. For example, one of the assigned roles was a Reporter who reports back to the whole class about their group's progress which contributes to the instructor's efforts to ensure equitable participation and minimize biases when asking groups to report out (Reinholz, 2023).

The four pillars of inquiry-based mathematics education are foundational for students to develop a *critical stance*. Our definition of critical stance draws on that put forth by Curzon-Hobson (2003, p. 201): A *critical stance* is "an attitude or disposition towards oneself, others and the object of inquiry that challenges and impels learners to reflect, understand and act in the milieu of potentiality." A critical stance therefore results in an awareness of and reflection on one's own experience, meanings, and knowing. In prior related work, Goodchild and colleagues (2021) distilled this characterization of critical stance into three key features: First, students must be aware of the possibility that their mathematical learning experience could be different, for this they need to experience variety in the way mathematical learning experiences are designed and implemented by the instructor. Second, students must be able to reach some judgment, based on their reflection and evaluation of their experience so that they might recognize when one experience of meaning, learning or teaching is better, deeper, or richer than another. Third,

students need to be aware of their agency to change things (for the better) through their own actions and future instructional practice as a secondary school teacher.

Methods

This report focuses on data collected during the Spring 2023 semester. The goal of this pilot study was to begin modifying an existing differential equations curriculum (Rasmussen et al., 2018) so that it explicitly deals with high school mathematics content and teaching and to investigate the impact of this course on prospective teachers' knowledge, beliefs, and their participation in the Standards for Mathematical Practices (Cruz et al., 2024).

We conducted semi-structured individual interviews with nine students from a class of 30 at a large, Hispanic-serving institution in the southwestern United States. Of the nine volunteers, five participants identified as women and four identified as men. One of the authors was the instructor of the class and they did not know who participated in the interviews until after the interviews and course were completed. In this report, we focus on interview questions related to their previous mathematics experiences and beliefs about learning and teaching mathematics as it relates to having a critical stance and their future professional practice. The relevant interview questions were:

- Have you had other math courses taught in a way similar to this class?
- Do you imagine yourself using this kind of teaching in your future practice? If so, how? If not, why not?
- In what ways, if any, have your experiences in this class affected your beliefs about teaching mathematics?
- Are there ways of experiencing or doing math in this class that have been powerful for your learning?
- How do these ways of experiencing or doing mathematics compare to your other undergraduate math courses? To your high school math courses?
- How about ways in which these ways of doing math in this class have affected your beliefs about what it means to learn mathematics?

The interviews took place in person with one of two interviewers participating over Zoom. Interviews were transcribed and anonymized. All names we include here are pseudonyms.

We first read the transcripts to familiarize ourselves with the data. We then used thematic analysis (Braun & Clarke, 2006) to identify, analyze, and interpret patterns within the data. During the initial coding process, we open coded the data with some a priori attention toward the components of a critical stance (awareness, self-evaluation, and agency). We coded in pairs and went through several rounds of reading and updating our codes until a 100% agreement was reached. During axial coding, we grouped codes according to the following five themes: (1) students' awareness of a different experience, (2) intellectual responsibility lies with students, (3) the role of social interactions, (4) instructor actions and decisions, and (5) course and facilitation design choices with an eye towards equity. In further axial coding, we related these themes to our theoretical perspectives of inquiry and critical stance.

Results

Research Question 1. Recall that our first research question is, *How do students describe their experiences in an upper division math course and how are these experiences similar to or different from their previous college and high school math experiences?* Our analysis of the interview data revealed that the pedagogical approaches experienced by students in the IODSM class are very different from their collective prior mathematics experiences. Seven of the nine

students indicated that their previous mathematics, high school or lower division mathematics undergraduate classes, were all or mostly lecture-based where they engaged in "mindless copying", "repetitive practice" and it was all very "fast paced" to keep up with the instructors. The newness of a different mathematical learning experience is addressed in the first of our five themes.

Theme 1: Students' awareness of a different experience. Recall one component of a critical stance is awareness: students must be aware of the possibility that their experience of the practice could be different. Three students in the IODSM course indicated that they were unaware that math could even be taught like this. For example, Chepi said:

> I never thought that a math class could be like this where you're just figuring it out for yourself and trying to make sense of it yourself with other people. You're getting new perspectives rather than your own, because sometimes you could think of things one way. There's no right way to do math, as we've seen and in a class like this, I've seen people do some weird things that you would never think for yourself and it works.

The remaining four themes further flesh out the various ways in which IBME offers a different, and, from students' perspective, more meaningful learning experience.

Theme 2: Intellectual responsibility lies with students. For the second theme students indicated overwhelmingly that they could develop mathematical ideas for themselves, with minimal input from the instructor. For example, George said, "I think that [the] process of having the students really dig into the material with minimal assistance from the instructor is very good." Students also reported feeling confident in reinventing mathematics where they have ownership of ideas. Here, the way this manifested for students was the importance of having intellectual responsibility for their own learning. For example, Hakeem said:

> Because, you're creating something on your own and obviously you're gonna take pride in that. When you have something that you created, you're very proud of it and you're very defensive of it also. So if someone says that you're wrong, you're definitely gonna want to counter argue that and defend yourself. And then they're gonna also, and it's that back and forth, that dialogue is where new ideas and true learning happens.

This theme is strongly connected to IBME Pillar 1, Students engage deeply with coherent and meaningful tasks, because of the intellectual ownership and need to "really dig into the material."

Theme 3: The role of social interactions. Another theme that emerged was the role of social interactions and the power of collaborative learning. The statements coded in this grouping were attributed to eight of the nine students. This theme resonates with the second IBME pillar, Students collaboratively process mathematical ideas, because students positively reflected on the importance of group work, group roles, and the opportunities for student-to-student discussion. For example, the collaborative processing of ideas is evident in Hakeem's reflection when he said "it's that back and forth, that dialogue is where new ideas and true learning happens." Hakeem also emphasized the value and benefit of students being the primary source of ideas:

> I think it's better to have those small groups and be able to talk to them about your understanding of where you're struggling with. I think that's way more beneficial and it just brings more comfort to the student with the material. And then eventually, I'm sure you could see it too, as the semester progresses, more students are being able to talk or come out on their own and being able to share their ideas. Whereas at the beginning of

> the semester, there's only probably like three people that would consistently be asking questions, consistently be sharing. So I definitely think having inquiry-based small group discussions where the lecturer is only there as a resource, not necessarily the source, is the best way to learn.

Theme 4: Instructor actions and decisions. Five students' descriptions of the IODSM course highlighted the instructor choices about the course design that indicated purposeful instructor inquiry into student thinking. For example, Jackie said the following about the end-of-class reflections: "...I think [it] is really nice that we get to see other students thinking in their writing as opposed to just presenting in class", whereas Hakeem commented on how he used the reflections: "I went back on my reflections and on the entire class's too, because [the instructor] posts them… gathering from their knowledge, adding it to my own and making it my own." We see this theme as implicitly aligning with the third IBME pillar, Instructors inquire into student thinking, because the instructor regularly used student thinking from the end of class student reflections to jump start the next lesson (i.e., move forward the mathematical agenda).

Theme 5: Course and facilitation design choices with an eye towards equity. Four of the nine students spontaneously commented that their new experiences in the IODSM course contributed to equitable learning experiences. It is notable that the interview questions did not directly ask about equity and hence student reflections related to this theme emerged organically from the interview data. For instance, Francis realized the facilitation effort that the instructor made to promote group diversity during collaborative working time:

> …I like how, as a student, you get to experience it. So I would want to give my students the same experience just because, like giving diversity, how he [the instructor] puts boys and girls in groups… So it's not just a boys club or a girls club. It's more of everyone just collaborating, working together, getting to know each other… It's not just like, oh, I don't know that person. That's more like, oh hey, how's it going?

Similarly, Jackie observed the impact of the course design in which each student in the group work has a role where they said, "We're in groups and each group member has a different role to help, I guess, function and make sure that everyone has a voice in their group." Gabby also addressed the value of group work when she said, "My favorite part of the class is working together as a class, where like we'll have our time to do our own group work and either some groups are excelling, some are struggling and everyone's kind of trying to keep each other in check." This theme aligns with IBME Pillar 4, Instructors foster equity in their design and facilitation choices, as the group work and group roles allowed for more equitable participation.

Research Question 2. We next address our second research question, *To what extent do students see their future selves using an inquiry-oriented instructional approach and what are their reasons for doing so (or not doing so)?* All nine students answered positively that they would like to use the inquiry-oriented instructional approach in their future practice. For example, Diem said "I like it… I would like to do the same format to teach in the future." Breanne similarly commented "I would want to… And the teacher that I've been shadowing in a high school, she kind of does similar things... everybody sits in little groups and like group presentations… but a little bit dialed down."

Three of the nine students saw themselves implementing similar instructional approaches, but with caveats that the "high school curriculum is packed" and "may not fit the school model." We view these awarenesses of the potential secondary school context as an indication of their critical stance, since they evaluated the practicability of the inquiry-oriented approach in a high school

setting. This shows their agency, transitioning beyond a learner perspective to a teacher perspective in their future professional life. For example, Gabby envisioned that:

> I would really like to. I know it takes a lot more time to do, and that's one of the bigger issues of doing this kind of thing in the classroom and just like the rest of the school not being set up this way or not being supported to set up this way. But ideally, yes. Even if I'm not able to fully do it, I have already started thinking about how I wanna do little things that we do in this classroom and incorporate that into a more traditional [classroom]…

Note that Gabby was explicitly aware that she might take a position in high school where "the rest of the school not being set up this way or not being supported to set up this way." She also started to brainstorm what she should change to integrate inquiry-oriented learning into her future teaching. Similarly, George embraced a critical stance by anticipating similar challenges. In particular, in the following excerpt, he recognized the trade off between covering a lot of material and the depth of understanding:

> But you have to think about it too in the sense that if you do try to fit in more material, it's less likely that the students will have as good of an understanding on the material that they can cover. So you kind of have to weigh how well these students really need to understand a concept versus how much material do they need to know.

These examples highlight how prospective teachers exercised their agency by hypothesizing the balance of time that an inquiry-oriented approach might require in their future teaching.

For the majority of students who see their future selves using an inquiry-oriented instructional approach to a great extent, we observed similar themes in their reasonings aligned with the pillars of IBME. For example, Chepi recognized the benefits and appreciated the IODSM course's collaborative thinking activities to "help kids learn to think for themselves rather than to be taught cookbook how to do anything in math" (Pillars 1 and 2). Many students, like Chepi, reflected on and evaluated their IODSM experiences to reason why they want to use this teaching from the perspective of learners. For example, George said,

> I think that the typical lecture while students just kind of watch model of teaching is outdated and not very beneficial to the students. So this class is just so reinforcing and I think it's very helpful to the students to acquire these ideas on our own and like really work our way through the concepts.

The students again embraced the agency to make the judgmental call that the intellectual responsibility of understanding and sense-making mathematics should lie within learners instead of teachers telling students what to do and how to think. This finding re-emphasizes the themes of students' awareness (Theme 1) concerning students' intellectual responsibility for learning (Theme 2).

Another reason why students favored inquiry teaching and learning is that the experience is "more class engaged, student engaged, rather than just everybody listening to one person talking and writing on the board" (Breanne). Christiano also elaborated on the engaging aspect stating that "it encourages my desire to teach. It makes me excited, because there's definitely other math classes that I've been in, and I definitely see, I think to myself, I don't want to teach like this and in this class… it kind of solidifies my desire." Breanne commented that learning from classmates with group work and the whole class was a "productive struggle" which helped her "retain

information better." In addition, students were well aware and highlighted the collaborative, safe, open, and supportive learning environment— "everyone kind of knows each other, so it's kinda open. No one's too shy to speak up" (Francis) and "I think that's way more beneficial and it just brings more comfort to the student with the material. And…. as the semester progresses, more students are being able to talk or come out on their own and being able to share their ideas" (Hakeem).

Discussion and Conclusion

Overall, results indicate that students' prior mathematics experiences were more different than similar to the pedagogical approach taken in the IODSM course. It is noteworthy that the pedagogical approach they experienced provided opportunities for them to increase their awareness that teaching and learning can be different, in positive ways, from the majority of their prior experience. Moreover, how the students embraced aspects of the pedagogical approach all align with the pillars of IBME. It should be noted that the pillars of IBME were in the mind of the instructor when designing the course structure, but these pillars were not explicitly discussed with students or brought to the attention of the students. Thus, their collective responses in the interviews about their intellectual responsibility, their collaboration with their peers, and their instructors' role in their learning and his attention to equity, all indicate that the IBME pillars were realized in this course.

In this report, we provided evidence that students embraced a critical stance—they were aware of the new mathematical experience with the IODSM course as compared to their previous experiences, were inspired to evaluate the experiences as a learner and a teacher, and recognized their agency to make changes for the better in their future teaching. Drawing from their experiences with the IBME-inspired instructional approach in the IODSM course, students reasoned positively about why they would see their future selves implement an inquiry-oriented instructional approach and the value that such an approach has for learners. Even if they had caveats, students explained their concerns and further proposed how they would modify the inquiry-oriented approach they experienced to adapt to their imaged secondary school settings. Further, student reflections on their experiences in this enactment of an inquiry-oriented course effectively empowered and fostered their embracement of a critical stance. Students were aware of the new mathematical experience, reflected on and evaluated whether the IBME experiences were more profound, and used their agency to imagine enacting an inquiry-oriented instructional approach in their future teaching. Our results provide an existence proof that, in this case, the particular enactment of IBME supported and nurtured a critical stance.

Going forward, in the context of the larger NSF study, we will go beyond interview data and collect classroom video data from other institutions with different instructors and contexts so that we can explore the potential for other IODSM class structures and specific teacher moves and decisions to positively affect future teachers' beliefs about mathematics learning and teaching and their embracement of a critical stance. The larger study also aims to understand how prospective teachers' knowledge of content related to high school mathematics deepens, the ways in which they engage in the eight Standards for Mathematical Practice (Common Core State Standards Initiative, 2010), and how approximations to their professional practices emerge and grow (Llinares, 2013).

An Exploration of Productive Student Reasoning About Equivalence Relations

Hudson Payne
Oklahoma State University

John Paul Cook
Oklahoma State University

Equivalence relations are a foundational concept in mathematics, yet productive student reasoning about equivalence relations remains largely understudied. Based on the descriptions of productive reasoning about equivalence that we have encountered in the literature, and the results of the data we collected from task-based interviews with advanced mathematics students, we argue that an essential aspect of productive reasoning with equivalence relations is the flexibility to transition between an element-wise, local perspective of the equivalence relation and an equivalence class level, global perspective of the equivalence relation.

Keywords: Equivalence Relations, Equivalence, Local Perspective, Global Perspective

Introduction

Equivalence relations are one of the most foundational concepts across the entire mathematics curriculum, ranging from numerical equality in early childhood (e.g., McNeil, 2014) to abstract algebra at the advanced undergraduate level (e.g., Cook et al., 2022). Additionally, as a prominent feature of many introduction-to-proof courses, various textbook authors describe equivalence relations as "a surprisingly powerful tool" (Dumas & McCarthy, 2007, p.59) "particularly valuable" (Smith et al., 1986, p. 145), "quite significant" (Hammack, 2013, p.184), and "extremely important" (Roman, 2006, p. 141). Yet despite their centrality in mathematics, student reasoning about equivalence relations, and in particular *productive* student reasoning about equivalence relations, remains largely understudied. In this report, we will synthesize the literature on students' reasoning about equivalence relations and use task-based interviews with an advanced mathematics student to provide an answer the question: What does productive reasoning about equivalence relations entail?

Based on the descriptions of productive reasoning about equivalence that we have encountered in the literature, and the results of the data we collected from the interviews, we will argue that an essential aspect of productive reasoning about equivalence relations entails a flexible transition between an element-wise local perspective and an equivalence class-based global perspective. These ideas are implicitly present in the existing literature about equivalence relations, but have not yet been explicitly articulated or empirically substantiated. The articulation and demonstration of reasoning from both local and global perspectives and the benefits of using these perspectives flexibly will be the primary contributions of this paper.

Literature Review and Theoretical Perspectives

This study is part of a broader effort to develop and refine a *conceptual analysis* (Thompson, 2008) that describes and accounts for students' reasoning about equivalence across mathematical domains. In alignment with the tenets of conceptual analysis, our efforts here aim to identify and describe elements of students' reasoning "that might be propitious for [their] mathematical learning" (Thompson, 2008, p. 60). The literature on students' reasoning about equivalence, broadly defined, is vast. For example, there is a wealth of research focused on how students productively reason about specific instances of equivalence in K-14 settings (e.g., Cook, Dawkins, & Reed, 2021; Jones & Pratt, 2012; Kieran, 1981; Smith, 1995). Here, however, we

aim to examine how advanced mathematics students might productively reason about tasks that involve an unfamiliar, formally defined equivalence relation. As suggested by quotations in our introductory paragraph above, these kinds of tasks are typical in proof-based mathematics courses. Indeed, while some of the challenges and difficulties of reasoning about such tasks have been reported in the literature (e.g., Brandt, 2013; Chin & Tall, 2001), descriptions and empirical examples of what constitutes productive reasoning has received substantially less attention. This is the primary gap we aim to address in this study.

The literature does provide some theoretically-based hypotheses about what productive reasoning about equivalence relations might entail, but they have not yet been empirically examined with students. Our primary argument in this paper (and the answer we offer to our research question) involves empirically examining one of these theoretical hypotheses: a key element of productive reasoning about equivalence relations entails viewing the relation through (and moving flexibly between) both a *local perspective* and a *global perspective* on the relation. A *local perspective* involves reasoning about whether or not specific pairs of elements are related with respect to a given equivalence relation. Researchers, however, have hypothesized that productive reasoning about equivalence relations requires going beyond this familiar element-to-element perspective to consider classes of related elements. Hamdan (2006), for example, argued that students' should be supported in "envisioning the equivalence classes corresponding to an equivalence relation, which requires going beyond the element-wise conception of a relation, to a more *global* perception of it" (p. 130-131, emphasis added). Similarly, Schumacher (1996) argued that moving flexibly between the relation (to focus on relationships between specific elements) and classes of related elements (the partition structure induced by the relation) "are two faces of the same problem. […] These two views complement each other, and it is useful to be able to cross over easily from one to the other" (p. 46). In both instances, we infer that the authors are acknowledging the importance of a local perspective on the relation but are also arguing that a focus on equivalence classes (or, more broadly, collections of related elements) is critical – other researchers have advanced similar theoretical arguments (e.g., Chin & Tall; Asghari; Asghari & Tall (2005)Therefore, following Hamdan's (2006) use of the term, we characterize a *global perspective* of an equivalence relation to involve reasoning that focuses on collections of related elements. We hypothesize that utilizing both perspectives is a key aspect of productive reasoning with equivalence relation tasks.

Methods

We employed the task-based clinical interview methodology (e.g., Goldin, 2000; Clement, 2000) in order to explore students' organic reasoning processes. Specifically, we conducted individual interviews with four graduate students studying mathematics at a large R1 university. Each student participated in two interview sessions conducted by the first author; each session was up to 2 hours in length. Since this project was largely exploratory in nature, we chose to work with students who would already have strong conceptions about or extensive experience with formal equivalence relations in order to observe and draw inferences about the nature of productive reasoning. In this short report, we focus on our analysis of the activity of one of the four students (pseudonym: Aspen). All interviews were recorded using an iPad application, which produced videos of students' written work with synchronized audio.

The interviews centered on a series of literature-informed tasks, each of which were derived from the exercises involving equivalence relations in proof-based mathematics textbooks. Per our research hypothesis, the tasks were designed to (a) be typical in form yet unfamiliar enough

to require legitimate mathematical reasoning to solve, (b) be open-ended (to encourage multiple approaches), and (c) elicit reasoning from both a local perspective and a global perspective. The task we focus on in this report is featured in Table 1.

To analyze the data, we conducted a theoretical thematic analysis (Braun & Clarke, 2006) that was organized around our characterizations of *local perspective* and *global perspective.* The interviews were transcribed, and the first author reviewed the transcripts, first classifying the approaches to each of the tasks as either productive (successful) or unproductive (unsuccessful), and then coding using notions of *Local Perspective*, *Global Perspective*, and *Transition*. Additional codes were applied to further describe students' approaches to each task. Throughout this process, the first author chose excerpts from the transcripts to discuss and review with the second author. These excerpts and the application and interpretation of the codes was discussed and refined, at which point the first author would revisit the data in light of any revisions or new insights that occurred.

Table 1. Statement of and rationale for one of the interview tasks.

Task:	Rationale:
Let $(x,y)R(w,z) \Leftrightarrow x^2+y^2=w^2+z^2$ be a relation that partitions the plane into curves. What is the maximum distance between two points on curves containing (1,2) and (0, 4)?	This is a modified version of a task from Smith, Eggen, and St. Andre's (2006) introduction to proof text. We included it because of its potential to elicit the use of a local perspective, a global perspective, or both.

Results

Our analysis and presentation of the results here focuses on the responses of one participant (Aspen) to the task in Table 1. We first discuss what we interpreted as Aspen's productive use of a local perspective on the equivalence relation and then do the same for her productive use of a global perspective.

Demonstrating Productive Use of a Local Perspective on the Equivalence Relation

Aspen began by checking to see whether (0,4) and (1,2) (the two ordered pairs given in the statement of the task) were related. She concluded that they are not by using the condition for the relation – see Figure 1 (left).

Figure 1. Aspen reasons that (1,2) and (0,4) are not related (left) and sketches various points related to (1,2) (in green) and (0,4) (in yellow), respectively (right).

Aspen then generated points that were related to each of these two points. She described her approach by directly referencing the statement of the equivalence relation and noting that, because $0^2 + 4^2 = 16$, the points related to (0,4) "have to be the x coordinate squared plus the y coordinate squared being 16." (She reached a similar conclusion about the points related to (1,2) and the sums of the squares of the coordinates as 5.) She proceeded algebraically by attempting to 'guess and check' some tractable values for x and y that might satisfy this condition. The elements she identified as related to (0,4) included $(\pm 4, 0)$, $\left(\pm 2\sqrt{2}, \pm 2\sqrt{2}\right)$, and $\left(\pm 2\sqrt{2}, \mp 2\sqrt{2}\right)$. Similarly, for (1,2), she identified $\left(0, \pm\sqrt{5}\right)$, $\left(\pm\sqrt{5}, 0\right)$, $(\pm 1, \pm 2)$, and $(\pm 1, \mp 2)$. We interpret that Aspen was demonstrating a local perspective here because she was focusing on relationships between pairs of points – specifically, (0,4) and whichever new point she had generated. This approach helped her develop familiarity with the equivalence relation and paved the way for her to turn her attention to collections of related elements, which we detail in the next section.

Demonstrating Productive Use of a Global Perspective on the Equivalence Relation

After generating these points by demonstrating what we interpreted as a local perspective, Aspen concluded that "it's not gonna be a ton of nice points," and then explained that she was "just gonna plot some points on this curve, see if I get anything that resembles a pattern." In her rough sketch, she used yellow to denote the points related to (0,4) and green to denote the points related to (1,2) – see Figure 1 (right). After she had sketched these points, she observed that "I think it's gonna be like a circle." When asked why, she explained:

> *Aspen*: I think this because I did 4 points on (0, 4) in the yellow one, um, and it happened to do that [referring to the four points on the yellow circle that intersect the axes]. […] This is $\left(2\sqrt{2}, 2\sqrt{2}\right)$, which also would work if it was $(-2\sqrt{2}, -2\sqrt{2})$. Same thing if one of them was negative more than the positive. […] If this, say, is my point that is $(2\sqrt{2}, \pm 2\sqrt{2})$, um, then I'll have the same exact point over here, over here, and over here, approximately [referring to the points of intersection of the circle and the lines $y = \pm x$]. […] So I think they're both gonna be circles.

Aspen's realization that the curves containing $(1,2)$ and $(0,4)$ were both circles was particularly propitious for her progress on this task, as she was then able to reason that the maximum distance between points related to (1,2) and points related to (0,4) could be quantified by reasoning about the radii of the two circles:

> *Aspen:* So really, if they're both circles, then the distance is gonna be the same at all the points. [...] I think *that* [referring to the length of the red line segment along the x-axis she drew from (-4, 0) to ($\sqrt{5}$, 0) - see Figure 2] would be the maximum distance. Because if I took any point on, say, the edge and took it to the opposite edge, that should give me [...] $2\sqrt{5}$ because that's the diameter of the [green] circle […], plus, uh, $4 - \sqrt{5}$.

In this way, Aspen (correctly) reasoned that the length of the red line segment could be computed by adding the length of the diameter of the green circle ($2\sqrt{5}$) to the difference between the lengths of the diameters of the two circles ($4 - \sqrt{5}$).

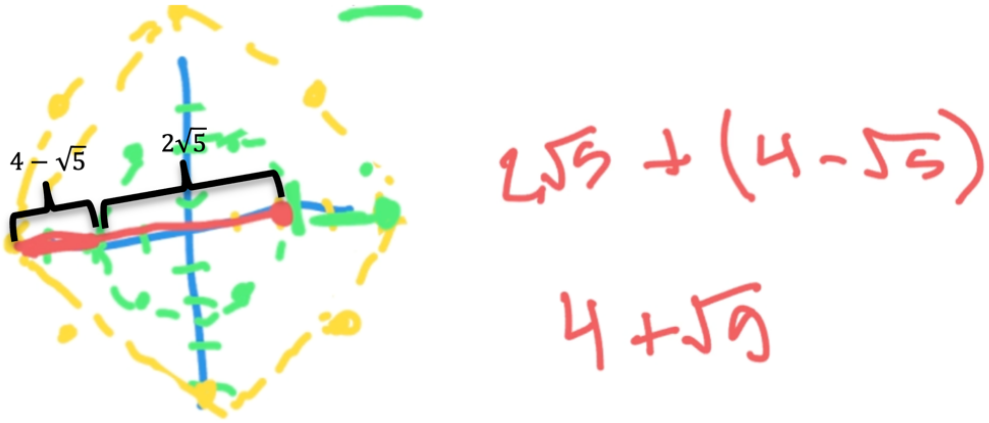

Figure 2. Aspen's red line segment, the length of which she reasoned was the desired maximum distance (we have labeled the two lengths she calculated), and her calculation of its total length.

In a subsequent interview session, the interviewer proposed two alternative line segments whose lengths, he suggested, might also represent the maximum distance (see Figure 3).

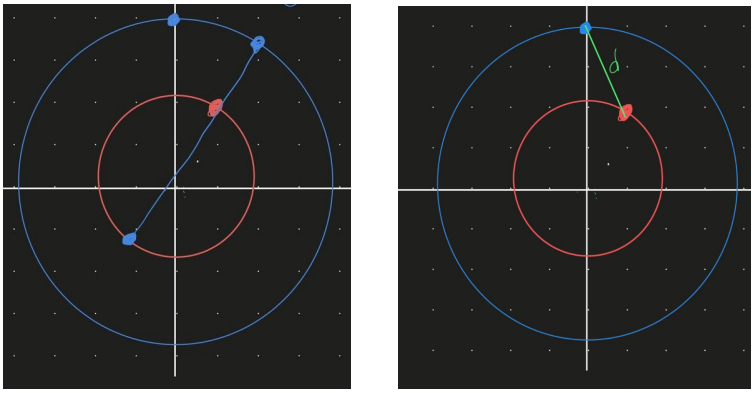

Figure 3. Interviewer's first (left) and second (right) alternative responses to the task.

After the interviewer prompted her to consider the image in Figure 3, left, Aspen responded that she also considered this a legitimate solution:

> *Aspen:* I would agree that this is the... It's the same concept that I have drawn here [referring to her own approach in Figure 2]. It's just using a different angle, but it's still gonna be the maximum distance. [...] The radius of the circle is always gonna be the same no matter where you're picking your point, so we are always gonna have this diameter of this circle in red, and then the difference between the, uh, [lengths of the diameters of the] blue circle and the red circle in this picture. [...] There are easier points to pick. I would say that this one is not the easiest point, um, but it doesn't matter which point you pick.

Aspen disagreed, however, that the second approach in Figure 3 was correct, arguing that the proposed length was not the maximum distance. She explained, however, how one could attain the maximum distance by 'moving' the red point along the red circle:

> *Aspen*: I would say that there can be a further distance. And, how I'd respond to that is say

your blue point on the blue [outer] circle is fixed. You can technically move this red point on the red [inner] circle as long as it stays on the red circle. [...] I can move this point anywhere on the circle […]. Is the distance getting bigger or smaller? And then, if it's getting bigger, then where's gonna be the biggest possible? And, hopefully, they would say that should be this point here [gesturing to $(0, \sqrt{5})$]. [...] You can't move in the between space.

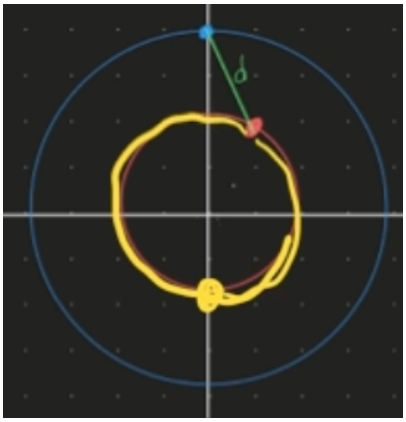

Figure 4. Aspen explains how to modify a proposed solution to attain the maximum distance.

We interpret that Aspen, after starting her response to this task by reasoning with a local perspective, had shifted to a global perspective because she began reasoning about collections of related elements. As evidence, consider that, after plotting specific instances of related points (that she had generated using a local perspective), she asserted that "they're both gonna be circles." Additionally, all of her subsequent comments about the maximum distance referred to these circles and specific distances between them (and not to specific pairs of related elements). Though Aspen identified specific locations on these circles (as in Figure 4), she did not specify coordinates for them, even arguing that "it doesn't matter which point you pick." This shift from local to global also involved a shift from algebraic reasoning (in which she used a 'guess and check' approach to identify pairs of values of x and y that would satisfy $x^2 + y^2 = 16$ or $x^2 + y^2 = 5$) to geometric reasoning (in which she plotted points in the Cartesian plane to observe graphical properties of the curves containing these points).

Discussion

In this report, we posed a question that has received very little direct attention in the literature: what does productive reasoning about equivalence relations entail? To answer it, we empirically examined and elaborated a theoretical hypothesis from the literature: that productive reasoning about equivalence relations entails attention to specific related elements as well as classes of related elements. We characterized the former as a *local perspective* and the latter as a *global perspective* on an equivalence relation and used these constructs to analyze the reasoning of an advanced mathematics student in task-based clinical interviews. We believe our analysis here supports and provides empirical substantiation for the literature-based hypothesis that, with regards to a local and a global perspective, "it is useful to be able to cross from one [perspective] to the other" (Schumacher, 1996, p. 46).

Use of both a local perspective and a global perspective supported Aspen's completion of these tasks in concrete ways. Using a local perspective, for example, enabled Aspen to develop

familiarity with the relation and generate a list of pairwise equivalent points via algebraic techniques. Generating these points was critical because it enabled her to identify the geometric patterns exhibited by the equivalence classes and thus facilitated the shift to a global perspective. Using a global perspective enabled Aspen to reason geometrically about the situation – specifically, she was able to use geometric properties of circles to efficiently identify that a way to compute the desired maximum distance without referencing any particular coordinates of points on those circles. This was a notable departure from her local approach, which centered on particular points and their coordinates.

Our primary contribution, therefore, is the description, analysis, and illustration of two perspectives that can support students in reasoning about equivalence relations. Through our conceptual analysis lens, in other words, we consider the local and global perspectives to "be propitious for students' mathematical learning" (Thompson, 2008, p. 60). This contribution addresses two gaps in the equivalence literature. First, while the equivalence literature is substantial, few studies have investigated students' reasoning with formal equivalence relations, and those that have are largely focused on the difficulties students encounter. This study contributes to the literature by provided theoretical descriptions of what students' *productive* reasoning could or should entail. Second, very little research had previously examined students' reasoning about equivalence from a global perspective, perhaps because all of K-14 mathematics approaches equivalence from a local perspective. This study therefore contributes to the literature by analyzing a student's use of a global perspective and how it supported her successful completion of a somewhat typical equivalence relations task; it also offers some insights into how a global perspective might be productively used in conjunction with a local perspective.

We acknowledge that our characterizations of a local perspective and global perspective – though useful classifications of students' reasoning – are very broad. They do not, for example, afford insight into *how* and *in what ways* students reason locally or globally. And while the literature does provide answers to such questions from a local perspective (e.g., Cook et al., 2022), much is still unknown about such specifics from a global perspective. We believe this is a fruitful avenue for future research. Our efforts here provide (at least) one promising suggestion in this respect: Aspen's use of the global perspective and her associated remark that "it doesn't matter which point you pick" aligns with researchers' suggestions in the literature that robust reasoning about equivalence relations and classes involves a certain indifference towards the specificity of elements in particular classes (e.g., Asghari, 2019). This could be a useful refinement of our characterization of a global perspective. Another limitation of this study is that we have only investigated the reasoning of advanced mathematics students who had already developed the capacities needed to reason productively with equivalence relations. How students might, for example, develop the capacity to employ and move flexibly between the local and global perspectives of equivalence relations remains unclear. Working with undergraduate students in similar problem contexts might provide insights into how productive reasoning about equivalence relations *develops* rather than only describing what it might entail.

Undergraduate Student Conceptions of Mathematical Syntax Meanings

Claire Wladis
City University of New York

City University of New York

Gellian D. Aly
City University of New York

This research investigates students' structure sense in algebra, focusing on how they conceptualize and interpret mathematical syntax. Here we focus on how students parse symbolic representations in algebra, in particular, how and why students recognize certain substrings to be unified subexpressions. We use prescriptive conceptions (desired mental images) to guide our noticing of students' descriptive conceptions (actual mental images) as they engage with conceptual algebra tasks from the Algebra Concept Inventory. The findings offer implications for instruction and curriculum, suggesting approaches that may better support students in developing a deeper understanding of algebraic structures and symbolic reasoning.

Keywords: Algebra concept inventory, student conceptions, syntactic structure, mathematical syntax, symbolic representations

Research in mathematics education shows that students often struggle with structure sense, or the ability to understand, recognize, and manipulate the underlying structure of algebraic expressions (Hoch, 2003; Linchevski & Livneh, 1999). Working with symbolic representations as objects (e.g., transforming expressions and equations), requires understanding of the structure of these objects. Existing research focuses on what students *do* with symbolic representations (e.g., Hoch & Dreyfus, 2006, 2010; Kirshner & Awtry, 2004; Vincent et al., 2017), but includes only limited analysis of *why* they perform specific manipulations, and what *conceptions* students have of syntactic structure in algebra. This research addresses this gap by investigating how students conceptualize the parsing and chunking of mathematical syntax.

Understanding specific student conceptions related to structure sense can help instructors develop effective teaching strategies (Hoch & Dreyfus, 2010), and address diverse learning needs (Tomlinson, 2001). It is also key to building curricula that enhance students' mathematical communication (Sfard, 2008), strengthen their foundation for advanced math (Taban & Cadorna, 2018), and improve problem-solving skills (Linchevski & Livneh, 1999).

We focus on two key aspects of mathematical syntax: (1) the extent to which students are able to conceptualize certain substrings of symbolic representations as unified objects (subexpressions), which relates to operational vs. structural views of syntax; and (2) which criteria they use to determine that structuring of symbolic representations, which relates to student definitions around syntax. More simply put, we are interested in *how* students parse symbolic representations, and *why* they parse them in the particular way that they do. Through student written work on algebra tasks and interviews with students in post-secondary math classes, we analyze their conceptions, particularly regarding how they parse or chunk mathematical syntax.

Literature Review

Existing research on structure sense has focused more on what students do with symbolic representations than on how they conceptualize them. Additionally, current literature is underspecified regarding the meaning of "structure" and which structures are most important. Our research seeks to clarify what structure sense is by framing it as a set of conceptions.

In this research we focus on one of the most basic components of structure sense: *syntactic meaning*, which we define as reading the intended grammatical meaning of symbolic representations. Syntactic meaning refers to the literal interpretation of symbols based on conventions (e.g., order of operations), without considering broader concept images or the ability to simplify or transform the expression. For instance, the syntactic meaning of $(2x + 1)(x - 7)$ refers to two subexpressions being multiplied, but it does not include concept images like multiplication or real-world meanings of x.

Research shows that students often assign syntactic meaning based on surface features, like spacing (Erlwanger, 1973), which Kirchner (1989) calls "visual salience," rather than on mathematically-salient features. For example, students may give precedence to operations that are visually closer together (Landy & Goldstone, 2007) or interpret spacing and grouping based on familiar visual cues from previous experiences (Nathan & Koedinger, 2000). Visual salience can overshadow mathematical salience, leading students to group elements visually rather than apply mathematical properties. Helping students distinguish between visual and mathematical salience can guide curriculum development and instructional strategies to focus on meaningful relationships rather than superficial visual cues.

Well-defined definitions allow students to interpret algebraic expressions consistently, using mathematically-salient criteria, rather than relying on surface features (Edwards & Ward, 2004). For instance, a student may have an extracted definition of syntax, where they identify subexpressions based on what "looks right" (visual salience) rather than on mathematically salient features. A mathematically well-defined, stipulated definition would use the order of operations and other syntactic conventions to determine how the representation should be "chunked" into subexpressions.

Process-Object Theories and Subexpressions

Research shows that students often struggle to recognize substrings of symbolic expressions as unified objects. This ability is crucial for algebraic manipulation, such as applying the distributive property or identifying forms like $a^2 - b^2$ (Hoch & Dreyfus, 2004). This is related to how and whether students conceptualize representations as processes vs. objects. For example, students might interpret $2(x + 1)$ as a process of adding 1 to an unknown value and then multiplying by 2—an operational view (Sfard & Linchevski, 1994); or they may be able to treat it as an object representing the theoretical result of calculation without needing to perform the operations—this is classified as a structural view. Pseudo-structural views (Sfard & Linchevski, 1994a, 1994b) occur when students treat symbols as objects that have not been reified from processes.

We extend this theory to focus specifically on what we call *subexpressions*, or substrings of symbolic representations that can be treated as unified objects without altering the syntactic meaning of the representation. For example, in the expression $3x^2$, students may conceptualize $3x$ as a unified object (subexpression) because of visual salience (3 and x are close together) or extracted experiences from instruction ("the instructor always treated $3x$ like a single thing in class"), or they may conceptualize x^2 as a unified object (subexpression) because the order of operations prioritizes exponents over multiplication. The latter is the necessary interpretation to understand the normatively-intended syntactic meaning of the expression $3x^2$. In existing structure sense literature, treating substrings as objects is often combined with other skills (see e.g., Hoch & Dreyfus, 2006), yet understanding this ability as a distinct conception is important, which is why it is the focus of this work. Identifying subexpressions is a critical precursor to

almost all other structure sense skills because it is the first step to identifying the structure of expressions and equations, which is essential to transforming them.

Method

This research focuses on the following questions: What conceptions do tertiary students have of structure sense, symbolic representations, and mathematical syntax? Specifically, what conceptions do tertiary students have of parsing and chunking mathematical syntax?

To address these questions, we use data from a broader study generating an algebra concept inventory for post-secondary students (AUTHORS, 2024). In this study, we collected thousands of responses to multiple-choice items, including 138 cognitive interviews of student thinking while completing these items. It is these cognitive interviews that we focus on here, specifically analyzing items where students were asked to attend to syntactic structure.

Our research is grounded in prescriptive conceptions (conceptions that serve as the intended goals of instruction) of symbolic representations and mathematical syntax. We generate these conceptions using literature and conceptual analysis, providing criteria for how students should "read" syntactic meanings and view mathematical syntax as reifications of normative processes. These can be seen in Figure 1, where the rows and columns represent broader categories, and the two cells at middle and bottom right represent combinations of these broader categories.

	Well-Defined Syntax Conception: Syntactic meanings must be unambiguous—the same syntax can't dictate more than one possible operational precedence at once, and different members of the mathematics community can't choose different conventions and operational precedence for the same symbolic objects.	**(Normative) Operational Precedence Conception:** Syntactic meaning is dictated by the order of operations and other mathematical conventions/norms stipulated by the mathematics community (whether or not those calculations can be carried out directly).
Structured Syntax Conception (Object): Symbolic representations can themselves be thought of as objects that can be "chunked" into unified subexpressions (or other unified sub-objects).	***Do-first Conception (operational):*** *The operational precedence norms govern the order of arithmetic (and where possible algebraic) calculations (e.g., which operation should be "done first").*	***Subexpressions Conception (structural):*** *The operational precedence norms govern how algebraic symbolic representations are structured, or "chunked" into unified subexpressions. (This may be a reification of the "do-first" conception or might be learned separately and linked to operational precedence later.)*

Figure 1. Prescriptive Conceptions of Mathematical Syntax

These categorizations of student thinking offer a way to classify students' *in-the-moment* thinking, providing insights for improving instruction and curriculum.

We used the prescriptive conceptions from Figure 1 to guide our noticing of student work, but also allowed themes to emerge more organically by employing theoretical thematic analysis

(Braun & Clarke, 2006) to constructed rich, thematic descriptions of students' structure sense conceptions. Our analysis led to the framework given in Figure 2, where we see student conceptions as a cross between operational vs. structural views and the extent to which they use non-mathematically salient vs. well-defined mathematically-salient features to determine syntactic meanings.

<table>
<tr><td>Reading syntactic meaning of symbolic representations (mathematically-salience features of syntax)</td><td>Non-mathematically-salient features, without being able to link this reasoning to stipulated criteria</td><td>Stipulated, logically-consistent and well-defined, normative criteria</td></tr>

Conceptualizing syntax as a structure that contains sub-structures (e.g., an expression is made up of multiple [potentially overlapping] sub-expressions) (object view)</td><td colspan="2">pseudo-object view ⟷ object view</td></tr>
<tr><td>"I know that $2x$ is a unit because I have just developed an instinct of how this works."</td><td>"I know that $2x$ is unit because multiplication comes before addition in the order of operations. Because the 2 is being multiplied by the x, $2x$ has to be thought of as a unit that could then be added to the other terms."</td></tr>
</table>

Results and Discussion

Classifying student work was our first step towards understanding student thinking. We allowed students' conceptions to emerge through the research but a priori theories also guided our noticing of students' conceptions as we attended to the following: (1) what criteria students were using to "read" the syntactic meaning of symbolic representations, and (2) whether students were able to conceptualize the syntax as dictating a process or describing an object, including how they "chunk" symbolic representations that they conceptualize as objects. We now provide examples of student work in each category (pseudo-process, process, pseudo-object, and object conceptions of syntax).

Pseudo-process Conceptions

Consider the following item: In the expression $3x^2 - 2(x^2 + 1)$, which part is being subtracted, or taken away? One student who was enrolled in a math course with elementary algebra as a prerequisite originally chose $2x^2$. During their cognitive interview, the student expressed uncertainty about the choice, so the interviewer followed up and eventually, the student says, "Honestly, the answer in my mind is not in the options." When asked to explain what is in their mind, the student and interviewer have the following exchange (Excerpt 1):

Excerpt 1:

Interviewee: It should be this one, like I would reverse this one like x square- I don't know. So, x squared minus two minus x squared plus one. So, this has to be taken away [pointing to $x^2 - 1$].

Interviewer: So, okay, so you would be subtracting the x squared plus one, kind of like what's in the parentheses?

Interviewee: Right.

Interviewer: And why would you do that?

Interviewee: I don't know.

Interviewer: It's just a feeling you have about how it should be done?

Interviewee: Yeah, but why is the parentheses still, it's not subtraction... If I'm going to multiply this one 3x- Wait, I think I did it wrong. 3x squared this, this [draws lines connecting $3x^2$ and 2 to other terms in the expression].

Interviewer: So, now you're multiplying the 3x squared by both of the things in the parentheses and also the two times both of those things in the parentheses?

Interviewee: Yes, 3x squared, it's going to be 3x four, am I correct? And then plus 3x squared and then this to the other negative 2x squared negative two.

Interviewer: Okay, so then would you be subtracting this minus 2x squared minus two?

Interviewee: Yes.

Interviewer: Okay, I got it. So, you're multiplying first and then whatever you're getting as a solution that is what you think you should take away, but that answer is not there?

Interviewee: Correct.

This student has an operational rather than structural view because they appear to struggle with identifying what is being subtracted without simplifying the expression. The student attempts to "distribute" every term that is outside the parentheses, even though the $3x^2$ is not being multiplied, which may be an extracted procedure from instructional experiences with the distribute property (e.g., AUTHOR, 2023). Further, the student appears to view $3x^2 - 2$ and $x^2 + 1$ as separate expressions to operate on, and are inconsistent with, the operations they apply. The student's attention to simplification appears to get in the way of being able to identify what is being subtracted in the expression in its current form, which may require conceptualizing $x^2 + 1$ as a unified subexpression. This student seems to be capable of thinking structurally, but they do not have a concrete justification for interpreting the syntax of the existing expression in a particular way. Thus, they may view symbolic representations as instructions to simplify rather than as an existing syntactic structure in and of itself, representing a pseudo-process view.

Process Conceptions

A different student displayed a process view for the following item: Consider $2 \cdot x^3$ in its current form (don't rewrite it or do anything to it). Which part of $2 \cdot x^3$ is being multiplied by 2?

Students were provided two options: "Only x^3" or "Only x ". This student chooses the first option because, "It's just that three is only being multiplied, not anything else. So, since it's to the third, then it would be only being multiplied by to the third because it says it on the question. And plus, it says what's being multiplied by two and it's obviously to the third." After some back-and-forth with the interviewer in which the student does not provide further detail about *how* they came to their answer, the interviewer asks, "How does the order of operations help you understand what's being cubed in the expression?" The pair then has the following exchange (Except 2):

Excerpt 2:

Interviewee: Well, since I know that there's no parentheses only thing that I will say is that there's an exponent here. So, we should focus on that first. Then we could get to the multiplication part.

Interviewer: Okay, so you said you noticed that there's no parentheses. So, where would the parentheses be if there were parentheses?

Interviewee: Now if it was a parentheses it would be around the x and then it would cube that. And once you cube that it will become x cubed.

Interviewer: Okay, if the parentheses were around let's say the $2x$ the two and the x how would that change things if it does at all?

Interviewee: Well, actually it would change both of them to my opinion, it would change both of them. Because you have to cube the two and the x.

The student uses a well-stipulated definition of the order of operations in their justification by when they describe how the order of exponents in operational precedence impacts the meaning of the syntax. However, their justification points to an operational view because they talk about processes (e.g. "multiplication", "cube") rather than describing any substrings of the syntax in a way that suggests that they view them as subexpressions. Further, since the student relies on mathematical (justification through operations) rather than visual salience, we classify this as a process view.

Pseudo-object Conceptions

We now consider an example from a student responding to the following item: In the expression $-(4x)^3 + 7$, which part is being cubed (or raised to the third power)? The item provided the following choices: a. $-4x$, b. $4x$, and c. x . The interviewee explains their choice of $-4x$ (Except 3).

Except 3:

Interviewee: So essentially the minus, the negative sign in the beginning gets distributed into the $4x$ that is within the parentheses, which is why I chose minus four x, which would get cubed.

Interviewer: Okay, so you're saying that the negative gets cubed as well as the $4x$?

Interviewee: Yes.

Interviewer: And I notice also that you included the 4 and some of the other answers don't include a 4. Why did you include the 4?

Interviewee: Because the 4 is together in the parentheses with the x.

Interviewer: With the x, what do the parentheses mean here in this expression?

Interviewee: It's saying that this whole expression, $4x$ is being cubed, not just one specific number.

Interviewer: Does the order of operations help you to understand what's being cubed here?

Interviewee: That didn't come to mind when I was doing this.

This student refers to $-4x$ as a unified object ("whole expression"), suggesting a structural conceptualization. However, what they consider the subexpression is not consistent with the standard order of operations, and when asked directly, the student admits to not considering the order of operations when doing the task. It is also notable that the alternate procedure of distributing the negative sign before cubing may also be indicative of a pseudo-process view, and thus this student may be moving between a pseudo-object and pseudo-process view or may hold both conceptions simultaneously.

Object Conceptions

For our final conception, we consider a student looking at the following item: In the expression $(x-7)^3$, which part is being cubed (or raised to the third power)? This student chose $x-7$ (over the other provided options -7 or 7).

The student explains how the third power, being "outside of the parentheses on the right side" means the third power should apply to the subexpression in the parentheses. The interviewer follows up with the question, "Do you know what the order of operations is?", leading to the following exchange (Excerpt 4):

Excerpt 4:

Interviewee: Yes, parentheses, exponents, multiplication, division, addition, and subtraction.

Interviewer: So, does the order of operations help you tell what's being cubed in that expression?

Interviewee: Correct, it does. It shows that what's in parentheses is actually being cubed. So, I would again follow what's inside the parentheses if I cannot do that equation then I would work outside of the parentheses.

This exchange reiterates the student's view of the string inside the parentheses as being a unified subexpression as well as their normative definition of the order of operations. This structural interpretation of the expression coupled with the normative definition leads to the object conception classification.

Conclusion and Implications

In this research, we not only classified conceptions, but also found interesting and common patterns of holding multiple conceptions that may have important implications for instruction and curriculum. For example, many students had a process conception of syntax in the context of numerical expressions but a pseudo-object conception in the context of algebraic expression. This may happen, for example, when students experience algebra as a sequence of transformation algorithms, without clear, consistent and ongoing connections to algebra as generalized arithmetic. We also observed students who had both process and object conceptions together, and where the object conceptions appeared to be reifications of the process conceptions. This illustrates that at least some students are able to reify processes into more structural object views in normative ways—better understanding how that happens for these students could help us to improve instruction so that all students have access to these conceptions when working with algebraic symbolism.

Overall, student responses illustrated how they often relied on surface-level cues or procedural steps when interpreting mathematical expressions, rather than understanding how symbolic representations can be conceptualized as objects that have a particular structure that is dictated by straightforward rules and conventions like the order of operations. Instruction could help students recognize and rely on mathematical salience for interpreting symbolic structures rather than visual patterns by using activities that encourage students to articulate why expressions or equations "chunk" into subexpressions in particular ways, and how this is linked to operational precedence and other notational conventions.

Students often identify subexpressions for non-normative reasons, relying on surface-level cues, and their process conceptions, such as the application of the order of operations, influences their ability to develop object conceptions, such as understanding subexpressions as unified structures. Instructors could also assist students' transition from process- to object-oriented conceptions by explicitly connecting the two, for example by consistently engaging students in tasks that illustrate how algebraic expressions are generalized representations of arithmetic.

Why Are YOU in the RUME?

Tim Fukawa-Connelly
Temple University

Aaron Weinberg
Ithaca College

Megan Wawro
Virginia Tech

Estrella Johnson
Virginia Tech

In this study we explored the intended outcomes that participants in the SIGMAA on RUME conference had for their conference participation. We conducted in-person, semi-structured interviews at the 2024 RUME Conference and engaging in thematic analysis to arrive at three broad categories of intended outcomes. People intended to achieve specific career-oriented goals such as 'gaining a line on a CV' and research-oriented goals such as getting feedback on their work. Finally, participants expressed multiple personal outcomes driven by their sense of the RUME participants as a community that they enjoy being part of. In addition, we found aspects of the conference and community that both support and inhibited the participants in their pursuit of their intended outcomes. The analog to the perception of a strong community is that participants find it difficult to become part of the intellectual and social conversations.

Keywords: professional conferences, professional development, undergraduate mathematics education researchers

Disciplinary conferences are believed to be critical sites in the academic trajectory (Henderson, 2015), yet their roles and purposes for participants are under-researched. Generally, conferences are understood as sites of networking and as an opportunity to present work and learn new ideas (e.g., Fakunle et al., 2019; Henderson, 2015; Hill et al., 2018). There has been some research focused on people at specific career stages such as undergraduates (Hill et al., 2018) or doctoral students (Fakunle et al., 2019), or on attending specific conference types (Weber & Fukawa-Connelly, 2023). There is, however, relatively little exploration of the value of disciplinary conference attendance to the participants, how and why those values might be different for different participants, and the aspects of the conference that facilitate or inhibit the participant's ability to realize those values.

Researchers have studied the value of disciplinary conferences (Hill et al, 2018), the importance of conferences for the discipline (c.f., Carpay, 2001; Walford, 2011), and linguistic explorations of the content (e.g., Hood & Forey, 2005). Fakunle et al. (2019) surveyed and interviewed doctoral students in Schools and Colleges of Education at four institutions in the US, UK, and Australia to explore their motivations for attending academic conferences. They found that student's primary motivations were to network with other academics—with a focus on career advancement—develop ideas for new research, develop new research collaborations, explore employment opportunities, and get guidance on research tasks. The students also claimed to view conferences as learning opportunities including learning about a new field, learning who works in a field, and honing their abilities to describe their work. Kneale et al. (2016) explored what undergraduates attending STEM conferences believed they might learn from giving presentations or posters. They found that students' main learning goals related to presentation skills, such as confidence in public speaking, structuring the presentation, and writing. In addition, the students valued getting critical feedback to gain knowledge and advance their research progress.

In this study, we explore the reasons that people at various stages in their careers attend the RUME conference–what they value about attendance, how they believe they (might) benefit from attendance, and how those values have changed (if at all) throughout their careers. We also explore how and why they might realize or be inhibited from realizing their intended outcomes. The themes we examine expand on prior research by including senior researchers and focusing on a narrow research field to better explore the ideas of networking and conferences as sites for learning. Our research questions are: *What are the different reasons that RUME participants give for coming to the conference? What helps or inhibits their ability to achieve the desired goals?*

Theoretical Perspective

We draw on Lave and Wenger's (1991) construct of *legitimate peripheral participation*. Conferences are ephemeral sites of congregation, although peripatetic, with no fixed participants. Instead, different groups of people, some within the discipline and some 'interested outsiders,' briefly gather for academic and quasi-academic purposes. These purposes are influenced by social and academic issues; disciplinary and social norms; issues of power and prestige, and career stages; and types of ties to a particular community. We find the notion of *communities of practice* (Lave & Wenger, 1991) salient in conceptualizing the practice of attending conferences. From this perspective, communities include "old-timers," who embody the socio-cultural practices of the community, and newcomers, who begin participating in the practices of the community and, in so doing, begin to adopt its activities, identities, and artifacts.

A conference can be framed as a sociocultural space where various aspects support and require different types of social participation, without clearly articulated rules. Participants have varying levels of familiarity with each other, academic spaces, and the conference itself. They are also members of disparate departmental, institutional, and disciplinary communities and have different reasons for attending the conference. Thus, we draw on communities of practice and legitimate peripheral participation to conceptualize the continual process of becoming a more central participant in the RUME conference community. We explore attendees' ways of and goals for participating, as well as what aids or inhibits attendees' participation.

Positionality

All authors are former elected members of the board. Two authors have been plenary speakers. Three authors have mentored students and supported (and expected) their conference attendance. Thus, we are most likely understood to be central members of the community. Although we tried to convey to participants that we were conducting research, some told us ideas for improving the conference, indicating they believed us to have influence in the structure and organization of the conference.

Methods

We recruited in-person participants at the SIGMAA on RUME 2024 Conference through convenience sampling—typically by asking people walking through the lobby if they would talk with us. We recruited 22 participants who agreed to participate in audio-recorded interviews. Two interviews were with pairs of participants. We attempted to interview conference participants with a wide range of experience with the RUME conference, from first-time conference attendees to those who have attended for nearly two decades, and from relatively new graduate students to full professors.

We collected data using a semi-structured interview protocol. Participants were first asked to give a characterization of their career and research trajectory and to relate different reasons for

conference attendance at different times in their careers. Subsequent questions asked participants to describe their reasons for attending the conference, what initially motivated them to attend (for those who had attended multiple times), what benefits they derived from attending, and how those benefits might be derived. Finally, we asked them to contrast attendance at the SIGMAA on RUME conference with another conference to explore other possible reasons for conference attendance. Each interview was approximately 20 minutes in length.

We drew on thematic analysis (Braun & Clarke, 2006), using inductive analysis to identify latent themes and construct codes. We consulted the relevant literature, with its focus on networking and career development, to guide our identification of themes, aligned with the theoretical framing of legitimate peripheral participation. Both notions—career development and networking—are forms of participation in the academic space with networking having explicit expectations for social connection. Two authors read three transcripts initially to develop and refine initial codes. Then, all four authors met and coded three transcripts using the refined codebook. Code categories were further refined. Then pairs of authors recorded the initial three transcripts and coded all remaining transcripts. Any disagreement was resolved via conversation among all four authors.

Preliminary Results

We organize people's reasons for attending the conference into three broad categories; career outcomes, research outcomes, and personal outcomes. Most of the career outcomes such as "earning" lines for a CV, networking as a means of professional advancement, or satisfying a job expectation are well-represented in the literature. Consequently, this report focuses on the research and personal outcomes as they are less well represented in the literature.

Research Outcomes

In terms of research outcomes, we categorized participants' goals as either related to engaging in collaboration, attending research presentations, and presenting their own research. Participants described two different types of goals that they might achieve through conference attendance: developing new or sustaining ongoing collaborations, acquiring knowledge from attending presentations, and sharing their own research.

Collaborations. Several participants reported attending to engage collaboratively with colleagues on already-established research projects. Other participants described a goal of developing new collaborations. For example, Darrell (advanced graduate student) said:

> I can pick people's brains and find ways to network and collaborate with them in person that just helps. There's papers I've written just purely by running into people here. And just asking them, hey, I have this idea. What do you think about this? We just kind of spiral off.

Attending presentations. Within this category, participants identified two goals: gaining an overview of the field and learning new research topics or methods. For example, Barbara (graduate student, first time attendee), who trained as a mathematician and was engaged in the process of becoming a mathematics education researcher claimed:

> It's a super succinct way to get exposure to, you know, a lot of things that are super relevant to you, new ideas, and you don't have to go sit and read a bunch of papers, you're like, given these nice, succinct entryways into it. And we've been taking copious notes of things to go look up later.

At a smaller grain size, participants claimed that they might gain inspiration for new projects in terms of either new questions to pursue or new methods to use. For example, Joe (professor),

who had participated in the conference for over 10 years, claimed that "you hear ideas that then you think about and wrestle with and they produce new ideas for you to cool study," and Dave (mid-career associate professor who has been attending since graduate school) described a goal of learning new methods:

> I still will come to go to talks and think like, oh, wow, that's a really interesting method. Like, I didn't think about that. Yeah, right. Maybe I could employ something similar. So there is still the potential for refining my understanding of appropriate methods and theories and so on.

In each case, these are outcomes that the participants take away from the conference based on hearing talks and do not, on the face, require discussion with other participants.

Sharing research. Several participants described benefits that resulted from presenting their own research. For example, Jenny (early assistant professor who started coming to RUME as a graduate student) claimed:

> I had now built up this big network system, and I knew everybody and, and then it became more of asking richer questions about detailed questions about my research, or how to improve my research. It's, I think it's rare like here, I come to a conference and I can literally like talk to anybody in the room. And they'll just sit down with me and go over technical stuff about research or advice or, like that's common, especially with like, the bigger names.

We interpreted Jenny as saying that she was able to have conversations about her work and get specific and individualized feedback from established members of the community. Participants suggested that access to journal editors and NSF program officers for discussion about ideas and papers was particularly helpful.

Participants also described a sense of excitement about their ideas and the fact that they're doing work they think the field would find interesting. Darrell, who had attended four prior RUME conferences, described a sense of ownership of and pride in his work:

> This is the first semester that I'm gonna get to present my work. So I'm excited to actually be able to do that ... It's mine! I remember hours and hours with [my advisor] just like pounding, her pounding me on, like let's start thinking about things… And it's like, this is something that I thought of, everything that's there is something that I did, and it's my idea … I get to talk about what I like and people have to sit there and listen to me for thirty minutes, they have to they chose to be there.

Other participants described presenting their research to mark one's place within the research community. For example, Dave said:

> I think it's through the establishment of a novel research program, or focus that hopefully, it's communicated persuasively to the people who are interested in this community, I think that that can really help establish a kind of personal identity as a researcher.

Personal Outcomes

Participants highlighted three interrelated personal reasons for their conference attendance: they think of the conference as their intellectual home, they enjoy the community, it supports their mental health in important ways.

Intellectual home. Several participants described the RUME conference as their intellectual home. For example, Brooke (associate teaching professor, trained as a mathematician) stated:

> RUME is consistently the conference where I feel like I belong, because it's more I feel like I find more people who are mathematicians and math ed researchers here. I like that I can talk about advanced mathematics but also frame it theoretically in conversation about

> research. So I got just really excited about that there are a lot of people here that I have a lot of respect for as mathematicians who are also doing really good math ed research.

Similarly, Ralph (associate professor) described the conference as an academic home:

> It's my academic home. … I've always tried to straddle – well, since grad school - like trying to straddle like, Math Department life and education mindset kind of life and RUME is like a really good place to do that. I think we're all kind of—a lot of people, have experienced similar kinds of issues. And they're like—most of us, or a lot of us, are housed in math departments and a lot of us are math ed or schools of ed. But like, just like understanding that kind of balance of like, needing to always like having to kind of put in a little bit extra work to get the cred among your own peers in your in your department, stinks. And then you come here, and it's like, we all kind of like, have earned this. Like, we don't have to do that in this group as much, I don't think. So that's good.

In both cases, the participants highlighted the importance of balancing significant mathematics with quality research. Ralph went farther than Brooke and noted that he, like other participants, may not feel valued or appreciated in his home department, but found that his work is valued and appreciated within the RUME community.

Community. This notion of professional and intellectual home was coupled with claims about enjoying the community of scholars who gather for the conference. For example, Sam (professor, attending for 15 years) said:

> This conference is a delight for me. I love coming to it. I'm paying my own way this time. Like, I am just doing it because I want to be here so much. You know, I have I don't have a grant this year. And we have no travel money in our department. So yeah, that's how much I like, really, like I love the people here. There's a lot of friends that I have that I don't want to miss.

Similarly, Robert (associate professor, attending since graduate school) described the community and friends that make the conference enjoyable:

> I just enjoyed, like, the ultra-supportive and just good group of people that this conference generally brings about, there's something different about this particular conference compared to other education conferences or other even math conferences.

For both Sam and Robert, the conference community included numerous friends who they enjoy reconnecting with each year.

Mental health. Participants described coming to the conference for a variety of reasons that we described as mental health, which included being re-energized, "loving people as human beings," and being offered support for life challenges. For example, Kelly (associate professor, attending since graduate school) said, "I come here to fill my cup. And I'm never disappointed. And I want that to be the title of the paper."

Structures that support goal achievement

In addition to describing personal attributes that supported their goal achievement, such as being willing to "just go talk to people," participants described two aspects of the conference that helped them achieve their intended outcomes. First, participants mentioned the importance of conference size. For example, Sally (full professor, first RUME conference in 2009) said, "this conference matters because is small, it's intimate," and contrasted this with larger conferences (such as PME-NA or JMM) where it can be challenging to find talks of interest and to find people among the other participants. Second, participants mentioned structural elements of the conference that they believed made it easier to participate both intellectually and socially, often

claiming that social interactions would facilitate subsequent intellectual ones. For example, Irene (first attended RUME in 2016) said:

> What I really appreciate is the intentionality that the RUME—like the RUME conference has done to make it more welcoming to have spaces where it's more inclusive. I mean, having more non-drinking options is great. Having like the faith community this year, having the trans community this year.

Marge (started attending RUME in 2017 as a graduate student) highlighted some of these same elements, concluding " Like, it makes it clear that our community is diverse and welcoming of that diversity".

Darrell also noted the importance of the option for conference buddies because:

> For outsiders, it can be intimidating. But I like that idea of the big buddy system.to at least get hey you're alone. … Here's someone that would be willing to like chaperone you or lead you to people or things like that. I thought that was really cool.

Darrell claimed that the conference space could be intimidating to outsiders but that by offering people the opportunity to sign up for a buddy, it could help decrease barriers to participation.

Factors that Limit Participation

The participants identified two factors that inhibited their ability to achieve their conference goals: a perceived lack of intellectual or disciplinary capital and a perceived lack of social capital or difficulty 'breaking into' the conversations. Barbara described feeling that she lacked disciplinary knowledge and expertise, which could have inhibited her participation:

> I guess the big takeaway from my first RUME, which was the Boston one … two things I took away; first thing was like, "Oh, my God, I know nothing." And the second thing was like, but that's okay, this community will accept me and nurture me and I will eventually know more. Not everything, but I will learn I will start knowing more.

Brooke highlighted a similar challenge, framing this perceived lack of disciplinary capital in terms of impostor syndrome:

> The first time I came to RUME was in 2017. And I was a massive imposter. I spent a lot of time in my room because I'm, like, so nervous, and I didn't know how to speak the language. Now I'm a lot more comfortable with that. And I'm, I'm more aware, like I'm, I still have plenty of gaps in my, I'm not formally trained as a researcher. So I have plenty of gaps. We're more aware of that. But I'm also aware of what different skills I bring to the table by being here.

Both Barbara and Brooke were trained as mathematicians and transitioned to mathematics education research. With Barbara stating that "My PhD is in mathematics. And then as postdoc, I started my transition into room. And I'm a rumer 100% of the time" and Brooke explaining "sort of sidestepped from algebraic topology into math education in 2016. Now I'm starting to feel like I kind of know what I'm doing".

Multiple participants described difficulty "becoming part of the conversation." For example, Marianne (fifth year attending RUME) framed this challenge in terms of access:

> I guess certain people have more regular access to key players in the field…. And it's hard to know how to get it'd be nice to be able to sit down sometimes with key players and just talk a little bit like see, even if it's just like as friends just to like, not feel so intimidated. So that then that could lead to conversations

Anne (mid-career, started coming as a graduate student) also described the amount of time and effort it could take to begin engaging in conversations:

> Yeah, cause you're right. I don't just like walk up to people during those breaks…. So, like, because it's every year and you see the same people every year, like, there's someone I met, maybe two or three years ago that I barely spoke to, but then I see them again the next year, and we speak a little bit more. And I'll find them during a coffee break and be like, oh, yeah, remember, we met last year and we'll talk a little bit more and then so even if it's a long term, slow relationship.

We might understand the difficulty in breaking into conversation to be a consequence of the existence of a strong community with tight friend groups among the conference participants.

Discussion

We make two minor claims advancing the literature on professional conferences, share some speculative points, and make a call for additional research. First, the participants we interviewed provided intended outcomes from attending a professional conference that went beyond what we found in the literature. They described the excitement of presenting their own work and ways that they learned from participating in the conference—in particular, through discussions with individuals—that could help them improve their research beyond what they might learn by only attending talks. Second, participants described numerous personal outcomes from attending the conference related to the fact that they felt a real sense of both intellectual and personal connection with the conference community. In contrast, though, some participants cited feelings of deficiencies in both their intellectual and social capital, and, thus, difficulty in being part of the ongoing conversations at the conference. Multiple participants cited the existence of conference structures such as affinity groups and the "buddy system" that lowered barriers to participation and signaled that all are welcome. Finally, as a speculative point, we noticed that claims about career advancement or technical goals tended to be cited by participants who were further from the "center" of the community. Conversely, participants near the "center" cited community and friendship as significant aspects of the conference. We suggest that if one reason for attendance drops in importance, another factor must continue to motivate attendance.

There are some significant limitations to the study that necessitate further research. Our sampling methods (approaching people in the lobby during breaks and throughout the conference) resulted in potential selection bias. In particular, our participant recruitment pool did not include people who were in-person RUME conference attendees but were not in the lobby when we were recruiting participants, people who attended RUME virtually, or people who had attended RUME in the past but were not in attendance in 2024. Potential participants could have also been too busy to participate in an interview or may have not been interested in or willing to participate. Thus, we cannot make claims regarding the generalizability to all RUME attendees – past, present, in-person, or virtual – regarding their intended and realized outcomes for their personal RUME conference participation. Further, while we noted career stage and prior attendance at the conference in the results as a proxy for centrality in the community, research is needed to understand trends and nuance. For instance, do attendees in different career stages value the social or community aspects in different ways, how does attending virtually facilitate or hinder attendees in achieving their intended conference outcomes, and is it the case that people who longer attend had outcomes that were not being met?

As computation becomes increasingly central to mathematics education, instructors must balance competing forces when choosing which computational tools to use in their courses. This is compounded in probability and statistics where computation is widely used. Grounded in a social constructivist perspective, we believe that tools mediate our activities and that different tools play different mediational roles. As such, this study explores how different computational tools mediate undergraduate students' mathematical activity of argumentation. Using Toulmin's argument model, this research investigates how two classes in probability and statistics using different computational tools, R or Minitab, performed on a mirrored assignment. Through analysis of students' assignments, a difference emerged across the classes use of visuals. Our findings suggest Minitab promoted more deliberate consideration and use of visuals than R, leading to a difference in arguments produced by the students.

Keywords: Computation, Toulmin's Model of Argumentation, Statistics Education

The use of technology in undergraduate mathematics settings has routinely been emphasized over the last fifty years. This emphasis has been supported by technology expanding the set of possible activities for students and enhancement of their learning experiences (e.g., Chan et al., 2023). One such framing of technology is that of *computation*. Computation positions the use of specific kinds of technological tools as a means of mediating and augmenting problem solving.

DiSessa (2018) directly emphasized the impact computation can have on mathematics by drawing a parallel between computation and symbolic algebra. Since the invention of symbolic algebra, algebra has been integrated into society and has expanded the availability of complex mathematical understanding. Similarly, the promise and ubiquity of computational tools opens new opportunities for people to engage with and experience new mathematical understanding.

Indeed, many computational tools have been used in mathematics education to improve student understanding (Chan et al., 2023). In probability and statistics, in particular, there has been a consistent push for the use of computation to better augment and improve their learning experience, but also to prepare students for their future careers (Carver et al., 2016). Instructors are left to balance different considerations when choosing which tools to use in their courses. This work explores how different computational tools used in introductory courses influence students' mathematical activity.

Theoretical Framework

Our work is grounded in two theoretical frameworks: Vygotsky's social constructivism and diSessa's computational literacy. A central tenant of social constructivism is the claim that learning does not occur in isolation and, instead, happens in relation with others (Vygotsky, 1978). Beyond relations between other individuals, learning also occurs through relations between an individual and a culture, and a primary way this happens is with cultural artifacts or tools (e.g., a computer for the culture of American society). Significantly, all actions performed

with a tool are transformed through the mediation of the tool. The higher quality the tool, the more influence it will have on our actions. According to Vygotsky (1987), this is characteristically illustrated by language, the quintessential tool of human culture.

For this study, we are interested in the broad set of cultural tools that leverage technology for problem solving, which we refer to as computational tools. Computational literacy (CL) is a framework that grounds our argument that computational tools are a cultural tool.

Computational literacy draws parallels between the use of computation and other representational forms that had, and continue to have, lasting effects on society (e.g., written language, algebraic symbols; diSessa, 2000). Framed in this way, computation shapes society and, as such, is a cultural tool. Computation can be explored through the material, cognitive, and social pillars of a literacy. Specifically, material CL encompasses the mechanisms of using computation (e.g., writing syntax); cognitive CL includes the application of computation to solve problems (e.g., using computation to visualize and solve differential equations); and social CL involves communicating through and about computation (e.g., the presentation of visualizations).

In summary, tools mediate our actions, different tools mediate differently, and computational tools are an important cultural tool. As such, the use of computation across society, and within mathematics specifically, raises several important questions about how computational tools mediate activities. Our research question guiding this project is as follows: *How do different computation tools mediate undergraduate students' mathematical activity of argumentation?*

Literature Review

Several projects have framed their inquiry of what we refer to as computation, broadly, under the exploration of technology in mathematics education (e.g., Biehler, 1997). Additionally, many projects have explicitly probed computation in mathematics education through the lens of computational thinking (e.g., Chan et al., 2023). Across both bodies of literature, there has been supporting empirical evidence for the use of technology to solve problems in mathematics.

While there is evidence supporting the use of computation at the undergraduate level—and in probability and statistics, in particular—there have also been contrasting claims about what those tools should look like. One school of thought centers on the opportunity to give students experience with technology that better prepares them for their future careers (National Science and Technology Council, 2023; Nolan & Temple Lang, 2010). For example, Nolan and Temple Lang (2010) proposed the importance of preparing introductory statistics students for the ever-evolving landscape of technology available to practicing statisticians. For these authors, this suggested that the tools being used should be versatile and have features that promote general computational skills (e.g., troubleshooting). On the other hand, many computational tools have been specifically designed for their use in introductory settings (e.g., TinkerPlots). For example, Biehler (1997) documented the design and possible uses of a tool called Modelling in connection with Exploratory Data Analysis and Stochastic Simulation (MEDASS). The goal of MEDASS was to provide a learning environment that leveraged the affordances of technology (e.g., for data analysis) in an easy-to-use environment. Ultimately, easy-to-use and versatile can be conflicting features. As such, instructors must balance the different affordances when choosing a tool for their introductory undergraduate courses (Johnson and Berenson, 2019).

To date, several projects have probed the affordances of different computational tools from either the expert or student perspective. In Abbasnasab Sardareh et al. (2021), four tools were compared (SPSS, basic R, Jamovi, and R Commander) across their usability (e.g., the presence of a graphical user interface [GUI]), technical features (e.g., variety of visualizations), and software capabilities (e.g., ability to manipulate data). Through the authors' assessment of these

software, they concluded that tools with GUIs (e.g., SPSS) are important for introductory statistics, but acknowledged "[through] real software in [students'] introduction to statistics, they will be better positioned to use that software for real-world purposes later (p. 159)." In a similar study, Johnson and Berenson (2019) identified 11 criteria of computational tools that they had 13 faculty teaching introductory statistics use to rank a set of computational tools. JMP, a menu-driven statistical software, was the highest rated tool. These studies suggest that experts believe user-friendly tools like SPSS and JMP best serve their instructional goals for teaching statistics.

There have also been a handful of studies comparing students' uses of differing tools. Myint et al. (2020) compared students' uses and peer assessment of plots done in base R to those done using ggplot2, in R. Myint and colleagues reported that the users' of ggplot2 were more persistent and more likely to complete the assignments. Furthermore, through peer assessments, the plots produced in ggplot2 were perceived as clearer, containing more labels, and aesthetically pleasing. In another comparative study, Rode and Ringel (2019) measured students' anxiety and confidence about the use of R and SPSS outputs after they were exposed to either R or SPSS in their statistics course. Rode and Ringel reported no differences across the treatments in their pre/post-test changes in anxiety or confidence. Interestingly, both treatments evidenced reduced anxiety in using R *and* SPSS. These studies suggest that a difference can emerge in statistics courses that use different computational tools, but that is not always the case.

A question arises as to how differing tools influence specific mathematical activities (e.g., the activity of argumentation). As Wilensky (1995) demonstrated, computation can influence students' argumentation. As such, in this study, we narrow our exploration to the difference in students' argumentation mediated by different computational tools.

Methods

To compare how different computational tools mediated students' mathematical argumentation, a comparative design study was conducted. A homework assignment was designed to be completed by two classes in introductory probability and statistics at a university in the Northeastern United States. The assignment was co-designed by two of the instructors of record for the respective classes. As a separate part of their course design, the instructors had chosen computational tools that best served their instructional goals. In one class, students used Minitab (a menu-driven statistical software), and in the other, students used R (a programing language designed for statistical analysis) in Google Colab.

The primary goals of the assignments were for students to learn to use their respective tools, explore the gamma and Weibull distributions, and communicate their results. The focus of this report's analysis centers on the students' exploration of the parameters of the gamma distribution. In the gamma task, students generate random data sets and use histograms to visualize the gamma distribution. The goal of this task was for the students to manipulate the parameters, explore how they affect the distribution, and describe and justify their conclusions.

The assignments were designed to mirror each other, but differences in the tools required small variations in the assignments. Specifically, in the assignments the process of using the specific tool to generate data and visuals was described. In the Minitab assignment, the sequence of menus and windows was described. For Minitab, generating a random set of data fitting the gamma distribution begins with menu navigation (*Calc > Random Data…*). In the *Random Data* window, the user must enter a sample size in *Number of rows of data to generate* and a column name in *Store in column(s)*. Next, they must select the distribution they want the data to fit in the *Distribution* drop down menu (i.e., *Gamma*). Finally, they must enter values for the parameters

in *Shape parameter* and *Scale parameter*. Once they select *OK*, a column of random data fitting the specifications of their gamma distribution will be generated under the chosen column name.

For R (in Google Colab), the analogous process can be done in a code cell using the function *rgamma()*. Thus, the R assignment began with a text block describing the *rgamma()* function and a linked resource describing the different parameters of the function (e.g., *n* for sample, *scale* for the scale parameter, *rate* for the rate parameter). Then, in a code block, scaffolded code was provided that required manipulation. This scaffolded code began with the assignment of a sample size, *n*. Students were told this through a code comment to "assign a number of samples to take." In the next line of code, a variable name is provided, "random_gamma_data," which takes the *rgamma()* function with input of *n*, and the two inputs of *shape* and *rate*. Students were prompted to set values for the latter two inputs, again, through code comments.

After following these steps in both assignments, students will have a set of random data fitting a gamma distribution either stored as a vector called "random_gamma_data" in R or as a column with a given name in Minitab. Next, both assignments described the process of turning that data into a visual in the form of a histogram. For Minitab, this again entailed instructions for the sequence of menus and windows to navigate. For R, scaffolded code, linked resource on the *hist()* function, and in code comments were used to guide students. After these instructions for using each tool, the assignments provided the same instructions, questions, and prompts.

Data and Analysis

Two data sources were used in this project. First, all students' work on the assignments were collected. In total, 68 artifacts were collected across the two classes (35 from Minitab users and 33 from R users) In addition, artifact-based interviews (Brennan & Resnick, 2012) were conducted with two students from each class. During the interviews, students were given their artifacts and asked to describe their work, thought processes, and documentation.

Analysis focused on students' work on the gamma distribution task because it was characteristic of students work throughout the assignment. Using Toulmin's model of argumentation (Toulmin, 2003), we coded for claims, grounds, and warrants. Claims, or conclusions, were centered on the effect the two parameters of the gamma distribution have on the distribution. Grounds are the ideas/data supporting the claim, and warrants provide the link between grounds and claims. The use of visuals as grounds emerged from our data. As such, artifacts were coded for the number of graphs included. This was further categorized into either no visual, one visual, or multiple visuals included. Open coding was used for interview data.

Findings

The following section is broken into two subsections. To begin, we present interview data showing that Minitab and R users' interpreted the goal of the task in the same way and engaged in a similar exploration process on the assignment. Next, we show the emergent differences within students' artifacts. This centers on an exploration of students' argumentation structure.

Students Goals and Processes

During the interviews, students were asked what they thought the goal of the gamma distribution task was. Both Minitab and R users claimed the goal was to use their respective tools to explore the distribution and its parameters. For example, one Minitab user said, "the main point of this task was … take those [distributions] and play with them, see what the different parameters do." Similarly, the other Minitab user explained, "[the goal was] predicting, trying to make a pattern … If I increase this parameter, do I expect the range to increase?" For the R

users, one stated, “the main task was creating the gamma and Weibull distributions, changing the shape value and rate value, and seeing how those affect the distribution.” The other R user said, “[the goal of the task was] to do a deep dive on this distribution, and you come up with your own ideas about what it means.” Consistently, students identified exploration as the goal of this task.

Next, during the interviews, students were probed about their exploration process and their choice to include visuals in their assignment. Both sets of students created multiple visuals that they did not include in their artifacts, but only Minitab users evidenced a consideration of which to include. For example, an R user who did not include multiple visuals in their artifact, described their process as, “just changing my histogram function over and over. Trial and error.” This user continued, “I didn't really, while I was going through, think to copy each iteration I had done or anything. So instead of leaving a trail, I was just rerunning the code every time I made the change.” This R user generated multiple visuals but explicitly did not think to leave “a trail” of them. Similarly, the other R user said “So it never came across my mind to show other graphs. I just thought, just change a value at a time, but then moved on.” While this R user included multiple visuals in their artifact, they claimed to not think about which of their visuals to include in their artifact. On other hand, a Minitab user, who included multiple graphs described a curation process in choosing visuals to include. They claimed, “I considered doing seven or five [visuals]. An odd number just to show a balance of decreased and increased parameters… Then I chose the three that made the most sense and, to me, display the most drastic changes.” Across the interviews, all students engaged in a similar exploration process of generating multiple visuals. Uniquely, Minitab users thought about which visuals to include in their artifacts.

Differences in Artifacts

A difference also emerged in the students’ artifacts. 34 (or 97%) of Minitab users included multiple visuals in their artifacts versus just 16 (or 48%) of the R users. For the remaining R users, 15 included one visual and 2 included no visuals.

The importance of the inclusion of multiple visuals was in the students’ ability to use the visuals as grounds for their claims. In the next two sections, we provide characteristic examples of the kinds of arguments contained in students’ artifacts. Namely, a difference emerged in arguments from students' artifacts that contained multiple visuals and those that did not.

Arguments using multiple visuals. When multiple visuals were included, the visuals served as grounds for students’ claims. Warrants supporting these grounds came in two forms. The first kind of warrant was a description of what the visuals illustrated. For example, one Minitab user included three graphs as *grounds* for each claim they made about the parameters. For the shape parameter, this user selected three graphs (Figure 1) and produced a warrant in their artifact:

> “In the three graphs above I varied the shape parameter to see how it affected the random data. It can be concluded that the shape parameter has an effect on the skewness of the data, as the [shape] parameter is increased the data becomes less positively skewed.”

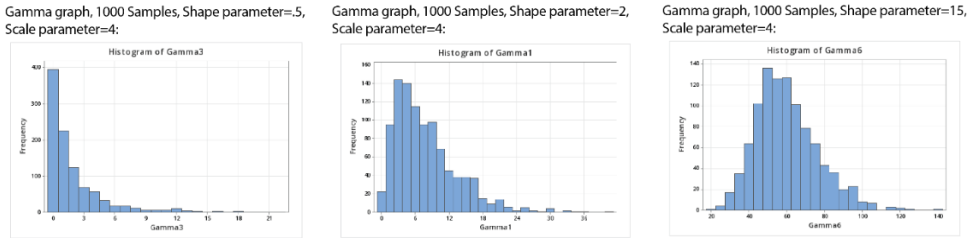

Figure 1. Three graphs generated by a Minitab user that served as grounds their claim.

This user made a *claim* that increasing the shape makes the skew "less positive." This was supported by the three graphs (Figure 1), thus the graphs served as the *grounds*. Additionally, this user provided a *warrant* connecting the graphs to their claim by connecting the visuals to the effect they were illustrating (i.e., increasing the shape parameter caused a change in skew).

Another way in which the grounds of multiple visuals were supported by warrants was through examples. In one R users' artifact, they produced multiple visuals, including two with a rate parameter of 100 (Figure 2). They wrote, "At a very high rate the points on the graph are extremely close together. For example, when using the sample size of 100 with a rate of 100, all the values became less than 1." This users' *claim* was about the relationship between large values for the rate parameter and the spread of the data. The *grounds* for this user came in the form of four different visuals (including two visuals generated by the code in Figure 2). Then, a *warrant* of a specific example was used to illustrate how the visuals (i.e., the grounds) support the claim.

```
gamma_data3 <- rgamma(100, shape = 1, rate = 100)
hist(gamma_data3, breaks = 20)

gamma_data4 <- rgamma(100, shape = 50, rate = 100)
hist(gamma_data4, breaks = 20)
```

Figure 2. Segment of code from an R user's artifact

Arguments without multiple visuals. When users did not include multiple visuals, their arguments lacked grounds for their claims. Many of these users included the last visual they produced and, as the R user from the interviews described it, "moved on." This resulted in claims that made no reference to their visuals. As such, the visual did not serve as grounds. For example, one R user included one visual in their artifact and made two claims with no grounds:

> "As the value for shape goes towards infinity, the shape of the curve appears more like a bell curve… The peak of this curve also becomes centered on the x-value of the shape. So if shape = 1000, the curve will be centered on x = 1000."

This users' first *claim*, about skew, was accurate, but they did not provide grounds because the visual they included was of a gamma distribution with a shape parameter of 1 (i.e., right skewed). Their second *claim* was that the curve is "centered" on the shape value. This student then produced an example. Ultimately, this student did not include a visual of this example. As such, the example was grounds for their claim, but the lack of a visual of this example meant their argument did not contain a warrant.

In addition to providing visuals as warrants for claims, the inclusion of multiple visuals could have served to clarify the claims of many R users. One R user wrote, "Increasing shape decreases maximum value of the distribution." One interpretation of this response is that the student *claims* shape and range are inversely related. Alternatively, this user's *claim* was related to the normalizing effect of increasing the shape parameter. In either case, the use of visuals as grounds for this claim would have supported *and* clarified their claim. Similarly, several students made claims about the skew moving away from a right skew, but what the skew was moving towards was vague. One user wrote, "The gamma data starts skewed right when the shape value is low, but as I increase it the graph starts to become skewed further left." In the same vein, another user wrote, "When I change the shape parameter k, the skew-ness of the graph changes. When I have $k < 1$, it is skewed to the right, and when $k > 1$, it begins skewing more to the left." If these students' claims are to be taken as written, then these R users are making a *claim* about a left-skewed gamma distribution. This is not possible for a gamma distribution because its skew is strictly positive (i.e., right). Through the process of producing grounds for their claims, these users may have made an important discovery or honed their claims, as well as their arguments.

Discussion

In exploring how students' argumentation was mediated by the computational tool they used, it emerged that Minitab users put more consideration into their use of visuals and used more visuals. We then showed how these visuals were used in arguments by students as grounds with warrants for their claims. When students did not have multiple visuals, their arguments contained only claims. The production of justifications for claims was an explicit goal of this task. Thus, the differences in R and Minitab users' arguments, consideration, and number of visuals included suggests the tools were mediating their mathematical activity of argumentation.

While possible, we do not believe that the assignment or students' interpretation of the assignment played a mediating role. As described in the methodology, the assignments were designed to mirror each other as closely as possible. Furthermore, through our interviews, we identified that both R and Minitab users had viewed the goal of the assignment in the same way. This suggests that the assignment was not mediating the emergent differences.

We conjecture that the difference in each tools' ease of manipulation could explain the differences in the students' artifacts. In R, students can easily modify a segment of code and immediately observe changes (e.g., the effect of increasing the shape parameter). In contrast, Minitab requires users to navigate a sequence of menus to make a similar change. As an R user described, they were "changing [their] histogram function over and over" to quickly explore the distribution. This evokes a dynamic process of students looking at a visual, changing a parameter in their code, running their new code, and watching as the graph changes. Ultimately, this process leaves no "trail," or grounds that could be used to support claims. In Minitab, on the other hand, the process is not quick, and users must navigate a series of menus and windows. To see the dynamic effect changing the syntax produced for the R users, the Minitab users had to have multiple visuals produced and change tabs to view them. As such, the Minitab users had multiple visuals simultaneously accessible, and were able to include them in their final artifacts. In fact, this led them to pick which of their graphs "display[ed] the most drastic change."

Furthermore, when users produced their artifacts, R users were working in an environment that they exported as their artifact (i.e., they submitted an exported Colab Jupyter notebook). This means they could quickly go from seeing a pattern, writing about it in a text block, and moving on with the assignment. The Minitab users, on the other hand, could not produce text blocks in Minitab. As such, they needed to move their visuals to another document along with their written claims and justifications. It is possible that this extra step for Minitab users necessitated deeper consideration and curation of visualizations being presented.

When considering what computational tool to use in introductory courses, instructors must balance the desire to use a tool that students can easily leverage, one that meaningfully impacts their mathematical activities, and a whole host of other considerations specific to a given context (Johnson and Berenson, 2019). Importantly, different computational tools can mediate students' mathematical activities in different ways. Our findings suggest that the methodical process of exploration in Minitab produced better argumentation, and R's dynamic visualization emphasized exploration over argumentation. While both are productive activities, instructors must weigh their own goals when choosing what tool best serves their students. One suggestion we have is, consider a balanced approach between multiple computational tools. Leveraging a beginner friendly tool like Minitab can ease students into the use of computation and can illicit stronger argumentation structures. Then, integrating more powerful tools like R, can give students the opportunity to explore, dynamically, concepts that are easy to visualize in R.

Tutors' Perceived Differences in Working With Students on Online and Written Homework

Isaiah DeHoyos
Oklahoma State University

Allison Dorko
Oklahoma State University

Mathematics tutoring centers are places where students learn math, but little work exists about learning from tutoring. Much of the research about tutoring is from an observer's perspective. We build on this work by presenting a study of tutors' experiences and actions when tutoring students with written and online homework, as described by tutors. We also suggest ways the Instructional Triangle could be adapted to account for the presence of a tutor as an agent in learning.

Keywords: tutoring, online homework, instructional triangle, written homework

Introduction and Background Literature

Undergraduate peer drop-in mathematics tutoring is generally defined as a collaborative educational support system in which experienced students assist their peers with course material with no specified time for a particular interaction (Burks & James, 2019; Johns, 2022; Johns & Burks, 2022; Johns et al., 2022; Mills et al., 2020). Previous research has indicated that the majority of higher education institutions in the United States provide some form of mathematics tutoring (Bressoud et al., 2015; Mills et al., 2020). Moreover, studies have shown that undergraduate peer mathematics tutoring may correlate with improved final grades, increases in students' mathematical confidence, and more ownership in the learning process (Byerly et al., 2018; Rickard & Mills, 2018).

Tutoring centers play a critical role in providing peer homework help, which is a crucial supplement to undergraduates' learning experience (Johns, 2022; Lepper & Woolverton, 2022; Topping, 1996). Undergraduate students are expected to dedicate significant time outside of the classroom to complete homework assignments and study (Dorko, 2020, 2021, 2024; Ellis et al., 2015; Krause & Putnam, 2016; Lew & Zazkis, 2019; White & Mesa, 2014). Instructors and students view homework as essential to learning (Dorko, 2019, 2021; Glass & Sue, 2008; White & Mesa, 2014). Hence, at the undergraduate level, students tend to have written and/or online mathematics homework (Kehoe, 2010; White & Mesa, 2014). However, there is a paucity of research comparing differences in online and written homework in terms of the activity of the people who might be involved in doing it – that is, students and tutors. Our study, which looks at tutors' experiences with tutoring online and written homework, contributes to a better understanding of learning from homework.

Although undergraduate mathematics peer tutoring is common, the research community is just beginning to focus on this out-of-the-classroom learning context. Some work has been done. For example, Johns and Burks (2022) discuss the general structure of a tutoring interaction as students seek assistance from a tutor, the tutor asks them what they need help with, students request help with broad content material or, more commonly, ask for assistance with a problem where they have hit a dead end or cannot find an error in their work. The tutor-tutee interaction concludes when the tutee has an answer accepted by the homework system or when the tutor and tutee agree upon an acceptable solution or summary of the problem. Johns et al. (2022) did a finer-grained analysis, looking at the observable actions tutors made during an interaction with a student. Their study identified 83 observable behaviors through the examination of 31 tutoring interaction transcripts. These behaviors were subsequently classified according to knowledge

type (i.e., Factual, Procedural, Conceptual, and Metacognitive) and further organized into specific categories (e.g., Supplied Facts, Immediately Reducing Cognitive Orientation, Heuristics, etc.).

The Johns et al. (2022) work was from an observer's perspective. Few studies have explored the knowledge and experiences afforded when carrying out the work of tutoring with different homework platforms (Johns et al., 2022). Our study, by interviewing tutors about their experiences and activities when tutoring written and online homework, aims to help fill that gap. That is, a key contribution of our work is adding to the knowledge of tutoring actions by documenting those actions from two tutors' voices.

A second contribution is the expansion of the Instructional Triangle theoretical framework (Cohen et al., 2003; Herbst & Chazan, 2012) to describe tutoring. This framework, which conceptualizes instruction as interactions between an instructor, students, and content, does not, in its current form, provide a useful way to look at tutoring. Hence, the paper focuses on the following three research questions:

1. What are some of the ways the Instructional Triangle can be adapted to account for the presence of a tutor?
2. What differences do undergraduate peer drop-in mathematics tutors experience while tutoring in the context of online homework as compared to the context of written homework when working with students?
3. What differences do undergraduate peer drop-in mathematics tutors describe in their tutoring actions when working with students in the context of online homework as compared to the context of written homework?

Introduction and Background Literature

We follow Cohen et al. (2003) in defining instruction as interactions between teachers, students, and content, situated in environments. Cohen et al. (2003) use the teacher, student, and content as vertices of the Instructional Triangle (IT). Edges of the triangle represent interactions between vertices, which need not occur face to face but are defined as encompassing the collaborative work of teachers and students. For example, an interaction may include a student engaging with a teacher-assigned written homework. Others have used the IT to study student learning in various environments, including student learning from homework (e.g., Dorko, 2020, 2021; Ellis et al., 2015).

Herbst and Chazan (2012) elaborated on the IT to frame studies of teachers' work. Their triangle, developed to focus on the teacher's perspective, does not account for the presence of a tutor in undergraduates' learning. In our study, tutors are humans who have face-to-face interactions with students around content. Tutors also have their own content knowledge and have historical and "present" interactions with instructors. As an example of the former, tutors may be tutoring for a class they previously took as a student and hence know something about the instructor's aims for a particular problem. As an example of the latter, professors may communicate with tutoring centers about homework to support more efficacious tutoring interactions. It is necessary to figure out where the tutor should be in the IT to employ the IT to study tutoring interactions. One possibility is as a resource, since the role of a tutor is that of a helper. We argue that because tutors are humans - like the student and teacher - positioning them as a resource is limited. Instead, we propose a theoretical modification to the IT framework that integrates a tetrahedral model with a tutor as one of the vertices (Figure 1). We developed this model on the hypotheses stated above: there are interactions between tutors and students, tutors and professors, and tutors and content. We propose that the incorporation of a tutor vertex within

the IT is imperative in fully elucidating the experiences and actions of undergraduate drop-in peer mathematics tutors during their interactions with students on both OHW and WHW. This model, shown in Figure 1, guided our data collection. In data analysis, we sought to verify and refine our hypothesized model.

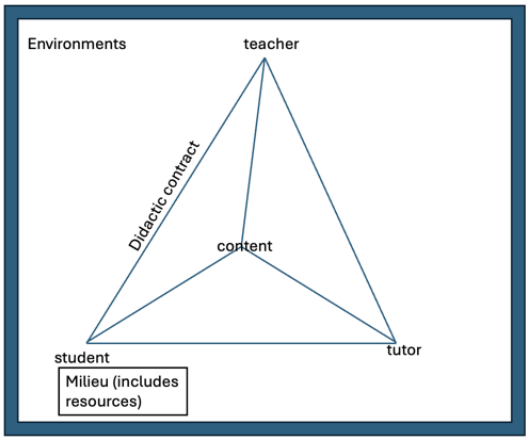

Figure 1. Our proposed modified IT with a tutor component resulting in a tetrahedral model.

Methods

The data comes from transcripts of 45-minute audio-recorded narrative interviews (Agee, 2009; Tracy, 2019) with two undergraduate drop-in peer tutors at a large public university in the United States in the spring of 2024. The first author selected two participants who worked at the university's mathematics tutoring center, possessed a minimum of two semesters of tutoring experience to ensure their familiarity with tutoring, and had experience working with students on OHW and WHW. Interview questions focused on having tutors describe their interactions with students when doing online homework and when doing written homework.

To analyze the data for RQ1, we aimed to verify and refine the six theoretical tenets we hypothesized (Figure 1; edges: tutor-student, tutor-professor, tutor-content; faces: tutor-student-content, tutor-student-teacher, tutor-teacher-content) and to identify theoretical tenets that are important but that we did not account for in our hypothesized model. We sought quotes that represented each of the six components (verify/refine our hypotheses) and instances that did not fit into those six components (identify new important parts of a model). This process allowed us to confirm, refine, and contest our expanded model. If we had at least one quote for a tenet, we kept it in the model. We had quotes supporting all six hypothesized components. With the quotes that did not fit in the model, we sought themes via grounded theory (Strauss & Corbin, 1998). That is, we looked for themes within the quotes. The emergent themes were the didactic contract and tutors' experience with the milieu. To analyze the data for RQ2 and RQ3, we used grounded theory to seek themes in tutors' experiences and actions.

In analyzing the data for RQ1, we read one transcript together, highlighted any statement that commented on an experience with a particular homework format, and then looked for themes in the statements. We then individually read the second transcript, coding it with the themes we had identified. We met to compare our coding of the second transcript, added to our list of themes, and then re-coded the first transcript together. This supported the validity of the analysis. The analysis for RQ2 and RQ3 was the same iterative, together/separate/together procedure. In the analysis for RQ1, the difference in coding was that we were looking for themes we hypothesized, with our minds open to themes we had not thought of.

RQ1 Results: Adapting the Instructional Triangle to Account for Tutoring

We found evidence of the three additional edges and three additional faces we hypothesized (Figure 1), as well as three emergent components. The emergent components were the didactic contract between the tutor and student, the didactic contract between tutor and instructor, and the tutor's knowledge of the milieu. Figure 2 shows the visual answer to RQ1; the verbal answer is that the IT can be adapted by adding a tutor vertex, the edges, and faces between the other vertices that represent the interactions with the other vertices/edges and make the model a tetrahedron; and by considering the didactic contract between the tutor and student, the didactic contract between tutor and instructor, and the tutor's knowledge of the milieu.

Due to space limitations, we provide evidence for only some of the edges and faces we hypothesized to be important, though the data contain evidence that all exist and are key components of an IT model that accounts for tutoring.

As an example of the tutor-content edge, tutors drew on their own content knowledge to make sense of questions in written homework. For example, Tutor 1 said, "written homework sometimes it's like okay, how should this be interpreted… I have to just say, 'I think this is how it should be interpreted'". We infer that the tutor drew on his knowledge of math to interpret the question. As an example of the tutor-content-instructor face, a tutor said online homework often followed class notes. We infer tutors looked at class notes to help students and see class notes as a way tutors and instructors interact because students tend to write what professors write (Lew et al., 2016). That is, the instructor communicates content to the tutors via class notes.

The first emergent component was that tutors felt there were expectations between the tutor and instructor, which we call a tutor-instructor didactic contract. For example, a tutor said tutoring interactions were "like trying to explain concepts, explain stuff, but you're not in a lecture situation… it's almost like you're trying to explain like the bare minimum to get this problem". Another tutor agreed, saying, "I catch myself… trying to explain this concept from scratch when that's not what I'm supposed to be doing… I'm not supposed to be replacing a professor." We infer the tutor expected the instructor to have explained the concept fully and the tutor expected to be able to fill in gaps or explain just enough for the student to connect back to what they had learned in lecture. These quotes are some of the evidence that tutors have expectations for instructors. They also support our hypothesized tutor-instructor edge because tutors thinking about the instructor represents a tutor-instructor interaction.

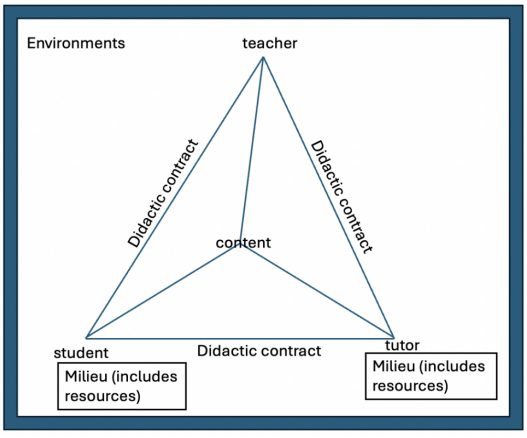

Figure 2. Our adapted tetrahedral model to include the three emergent components.

The second emergent component was a didactic contract between tutors and students. Tutor 1 said, for instance, his job "isn't to make sure the student gets homework right" but rather "learn with the student or like help, bare minimum, make sure the student is better off than when you sat down with them." This emphasizes the role of tutors as supporters of learning and growth, rather than just correctors of mistakes.

The third emergent component was the tutor's knowledge of the online homework platform (in this framework, a milieu). Tutors described how their experience with online homework affected their interactions with students. For example, Tutor 1 described, "the student is frustrated because they're like, I thought I did this right' and then I look at it and I'm like, oh, well, actually, I've seen this before, you have the right answer, there's a formatting thing that's wrong." This quote shows how the tutor knew online homework platforms often have precise expectations for answer format. A tutor also described how he felt written homework was "more detailed, it's more intricate… questions that require you to think about things in certain ways" whereas he felt the online homework was "practice, practice, practice." That is, tutors had different expectations and activities for the different milieu, which was reflected in their activity with students because of the ways they helped students navigate the two milieu. RQ2 and RQ3 lend insight into the nature of that navigation.

RQ2 Results: Differences in tutors' experiences working with students on OHW vs WH

The answer to RQ2 is the list of themes that describe the differences in tutors' experiences working with students on online homework as compared to written homework. These themes were the frequency with which they were asked questions about either, that students were more reliant on solution templates and online resources for OHW, that they thought more about the instructor while tutoring WH, that the expectations for correctness felt different, that students were more willing to write for WH, and that the differences between OHW and HW depended on course level.

Tutors differed in whether they said they answered more questions about written homework, or more questions about online homework. Tutor 2 said he fielded more written homework questions because those assignments were "usually created by the professor, so [students are] not going to Google and find that. [They] have to come in person". That is, he attributed the difference in number of questions asked to the availability of resources. In contrast, Tutor 1 answered more questions about online homework, which he thought was because students simply had more online homework tasks than written homework tasks.

Tutors said one difference in their experience with the two formats was that for lower division courses, HW and OHW were similar and tended to follow the notes, but upper division courses' WH differed from OHW because "[instructors] are able to get a lot more creative and force a lot more of like critical thinking into [it]" (Tutor 1).

Both tutors described a key part of their experience with OHW was working with students on template-based solutions, which was not the case with WH. Tutors detailed how, on OHW, students often defaulted to pattern-matching strategies from worked examples and were less inclined to engage deeply with the material. Tutor 2 said, "the most frustrating thing sometimes is the trying to pull them away from 'I saw [the solution] online, and they did it this one way'… it kind of like sucks them in… I try and be like 'yes, I understand that, but let's look at it like this'… in terms of like online versus written homework… the biggest struggle… it's just trying to get them in the realm where they're open to like different approaches to solving the problem." That is, the tutors felt students were attached to worked examples in OHW, and more open to problem-solving in WH.

Tutors described how they thought more about the instructor's goals and expectations with WH than they did with OHW. They often discerned the instructional design of the problems, in part because they often had taken a particular class with that professor. Tutor 2 commented, "different professors will look at things very differently" and that they knew professors often wanted "certain things shown in certain ways."

Part of tutors' experience with the two formats was helping students navigate their affect toward the two formats. Tutors described helping students work through frustrations with OHW platform constraints, something they did not have to do with WH. For instance, the tutors talked about students being frustrated with OHW wanting answers in particular formats, or students feeling demoralized by having limited attempts. Tutors also described students "enjoy [WH] less" than OHW because students felt WH sometimes had "confusing wording" or required more critical thinking. They also said students were more willing to write on paper on WH, while getting students to write anything down on an OHW task was challenging.

Tutors described one difference in formats was whether they knew their answers were correct, though Tutor 1 said he knew his job "isn't to make sure the student gets homework right. Your job is to learn with the student or like help, bare minimum, make sure that the student is better off than when you sat down with them… written homework… we don't get feedback on it." The tutor noted that OHW gave immediate feedback as to correctness.

Finally, tutors noted that a key difference in their experience between working with students on the two formats was students' willingness to write. Tutor 2 said, "in WH… you have to write it. It's not on a screen… it takes less effort for me to get them to be doing stuff… in WH… they are expecting to write. Online HW, it's on the computer… you do see students more willing to engage [with WH] because the more that they're writing, the more that they're thinking about it". In summary, the tutors found students were more willing to write and engage in work on WH than OHW.

RQ3 Results: Differences in tutoring actions for OHW and WH

To identify the differences in tutoring actions for OHW and written homework, we found themes in their actions for both milieu, then compared and contrasted the themes. We found in OWH, tutors worked with students to navigate using platform-provided similar examples; sought procedural and conceptual mistakes in students' work; had students explain problems; leveraged immediate feedback; directed students to resources; encouraged students to write down their work; and had students attend to particularities in the formatting of answers. We found in WH, tutors worked through problems themselves while modeling their process for students and directed students to use their course notes.

As an example, both tutors talked about how a key difference in their activity for OHW and WH was that in the former, they spent a lot of time helping students make sense of the worked solutions available in most OHW platforms (called "Help Me With This" (HMWT) in one platform) at the click of a button or directing students away from that resource. For instance, Tutor 2 tried to avoid HMWT. He said, "I always try to steer away from…usually I have them explain the problem, and then if [the students] have work, I'll start to go through that, and that's usually where I catch mistakes. Sometimes I'll catch the conceptual mistakes". Tutor 2 also describes here how when tutoring with OHW, one of his actions was to try to identify mistakes.

As another example, tutors leveraged electronic resources with OHW and directed students to those resources. For instance, Tutor 1 said he used the immediate feedback and multiple tries with online homework to try ideas, telling students, "I like the idea that you have, let's go through that, see if that answer's right". Tutor 2 said he used online resources a lot, describing

"online homework, it's easier to get them to approach a question graphically. 'Oh hey, can you open a tab of Desmos? Like that kind of stuff is a lot easier to show online than written".

As a final example of a difference tutors noticed in their activity with OHW versus written, tutors said they spent time encouraging students to write their work down in OHW. One said of WH, "this is on paper, you have to write it" and so students more naturally wrote steps in written homework, but had to be reminded the same could be useful for online homework.

Tutors described in written homework, some of their activity entailed thinking about how the professor wanted the students to approach the problem, and they often directed students to look at their class notes. Tutor 2 described that the WH were usually "tailored specifically to the notes".

In summary, the answer to RQ3 is that the key differences in tutoring actions between WH and OHW were related to the nature of the various milieu. In OHW, much of the tutors' activity was helping students to navigate the resources available online, while in WH, much of their activity was helping students to leverage their resources from class.

Discussion and Conclusions

We aimed to build the body of knowledge about tutoring by adding tutors' voices to complement literature about tutoring actions from an observer perspective. While Johns et al. (2022) conducted a fine-grained analysis of tutoring session transcripts by open coding, our study introduced the invaluable voices of the tutors themselves, thereby contributing new insights to the field. In akin with Johns et al. (2022), our research also identified specific instances where tutors employed specific actions to actively engage students and facilitate their understanding of mathematics.

We also aimed to build the body of knowledge about student learning from homework. We did this by comparing written and online homework from a tutoring perspective. We found many of the differences in tutors' actions and experiences were related to differences in milieu, in particular, students' reliance on worked solution templates in online homework. Our finding affirms those of Dorko et al. (2023) and Dorko (2021, 2020) that such templates often play a key role in students' online homework completion.

A key area for future work is to describe the specific content students learn from tutoring interactions, and how tutors contribute to that learning. We hypothesize the adaptations to the IT that we have proposed are a possible frame for such work. Another area for future work is to continue to develop this adapted model of the IT, in particular, because our adaptations were based on interviews with only two tutors.

An Exploration of Differences Between Undergraduate Mathematics Students' Knowledge About Graduate School at R1 versus Liberal Arts Institutions

Edwin "Ted" Townsend
West Virginia University

Tim McEldowney
College of the Holy Cross

David Miller
West Virginia University

Lynnette Michaluk
West Virginia University

Jessica Deshler
West Virginia University

The Carnegie Classification sorts institutions by their different styles of education. Two prominent types of institutions are high research activity universities (R1) and liberal arts focused colleges (LA). Institutional characteristics may positively (e.g. Eide et al., 1998) or negatively (e.g. Astin, 1997) affect graduate school aspirations. We analyzed responses from a national undergraduate mathematics major sample using chi-squared and Mann-Whitney U tests to identify differences between students' knowledge about graduate school and its application process by these two types of institutions. Using this same sample, we used chi-squared tests to explore the differences between departmental (professors, advisors, and mentors) support by institution type. We interpret these results with the theories of social and cultural capital and offer suggestions for future research investigations.

Keywords: Graduate School Applications, Graduate School, Liberal Arts, R1, Social Capital

Introduction

Higher education institutions are diversified to accommodate different educational goals. Some universities and colleges focus on research activity, others focus on teaching and mentoring of smaller student bodies, and others prepare students for specific skills-based professions. Studies show that these institutional characteristics affect student outcomes including whether or not students attend graduate school (Adedokun et al., 2012; Astin, 1997; Blaney & Wofford, 2021; Bruthers & Matyas, 2020; Eide et al., 1998; Ethington & Smart, 1986; Faurot et al., 2013; Hanson et al., 2016; Hathaway et al., 2002; Hearn, 1987; Kot, 2014; Mu & Fosnacht, 2019; Ostrove et al., 2011; Willis et al., 2013; Zhang, 2005).

Institutions with a similar focus often have many characteristics in common. The categorical system used in classifying institutions is the Carnegie Classification of Higher Education Institutions or Carnegie Classification for short (Indiana University Center for Postsecondary Research, n.d.). The Carnegie Classification sorts universities into doctoral universities, master's colleges and universities, baccalaureate colleges, baccalaureate/associates colleges, associates colleges, and special focus institutions. Each category contains smaller subcategories and the two main categories we will focus on are doctoral universities with high research activity (R1 institutions) and baccalaureate colleges with a liberal arts focus (LA institutions). In the most recent classification from 2021, the baccalaureate colleges with a liberal arts focus were labelled as baccalaureate colleges with an arts and sciences focus. We maintain the LA (liberal arts) label since most of those institutions still self-identify with that label.

Literature Review

Devereux (2023) states that an institution's classification ranking has a direct linear relationship with its level of sponsored research and foundation funding with higher rankings associated with larger amounts of funding demonstrating a Matthew effect, in that institutions

with resources are more adept at securing more resources (Devereux, 2023). Thus, non R1 institutions experience limitations or barriers in growing their faculty and administrative resources leading to strain on existing faculty and staff to secure externally sponsored funding (Devereux, 2023). Grunig (1997) discusses similar findings with research and reputation arguing that institutions increase their research levels to supply satisfaction to their customers so that they can receive the resources (funding) needed to continue their mission (education). Thus, the higher the institutions' classification, the more resources they obtain, and thus their customers (students) perceive higher quality service (education).

Before examining the literature on undergraduate institution effects on students' graduate educational goals, it must be noted that Etmanski (2019) suggests that the "cooling out" hypothesis (students opting out of pursuing an advanced degree) does not play out within the Ph.D. program, but instead prior to the entrance into the program. Additionally, Astin (1997) reports that attending an R1 institution negatively affects graduate school aspirations. Thus, it is imperative for all undergraduate, but especially R1, institutions to not adopt cultural characteristics that discourage students from pursuing a Ph.D.

Some studies note that the quality of the undergraduate institution affects graduate school aspirations and attendance. Eide et al. (1998) and Zhang (2005) report that graduates from high quality or elite colleges were more likely to enroll in graduate programs and for that program to be at a R1 institution. These studies viewed attending R1 institutions for a Ph.D. positively since these institutions focus on providing Ph.D. students with necessary and higher quality research experiences due to their additional resources (Devereux, 2023; Grunig, 1997). With regards to undergraduate research experiences, participating in research experiences in general have been shown to have positive effects on graduate education (Adedokun et al., 2012; Bruthers & Matyas, 2020; Hathaway et al., 2002; Willis et al., 2013). Personal connections with professors through interactions or teaching also affects graduate school aspirations. Researchers have shown that good teaching practices (e.g. non-classroom interactions, frequency of interactions, teaching clarity and organization), mentorship by faculty on undergraduate research projects, integration within the social and academic systems of the institution, and supportive departmental climate have positive effects on persistence to graduate school (Ethington & Smart, 1986; Faurot et al., 2013; Hanson et al., 2016; Ostrove et al., 2011). Researchers have also shown that personal relationships with faculty have a strong positive effect on graduate school aspiration (Blaney & Wofford, 2021; Hearn, 1987). Thus, personal relationships with professors impact graduate school aspirations.

A different aspect of relationships with professors and departments is the quality of advising the students receive. Mu and Fosnacht (2019) found that students' interactions with advisors were crucial for learning outcomes and that the quality of their peers' interactions with advisors influences students' self-perceived gains, over and above their individual interactions. With regards to centralized advising, students with centralized advising reported a better perception of advising compared to faculty advising and achieved better grade point averages (GPAs) compared to students without any advising (Kennedy-Dudley, 2007; Kot, 2014). It must be noted that these studies have primarily occurred at R1 institutions where faculty members may not have enough time or be offered incentives to invest the necessary amount of time and resources to advise and mentor students well (Faurot et al., 2013; Kot, 2014). Thus, faculty advising at LA institutions might have similar effects since the professors are more likely to be offered the necessary incentives. Therefore, advising affects graduate school aspirations.

In this paper, we address the following research questions:

1. What are the differences between R1 and LA mathematics students' interest in attending graduate school? What are the differences between R1 and LA students with respect to their knowledge about graduate school and applying to graduate school in mathematics?
2. What are the differences between R1 and LA mathematics students with respect to the quality of their relationships with their mathematics departments? Do these relationships have an impact on the answers to the previous question?

Theoretical Framework

In this paper, we apply the theories of social and cultural capital (Bills, 2000, 2003; Bourdieu, 2018; Coleman, 1988). Coleman (1988) defines social capital by its function, as a "variety of different entities all sharing two elements in common: they all consist of some aspect of social structures and they facilitate actions of actors, whether persons or corporate actors, within the social structure" (p. S98). For this paper, we consider the potential for information abiding in social relations as social capital (Coleman, 1988). Specifically, Coleman (1988) describes "social capital relations that constitute a form of social capital that provides information that facilitates actions" (p. S104). In our case, we view the relationships that undergraduate students have within their departments (peers, advisors, staff, professors, and mentors) as this form of social capital with respect to applying to graduate school in mathematics. Another form of social capital inherent to relations within departments is access to letter writers. Possessing a strong enough social relation with a person (in our case, a mathematics professor) enables the action of asking for a letter of recommendation. In this paper, we focus on student social relationships with their advisors, professors, and mentors.

Bills (2000) defines cultural capital to be "the degree and ease of familiarity that one has with the dominant 'culture' of society" (p. 90).[1] For our purposes, since most graduate schools in mathematics are located at R1 institutions, we argue that R1 students have more cultural capital than LA students regarding graduate school aspirations. Indeed, R1 students are surrounded by graduate students and graduate faculty, and even more so, graduate students at R1 institutions teach undergraduate courses. So, undergraduate students might interact with graduate students as much as the faculty. Therefore, this observation leads to the fact that R1 students have more exposure and so more opportunities to learn about graduate school compared to their LA peers.

Methods

Instrument Development

The research team created a survey partly based on another used to investigate undergraduate physics majors' interest in graduate school and how important they believed different aspects of the application process were (Chari & Potvin, 2019).[2] Nineteen survey items were adapted from that instrument. Our survey also provided an opportunity for participants to express their lack of knowledge about different parts of the application process. The final survey had 57 items in four categories: (a) knowledge about different aspects of the application process, (b) barriers for applying, (c) interest in graduate school and what students want in programs they apply to, and

[1] The published manuscript does not contain this quote, but an earlier study cites the unpublished version containing it (Bills, 2000, 2003; Pascarella et al., 2004).
[2] The full survey is available at this link: https://researchrepository.wvu.edu/faculty_publications/3291/

(d) demographic items. Most were Likert scale or multiple choice, but four were open-ended and some multiple-choice items allowed participants to type in text responses.

Data Collection

The research team sent the survey to department chairs and undergraduate program directors at all undergraduate mathematics programs at U.S. colleges and universities with at least 1000 students total ($N = 985$). We asked programs to distribute the survey to all undergraduate mathematics majors. Emails were sent Fall 2022 through Spring 2023, via Qualtrics, and follow-up emails were later sent to increase response rate. The survey was also posted on social media, listservs, and in several professional mathematics organizations' newsletters.

Data Analysis

We received 1090 responses from students at 181 colleges and universities, with 519 complete responses. Note that students could miss part of a question and still have their response marked as complete. Thus, the *N*s for different items are not always the same. Statistical tests were run in IBM SPSS.

To address our research questions, we analyzed responses to six survey items. Four were multiple choice items. The first asked participants about their interest in graduate school in mathematics. Possible responses included not interested, interested in earning a masters degree only, interested in earning a masters then a doctorate, interested in attending a post baccalaureate program before a doctorate, interested in earning a doctorate without a masters or a post baccalaureate first, and not sure. The second asked participants to rate their familiarity with the following concepts about the GRE Mathematics Subject Test; response choices included never heard of the item or if they have heard of the item before. The list of sub-items included the subject tests are only available three times a year, the subject test is not available to take from home and you must travel to a testing center to take it, and the Mathematics Subject GRE costs $150 to take. The third asked participants if their advisor (the person who helped the participant sign up for their courses) was faculty in mathematics, faculty in another discipline, staff (not faculty), or other. Then, the fourth asked if their advisor would support them in applying to graduate school. Possible responses were Yes (but I have not asked), Yes (they either suggested it and/or are actively supporting me), No (I have not asked), and No (I have asked). Another item was binary asking if students had a mathematical mentor (someone who had not necessarily been formally assigned to the participant by their institution but gives them advice on how to advance their career in mathematics). The last two were Likert scale items: *To what extent are the following factors a potential barrier to your pursuit of graduate school?* and *To what extent do you…* (followed by a set of phrases). The first item was adapted from Chari and Potvin (2019) and had 17 sub-item topics rated on a scale of 1 (not at all a barrier) to 5 (very significant barrier). The second item had 11 sub-item topics rated on a scale of 1 (not at all) to 5 (very much so). Chi-squared tests of association were employed to analyze the multiple-choice items. For the Likert scale items, a one-way analysis of variance (ANOVA) was not employed because for three out of the four sub-items, the Homogeneity of Variance assumption was violated. Thus, for ease of comparison and consistency, Mann-Whitney U tests were performed using the R1/LA variables for all sub-items.

Results

Before we present our main results, a few small reports are in order. First, a chi-squared test of association found that there was no significant difference between R1 and LA participants in wanting to attend graduate school. Second, for all the χ^2 tests of associations applied to questions regarding knowledge of graduate school, only two questions were statistically significant and they covered knowledge about the GRE Mathematics Subject Test, specifically whether participants knew: (1) Subject Tests are only available three times a year in September, October, and April [$\chi^2(1, 211) = 4.279$ ($p = 0.039$, $V = .14$)]; (2) The subject test is not available to take from home and you must travel to a testing center to take it [χ^2 $(1, 211) = 4.244$ ($p = 0.039$, $V = .14$)]. For those questions, only participants who recorded that they knew about the GRE Mathematics Subject Test saw them. Thus, there was not a significant difference between the populations with knowing about the GRE Mathematics Subject Test, but there was a significant difference in specific knowledge about the test.

Table 1. Descriptive statistics for the question, "Who is your undergraduate advisor?" using the R1/LA variable.

Group	Type	Faculty in Mathematics	Faculty in Another Discipline	Staff (not faculty)
R1	Observed	115	31	70
	Expected	139.1	32.0	50.3
LA	Observed	98	18	7
	Expected	73.9	17.0	26.7

Table 2. Descriptive statistics for the question, "Do you think your undergraduate advisor would support you in applying to graduate school in mathematics?" using the R1/LA variable.

Group	Type	Yes (not asked)	Yes (suggested or actively supporting)	No (not asked/asked)
R1	Observed	144	39	41
	Expected	138.7	57.9	27.4
LA	Observed	74	52	2
	Expected	79.3	33.1	15.6

Table 3. Descriptive statistics for the question, "Do you have someone you consider a mathematical mentor?" using the R1/LA variable.

Group	Type	Yes	No
R1	Observed	119	123
	Expected	137.6	104.4
LA	Observed	92	37
	Expected	73.4	55.6

When analyzing between the populations about departmental support, we found that LA participants were more likely than R1 participants to have an advisor that is a faculty member in mathematics [χ^2 $(2, 339) = 38.384$ ($p < 0.001$, $V = .31$)] (Table 1), feel supported in applying to graduate school by their advisor [χ^2 $(4, 372) = 45.248$ ($p < 0.001$, $V = .35$)] (Table 2), and have a

math mentor [χ^2 (1, 371) = 16.823 ($p < 0.001$, $V = .21$)] (Table 3). All these results were statistically significant differences ($p < 0.05$). The first two have a medium effect size (r between 0.3 and 0.5) and the third one has a small effect size (r between 0.1 and 0.3).

Note that only 2 (< 2%) out of 128 LA participants reported not feeling supported by their undergraduate advisor in applying to graduate school compared to 41 (18%) out of 224 R1 participants. This perceived lower lack of support, mentorship, and connection in mathematics was also reflected in Tables 4 and 5, related to Mann-Whitney U results on four Likert scale items.

Table 4. Mann-Whitney U test results for selected items for the question, "To what extent are the following factors a potential barrier to your pursuit of graduate school?" using the R1/LA variable.

Item	Group	*N*	Mean	Mean Rank	*U*	*Z*	*p*	*r*
Obtaining letters of recommendation	R1	242	2.77	208.79	10335	-5.61	<.001	0.29
	LA	130	2.01	145.00				

Table 4 contains Mann-Whitney U test results for R1/LA groups for the 372 participants who responded to the selected sub-item. The output of a Mann-Whitney U test is a Z value on a normal distribution. The Z value in Table 4 indicated that the mean of the R1 group was higher than the LA group. The result shows that there was a significant difference ($p < 0.05$) between the R1/LA groups. The R1 participants were more likely to view obtaining letters of recommendation as a barrier to their pursuit of graduate school compared to the LA participants. This result has a small effect size (r between 0.1 and 0.3).

Table 5. Mann-Whitney U test results for selected items for the question, "To what extent do you…" using the R1/LA variable.

Item	Group	*N*	Mean	Mean Rank	*U*	*Z*	*p*	*r*
Have mentors who encourage you to study mathematics	R1	243	3.42	168.41	11278	-4.63	<.001	0.24
	LA	129	4.14	220.57				
Relate to your classmates in mathematics classes	R1	243	2.88	174.65	12794.5	-2.99	0.003	0.16
	LA	129	3.29	208.82				
Feel like you belong in mathematics classes	R1	243	3.42	176.27	13187	-2.60	0.009	0.13
	LA	129	3.78	205.78				

Table 5 contains Mann-Whitney U test results for R1/LA groups for 372 participants who responded to the selected sub-items. The Z value in Table 5 indicated that the means for the LA group was higher than the means of the R1 group. The results show that there were significant differences ($p < .05$) between the R1/LA groups. The LA participants were more likely to have mentors who encourage them to study mathematics, relate to their classmates in mathematics classes, and feel like they belonged in mathematics classes compared to their R1 peers. These results had small effect sizes (r's between 0.1 and 0.3).

Discussion

Results from this exploratory study revealed that there was no statistically significant difference between our R1 and LA participants about knowledge of graduate school and the graduate application process except for specific knowledge about the GRE Mathematics Subject Test. We find these results encouraging, suggesting that in general, relationships at both institutions provide students with similar information. This is important given all the additional opportunities and resources available to R1 institutions and students (Devereux, 2023; Faurot et al., 2013; Grunig 1997; Hathaway et al., 2002). We conclude that LA students are receiving the same resources from their institutions or outside of their institutions, e.g. research experiences (Adedokun et al., 2012; Bruthers & Matyas, 2020; Faurot et al., 2013; Hathaway et al., 2002; Willis et al., 2013). Further research needs to be done to figure out which relationships are giving these students their social capital. Further, we found no statistically significant differences in aspirations to attend graduate school between these two groups.

We believe the supportiveness of the LA departments is providing their students with their capital (see results from Tables 1 through 5). In congruence with the literature, it seems that their personal relationships with their professors, advisors, and mentors are leading them to want to aspire to graduate school (Blaney & Wofford, 2021; Hanson et al., 2016; Hearn, 1987; Mu & Fosnacht, 2019). In further congruence, it appears that the supportiveness of their departments is also contributing to them wanting to aspire to graduate school (Ostrove et al., 2011). However, we note that, based on Table 1, 32.4% of the R1 participants had an advisor who was staff and only about half (53.2%) of our R1 participants had an advisor who was mathematics faculty. Based on the literature, these results are not surprising (Kennedy-Dudley, 2007; Kot, 2014), but they show that a sizeable portion of our R1 participants perceive that they are missing out on a crucial component of support from their mathematics community compared to the LA participants. We see this lack of support in Table 2 where 18% of R1 participants either assumed their advisor would not support them or that their advisor refused to support them in applying to graduate school. This leads us to conclude that our R1 participants are not forming personal connections with their professors, advisors, and mentors, or, at least in the case of mentors, they do not have one (see Tables 3 - 5). Further research must be done to investigate why this phenomenon occurs. However, these students still acquire the same knowledge as the LA students but without utilizing the social capital within relationships with their professors, advisors, and mentors. Instead, we argued that they acquire it through their cultural capital. We also hypothesize that they wield social capital but through their relationships with their peers and within math clubs. Further research must be done to confirm this argument. In conclusion, the LA participants acquire through their social capital the same advantages that the R1 participants acquire through their social and cultural capital, but further research must be conducted to decipher where R1 participants are acquiring their knowledge.

Exploring the Concept Image and Concept Definition of Periodic Functions

Ishtesa Khan
Arizona State University

This paper presents the results of a study where a student's concept image and concept definition of periodic functions were explored. The findings suggest that a student thinks about periodic functions as visual repetition of patterns within a function's graph. He also analyzes output values, particularly at distinguishable points such as maxima, to determine whether a function is periodic. His concept image and concept definition include the idea that a function's period represents the length between any two points where the output values are the same and the pattern repeats throughout the domain.

Keywords: Periodic Function, Concept Image, Concept Definition

Introduction and Background

The periodic function is an important mathematical concept that plays a central role in understanding various topics in mathematics, physics, and engineering (Jia et al., 2011; Mays & Loverude, 2019). Some researchers have mentioned the concept of periodic functions through the lens of students' understanding of trigonometry and focused on periodicity as a property of trigonometric functions (Weber, 2005; Ortega, 2017; Brown & Rice, 2011). Dreyfus and Eisenberg (1980) noticed that although most students hold an intuitive understanding of the periodicity of a function, applying the properties of a periodic function in different contexts is often difficult for them. Although the literature on students' thinking of periodic functions is rare, I found a limited amount of work that discusses students' understanding of the concept of periodicity. The analysis of Buendía and Cordero's (2005) study revealed that predicting future movements based on the movements of the graph of a function is a characteristic that students may use to make meanings for the notion of periodicity. Shama (1998) investigated ways of understanding periodicity. The findings suggest that (1) the students consider periodicity a dynamic collection of elements (time dependency, motion, etc.), (2) the students think about periodic phenomena as a whole unified structure (the segment bounded between two points in one-dimensional space is considered to be a period as whole). Although both studies (Shama, 1998; Buendia & Cordero, 2005) primarily focused on students' perception of periodicity, they did not delve much into the role of periodicity in the concept of periodic function in mathematics. This study aims to contribute to the limited literature on the students' thinking of a periodic function.

Therefore, this paper's motivation is rooted in the fact that the mathematics and STEM education research community will benefit from learning the students' conceptual understanding of a periodic function. The results of this study provide opportunities for researchers to explore the role of a periodic function in various mathematical topics and use the ways of thinking to teach students. In this paper, I explore how an undergraduate engineering student describes his thinking of a periodic function while he works through a series of tasks.

Theoretical Perspective

The constructs *concept image* and *concept definition* were first introduced in a PME article (Vinner and Herschowitz, 1980). Then Tall & Vinner (1981) published the first journal article on these constructs and applied them in reference to limits and continuity. This research uses

concept image and *concept definition* to frame a student's thinking about periodic functions. These constructs provide researchers with viable ways to interpret the data and categorize students' mental pictures based on what they say, do, draw, point at, etc.

Tall & Vinner (1981) introduced the concept image as follows: "*We shall use the term concept image to describe the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes. It is built up over the years through experiences of all kinds, changing as the individual meets new stimuli and matures" (p. 151).* The concept definition was mentioned as follows: *"We shall regard the concept definition to be a form of words used to specify that concept. It may be learnt by an individual in a rote fashion or more meaningfully learnt and related to a greater or lesser degree to the concept as a whole. It may also be a personal reconstruction by the student of a definition. It is then the form of words that the student uses for his own explanation of his (evoked) concept image. Whether the concept definition is given to him or constructed by himself, he may vary it from time to time. In this way a personal concept definition can differ from a formal concept definition, the latter being a concept definition which is accepted by the mathematical community at large" (p. 152).*

We have adopted this framework to analyze our data. We use the construct *concept image* as a whole structure that includes evoked mental snapshots of the student we interviewed while he worked through a series of tasks about periodic functions. We also use the term *concept definition* to describe the evoked personal definition he developed from his intuition after exposure to the tasks we presented. We address the following research question in this study by adapting the concept image and concept definition as our theoretical background-
What concept image and concept definition of periodic functions may a student hold while he works through a series of tasks?

Methods

Data Collection

I conducted a semi-structured clinical interview (Clement, 2000) with one participant, Fred (pseudonym). He was enrolled in an engineering major at a large southwestern university. The only requirement to participate was to have completed at least the first level of the Calculus course. Thus, Fred was familiar with the concept of functions, and upon asking, he mentioned that he associates periodic functions with trigonometry. However, periodic function concepts were never discussed in his Calculus classes. Fred participated in two interviews (each about an hour long) over Zoom. The sessions were video recorded via Zoom. The interviewer shared a screen with Fred with the tasks for each session. Blank spaces between the questions allowed him to annotate or write to capture his ideas and diagrams. He worked on a total of 12 tasks during the interviews. The tasks involved some open-ended questions such as: Have you heard of the concept of 'periodic function?' If yes, can you please say about your conception of periodic function? Some tasks presented graphical and imaginary situations to the participant, and interview questions were designed to learn what thinking process students use and how they use it in specific given scenarios.

Data Analysis

For analysis, I utilized in-vivo coding (Saldaña, 2021). A researcher uses in-vivo coding when s/he focuses on the words from data as a first step to code. I first transcribed using Adobe Premier Pro and then manually corrected auto-transcription errors. I read through the data and

named codes based on words and phrases. I labeled the data into discrete parts based on the codes I created. Next, I compared similar events in the data and collated excerpts that were labeled with a particular code. Then, I drew connections between the codes with the goal of finding how the codes can be grouped into categories. These steps of analysis aimed to open new theoretical possibilities. I used the terms concept image and concept definition constructs to frame the thinking of periodic functions students inhibited during the interviews by thinking out loud, drawing, gestures, pointing out, etc.

Results

In this section, I highlight the various ideas of periodic functions in Fred's concept image and his choice of a personal concept definition that has evolved while he worked through Tasks 1-7.

Periodicity as Repeating a Pattern

Fred was never exposed to the formal definition of a periodic function. Tasks 1 and 2 explored the student's current conception of periodic functions, followed by an example. In response, Fred described periodic functions as repeatable functions. To elaborate on Fred's description of a 'repeatable function,' he used the example of the sine function-

> "So, I mean, like, there might be some function like probably $\sin(x)$. Right. So, it would go like it would be a periodic function starting from zero that would go on to one and then come down again and then come to zero again. Right. So, if that's a period, it would be the same. The same. How do I say this? The same pathway of that function would be repeated after the period itself, like the period of the function".

I note that Fred was imagining the graph of a sine function within the interval of 0 to 2π. He then imagined the same pattern of the graph being repeated onwards. Here, Fred was thinking about the unchanged pattern of the graph within an interval as the period of the function.

Focus on Output Values

Task 3 presented a graph of a function that represents a recurrence pattern but does not return the same output value for any period. Fred acknowledged that the pattern is repeating but also mentioned that the graph does not represent a periodic function. He noticed that although the pattern is similar, the function does not have the same output value for any period. To validate his reasoning, shown in Figure 1, Fred chose segments of patterns within the graph. First, he separated intervals where the pattern repeats, and then he chose half segments within those intervals. He chose imaginary points where he assigned half segments of the pattern within the first two intervals, and then he chose imaginary corresponding output values for the input values. Then, he drew horizontal and vertical lines to show how the output value of the function does not return for a period.

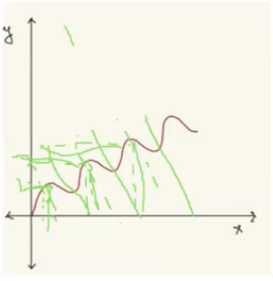

Figure 1. Fred's scratch work shows how the function does not return the same output values for any period.

Task 4 presented three apparent graphical examples of periodic functions, and one graph of a non-periodic function and the interviewer asked Fred to determine which of the following graphs represents periodic functions. This task aimed to determine whether a student demonstrates a consistent conception of periodic functions in relation to his/her previous responses and to learn what thinking process students use and how they use it to determine whether a function is periodic from graphs. Looking at the graphs, Fred quickly determined the three graphs representing periodic functions. The interviewer then asked him to explain his rationale for choosing each graph as a periodic or non-periodic function. Fred chose the word cycle to refer to one complete graph pattern within a period. To justify the first graph of the choices as a periodic function, his responses are as follows-

Fred: So suppose we are looking at this point x equals to something between -2π to $-\frac{3}{2\pi}$, okay? And if we take this one here (Fred points to another input value on the graph for which the output is the same as the point he initially chose) it would give the exact y value. It's the same y value for that point. That is why I would say this is a periodic function. And the cycle repeats itself. And it's exactly the same over here on the left side as on the right side. And it also, like the same interval, same time values. If you start from here, then after that, it would give you the same.

Interviewer: so, when you say, start from here, what do you mean? …

Fred: ….So, start over here, I mean, when the cycle starts here, (pointing to a value in the graph), we mentioned like…

Interviewer: -2π?

Fred: …Yeah. When the -2π starts and after a small interval…..probably like π over this (pointing to another point where the repetition occurs). If we consider this point, this would give the exact same y value as if we started here and took the same interval, like 0.2π. … It would give the same exact y value. So that's the reason I think it's periodic.

Interviewer: Okay…then like what is the period? How would you determine the period of this function?

Fred: Yeah. So, the same thing as I said before. So, whenever we have a function, and it starts, the cycle starts repeating itself, and we can see a trend. Right? So, that's how we divide it (he made segments of repetitive patterns in the graph). So, I can see that at x equals to 0, there, the cycle starts repeating itself again from here to here (pointing to the pattern within a period in). And it's the same exact function that starts from here again.

Figure 2 represents Fred's annotation in relation to the excerpt above.

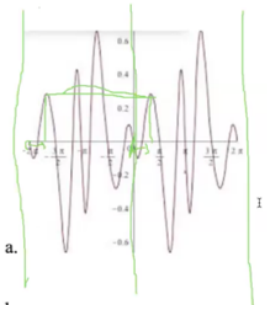

Figure 2. Fred shows repetitive patterns in the graph with the repetition of output values.

To determine whether a function is periodic, Fred initially identified a pattern of the graph that repeats, and he referred to the pattern within a period as a cycle. Then, in support of his

argument, Fred chose two points where the output values are the same for two different input values. He thinks about periodic functions as functions when the same pattern repeats after a period, and the output values repeat for different input values after each period. Figure 2 shows Fred's way of separating periods of a function and identifying the same output values for different input values as the pattern repeats. Fred drew a green horizontal line from one point to another to show an interval between two same output values. He also identified this length of the horizontal green line as the period of the function. Fred maintained similar reasoning to identify other periodic functions in task 4.

Fred's Concept Definition

Task 5 presented five statements that describe periodic functions. Fred used the ideas of repeating a pattern and finding the same output values while he comprehended those statements. I designed task 5 anticipating that students would use these statements to organize the cognitive structures they would have developed about periodic functions.

Task 6 asked Fred to reflect on the tasks he had worked through thus far and to define a periodic function. Initially, Fred mentioned that a periodic function is like a cycle that repeats itself, and for a specific interval after the cycle starts, it would give the same output value. He drew Figure 3 to elaborate on his definition of a periodic function.

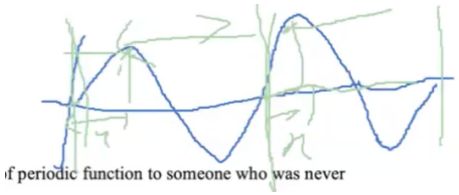

Figure 3. Fred shows a periodic function with two repeating cycles.

Here, Fred drew the graph of a function with two repeating patterns. He wrote two x's to show the starting points of each cycle. He also highlighted the length between two maximum points in the graph to show the period of the function. The interviewer asked Fred to pretend to explain the concept of periodic functions to someone who had never been exposed to it and how Fred could tell whether a function is periodic or not. Fred mentioned that he imagines a periodic function as a uniform repetition of patterns. In his words-

> "These two parts (referencing two repeating patterns in Figure 3) are uniform here. That's (uniformity) one of the criteria is that we can define it as a periodic function. And then again, we have the fact that a specific interval, for example, this (choosing $(0,0)$ point) is a starting point of this period for a specific interval. This length, (a length Fred chose named x in the graph) probably x, will give us the same y (output) values here from x (pointing at the starting point of the second repeating pattern). Here, it's going to be exactly same y values here. So, two things to keep in mind are uniformity and the cyclical nature of the function. And the other thing is that whenever we take a small interval after the periodic function starts, it would give us the same output on both intervals".

Fred summarized his concept definition again when the interviewer asked how he could tell whether a function is periodic. Fred defined periodic functions as functions that maintain a uniform repetition of patterns throughout the domain after certain intervals, and the functions have a cyclical nature. He also included the idea of the same output values in his definition, as he mentioned that for a function to be periodic, we can choose any length of intervals from the

starting points of each period, and the output values for the corresponding input values would remain the same. As we see in Figure 3, Fred noted two lengths of intervals named x's from the starting points of each segment of repeating patterns. Fred mentioned that the output values for the corresponding input values in both intervals would be the same.

The Distance Between *Turning* Points is the Period

Fred's primary criterion for determining a periodic function is to look for a pattern that repeats throughout the function's domain. However, to locate the period of the function from the graph, Fred relied on choosing a distance between two maximum points instead of choosing the distance between the starting and end points of one pattern that repeats itself. The interviewer asked his reasoning for choosing these points, and he replied that these are turning points in the graph. Fred used the term turning points to note the visually easier points (shown in Figure 3) so that he could measure the length in between without calculations.

In task 7, Fred encountered three imaginary periodic situations. The interviewer asked him to represent the context graphically and determine the function's period. The first context given was- *when the heart contracts, blood pressure in the arteries rises rapidly to a peak (systolic blood pressure) and then falls off quickly to a minimum (diastolic blood pressure). Blood pressure is a periodic function of time.* Fred chose some imaginary measurement of the blood pressure. The blood pressure would vary between 65 to 115 units of measurement, and at the initial moment, the blood pressure would be 90 units of measurement. A part of Fred's reasoning for graphing the situation and finding the period is mentioned here-

Fred: I am assuming that we're starting in the middle….90 blood pressure. I'm not sure about the unit…..so this goes up from there, the maximum which is 115. And it reaches a maximum of 115. It goes down again to the minimum. To 65. Then, when it hits the minimum, it starts going up again. And it hits 115 again. It starts coming down again, and the *cycle* keeps repeating itself. So, here we are considering that we're starting from the 90 and we're just stopping at 90 here as well. Let's assume that this is two seconds that it took for one *cycle* to be completed. So, two seconds would be the period for this function.

Interviewer: So, where does the *cycle* start, and where does it end? Tell me this, using the context.

Fred: So, for this case, …..we could just make it easier for us to say,….whenever we reached the maximum pressure in the heart, like blood pressure. The next time, we reached the maximum blood pressure again. We can say that it is one *cycle*.

Interviewer: Can you use a horizontal line to show me one *cycle*?

Fred: Yeah, this would be one cycle.

Interviewer: So, one maximum to another maximum?

Fred: Yeah.

Interviewer: Okay, so that's one cycle. And what is the period?

Fred: It would be the same. The period here is two seconds. That's what we assumed. Suppose this is 0.5, and here, it's 1, it's 1.5, this is 2, and this is 2.5. So, 2.5-0.5. That would give us 2.

I note that Fred used the words cycle and period interchangeably when he was thinking about the cycle length as the period of the function. To determine the period of the function from a graph, Fred relied on the easily distinguishable points on the graph. While working on task 6, Fred named his choice of maximum points (shown in Figure 3) as turning points when he was using a graph of a periodic function without context to determine the period of the function. His reasoning for choosing turning points to determine the period of the function was sustained in

task 7. However, this time, Fred was graphing a real-life situation, and he assigned numerical output values. Fred chose the distance between two maximum points of the function to determine the period. The contrast between tasks 6 and 7 is that in task 6, Fred chose a cycle from the starting to end point of a pattern that repeats, but in task 7, Fred mentioned the pattern between two maximum points as one cycle. When the interviewer asked Fred to determine the period of the function, he assigned numerical input values. He determined the distance between one maximum point and another as the period of the function.

Discussion

In this section, I summarize the important findings and discussion points based on the results. I highlight the key ideas of periodic functions in Fred's concept image and distinguish his personal concept definition of a periodic function from a formal definition.

Fred's concept image of periodic functions centers on the idea of a repeating, unchanged graph pattern. He refers to this as the same pathway of the function, emphasizing the consistent repetition of the graph's structure. To determine whether a function is periodic and to identify its period, Fred primarily focuses on the function's output values. He prefers choosing clearly distinguishable points on the graph, such as maximum points, as reference points. According to Fred, selecting these prominent points makes it easier to visualize the period of the function without needing to assign specific numerical values. Moreover, Fred's concept image includes a flexible understanding of the period as the distance between any two points where, for different input values, the output values return to the same value. He perceives the pattern between these two points as repeating consistently for subsequent intervals throughout the domain.

Dreyfus and Eisenberg (1980) formally defined a periodic function as $f(x)$ being periodic if there exists a positive number, p, such that $f(x+p) = f(x)$ for all x in the domain of f. In contrast, Fred's concept definition focuses on the idea of repeating patterns that remain consistent throughout the domain and the recurrence of the same output values after each period. Since Fred had not encountered the formal definition of periodic functions, it is reasonable that his concept definition did not include any mathematical notation. Instead, Fred relied on an evolving, descriptive understanding of a periodic function and how to recognize periodicity based on patterns without formal mathematical expressions.

Fred's understanding of periodic functions reveals an intuitive grasp of the concept, despite his lack of exposure to formal mathematical definitions. His focus on visual patterns and the repetition of output values allows him to construct a personal definition that aligns with certain aspects of the formal definition. By examining Fred's understanding of periodic functions, the study highlights how learners can meaningfully engage with mathematical concepts through visual and experiential reasoning, even in the absence of formal definitions. By understanding how individuals like Fred perceive mathematical concepts, educators can tailor their teaching strategies to help students connect intuitive understandings with formal mathematical language. Overall, Fred's case emphasizes the value of concept image and concept definition as a foundation for developing a deeper comprehension of mathematical ideas.

Linear Algebra Student Thinking of Magnitude, Unit Size, and Coordinates

Inyoung Lee
Utah Valley University

This study explores how linear algebra students reason with three entities: magnitude, unit size, and coordinates in change of coordinate systems during teaching experiments. Two conceptual frameworks are employed in this study. The first framework, the coordinate system framework, was developed prior to the study and is used to frame a larger study that includes clinical interviews and teaching experiments. The second framework, the entities framework, was developed from the results of clinical interviews and is used to analyze student work from the teaching experiments. Students interacted with a GeoGebra applet that creates coordinate planes using matrices. The results present how students establish relationships among the three entities while working with the applet and how they represent their reasoning through matrix entries.

Keywords: Linear Algebra, Change of Coordinate System, Framework, Entity

Introduction and Literature

Coordinate systems are widely used in undergraduate mathematics. Students work with various coordinate systems, such as the Cartesian and Polar coordinate systems, and may switch between them in their courses. In linear algebra, students also encounter non-traditional linear coordinate systems that are similar to the Cartesian coordinate system but scaled and/or rotated. To graph a mathematical expression in a coordinate plane, students start by identifying coordinate pairs and comparing the components of each pair (a, b) with the unit length imposed by the coordinate system in each direction. (Lee, 2023) Observing this process, the author recognized the three entities that students engage with: coordinates, unit size, and magnitude.

Numerous studies have explored how students conceive of the magnitude of an object and how they interpret measures with changing units. (Steffe & Olive, 2010; Thompson et al., 2014; Vergnaud, 1988; Wildi, 1991). Attending to relationships of quantities or coordinating quantities has been a decent way to promote students' flexible reasoning with multiple coordinate systems in precalculus and calculus context (Joshua, Musgrave, Hatfield, & Thompson, 2015; Levenberg, 2015; Lee, 2017, 2020; Moore, 2015; Moore & Thompson, 2015). In linear algebra, change of coordinate systems is primarily discussed in the context of change of basis. Hillel (2000) pointed out that students tend to think of coordinate systems as the coordinate axes rather than something generated by a pair of basis vectors. Some studies concerned with students' difficulties in understanding matrix representations (Hillel, 2000; Hillel & Sierpinska,1994; Sierpinska et al., 1999). Specifically, Hillel & Sierpinska (1994) claimed that it is particularly hard for students to distinguish between the matrix representation of a linear transformation operator and the transformation itself. Wawro et al. (2013) developed a task sequence that helps students reinvent the [1]matrix diagonalization $A = PDP^{-1}$ in the context of Re-Naming points in a non-traditional coordinate system which uses y=x and y=-3x as the new axes.

Building on prior studies' insights into student conceptualizations of quantities, numbers, operations, and matrix representations, this report highlights the three entities (magnitude, unit size, and coordinates) and examines how students reason with them in coordinate planes. Given

[1] P is an invertible matrix and D is a diagonal matrix.

the increasing importance of linear algebra in STEM education (Tucker, 1993; Stewart et al., 2022), this study focuses on linear algebra students' thinking when working with non-traditional *linear* systems and matrix representations.

Conceptual Framing

Naming, Locating, Re-Naming, and Re-Locating

The coordinate system framework was developed from the author's calculus and linear algebra textbook analysis (Lee, 2023). I found that the types of examples illustrated in the textbooks handle coordinate systems differently, and that readers become engaged with different ways of thinking accordingly. The framework starts with two fundamental processes of representations: Naming and Locating. In Naming, a location in space is being measured following the convention imposed by a coordinate system and creates the measurement, a name. For example, a location in the 2D plane gets its name as (1,1) with the Cartesian coordinate system. On the other hand, in Locating, an existing name creates its location in space following the convention imposed by a coordinate system. An example of Locating is that the ordered pair (1,1) puts on a specific point in the Cartesian coordinate plane. Figure 1(left) illustrates that Naming and Locating are the reverse processes to each other. The two processes can be extended to represent an object with multiple coordinate systems: Re-Naming and Re-Locating. In Re-Naming, a location that has been measured by a coordinate system gets its new name measured in a new coordinate system that is laid atop the location. That is, the location previously paired with (1,1) is being renamed with $(\sqrt{2}, \frac{\pi}{4}) \approx (1.414, 0.785)$ in the same space using the Polar coordinate system (Figure 1, middle). On the other hand, in Re-Locating, an existing name creates two different locations in space depending on coordinate systems being used. The new location may appear different from the first, but they share the same name. For example, (1,1) corresponds to two locations: one defined by a horizontal and vertical distance of 1 each, and the other determined by a distance of 1 from the origin and an angle measure of 1 radian from the horizontal axis. (Figure1, right)

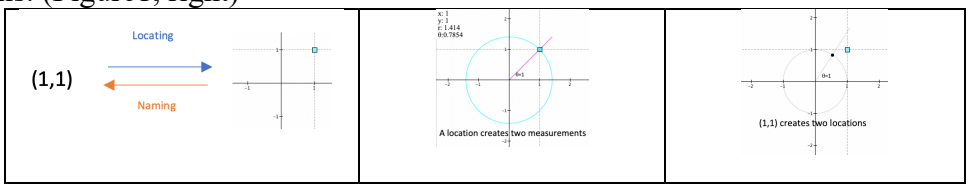

Figure 1. Naming and Locating (left), Re-Naming (middle), Re-Locating (right)

Three entities: Magnitude, Unit size, and Coordinates

The entities framework was developed from a part of a larger dissertation study (Lee, 2024). Through the process of Locating and Naming, I found that students engaged with three distinct entities in clinical interviews: magnitude, unit size, and coordinates. Magnitude refers to the size or extent of an object, characterized by its measurable attributes such as length, area, and volume. In Locating, students recognize the location of a coordinate as the distance of an object in each direction from the origin, which I specify as 'location magnitude'. Unit size refers to the measuring scale or dimension associated with each unit of measurement within a given coordinate system. When Locating, students compared a coordinate with a value 1 to determine the coordinate's location. In this case, unit size itself is a magnitude but is used as a measuring stick. Coordinates refer to number values assigned to the magnitude after measurement utilizing the corresponding unit size. The number value implies the amount of unit size. The three entities are conceptualized in a formula:

$$M(Magnitude) = U\ (Unit\ size) \cdot C\ (Coordinates).$$

The magnitude of an object is characterized by U (unit size), the measuring scale, and by C (coordinates), the amount measured. In Locating, the measured amount (C) is given, and then the location magnitude (M) is determined by multiplying the C by its measuring unit size (U). For example, in a clinical interview when locating an ordered pair (1.3, 0.5) on a plane, a student said " *the y* [0.5] *is the midpoint here* [points on the vertical axis]…*and…this is 1* [points to the unit in the horizontal axis], *then 1.3* [marks on the horizontal axis the right of 1]." The student needed the unit size of 1 to determine the magnitudes of 1.3 and 0.5 using multiplication either by scaling or through repeated addition. In Naming, the location magnitude (M) is fixed on the coordinate plane, and then its coordinate (C) is named by determining the amounts the measuring unit size (U) covers. For example, another student in the clinical interview rewrote the coordinate pair for a location $\begin{bmatrix}1.3\\2\end{bmatrix}$ as $1.3\begin{bmatrix}1\\0\end{bmatrix} + 2\begin{bmatrix}0\\1\end{bmatrix}$, breaking it down into components along the unit vectors consistent with the conceptualized formula. This formulaic idea extends to situations where the unit size changes to another size with multiple coordinate systems, leading to two scenarios emerged with switching from one coordinate system to another: 1. Under constant magnitude M: If U_2 (unit size for the second coordinate system) is k times U_1 (unit length for the first coordinate system), then C_2 (coordinate in the second coordinate system) will be $\frac{1}{k}$ times C_1 (coordinate in the first coordinate system). (Figure 2, left) 2. Under constant coordinates C: If U_2 (unit size for the second coordinate system) is k times U_1 (unit length for the first coordinate system), then M_2 (magnitude in the second coordinate system) will be k times M_1 (Magnitude in the first coordinate system). (Figure 2, right)

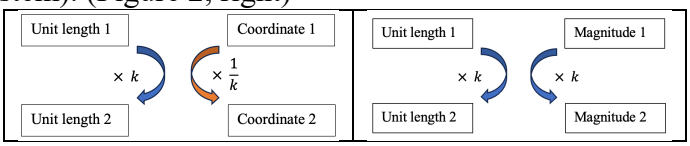

Figure 2. Re-Naming (left), Re-Locating (right)

This proposal reports on student reasoning with non-traditional linear coordinate systems in a teaching experiment to address the research question: How do students interact with various entities, such as magnitude, unit size, and coordinates when a coordinate system switches to another?

Methods

As part of a larger dissertation study, I conducted individual face-to-face teaching experiments with three students: Hann, Wilson, and Jeraldo. At the time of interviews, the participants were STEM majors who had completed Calculus 1 or 2 as prerequisites and had taken linear algebra at a large public university in the United States. Both their written work and interview conversations were recorded. The interview data were transcribed into spreadsheet and coded line by line, based on the author's entities framework. All the names used in Results are pseudonyms.

Description of the Applet (https://www.geogebra.org/classic/vz2mcxqr).

The teaching experiment utilized a GeoGebra applet created by the author. The applet was designed to engage students actively in creating a new coordinate system by modifying matrix entries. The applet features two panes: one on the left displaying the Cartesian plane in black, and one on the right showing the new coordinate plane in pink, generated by the matrix entries.

(Figure 3) Earlier part of the teaching experiments, the students interacted with the applet and learned how each entry in the matrix M (top left in Figure 3) influences the new coordinate plane on the right pane. They began to conceptualize the 2 × 2 matrix as a set of two column vectors, with each column vector representing a basis vector in the plane. For example, with $M = \begin{bmatrix} 6 & 1 \\ 2 & 2 \end{bmatrix}$, the students recognized it as $\{\begin{bmatrix} 6 \\ 2 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \end{bmatrix}\}$ generating a basis on the plane. (Figure 3, right pane)

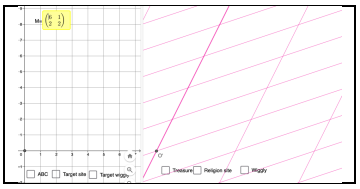

Figure 3. An example of the GeoGebra applet screen

Description of the Task

I designed the task protocols in three packets each called clinical interview, teaching experiment 1, and teaching experiment 2. This proposal includes Task 7 and Task 8 (Figure 4) in the teaching experiment 1 which aims to teach and learn matrix representations with a focus on individual entries. Previously, the students participated in the clinical interview tasks themed around Gulliver's Travels, where one of the main tasks was a treasure hunt, following the central idea of Realistic Mathematics Education (RME). During the clinical interviews, the students identified the location of the Treasure on Gulliver's coordinate system as (1.23, 2). In Tasks 1-6 of teaching experiment 1, the students engaged with matrix entry modifications using the GeoGebra applet and found that Gulliver's coordinate system can be generated using the two vectors $\begin{bmatrix} 6 \\ 2 \end{bmatrix}$ and $\begin{bmatrix} 1 \\ 2 \end{bmatrix}$. Thus, the matrix M for Gulliver's gridlines is $M = \begin{bmatrix} 6 & 1 \\ 2 & 2 \end{bmatrix}$. Task 7 (Figure 4) revisits the treasure and provides the students with a new coordinate pair (Josh's) for the same treasure, asking them to describe the new coordinate system. Task 8 then requires them to generate the coordinate gridlines using the 2 × 2 matrix. These tasks involve multi-step thinking commitments. Students determine what has changed (or not changed) in each component of the coordinate pairs, understand the implications of the change, identify the causes of the change, and modify the matrix entries accordingly to match the new coordinate pair.

Task 7: You just got a phone call from your friend, Josh, and he said that the treasure is at (1.23, 6) on his map, what does the Josh's map look like? (The treasure is at (1.23, 2) on the Gulliver map.)	Task 8: Find the entries of matrix M for Josh's map. In other words, the matrix M for Josh's map is $\begin{bmatrix} \square & \square \\ \square & \square \end{bmatrix}$.

Figure 4. Task 7 and Task 8 (From Teaching Experiment 1)

Result

As shown in Figure 4, each task has its own goal aimed at examining student reasoning related to entities and matrix representation. In this section, we will explore the different ways that linear algebra student reasons with the three entities (magnitude, unit size, and coordinates) as they modify the matrix entries.

Hann: Reciprocal Relationship between Coordinates and Unit Size

Hann: I'm noticing that our x coordinates are the same, which means that our horizontal unit vector is the same. Um, so Josh's unit vectors… it's going to be the same as Gulliver, which means that our horizontal is 6 2 [$\begin{bmatrix}6\\2\end{bmatrix}$].

Interviewer: Why is it the same as Gulliver's horizontal?

Hann: Because we have the same x coordinate as Gulliver does. so that means I think it means it has to be the same… so now I just need to find his vertical vector and I'm noticing that it [coordinate]'s just *three times* what ours [Gulliver] is. So, for his [Josh] vertical [unit] vector, it's just going to be *one third* of ours, so it's going to be one third and two thirds, one third.

Interviewer: Why does it have to be reciprocal?

Hann: The location of the treasure [on Josh's map] is at six vertical units, whereas for us [Gulliver] it's two, so the only way that that can be true is that each of his units are three times smaller.

Hann recognized a reciprocal relationship between coordinates and unit size: enlarging the coordinate implies reducing the unit size. When the coordinate increases threefold from Gulliver to Josh, the unit size decreases to one third. His reasoning for multiplication relationship between unit size and coordinate is depicted in a diagram. (Figure 5) Then, Hann modified the second vector in the Gulliver matrix M by multiplying by 1/3.

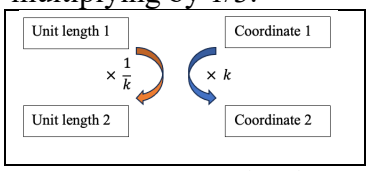

Figure 5. Hann: Reciprocity

Wilson: Proportional Thinking to Reciprocal Thinking with Coordinates and Unit Size

Wilson: His [Josh] vertical axis is three times what the value for I guess ours would be. This would probably look closer to 3 6 [$\begin{bmatrix}3\\6\end{bmatrix}$]… [after modifying the GeoGebra app] Oh, jeez.

I note that Wilson's visualization and verbal expression of Josh's vertical gridline was fine; However, when he tried representing the unit utilizing vectors, he modified from $\begin{bmatrix}1\\2\end{bmatrix}$ to $\begin{bmatrix}3\\6\end{bmatrix}$ to the GeoGebra applet. Then, he encountered a discrepancy between his expectations and what he observed in the app. It appeared that Wilson reasoned that the unit needed to be scaled by a factor of 3, as the coordinate changed three times from 2 to 6. Consequently, he modified the second column from $\begin{bmatrix}1\\2\end{bmatrix}$ to $\begin{bmatrix}3\\6\end{bmatrix}$, managing unit length and coordinate at a proportional manner (Figure 6, left).

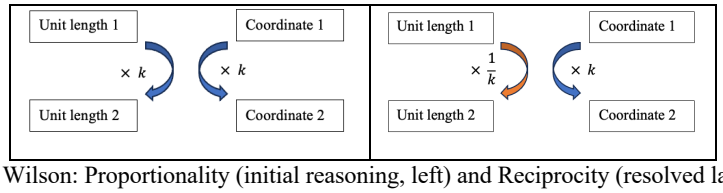

Figure 6. Wilson: Proportionality (initial reasoning, left) and Reciprocity (resolved later, right)

When Wilson discovered the discrepancy between his anticipated grid lines and the actual grid lines after modifying the entries of M on the applet, I followed up on him:

Interviewer: So, when you just hear the two coordinates, (1.23, 2) in Gulliver's while the treasure location is right here (1.23, 6) on [Josh] map, it has the same x value, right? The

second coordinate is six now. When you're picturing the grid line using these two coordinates for the same location, what kind of image you have in terms of the grid line?

Wilson: There [Josh's map] would be an extra … lines… [then modified the second column in the app to 12 6 [$\begin{bmatrix}12\\6\end{bmatrix}$].

Interviewer: Why did you make it to 12 and 6?

Wilson: So, with the horizontal point being the 1.23 being the same between both maps, that's where my thoughts are thinking. That first column isn't going to change. That second column is where the big change will be. I was initially thinking with the 6 and 3 and 12, that's something along those lines could change, could scale it in a way that it is on the six…So, I think the point I need to find is what would one that would scale it down or closer….[later] What I think needs to happen for is that it needs to keep the same slope, … but also needs to be scaled down. So maybe about one third Oh, so maybe one third, two thirds because it [coordinate] needs to be scaled two, three, four, five, six.

In this episode, Wilson initially attempted to modify the entries of the second column using larger numbers, such as $\begin{bmatrix}3\\6\end{bmatrix}$ then $\begin{bmatrix}12\\6\end{bmatrix}$. It seemed that he continued to reason proportionally between coordinates and unit size when Re-Naming the treasure location. Upon discovering its invalidity of this approach with the applet, he experimented with small numbers while maintaining the same ratio to ensure that the slope of grid remains constant. Eventually, he figured out that the entries should be 1/3 and 2/3. He realized that to scale the coordinate up from two to six, he needs to scale the unit size down by one third, discovering the reciprocal relationship in matrix representation.

Jeraldo: Reciprocal Relationship between Coordinates and Unit Size

Jeraldo: On the horizontal direction, it stays the same. They have the same exact, um, the same exact number in the first entry [column]. The only difference I would say is that it probably looks the same with the angles and everything like that. It's just a little bit smushed down. So, there would be more lines… I'm thinking of smashing this down by a factor of three, but it has to be the same exact line [same slant]. Because if I change the entries [not holding the same ratio], then that would change the vector. So, if we keep one, two [$\begin{bmatrix}1\\2\end{bmatrix}$], it looks like this [same slant], right? But if I change this entry [not holding the ratio, one two], it would be at a different angle and completely different.

Jeraldo employed reciprocal reasoning between two entities, unit size and coordinate, in Task 7. Given the Treasure coordinate pair (1.23, 2) and (1.23, 6) in the Gulliver coordinate system and in the Josh coordinate system, respectively, where the vertical coordinates are tripled from 2 to 6, Jeraldo focused on the ratio of the vector components. He emphasized that the ratio needs to remain the same for the Josh's unit vector to hold the same slant of grid lines. He divided the Gulliver's unit vector $\begin{bmatrix}1\\2\end{bmatrix}$ by the scaling factor 3 to make it smooshed down. (Figure 7, left)

[On the second day of teaching experiment when revisiting the same task]

Jeraldo: So if I can keep this same line and smush it down, then we would able to have this [coordinate of 2] to be equal at six. So, I imagine if we just scale this down by three…scale down every entry by three. So essentially, take the original unit vector [Gulliver unit vector $\begin{bmatrix}1\\2\end{bmatrix}$] and divide it by the same factor.

Interviewer: Not multiplying?

Jeraldo: I guess you could multiply it by the reciprocal of the scale factor, but in my mind it makes more sense. If he wants to switch from, then you're gonna divide it. But I'm not sure how I will find the scale or the scale factor, but I think this might be the closest I'll get from

Interviewer: Why did you pick the number 3?

Jeraldo: Just because 2 and 3 are factors of 6. I just assume since we already have 2 right there, we can use 3. (Figure 7, middle)

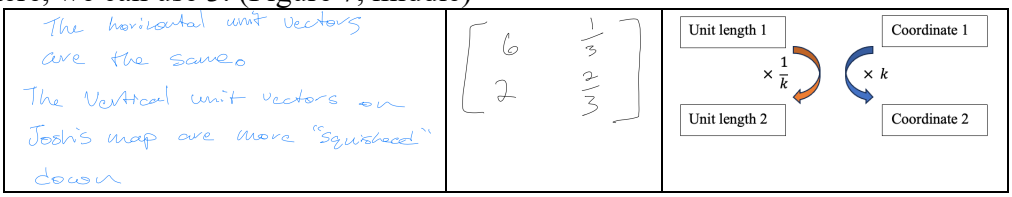

Figure 7. Jeraldo: Description for Josh's map (left), Matrix M entries (middle), Reciprocity (right)

Jeraldo recognized the reciprocal relationship: enlarging the coordinate implies reducing the unit length. His reasoning for multiplication between unit length and coordinate is depicted in a diagram (Figure 7, right).

Discussion

Reflecting on the entity framework, which initially began with the analysis of student work in clinical interviews, the formulaic idea, $M(Magnitude) = U(Unit\ size) \cdot C(Coordinates)$, extends to situations where the unit size changes to another size with multiple coordinate systems. This leads to two scenarios emerged with switching from one coordinate system to another (Figure 2).

First, under constant magnitude M: If U_2 (unit size for the second coordinate system) is k times as large as U_1 (unit length for the first coordinate system), then C_2 (coordinate in the second coordinate system) will be $\frac{1}{k}$ times C_1 (coordinate in the first coordinate system). Task 7 is designed to support students in thinking of coordinates in relation to unit size while keeping the location magnitude (the Treasure) constant across coordinate systems. According to my coordinate system framework (Lee, 2023), this task was developed under the Re-Naming perspective. As a coordinate system switches to another, the results show that students engaged with the three entities, establishing the reciprocal relationship between coordinates and unit size in Task 7.

Second, under constant coordinates C: If U_2 (unit size for the second coordinate system) is k times as large as U_1 (unit size for the first coordinate system), then M_2 (magnitude in the second coordinate system) will be k times M_1 (Magnitude in the first coordinate system). Even though Task 7 is better suited for the first scenario, where the location magnitude remains constant, students also demonstrated an understanding of the proportional relationship between unit size and magnitude. Specifically, when the unit size decreases to one third from Gulliver's unit to Josh's unit, the magnitude also decreases to one third (Figure 8), establishing a proportional relationship between unit size and magnitude: reducing the unit size leads to a reduction in magnitude.

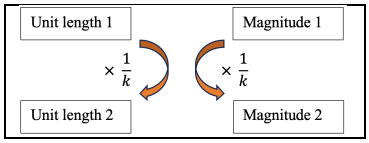

Figure 8. Proportionality between unit size and its magnitude

Navigating the Transition from University to School: A Case Study of Incorporating Reasoning and Proving in Secondary Mathematics Teaching

Orly Buchbinder
University of New Hampshire

Sophia Brisard
University of New Hampshire

University teacher preparation programs extend significant efforts to support the development of secondary teachers' competence in teaching mathematics. However, it remains an open question whether or to what extent beginning mathematics teachers enact ambitious practices in their teaching – specifically, engaging students with reasoning and proving. We report on one teacher, Nancy, who, after two years of autonomous teaching seized the opportunity to design and enact a "proof unit," by utilizing materials from her undergraduate studies. Using the framework of practical rationality and four professional obligations, we examine Nancy's discourse over various time points on her professional journey, focusing on how she held on to the ideas from her university training, culminating in the reasoning-and-proof unit. Implications for strengthening mathematics teacher preparation beyond university programs are discussed.

Keywords: Reasoning and proof, Internship, Beginning secondary teachers

University teacher preparation programs are pivotal in strengthening knowledge and shaping the pedagogical practices of future mathematics teachers (AMTE, 2017; Wasserman et al., 2023), including their competence to integrate reasoning and proving into their teaching (e.g., Conner et al., 2014; Buchbinder & McCrone, 2020). However, transitioning from university to classroom teaching poses significant challenges for beginning teachers, who must balance conflicting commitments to both the university and their mentor teacher during student teaching (Bieda et al., 2015; Thompson et al., 2013). Stylianides et al. (2013) describe specific challenges beginning teachers face when attempting to enact reasoning and proving activities in classrooms, like teachers' limited knowledge of students' proof conceptions and pre-existing school cultures. When entering their first teaching job, teachers may be overwhelmed by the increased responsibilities and competing dilemmas (Gainsburg et al., 2012), which they need to reconcile to support students' engagement with proof (Conner et al., 2014). Stylianides et al. (2017) alert to the limited number of studies that explore the development of proof-related practices of beginning teachers longitudinally. This study attempts to contribute to this research gap.

We use a case study of Nancy (a pseudonym) to investigate beginning mathematics teachers' proof practices. As part of a larger NSF-funded study, we followed Nancy for four years, from her participation in the undergraduate capstone course *Mathematical Reasoning and Proving for Secondary Teachers (*Buchbinder & McCrone, 2023), her year-long supervised internship, and first two years of autonomous practice. In her second year, Nancy seized the opportunity to design and implement a unit centered on reasoning and proving, drawing on ideas and materials from the capstone course and the professional learning community on reasoning and proving comprised of her former classmates. Nancy's case provides a unique window into the long-term effects of university training on teaching practices. We utilize Herbst and Chazan's (2003, 2011) framework of four professional obligations (described below) to explore the following research question: *How did Nancy navigate the university-to-school transition, balance various professional obligations, and apply reasoning and proving practices in her classroom?*

Theoretical Perspectives

Reasoning and Proving in Secondary Schools

The term *reasoning and proving* denotes a collection of disciplinary practices involved in creating and validating mathematical knowledge, like identifying patterns, conjecturing, explaining, justifying, and proving (Ellis et al., 2012; Reid & Knipping, 2010). We adopt a definition of proof as "a mathematical argument for or against a mathematical claim that is both mathematically sound and conceptually accessible to the members of the local community where the argument is offered" (Stylianides et al., 2017, p. 238). That is, both formal and informal mathematically valid arguments can be accepted as proof by a particular community.

While the main purpose of reasoning and proving in classrooms is to support student mathematical learning and understanding, research consistently shows that teachers find it challenging to establish such classroom environments (Stylianides et al., 2017). One of the challenges may be rooted in teachers' limited knowledge of proof or unproductive views of proof (Ko, 2010). In response, several university-based teacher preparation programs attempted to support future teachers' competencies to enact reasoning and proving in classrooms (e.g., Buchbinder & McCrone, 2020; Conner et al., 2014). Other researchers suggest that the barriers to the integration of reasoning and proving in classrooms are rooted in sociocultural factors inherent in the institutions of schooling (Chazan et al., 2016). Teachers need to navigate a complex system of often competing expectations by various stakeholders: students, parents, and administration. In such an environment, a teacher's desire to enact reasoning and proving is weighed against a "need to cover" the curriculum (Kotelawala, 2016).

Practical Rationality and Four Professional Obligations

The theory of *practical rationality* (Herbst & Chazan, 2003, 2011) suggests that becoming a mathematics teacher involves adopting a particular framework for making decisions about classroom teaching. This framework involves balancing four types of professional obligations. The obligation to the *discipline* of mathematics involves accurately representing mathematical concepts and engaging students in meaningful mathematical practices, such as reasoning and proving. The obligation to students as *individuals* involves attending to fairness and catering to each student's cognitive and emotional needs. *Interpersonal* obligation considers the class as a whole, requiring the teacher to manage social dynamics and intergroup relations to ensure fair sharing of resources. The *institutional* obligation requires the teacher to follow school, district, and state policies related to curriculum assessment and standards, and adhere to practices and guidelines shared by members of school mathematics departments. While obligations do not prescribe actions, they collectively influence how teachers navigate their professional roles, regardless of their personal beliefs or competencies (Chazan et al., 2016).

We draw on the theory of *practical rationality* and the four professional obligations to explore how Nancy navigated different spaces—her university-based teacher preparation program, supervised internship, and autonomous teaching —and how she balanced various obligations while developing her own teaching practices around reasoning and proving.

Method

Nancy was one of eight beginning secondary mathematics teachers whom we followed for four years as a part of the larger, NSF-funded longitudinal project, and for whom we compiled the most complete data set. Nancy had a strong mathematical background and expressed productive dispositions toward reasoning and proof, making for a rich case study (Yin, 2003).

Data Collection and Analysis

As a preservice secondary mathematics teacher (PST), Nancy took a specially-designed capstone course *Mathematical Reasoning and Proof for Secondary Teachers* (Buchbinder & McCrone, 2020, 2023). The course focused on four proof themes—topics considered in the literature particularly challenging to learn and teach: direct proof and argument evaluation, conditional statements, quantification and the role of examples in proving, and indirect reasoning. This course supported PSTs' developing proof-specific mathematical knowledge for teaching by providing opportunities to crystalize their knowledge of the four proof themes; connect it to students' conceptions of proof and apply this knowledge by designing and teaching in local schools four proof-integrated lessons. Of all the data sources, for this paper, we focused on analyzing Nancy's written reflections about teaching in the course.

An internship is a one-year, post-graduate, supervised teaching experience. Nancy was present full-time in the classroom of her mentor teacher (MT), gradually expanding the scope of her classroom responsibilities. The data for this period included five lesson observations, related instructional materials, and follow-up debrief interviews with a researcher on the project.

As a novice teacher (NT), Nancy moved to another state across the country, so data were collected through online interviews (two in year 1 and three in year 2). Nancy also participated in the Professional Learning Community on Reasoning and Proving (PLC-RP), led by the first author of this paper. The PLC-RP met online, four times a year for 1.5 hours. The video recordings of individual interviews and the PLC-RP meetings comprised the main data sources for the NT period, supplemented by lesson plans and sample student work.

Nancy's transcribed interview recordings from INT and NT years and the written report from her PST period were segmented into thematic units of varied length (from a single utterance to ~10 sentences). Each segment was analyzed to identify Nancy's actions or decisions and her justifications for these decisions. The justifications were examined to discern underlying obligations according to Chazan et al.'s (2016) framework of four professional obligations. Subcategories for each obligation were developed through open coding and the constant comparative method (Corbin & Strauss, 2015) based on Nancy's specific circumstances, e.g. her interactions with her MT during the internship reflect how she upheld the institutional obligation. Some actions were justified not by obligations but by Nancy's personal beliefs and values reflecting her emerging educational approach. We illustrate these in the results section.

Results

The PST Period

As a PST, Nancy did not have to attend to institutional obligations – her sole focus was on developing her mathematical and pedagogical knowledge and experimenting with proof. Nancy shared, "before taking this [capstone course], I only associated proofs with high school geometry and didn't realize all the different proof topics that can be integrated into a [secondary] math classroom." While Nancy did her course practicum in a high-school geometry class, she felt that the course allowed her to develop a more open approach to proof, saying, "I've learned […] a number of ways to integrate these [proof] topics into math classrooms." Illustrating how she integrated the proof themes into her lessons, Nancy wrote:

> For example, with conditional statements, I had the students investigate the P & Q, the truth value, and the converse and its' truth value of conditional statements about triangles and segments in triangles since that was what they were learning at the time.

Nancy felt that direct proof and conditional statements proof themes could be "seamlessly" integrated into her lesson plans compared to quantification and role of examples in proving, and indirect reasoning, which she described as "a little forced." Still, Nancy found creative ways to integrate these proof themes into her lessons. For example, for the lesson on indirect reasoning[1], Nancy designed *The Quadrilateral Detective* game, where students used analytic geometry to determine the type of quadrilateral from the given coordinates. Students applied indirect reasoning by writing statements of the form "A quadrilateral cannot be __because__" (e.g., "cannot be a square, because not all sides are congruent") (Liu & Buchbinder, 2022).

Reflecting on the course, Nancy described that it expanded her view of proof and provided her with experiences she wanted to enact in her future classrooms. She wrote:

> My teaching philosophy is centered around exploration and reasoning, but before [the course] I wasn't really sure how to enact it in my classroom. […] This course challenged me to think about proving in new ways and helped me to see its benefit in all math classrooms [and] gave me confidence in my abilities.

This quote, while containing no action, shows Nancy's emergent commitment to disciplinary values - "exploration and reasoning." She attributed to the capstone course her increased understanding of what integrating reasoning and proving in mathematics classrooms means, and increased willingness and confidence to do so in her own classrooms.

The Internship (INT) Period

Nancy's internship was with an experienced 8th-grade MT, who shared Nancy's commitment to fostering student mathematical engagement. However, they both found it challenging to enact these values due to the institutional constraints – a rigid curriculum. Nancy appreciated that "the curriculum is good about doing reasoning and proof stuff," but it came in the form of "a booklet that tells us all the lessons that we need to do, and [the] estimated times for everything." To address this, Nancy and her MT redesigned lessons to make them more rich. One example was Nancy's *Halloween Scavenger Hunt*–a Halloween-themed activity that she designed to replace a mundane exam review packet on transformational geometry. Working in groups, students solved problems worded as riddles hidden around the room; each solution led them to a new problem location and a clue to a combination lock box containing a prize. But, except for one problem involving indirect reasoning ("Of the four given sequences of transformations, identify one that does *not* result in transforming a shape FRANK into F'R'A'N'K'"), all other problems focused on calculations since Nancy's goal was for students to "enjoy doing some practice problems."

Thus, Nancy's focus was on the obligation to individual students' engagement, while the disciplinary obligation to reasoning and proving moved to the background. When asked directly about this, Nancy explained that "eventually students are going to prove […], but right now, day to day, we're doing a lot more reasoning than we are doing proving." She also intentionally tried "to ask a lot of *why* questions because it gets them thinking about justifying and explaining."

Compared to Nancy's PST period, this might seem like lowering the bar for integrating reasoning and proving. However, the institutional context is critical to this change. While Nancy enjoyed the support of her MT to follow her aspirations, she was constrained by the institutional

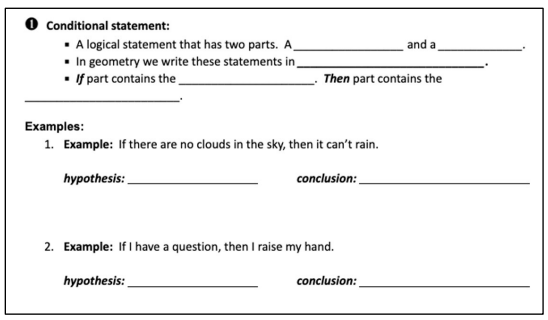
[1] We refer to indirect reasoning as any reasoning of the form "it cannot be so because otherwise", whereas indirect proof is a proof by contradiction or contrapositive (Yopp, 2020).

obligation to adhere to her school's rigid curriculum and procedures. Thus, sustaining a classroom culture where students are actively engaged in "fun" activities became Nancy's primary goal, a pre-condition for enacting her "teaching philosophy centered around exploration and reasoning." This is evidenced in her repeated use of "why does it work?" questions, supporting students in "justifying and explaining" and "understanding mathematics as a whole." She also used self-designed problems to substitute or supplement the curriculum. Nancy's approach reflects the tensions between her own values, aligned with individual and disciplinary obligations, and the obligation to meet the institutional standards of her internship school.

The Novice Teaching (NT) Period

Nancy started her first year as a high school teacher in a different US state. In the spring of her first year of autonomous teaching, Nancy described tensions between her desire to support students' mathematical learning and the need to adhere to school standards and curriculum, saying, "the standards and the things that [the school] wants [teachers] to teach are taking away from some of the fun stuff." Nancy also shared her frustration with some of the pedagogical approaches of her colleagues, especially the teacher with whom she was expected to coordinate. Nancy said: "Basically what she [the teacher] does is […] walks through guided notes for 30 minutes and then gives them [students] practice problems for 30 minutes. And that kills me!"

Several teachers in Nancy's school shared her desire to "move away from the guided notes" toward a "more student-focused curriculum" but met with opposition from other teachers whom Nancy described as "old school," clinging to "old traditional ways." Despite the institutional challenges: the divisive school culture, traditional teaching practices of her direct colleague, and teacher-centered instructional resources "handed to her," Nancy strived to teach her classes in student-centered ways, aligned with her teaching philosophy, even at the cost of extra work hours. Her persistence paid off in her second year when she developed her *Proof Unit*.



1. Introduction to Proof Concepts ❑ PowerPoint defining conjectures, indirect and inductive reasoning and counterexamples. ❑ Interactive Activities: SET Rules, Snowflake Activity ❑ Practice with patterns and counterexamples	2. Conditional Statements and Logical Puzzles ❑ PowerPoint presentation on vocabulary: conditional statements, converses, contrapositives and inverses. ❑ Practice creating conditional statements ❑ Interactive Activity: Sudoku	3. Proving the Area of a Circle ❑ Proof 1: Rearranging sectors of a circle to form a parallelogram and a rectangle (hands-on task) ❑ Proof 2: Unfolding concentric rings to form a triangle

Combining Mathematical Concepts and Problem-Solving ❑ Continuation of the "Handshake Activity" ❑ Triangle Inequality Theorem Exploration ❑ Fibonacci Rectangles Exploration ❑ Sudoku puzzle for Problem-Solving	6 & 7. Summative Assessment ❑ Poster Project: students work individually to create a poster summarizing and expanding on one of the proof activities from the unit. ❑ Followed by a gallery walk.

Figure 2. Nancy's Proof Unit outline.

Nancy's Proof-Unit. The 11th-grade geometry new state-wide curriculum standards called for a unit on "reasoning and proof." However, there were no pre-existing curriculum materials. As a result, the school allowed the teachers to use curriculum materials of their choice and relaxed the usual requirement for teachers to coordinate assessments across classes. In Nancy's words, this was a "rare situation." With this relaxed institutional pressure, Nancy jumped on the opportunity to integrate her desired teaching practices, saying: "I got this! I have all these really great ideas, I have the PLC where we do proving and reasoning, like, I can come up with this really cool thing!" Undeterred by the lack of her colleagues' collaboration, Nancy decided to

"pull from the proofs […] that we've done [in the course and the PLC] to do some of the cooler parts of math." The outcome was a three-week unit (Figure 2) where each lesson involved "different activities about reasoning and proving." For the summative assessment, Nancy had each student create a poster that summarized and extended one of the unit's proof activities.

Nancy utilized many activities from the PLC-RP (e.g., proving the area of a circle) and the capstone course, like introducing proof-related (e.g., conjectures, patterns) and logic-related concepts (e.g., conditional statements, contrapositive) using both mathematical and real-world examples (Figure 3a). She started by having students explore visual and numeric patterns, introducing them to conjecture, inductive reasoning, and counterexamples (Figure 4).

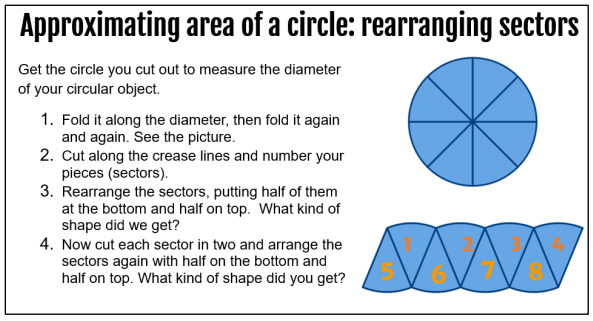


Figure 3a (on the left). A slide introducing conditional statements using non-mathematical examples. Figure 3b (on the right). A slide from the "proving the area of a circle" activity (lesson 3).

Nancy explained that the first two lessons in the unit "weren't necessarily proof, but they were just like, things that have to do with proving." The rest of the lessons involved what Nancy called "a bunch of different mini-proofs" – pattern explorations and informal arguments. For example, describing lesson 3 on proving the circle area formula (Figure 3b), Nancy said:

> [We] did the proof of the area of a circle, where the students have a circle and then they change it into a parallelogram […] That was kind of a fun day because […] I had them go through the exercise of folding [the circle] and cutting it and laying it out on their desk […] So, they actually had hands-on proof that they engaged in the entire time.

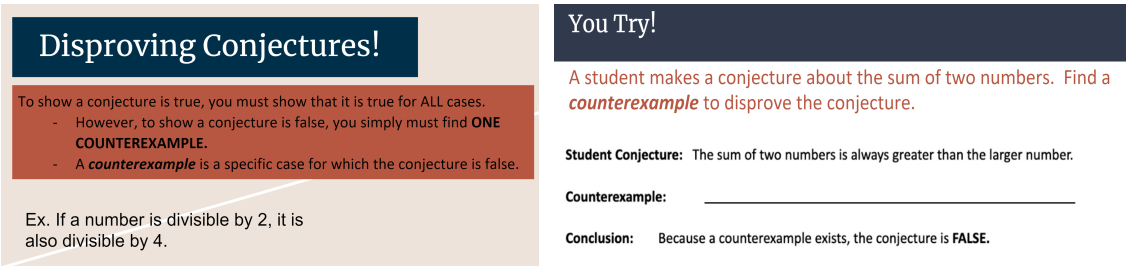

Figure 4. Explanation of the meaning of a counterexample and a task for students to do on their own.

These examples show that Nancy's focus was not on writing formal proofs, but on having them visualize, generalize patterns, formulate conjectures, and justify their thinking. This aligned with her disciplinary obligation to introduce mathematical reasoning and proving while considering students' minimal prior knowledge (individual obligation). The individual obligation is also evidenced in the focus on students' active engagement through games, hands-on tasks, and explorations. Nancy worked to make reasoning and proving enjoyable and appealing.

Takeaways and community reactions. Nancy enacted her Proof Unit with two lower-level

geometry sophomore classes. She was pleased with the outcomes, especially when some students took the initiative to explore concepts beyond class notes. Nancy's feelings were apparent in her voice and discourse: in a 49-minute interview, she used the words "cool" 30 times and "excited" 15 times. Encouraged by the positive experience, Nancy planned to revise the unit next year, to further emphasize proof, which reflects her increased attention to the disciplinary obligation.

Returning to institutional obligation, Nancy shared her unit and student outcomes with the administration and other teachers. She felt that many of her colleagues "were inspired," but some had reservations, motivating them by the need for consistency in teaching. Nancy, apparently, refused to be constrained by this. She said: "The big takeaway for me is - try new things even if other people aren't on board. Still do it, and you might get some really good outcomes from it."

Summary and Discussion

Putting Nancy's experiences in the broader context of preparing mathematics teachers to enact reasoning and proof in schools, we ask: What is Nancy a case of? Nancy is a well-prepared teacher candidate (AMTE, 2017) with robust mathematical knowledge, a strong pedagogical orientation toward active learning, and a commitment to engaging students with reasoning and proof—ideas she cultivated in the capstone course (Buchbinder & McCrone, 2023). As a PST, Nancy was shielded from the institutional obligation, enabling her to focus on mathematics, students' interactions with it (i.e. disciplinary obligation), and her own professional growth. As an INT, Nancy faced institutional constraints, including a rigid curriculum and a quick teaching pace. However, with her MT's support, Nancy was able to design and enact some reform-oriented activities to uphold her obligation to student engagement and to the discipline, which Nancy described as "interactive things and exploratory things and proof-based things," like her *Halloween Scavenger Hunt.* This illuminates the importance of placing INTs with mentors whose teaching philosophy aligns with that of university teacher preparation programs, and who can support rather than constrain INTs' professional aspirations (Gainsburg, 2012; Thompson et al., 2013), in this case – Nancy's "teaching philosophy centered on exploration and reasoning".

As an NT, Nancy faced increased institutional constraints and found it even more difficult to balance them with disciplinary and individual obligations. The need to coordinate assessments with other teachers, some of whom had vastly different pedagogical approaches from Nancy's, created tension for her. This is consistent with Wang et al., (2008) and Feiman-Nemser's (2003) findings on the influence of school culture on the nature and quality of the early years of teaching practice. Despite this, Nancy remained determined to teach in the way she saw as most advantageous to student learning. She utilized activities from the capstone course ("I did pull a couple of things from my time [in the capstone course]") to integrate "exploratory" and "proof-based activities." Nancy's nonconforming attitude and sense of agency are possibly unique to her personality. However, what is not unique is the fact that she had strong mathematical and pedagogical foundations, as well as access to instructional resources and continued professional support around reasoning and proof, aspects that have been identified in the literature as positively affecting novice teachers' practices (Wang et al., 2008; Vescio et al., 2008). Nancy's case illustrates that despite the challenges, novice teachers can draw on their professional preparation to develop rich opportunities for student learning of reasoning and proving.

Examining Connections Between Students' Mindsets and Beliefs About Mathematics

Emmanuel Osamau
University of Nebraska at Omaha

Karina Uhing
University of Nebraska at Omaha

Nicole Infante
University of Nebraska at Omaha

Thomas Spoehr
University of Nebraska at Omaha

Students' beliefs influence the ways in which they learn mathematics. These beliefs can be categorized in different ways and related to growth or fixed mindsets towards mathematics. In our work, we seek to better understand connections between students' beliefs and mindsets about learning mathematics. We present case studies of two undergraduate students who were enrolled in a first-year college algebra course who demonstrated a shift in mathematical mindset. Our findings highlight the complexity of students' beliefs and how students can hold both growth and fixed mindsets towards mathematics. We explore how mindsets can be tied to specific categories of beliefs and how those beliefs can influence a student's overall perspective about learning mathematics. We conclude that mindset interventions and future research should consider how to leverage these mixed mindsets to help students foster more growth-oriented beliefs about mathematics.

Keywords: Beliefs, Mindset, First-Year Mathematics, College Algebra

Students' beliefs influence the ways in which they learn mathematics. These beliefs are situated at the intersection of the cognitive and affective domains and have been categorized in various ways. For example, McLeod (1992) emphasized the affective aspect of belief systems and distinguished between beliefs about mathematics, beliefs about the self, beliefs about mathematics teaching, and beliefs about the social context of mathematics education. Similarly, Kloosterman (1996) organized beliefs into two primary categories: beliefs about mathematics as a discipline and beliefs about learning mathematics which also includes beliefs about oneself as a learner of mathematics and beliefs about the role of the teacher as subcategories. Building on past research, Op't Eynde and colleagues (2002) used models of different student beliefs to develop a theoretical framework of beliefs related to mathematics learning and problem solving. More recent work relating to affect and beliefs in mathematics has focused on mindsets (Dweck, 2016; Boaler 2016) and how these can influence the ways in which students engage in learning mathematics. In our work, we seek to better understand connections between students' beliefs and mindsets. We present case studies of two undergraduate students who were enrolled in a first-year college algebra course. These cases highlight how mindsets can be tied to specific mathematical beliefs and how those beliefs can influence a student's overall perspective about learning mathematics.

Theoretical Framing

Our research draws on the concepts of mindsets and mathematical beliefs. In her seminal book, Dweck (2016) described two types of mindsets that affect the way students view their learning abilities. Students with a growth mindset believe that their mathematical abilities can be improved with practice, while students with a fixed mindset believe that they only have a certain amount of intelligence or mathematical ability (Dweck, 2016). Boaler (2016) applied Dweck's mindset theory to the field of mathematics, describing how growth and fixed mindsets can affect

students' views of themselves as mathematical learners. In her work, Boaler framed having a mathematical mindset as "knowing that math is a subject of growth and that [a student's] role is to learn and think about new ideas" (Boaler, 2019, p. 29). Students' mathematical mindsets are tied to their beliefs about themselves, the nature of mathematics, and their role in relation to it (Boaler, 2019).

In our study, we draw connections between mathematical mindsets and beliefs using Op't Eynde et al.'s (2002) beliefs framework. We analyze how students' expressed mindsets may be linked to their mathematical beliefs. Op't Eynde et al.'s (2002) framework, outlined below in Table 1, describes how students' beliefs about mathematics fall into three categories: beliefs about the discipline of mathematics and mathematics education, beliefs about themselves, and beliefs about the social context of learning. Our findings suggest that students can have a certain mindset linked to beliefs in one category, but a different mindset about beliefs in another category. In addition, we postulate how mindsets and beliefs in one category may influence those in another category. This research gives practitioners insights into undergraduate students' mathematical mindsets and how they might change over a semester. Our work also provides a basis for researchers to continue investigating connections between mathematical mindsets and beliefs.

Table 1. A Framework of Students' Mathematics-Related Beliefs (Op't Eynde et al., 2002)

Category	Belief	Example
Beliefs about mathematics education	Beliefs about mathematics as a subject	Mathematics is a collection of facts and procedures to be memorized.
	Beliefs about mathematical learning and problem solving	There is only one correct way to solve a mathematics problem.
	Beliefs about mathematics teaching in general	A good teacher will show me how to solve a problem before I am expected to do it myself.
Beliefs about the self	Self-efficacy beliefs	I am confident that I can understand the mathematics material in this course.
	Control beliefs	I will be able to learn the material if I put in enough time and effort.
	Task-value beliefs	It is important for me to learn the material in this course.
	Goal-orientation beliefs	Fully understanding the mathematics material will give me great satisfaction.
Beliefs about the social context	Beliefs about social norms in their own class	If I speak up during a class discussion, my classmates and teacher will consider my ideas and value my contribution.
	Beliefs about socio-mathematical norms in their own class	I must be able to explain my thinking to present a good mathematical solution to my classmates and teacher.

Research Question

The purpose of our research is to better understand how students' mathematical beliefs and mindsets are related. In this paper, we address the research question: *What types of mathematical*

beliefs are expressed by students who exhibit changes in mathematical mindset in a first-year mathematics course?

Methods

The research presented in this paper comes from a larger study of students' perceptions of a first-year mathematics course. Data for this study comes from two written mathography reflections that were assigned to 611 students enrolled in 15 sections of a corequisite college algebra course at a large, Midwestern, metropolitan university during Fall 2023. This course involved active learning strategies and standards-based grading; it was designed to help students foster a more positive relationship with mathematics. Mathographies were collected at the beginning and end of the semester. These reflection assignments were based on past work by Drake (2006) and had students respond to prompts such as "What do you think it takes for a student to be good at math?" Out of the 611 students, 445 students submitted a reflection at the beginning of the semester. Of these 445 reflections, 55 were selected for further analysis using results from a Qualtrics survey on mathematical mindset and self-efficacy that was also administered at the beginning of the semester.

Beginning mathographies were analyzed during the Fall 2023 semester using MAXQDA 2022 (VERBI Software, 2021). These reflections were coded using a set of primary codes including Growth Mindset, Mixed Mindset, and Fixed Mindset. We coded excerpts that included both fixed and growth mindset characteristics as a "Mixed Mindset." For example, "I believe math is a strong suit for some but not for others but if you really took the time to practice and pay attention you can be successful." At least two authors independently coded the mathographies and met to reconcile differences until agreement was reached. At the end of the semester, ending mathographies were collected from the same cohort. Of the 55 students whose beginning mathographies were coded and analyzed, 51 students submitted an ending mathography. These ending mathographies were tagged using the same codebook and coding process as the beginning mathographies, with at least two authors meeting to reconcile differences to ensure consistency.

To understand how the mathematical mindsets of students expressed at the beginning of a semester compared to mathematical mindsets shown at the end of a semester, each of the 51 student's beginning and ending mathographies were analyzed side by side, specifically examining any potential changes in mathematical mindset codes. From this secondary analysis, we selected six students who exhibited a noticeable shift in their expressed mindset for further analysis. We then analyzed each student individually and created a detailed description of their expressed mindsets and mathematical beliefs as categorized by the Op't Eynde et al.'s (2002) framework from both their beginning and ending mathographies. Our goal was to compare the different types of beliefs relating to changes in mindset from the beginning to the end of the semester. In this paper, we use a case study approach (Stake, 2003) to better understand the mathematical beliefs and mindsets of two students who exhibited a change in mindset from the beginning to the end of the semester. To protect the privacy of the students, both names are pseudonyms.

Findings

In studying the mathematical beliefs expressed by students who had a change in mathematical mindset during a first-year mathematics course, we looked closely at individual stories. We found that students hold different beliefs about math, which potentially influence

their mindsets. Some students stuck to their initial mathematical mindset that they expressed at the beginning of the course, while others seemed to exhibit a change in mathematical mindset by the end of the semester. These case studies help us understand what types of beliefs are expressed by students, and why some students might have a change in beliefs and mathematical mindset.

Case 1: Emily

Emily's case provides an example of a student who initially demonstrated a fixed mindset towards mathematics but ended the semester with more of a growth mindset. In her intro mathography, Emily expressed a fixed mindset relating to her beliefs about mathematics as a subject stating, "I think students who are good at math honestly were able to grasp the concepts at a young age like in elementary school," and "I believe math is a strong suit for some but not for others." This view of mathematics as an innate ability corresponds to having more of a fixed mindset about mathematics as a subject. However, Emily went on to add "but if you really took the time to practice and pay attention you can be successful," which reflects more of a growth mindset relating to control beliefs about the self. Thus, in her initial mathography, Emily demonstrated both a growth and a fixed mathematical mindset relating to two different categories, beliefs about mathematics education and beliefs about the self, under Op't Eynde et al.'s framework.

In addition to discussing beliefs about the self and mathematics education, Emily also discussed past experiences with mathematics teachers relating to beliefs about the social context in her initial mathography. She explained that "when asking for help [my high school teacher] would make me feel not smart with the way she responded to me." She also described negative experiences with assessment: "when taking a test and not understanding I would breakdown and cry and have to step out of the classroom. I felt like the odd one out like everyone else understood but I did not." Thus, the social context in Emily's past mathematical experiences potentially contributed to her statements reflecting a fixed mindset, shaping her belief that mathematics ability is innate, with some inherently or 'naturally' strong in it while others, like herself, struggled due to negative interactions with teachers and comparing her abilities to her classmates.

At the end of the semester, Emily's reflections had transformed. She acknowledged her capability in math, attributing her progress to consistent study and support from her instructors and colleagues in class. Emily wrote, "I learned that I am capable of doing math and doing a good job as long as I keep studying and making time for math outside of school." She highlighted the positive impact of a supportive learning environment and her beliefs about the social norms in the class, noting that her interactions with teaching assistants were judgment-free and beneficial. She reflected that, "On some problems I just did not know what to do and when I would get help, I felt no pressure whatsoever when getting it incorrect." Emily added that,

> I really enjoyed how much assistance we got during class and the involvement with other students really helped me out, because when I would find myself confused my group would always make sure to ask if we all understood, it was like a team effort.

In her ending mathography, Emily's beliefs about the socio-mathematical norms were different than the ones she expressed in her initial mathography when she felt like "the odd one out" and "not smart" because of the social context. In her initial mathography, Emily demonstrated both fixed and growth mindsets in the category of beliefs about the self. In terms of control beliefs, she expressed more of a growth mindset, using the third person language of

"...you can be successful". However, Emily demonstrated a fixed mindset pertaining to her self-efficacy belief shaped by her previous class experiences. In her ending mathography, the social context in the class seemed to influence her self-efficacy beliefs positively as she used first person language to state, "I learned that I am capable of doing math." Thus, Emily's mathematical mindset changed from a fixed to a growth mindset in relation to her self-efficacy beliefs while also internalizing a growth mindset about her control beliefs. Emily's case exemplifies the types of mathematical beliefs expressed by students who experience a change in mathematical mindset during their first-year mathematics course. This finding underscores the role of the mathematics teaching and learning environment in influencing students' mathematical beliefs and mindset development.

Case 2: Ryan

Ryan's experience in mathematics shows a transformation from a mixed mathematical mindset at the beginning of the semester to a growth-oriented mindset at the end of the semester. In his intro mathography, he reflected, "In general, my experience with math has been pretty poor. My intelligence favors the English/Reading side of education by a vast margin." Ryan's mathematics experiences prior to college seemed to have created a self-efficacy belief that he was intelligent in subjects other than mathematics, corresponding to a fixed mathematical mindset. However, in addition to stating his limitations with mathematics as a subject, he discussed how with hard work, one can be successful at learning mathematics. He wrote,

> I used to think that some are born with the ability to do math, and some aren't. Although I feel that still applies to a certain extent, it's not that black and white. It's true that for some people, it just clicks and for others it doesn't. However, I have learned that working hard and applying yourself is all it takes ... I know it's a bit cliché saying, "all it takes is just hard work."

Here, Ryan shared a belief about mathematics education learning and problem solving – that some people are "born with the ability to do math" and "for some people, it just clicks." Yet he also expressed a control belief about the self that one can be successful in mathematics through hard work. Thus, we can see in this example how someone can hold a fixed mindset relating to beliefs about mathematics education (learning and problem solving) while demonstrating a growth mindset about control beliefs relating to the self.

In his intro mathography, Ryan compared his current classroom experience to past ones. He stated, "I really like how this class emphasizes group work […] also, the attitude in the classroom is very open and non-judgmental. I feel like in my previous math experiences, as horrible as it sounds, I would feel dumb for getting help or the teacher would try not to roll their eyes when I asked a question like they were thinking, 'Again? Seriously?'" This quote shows how social contexts have the potential to shape beliefs, although those beliefs may be difficult to identify. Ryan's comparison of classroom norms may relate to a belief that the role of the teacher should be to support and help students, rather than to judge their mathematical worth. This belief may also affect mindsets and beliefs in other categories such as beliefs about the self and mathematics education. Students who have these types of negative experiences in their educational past (e.g. mathematics teachers who make them feel "dumb") are more likely to view mathematical ability as innate and hold fixed mathematical mindsets as the classroom social norms contribute to defining students who are or can be good at mathematics.

In his ending mathography, Ryan expressed more of a growth-oriented mindset stating that anyone could succeed in math with enough effort. He reflected,

> I do believe that any student can succeed in math. My 16-year-old self wouldn't believe this, but all it takes is effort. It may seem like you're predestined to suck at math, but that isn't the case. It'll just take you a little more work and effort. If you really want to succeed, you will.

This statement corresponds to a control belief about the self where Ryan used third person language to describe what it takes to be successful at mathematics. In addition, Ryan also used first-person language to discuss another control belief specifically relating to himself, which potentially was influenced by being in a positive and non-judgmental environment. He stated,

> When it comes to new aspects, I've learned about myself that relates to Math, one of them would be just show up. As long as you just go (to the class, in this instance), then 75% of the work is done.

Thus, Ryan's experience in a positive and non-judgmental classroom environment promoted a control belief in the value of participation and effort. He realized that engaging in a supportive class setting can significantly contribute to a student's success and that he could be successful at mathematics by "just showing up."

Ryan's case highlights how an encouraging learning atmosphere can help promote growth-oriented control beliefs about the self. Having held a mixed mathematical mindset at the beginning of the semester, Ryan's development towards having a growth mindset was facilitated by his beliefs about the social norms in the class and the support from his instructors and peers.

Discussion

The mathematical beliefs of students are complex and often show characteristics of both fixed and growth mindsets. This phenomenon, which we call having a "mixed mindset," is evident in the expressed beliefs of our participants. For example, Emily expressed a fixed mindset belief about mathematics as a subject, i.e. "I believe math is a strong suit for some but not for others" while maintaining a growth mindset belief about their mathematics learning and problem solving, i.e. "but if you really took the time to practice and pay attention you can be successful." This complexity exists between the general categories of the beliefs framework (beliefs about mathematics education, the self, and the social context) and also between the subcategories of the main mathematical beliefs (e.g. different beliefs about self-efficacy and control beliefs in Ryan's case). This finding suggests that if students express different mathematical mindsets and beliefs about mathematics education, the self, and the social context, then a one-size-fits-all approach to mindset interventions may not be sufficient to address the full spectrum of students' beliefs.

Our findings also show that the social context plays a crucial role in shaping students' mathematical mindset, although these influences are often more nuanced and harder to categorize as strictly fixed or growth oriented. In our analysis, it was more straightforward to classify beliefs about mathematics education and the self as either fixed or growth. However, it became more difficult to apply the same classification to beliefs about the social context because oftentimes this relied on making inferences from students' mathematical experiences. For example, Ryan's experience of his teacher making him "feel dumb" potentially relates to a belief that the teacher's role is to support and assist students, which could be classified as a growth mindset. We were able to infer this based on Ryan's other statements about the social context of his current mathematical classroom. However, without this context, a statement similar to Ryan's could be taken as a belief that a teacher's role is to pass judgment on students, which may suggest more of a fixed mindset. Thus, while it was sometimes difficult to categorize beliefs

about the social context as relating to fixed or growth mindsets, it was possible in some cases by looking at the broader set of student experiences.

Finally, beliefs about the social norms in the class can influence a student's beliefs about the self and mathematics education. A supportive and encouraging classroom atmosphere can foster a growth mindset by helping students feel capable of improvement. The social context defines expectations of what it means to be a good student, and these expectations are assimilated by students as a personal belief about the self, which influences the student's mathematical mindset. Ryan's experience illustrates this point. Similarly, Emily's story tells how positive social norms in the class can nurture growth mindsets in beliefs about mathematics education. Mathematics-related beliefs in one category can influence and even change beliefs in another. For instance, a student's belief about the self can impact their attitudes toward mathematics education and whether they hold fixed or growth mindsets along with these beliefs.

Our findings raise important questions about different types of mathematical mindset related beliefs and the role of the social context in influencing these beliefs. As students begin to adopt different mathematical beliefs through shifts in social norms in their class, they may revise their beliefs about what it takes to succeed in mathematics, hopefully pushing them towards developing more growth-oriented mindsets. Interventions should address specific areas of fixed mathematics-related beliefs while building upon existing growth-oriented beliefs. In our data, we found that students appreciated the supportive classroom environment and multiple opportunities given to understand the material and demonstrate their knowledge. Interventions instructors incorporated in the course included activities related to productive struggle and metacognition (McGuire, 2015). In addition, the course curriculum emphasized understanding mathematical structures rather than only developing procedural knowledge. These types of interventions and teaching practices can help shift student beliefs and mindsets. It is important to acknowledge that even though a student may display a fixed mindset related to a certain type of mathematical belief, they may still hold a growth mindset related to other belief categories, what we have termed in this paper as a "mixed mindset." Future research could explore how educators can leverage this concept of mixed mindsets to foster more growth-oriented beliefs in students, particularly in areas where fixed mindsets persist.

Examining Inequitable Talk and Perceived Status During Group-Worthy Tasks in an Undergraduate Topology Course

Brittney M. Ellis
Texas State University

Christine K. Austin

Kathleen Melhuish
Texas State University

We report on the initial findings from a project aimed at enhancing equitable group work in undergraduate proof courses through the design and implementation of group-worthy tasks. This mixed methods study reports on three group-worthy tasks implemented in a topology course. We investigated the extent to which student interactions in these small groups reflect participatory and relational equity in relation to perceived academic status. Quantitative results indicate patterns in which the group-worthy tasks may disrupt students with high status from dominating talk turns taken, the amount of talk turns taken, and number of words spoken by the students, or neither depending on the tasks. Qualitative results explored relational inequity via silencing, ignoring, or no talk during these three tasks. Our initial findings suggest that group-worthy tasks alone may not guarantee equitable participation or relations in group interactions.

Keywords: Status, Equity, Group-Worthy Tasks, Proof

There is a growing consensus that active learning approaches can benefit students taking undergraduate mathematics courses (Freeman et al., 2014). While there is some evidence that active approaches may lead to more equitable outcomes (e.g., Laursen et al., 2014; Theobald et al., 2020), it is important to recognize that such strategies do not automatically guarantee equitable participation among students. Research in inquiry-based settings suggests that inequities can persist, including in proof-based courses where group work is a central component (Brown, 2018; Ernest et al., 2019; Johnson et al., 2020). A possible cause for these inequities is how students perceive each other's status; that is, their assumptions about who is "better" or "smarter" at math influence their participation in group work.

One factor that can amplify or attenuate inequitable participation is the nature of group work tasks themselves (Shah & Lewis, 2019). Both content and structure can create opportunities for every student to engage and contribute mathematically. For example, well-designed group-worthy tasks can help address status-related dynamics that may otherwise hinder some students' participation (Cohen et al., 1999; Esmonde, 2009). Our understanding of the interplay between group-worthy tasks, status dynamics, and equity in undergraduate courses using active learning strategies is far from complete (Adiredja & Andrews-Larson, 2017), especially in advanced mathematics courses. This setting may exasperate status issues as the formal proof becomes the focal object of study (Weber & Melhuish, 2022). Here, we share analysis of a subset of data from the STructuring Equitable Participation in Undergraduate Proof (STEP UP) project aimed at supporting instructors in designing and implementing group-worthy tasks in proof-based courses. We investigated the following research question: To what extent do students' interactions in small groups reflect participatory and relational equity in relation to perceived status during three group-worthy tasks in a collaborative topology course?

Background and Framing

In our work, *equity* is when every student in a group has the necessary resources to support their learning (Shah & Lewis, 2019). *Inequity*, in contrast, occurs when power dynamics are structured in a way that prevents students from accessing these resources. Some resources might include physical access to the shared workspace (e.g., whiteboard, worksheet), opportunities to make written or verbal contributions to the group's work, and access to another group members' ideas. Two aspects of equity related to group dynamics are participatory and relational equity. *Relational equity* (Boaler, 2008) is characterized by interactions that allow each student in a group to have the opportunity to develop an identity as a capable learner. *Participatory equity* refers to the fair distribution of both opportunities to participate and the actual participation among all students involved in a learning interaction (Shah & Lewis). No situation is entirely equitable or inequitable; instead, relational and participatory equity fluctuate in subtle ways from moment to moment and can be influenced by social factors.

Inequities in group work can emerge due to imbalanced power dynamics rooted in differences in status. A status characteristic is defined as a "social ranking that everyone agrees is preferable to have a higher rank rather than a lower one" (Cohen et al., 1999, p. 84). In the classroom, academic status characteristics, such as perceived mathematical ability, are particularly influential (Cohen & Lotan, 2014) and can be affected by broader status characteristics like gender, race, and ethnicity (Cohen et al., 1999; Ridgeway, 2018). Students with higher status often have more chances to participate and contribute, which can lead to greater learning opportunities (Cohen & Lotan).

Small group interactions impact opportunities to learn during group work because students who have more opportunities to participate often participate more, and as a result, learn more (Esmonde, 2009). Research has shown that the nature of the task influences the extent to which participation is inequitable between group members (Chizhik, 1999, 2001). One strategy to balance participation and status is to utilize group-worthy tasks, a term borrowed from Complex Instruction (Cohen et al., 1999). A task is "group-worthy" if it affords various ways to approach the task, includes mechanisms to ensure that every participant is engaged and learning, and promotes a positive sense of interdependence among group members (Cohen & Lotan, 2014). Such tasks can elicit more opportunities for each member to participate in mathematically meaningful ways, potentially disrupting imbalanced participation due to status differences.

Methods

Participants and Procedures

The data comes from an NSF-funded collaboration between mathematics educators and mathematicians to design and implement group-worthy tasks in proof contexts. The research team video and audio recorded student interactions during three group-worthy tasks in a Topology course at a Hispanic-serving institution with a high first-generation population in the southern United States. The class was taught by a topologist during the Fall 2023 semester and consisted of 17 undergraduates and 3 graduate students (see Table 1). Daily classroom activity included randomized group work, usually with students working in groups of 3 or 4 at whiteboards. The three group-worthy tasks had different content and structure from the usual group activities. The three tasks were implemented on non-consecutive class days in weeks 8, 9, and 12 of the 16-week semester. All audio was transcribed and cleaned alongside the video data.

Task 1 focused on proof comprehension of the Universal Property of Quotient Spaces Theorem, with four groups of four students studying two examples to understand the quotient

space and its induced map. Each individual student worked on one part (a-d), then collaborated on part (e) to create a composite function. Task 2 focused on constructing a proof of the proposition stating, "The diagonal is closed if and only if X is Hausdorff", with groups of four investigating two examples, answering questions for each, and recording their findings on the front whiteboard to identify patterns. Each group member was assigned a unique role[1] with specific information needed to complete the task. Task 3 focused on proof analysis of the proposition stating, "Let $f: X \to Y$ be homeomorphisms. If X is connected, then Y is connected." In this task, pairs of students compared two proofs (A and B). Each student studied one proof, then explained it to their partner to compare and identify similarities and differences.

Table 1. Participating Student Demographics, Perceived Status, and Task/Group Information.

Task #.Group Name	Name (Perceived Status)	Gender	Race/Ethnicity
Group 1.A, Group 2.C, Pair 3.B	Lily (low)	Woman	Hispanic
Group 1.A, Group 2.B, Pair 3.C	Zahir (low)	Man*	Hispanic*
Group 1.A, Group 2.A, Pair 3.A	Pink (mid)	Woman	White, Hispanic
Group 1.A, Group 2.B, Pair 3.D	Kieran (mid)	N/A	South Asian
Group 1.B, Group 2.C, Pair 3.A	Kendra (high)	Woman*	Black*
Group 1.B	Brandon (mid)	Man	White
Group 1.B, Group 2.A, Pair 3.D	Joe (mid)	Man	Spanish
Group 1.B, Group 2.C, Pair 3.E	N (mid)	Woman	Mexican
Group 2.A	Alexis (high)	Woman	White-Caucasian
Group 1.C, Group 2.A, Pair 3.B	Luke (mid)	Man	White
Group 2.B	Ariella (low)	Woman*	Hispanic*
Group 1.C, Group 2.B, Pair 3.C	Xander (high)	Man*	White*
Group 1.C, Pair 3.E	Julie (high)	Woman	White
Group 1.C	Samantha (low)	Woman*	White*

*Indicates researcher assumption; all other data is student self-identified. Note: Group 2.C was not analyzed qualitatively due to a non-consenting fourth member.

Data Analysis

This study used a convergent mixed methods design, combining quantitative and qualitative results (Creswell & Plano Clark, 2018). The goal was to gather complementary data on students' interactions in a topology course to assess participatory and relational equity in group tasks (Morse, 1991). Phase one involved coding video transcripts of group work for three group-worthy tasks, calculating turn and talk point ratios, and conducting a Spearman Rho analysis. Phase two merged these results to explain group interactions and interpret the findings.

Quantitative Analysis. The constructs captured in the quantitative analysis are: Perceived Status, Turn Ratio, and Talk Ratio. Perceived Status was determined through the results of a status survey that each participating (and present) student completed the class period following the third group-worthy task implementation. For the status survey, students (n = 10) circled peers they thought were "best at math" which captured perceived academic status via mathematical

[1] (1) Linguist assisted group with provided key definitions of Hausdorff, diagonal, and closed. (2) Zoologist assisted group's understanding of provided "strange and exotic" topologies: trivial, discrete, finite-complement, and poset topologies. (3) Product Manager assisted group with provided definition of the product topology. (4) Summoner assisted group by "enlisting additional resources" for the group.

ability. Those circled four or more times were "high" status (coded as 2), two to three times were "mid" status (coded as 1), and less than two were "low" status (coded as 0).

We adapted Reinholz and Shah's (2018) ratio approach to quantifying participatory equity to the individual level. We calculated Turn Ratios and Talk Ratios. Turn Ratios were calculated based on each student's talk turns divided by the total talk turns and then by the ideal portion (e.g., 0.25 for a group of four). A turn is defined as a continuous segment of uninterrupted speech by a student. A new turn starts when a different student speaks, or is addressed by the instructor. Talk Ratios were calculated using a word count total by summing words per talk turn, coding as 1 for < 5 words, 5 for ≤ 20 words, and 20 for >20 words (Reinholz & Shah, 2018). The overall Talk Ratio for everyone was then calculated in a similar manner to the Turn Ratio.

Turn Ratios and Talk Ratios both provide information about participatory equity. Spearman Rho was calculated for Task 1 ($n = 12$), Task 2 ($n = 11$), and Task 3 ($n = 10$) to evaluate the correlation between Turn and Talk Ratios. Given that Turn Ratios are based on talk turns and Talk Ratios on word count, they are expected to reflect each other. A Spearman Rho was chosen over Pearson correlation due to the analysis being more appropriate for a small sample size and ordinal data (Siegel & Castellan, 1988). Additionally, Spearman Rho requires, and considers, the variables to be ordinal for the objects to be ranked (Siegel & Castellan, 1988).

Qualitative Analysis. We used Stovall et al.'s (2023) concepts of Silencing, Ignoring, and No Talk to analyze relational *in*equity in group interactions. "Silencing" occurred when one or more students interrupted or talked over another so that the former student did not finish their idea. "Ignoring" occurred when one or more students did not verbally acknowledge another student's verbal contribution. "No talk" occurred when a student did not verbally contribute during the entire activity and the other students and/or instructor did not address this. We reviewed videos together to resolve disagreements and only finalized codes after reaching a consensus. After coding, we wrote memos summarizing group dynamics (including physical space and student actions), inequitable talk instances, and initial inferences. The memos also included each group member's perceived status to further link the qualitative summaries with the quantitative results. A research team member, also a student in the class, provided insider knowledge on classroom dynamics, which helped resolve coding conflicts and clarify norms.

Results

Quantitative Results

Since both Turn Ratio and Talk Ratio reflect participatory equity to some degree, we used Spearman's Rho to assess their correlation, expecting to find a relationship between the number of talk turns and the number of words spoken. As suspected, the relationship between a student's Turn Ratio and Talk Ratio was found to have a strong positive correlation that was statistically significant for both Task 1 ($\rho = .874$, $p = <.001$) and Task 2 ($\rho = .897$, $p < .001$). This means that students with a high Turn Ratio are likely to have a high Talk Ratio, meaning the more talk turns a student has the more likely they will say more words. However, unexpectedly, the relation between the two ratios was not found to be statistically significant ($\rho = .530$, $p = .115$) for Task 3. To potentially explain the relationship between the ratios, we parsed the relation via perceived academic status (see Figure 1). In Figure 1, the red circles represent a student with high status, the blue diamonds represent a student with mid status, and the green squares represent a student with low status. We note three patterns from that data when accounting for status.

First, with Task 1, the Turn Ratio and Talk Ratios are highly associated, and perceived status is consistently spread throughout. This suggests that, when regarding Task 1, status did not

influence a student's Turn or Talk Ratios. Second, with Task 2, Turn Ratios and Talk Ratios are highly related, however, those with high status are clustered at the top right meaning that those with perceived status talked more in both the amount of talk turns taken and words spoken. This relationship would not be captured by Spearman Rho. Furthermore, other than one green square on the right (low status), those with low status are clustered at the bottom left. Lastly, with Task 3, we note that most of the students had a Turn Ratio between 0.90 and 1.05, however students with high status (red circle) have higher Talk Ratios than those with low status (green square). Our initial findings suggest that the group-worthy tasks may disrupt high status students from dominating talk turns taken (only), talk turns taken and amount of talk, or neither depending on the task. Thus, while the Talk Ratios and Turn Ratios may be related in some instances, our tasks may not be disrupting status as originally conjectured. These patterns may not be generalizable and could result from various factors such as task design (e.g., Task 3 was paired), course culture, timing, or student interactions.

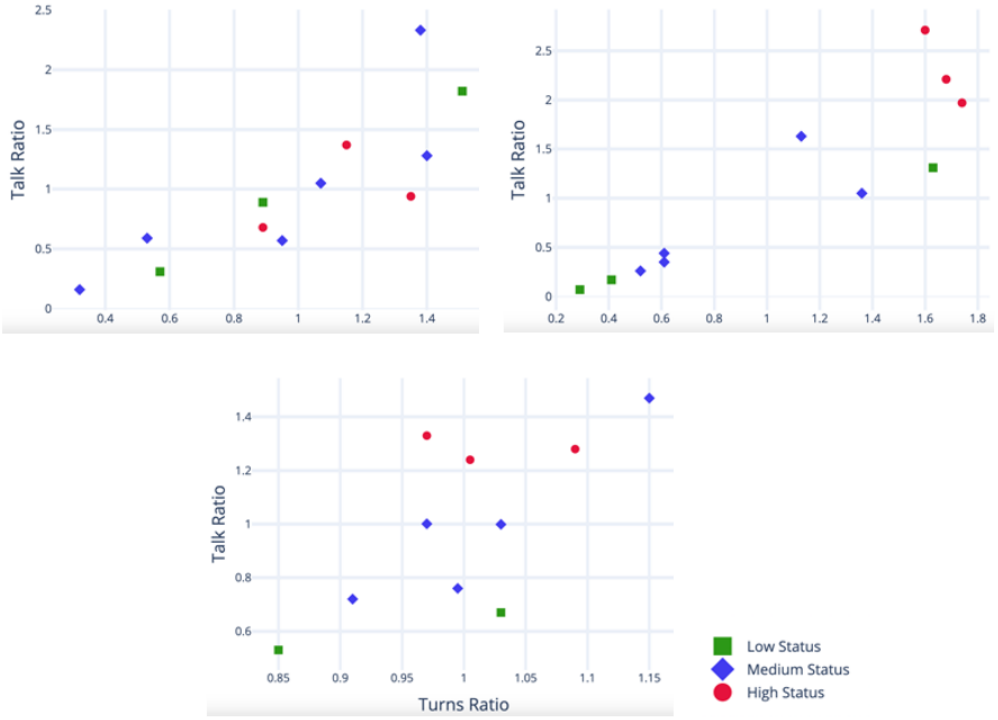

Figure 1. Correlations between Turn Ratios (horizontal axis) and Talk Ratios (vertical axis) Parsed by Perceived Status for Task 1 (Top Left), Task 2 (Top Right), and Task 3 (Bottom Middle).

Qualitative Results

The qualitative analysis occurred concurrently and focused on the relational equity element. In this section, we report an overview of these results for each task and consider how relational and participatory equity may relate.

Task 1: Proof Comprehension. Task 1 showed a more equal distribution of talk and turns during the task. There were no instances of "no talk", meaning everyone in each group verbally contributed to the group's mathematical work. However, there were some instances of ignoring and silencing. In Group 1.B, there were two cases of ignoring directed toward N (mid status) and Joe (mid), three instances of Brandon (mid) silencing N, and two instances of Brandon silencing

Kendra (high). Although Kendra spoke often, she asked many questions and listened to her peers' responses without talking over them. Kendra was the only member of this group that attempted to engage collaboratively with all members. Comparatively, Group 1.A, Kieran (mid) was ignored by everyone else in the group many times, and silenced (both physically and verbally) several times by Lily (low). Interestingly, Lily, who had low perceived status, dominated this group interaction and engaged in inequitable talk the most compared to her group mates. At one point Kieran stated, "So... this is something—" then Lily interjected, "We know this because of this," which cut Kieran off and he did not get a chance to finish his idea. In Group 1.C, inequitable talk occurred as students of equal or lower status silenced or ignored others, while a high-status student encouraged collaborative engagement. This suggests that relational inequities may account for the more evenly distributed participation ratios.

Task 2: Proof Construction. In this task, there were students who dominated the talk time and talk turns according to the quantitative analysis. The two focal groups had different patterns of interaction relationally. Group 2.A's interactions were largely respectful and inclusive with no instances of ignoring. Alexis (high status) made sure everyone contributed to the work by passing the marker and explicitly saying things like, "Okay. Who wants the marker next?" There were three instances of silencing directed towards Joe (mid) by Alexis and Luke (mid). For example, after Alexis made an observation, Joe tried to make a statement ("Yeah. I think it-") but was interrupted by Luke, and Alexis continued talking. Alexis and Luke's verbal contributions took up a majority of the overall talk time.

In contrast, "no talk" was indicated for Group 2.B because Zahir (low) contributed only one-word responses (e.g., "yeah", "oh okay") and only spoke more than one word to the instructor when he joined the group to ask how things were going. There was one instance of Kieran (mid) and Xander (high) ignoring Ariella (low), and one instance of Xander (high) silencing Ariella. For example, Ariella started to say something (although it is unclear if she was reading to herself or talking to the group), and Xander interrupted her to ask for the definition of a product topology (she was the "Product Manager"). She stopped talking, gave him the paper with the definition on it, and said, "It's right over here. I guess it's the product topology." She did not continue speaking. Kieran and Xander contributed almost all of the mathematical work, with Xander writing on the whiteboard nearly the entire time. Together, Xander and Kieran's verbal contributions took up about 84% of the total talk time. This group exemplified relational inequities in which higher status students ignored and silenced lower status students. That is, the participatory inequities may be at least partially explained by the relational inequities.

Task 3: Proof Analysis. The quantitative results pointed to this task having balanced turns in talk, but an imbalance in how much talk occurred. There were no cases of ignoring or "no talk" across all five pairs. There were few instances of silencing across each pair (except Pair 3.C), Xander (high) and Zahir (low), in which Xander repeatedly silenced Zahir. For example, while Zahir was explaining his proof, he stated "And then—" but Xander interrupted him by saying, "We know F is a homeomorphism…" barely giving Zahir time to talk before he started explaining to Zahir how to do the proof. Xander's verbal contributions took up about 67% of the total talk time, while Zahir's took up only 33%. Comparatively, there were some instances of silencing between partners in Pair 3.D, Joe (mid) and Kieran (mid), however one person was not overly silencing the other throughout the interaction, unlike with the previous pair.

Overall, the interactions across the remaining pairs were respectful and collaborative. In Pair 3.A, Pink (mid) and Kendra (high), there were no instances of silencing. The two made sense of both proofs together throughout the task, with Kendra asking a lot of questions when she was

confused and Pink helping Kendra process through the reasoning behind both proof approaches. Kendra's verbal contributions made up 62% of the talk time and Pink's took up 38%. Then, in Pair 3.B, Luke (mid) and Lily (low), there was only one instance of Lily silencing Luke. They noticed the proofs were similar, and while Luke shared what he noticed, Lily interrupted him to share her own noticing. Luke's verbal contributions made up 73% of the pair's verbal contributions, meaning Lily's verbal contributions made up only 27%. For Pair 3.E, Julie (high) and N (mid), there were very few cases when Julie silenced N. For instance, at one point N stated, "So then because of the surjection or the bijection, we know it's—" then Julie interjected, "It's a bijection, just cover both bases." N did not have a chance to finish saying what she knew. Julie's verbal contribution took up 64% of the total talk time while N's took up 36%. In four of the pairs, the Turn Ratios were overall balanced, yet the partner with higher perceived status spoke more words than the other partner. This trend did not apply to the only status-balanced pair, Joe (mid) and Kieran (mid), in which both Turn and Talk Ratios were balanced. We found that in the low-high pairing, there were substantial relational inequities that may account for the imbalanced talk, but this did not account for the imbalance in the mid-low status pair.

Discussion

This study set out to examine the extent to which group interactions reflected participatory and relational equity during three group-worthy tasks in an inquiry topology course. Task 1 seemed to disrupt inequitable status and participation patterns, despite some instances of relational inequities. In fact, the inequities appeared to disfavor those with higher status. Task 2 seemed to reproduce inequitable status and participation patterns and was the most relationally inequitable of the three tasks, with the only instance of "no talk" occurring, and higher-status students ignoring and silencing lower-status students. Task 3 seemed to balance the number of talk turns, but high-status students still dominated the conversations in words. There were some relational inequities with silencing in a low-high pairing, but this was not sufficient to account for the overall imbalance in talk across the pairs.

Reflecting on the task design, we can form further conjectures about participation differences. Task 1, which had the most balanced participation, was structured for group members to become experts on specific parts and assist others, culminating in collaborative work for the final part. This design fostered individual accountability and interdependence, making each member's contribution essential for the group's success. In comparison, Task 2 used group roles and it was observed that students largely ignored these roles. Each role card had important information on it, but students did not have to become "experts" on their role. In Group 2.B, we saw that Ariella was assigned the "Product Manager" role and was meant to be the expert on the product topology definition. However, since the definition was written on a card, Ariella simply handed it to Xander, rendering her role obsolete. It may be that students perceived these types of group roles as unnecessary to complete the task. Finally, Task 3 was a paired task with distributed expertise of two different proofs, which necessitated student interaction and contributions, leading to more balanced Turn Ratios. However, Talk Ratios showed that higher-status students still dominated the conversation.

What is clear is that group-worthy tasks alone may not guarantee more equitable group interactions. In the qualitative analysis we noticed the impact the instructor had on disrupting inequities. Instructors can engage a quiet student or highlight a contribution that may otherwise be ignored. Future work will explore the relationship between instructor interventions during group work (e.g., assigning competence; Cohen & Lotan, 2014), as well as how the culture of the classroom and the interplay of race and gender may also impact group work dynamics.

Examining Subjective Factors Shaping Students' Combinatorial Thinking

Niusha Modabbernia
Simon Fraser University

Research on combinatorics education indicates a crucial need in mathematics education to address students' ways of thinking at a level that benefits a deeper understanding of how students conceptualize counting problems. Attending to the ways in which students approach and interpret counting problems reveals the subjectivity in their decision makings. In this study, I report data from written works submitted by thirty five prospective high school teachers as they considered a disagreement between two possible responses to a combinatorial problem. Defining subjective combinatorics as a subjective aspect of students' interpretations of sets of outcomes facilitates describing students' counting activity. I propose subjective combinatorics as a construct to shed light on our understanding of students' counting activities, focusing on the subjectivity inherent in their combinatorial thinking.

Keywords: combinatorics, conceptual analysis, counting problems, undergraduate mathematics education, subjective combinatorics

Enumerative combinatorics, the area of mathematics focused on solving counting problems, is part of many K-12 and undergraduate mathematics curricula. This prominence is justified, as counting problems not only have practical applications in fields like computer science and probability (e.g., Abrahamson, Janusz, & Wilensky, 2006; Shaughnessy, 1977) but also challenge students to engage in critical mathematical thinking (e.g., Kapur, 1970; Martin, 2001; Tucker, 2002). In recent years, the mathematics education research community has placed greater focus on students' combinatorial reasoning. Numerous studies have examined common errors, strategies, and different ways of thinking involved in solving counting problems (e.g., Annin & Lai, 2010; Batanero, Navarro-Pelayo, & Godino, 1997; Eizenberg & Zaslavsky, 2004; English, 1991, 2005; Halani, 2012; Lockwood, 2011, 2013; Lockwood, Swinyard, & Caughman, 2015; Tillema, 2013). Despite the critical role of combinatorial reasoning, many of these studies highlight the difficulties students face in solving counting problems. Given these difficulties, it became apparent to investigate the factors that influence students' success in combinatorics. Understanding these factors requires a detailed examination of the elements involved in students' combinatorial thinking. To this end, research on combinatorics education has progressively focused on understanding students' ways of thinking about counting problems. Lockwood (2013) conceptualized students' combinatorial thinking by identifying three primary components: formulas/expressions, counting processes, and sets of outcomes. This model has significantly enhanced educators' ability to analyze and understand students' combinatorial thinking. This study aims to focus on how personal interpretations and subjective judgments impact students' combinatorial thinking. By investigating this dimension, I propose subjective combinatorics as a construct to better understand the role of subjectivity in students' combinatorial thinking.

Literature Review and Contextual Insights

This research focuses on subjectivity in students' combinatorial thinking. I am not aware of any research that attends to this explicit focus. As such, in this section I turn to prior research on the related topics; I first describe several studies on subjectivity and then focus on research on students' combinatorial thinking.

On Subjectivity

To explore how subjectivity can influence the process of solving counting problems, it is essential to start by considering the definition of counting problems themselves. A counting problem highlights restrictions in representing a set of outcomes and tasks students with determining the cardinality of the set of outcomes. Expanding upon the definition of counting problems, the highlighted restrictions can be presented either explicitly or implicitly. When restrictions are given implicitly, they can be interpreted subjectively. For example, in counting the number of outfits when there are two shirts, five pairs of pants, and three hats, the word "outfit" could be interpreted subjectively. For one student, having a hat as part of an outfit might be a necessity, while another student might find a shirt and pants sufficient. As exemplified, the word "outfit" has many distinct interpretations. Hence, students' answers will depend on how they interpret "outfit". Since a counting problem can be interpreted differently from one person to another, the set of outcomes that needs to be counted could therefore be different.

Attending to the ways in which students specify outcomes while solving counting problems highlighted the subjectivity in their combinatorial thinking. This led me to consider a new aspect of combinatorics, to which I refer as *subjective combinatorics*. Although the subjective aspect of some areas in mathematics such as probability has been considered in the mathematics education literature (Chernoff & Zazkis, 2011; Jones, Langrall, & Mooney, 2007) the subjective aspect of combinatorics has not been studied explicitly.

According to Jones et al. (2007) "*subjective probability*, describes probability as a degree of belief, based upon personal judgment and information about an outcome" (p. 913). Batanero et al. (2005) highlighted "in this subjective view, what is random for one person might be nonrandom for another…a degree of uncertainty specific for each person" (p. 24). Borovcnik et al. (1991) clarified "the basic assumption here is that subjects have their own probabilities which are derived from an implicit preference pattern between decisions" (p. 41). According to Hawkins, & Kapadia (1984) "to a greater or lesser extent the probability is an expression of personal belief or perception" (p. 349). Combinatorics, like probability, involve a degree of subjectivity influenced by the problem itself and the solver's knowledge and experience. I introduce the notion of *subjective combinatorics* and in what follows, I provide further motivation for this construct. I make a case that subjective combinatorics provides a valuable lens through which to study the learning and teaching of combinatorics. In particular, I argue that recognizing subjectivity in students' combinatorial thinking is beneficial to enhance our understanding of how students conceptualize counting problems. To this end, my research aims to develop a detailed description of subjective combinatorics and to explore its potential effect on students' combinatorial thinking. This dual focus aims to provide evidence for – and to lay groundwork for – future studies to examine subjectivity in students' combinatorial thinking. In particular, this study attempts to answer the following research questions: *How does subjectivity affect students' combinatorial thinking? How do students generate restrictions as they solve and evaluate counting problems that are susceptible to be considered subjectively?*

On Students' Combinatorial Thinking

Lockwood (2013) introduced a model of students' combinatorial thinking that included three components: formulas/numerical expressions, counting processes and sets of outcomes. Building on Lockwood's model, this study explores how subjectivity influences students' combinatorial thinking, particularly in their interpretation and generation of sets of outcomes. The concept of subjective combinatorics, introduced in the following section, serves as a guiding theoretical principle, with a central focus on the role of personal judgment in interpreting.

Theoretical Framework: Subjective Combinatorics

Drawing from the concept of subjective probability, *subjective combinatorics* views combinatorics as a matter of belief, shaped by personal judgment and information about outcomes. It depends on two things: the combinatorics problem and the knowledge and experience of the person solving the problem. Just as in subjective probability, where the likelihood of an event is assessed based on personal perspectives, subjective combinatorics acknowledges that different solvers may approach counting problems with varying assumptions, leading to different yet potentially valid solutions. This construct emphasizes the variability in how individuals conceptualize and reason through combinatorial tasks, which have been shaped by their experiences, understanding of the problem, and the context in which the problem is presented. I propose that the differences between "correct" and "incorrect" responses to counting problems, which stem from different subjective interpretations, are merely differences in the description of sets of outcomes. To determine the specific interpretation applied among the possible ones, insights can be gained by examining the comments from individuals who have solved the problem.

In daily life context problems, students might need to navigate two different interpretations simultaneously: one based on their understanding of the problem's requirements and another shaped by their personal experiences and prior knowledge. Balancing these interpretations can be challenging as they may need to reconcile what the problem explicitly asks with how they relate to it from their own experience. The notion of subjective combinatorics can shed light on understanding these diverse interpretations.

Methods

In this study, as part of a larger study, thirty-five preservice secondary mathematics teachers participated. At the time of data collection, they were enrolled in a mathematical methods course for teaching secondary mathematics within a professional development program in mathematics education. While their mathematics background and experience varied significantly, all held degrees in mathematics or science. The course is typically completed in the final semester of studies toward teaching certification. In this course, students are expected to enhance their personal mathematical knowledge and investigation skills, and to explore pedagogical approaches to secondary mathematics. The focus is on topics often overlooked in school but not requiring knowledge beyond the school-level mathematics.

Counting problems was one of the chosen topics for exploration. During class sessions, the participants were either reminded of or refreshed their knowledge of the multiplication principle and addition principle from their high school studies and discussed combination, permutation, the binomial theorem, and combinations with and without repetition. The students revisited different counting problems and discussed possible errors in counting problems. After these discussions, participants were given the following task:

You work with a class on counting problems. One of the problems asks students to solve the *Kittens problem*: There are 10 kittens up for adoption. How many different ways are there to distribute kittens to 7 people so that everyone gets at least one kitten and at most two kittens? Two students suggest two different answers.

Jamie's answer: $\binom{7}{3}$

Lucas's answer: $\binom{7}{3} \times \binom{10}{2} \times \binom{8}{2} \times \binom{6}{2} \times 4!$

1) Which answer do you agree with? Explain your reasoning. If you disagree with both, please provide your own answer and justify your reasoning. 2) What do you think was implicitly

assumed in each answer? 3) Why do you think the students made these assumptions? 4) Reflect on your engagement with the assignment: How have you dealt with it? Did you have any difficulties and/or dilemmas while working on the assignment? What have you learned through the process? The suggested length for responding to each question is about 150 words.

The *Kittens problem* was intentionally designed to allow for subjective interpretation, making it a suitable task for exploring subjective combinatorics. Some students might view the kittens as identical, while others might treat them as distinct entities. Additionally, one interpretation might require that all 10 kittens be distributed among the 7 people, whereas another might allow for scenarios in which only 9, 8, or 7 kittens are adopted. In the latter case, this would result in 2, 1, or 0 people receiving an extra kitten, respectively. Both suggested responses in the task are correct based on different interpretations. Jamie's and Lucas's responses suggest consideration of distributing 10 kittens among the 7 people, however, they do not share the same consideration for kittens. Jamie's answer assumes that the kittens are identical and focuses on choosing 3 out of the 7 people who will each receive 2 kittens. Since Jamie considers the kittens to be identical, there is no need for any additional counting processes or any additional consideration of the set of outcomes. Lucas's approach builds on Jamie's by considering the kittens as distinct entities. While Lucas also starts by choosing 3 out of 7 people to receive 2 kittens each, he incorporates additional steps to account for the distinct nature of each kitten. Lucas counts the number of ways to assign 2 distinct kittens to each of the 3 chosen people and then distributes the remaining 4 distinct kittens to the remaining 4 people. This involves considering $\binom{10}{2}$ for the first person, $\binom{8}{2}$ for the second, $\binom{6}{2}$ for the third, and 4! for the final distribution.

The participants' written works comprise the data for this study. The claims highlighting subjective interpretations served as a unit of analysis. Having repeatedly read the data, I looked for common themes by highlighting noteworthy explanations. I then categorized them based on participants' views on the uniqueness or interchangeability of kittens. This process involved examining how unconscious assumptions, real-world experiences, personal and mathematical connections, and level of detail influenced participants' interpretations.

Results

In the following analysis, participants' interpretations of the problem, whether viewing the kittens as identical or unique, are presented along with their reasoning. While the excerpts primarily focus on participants' interpretations and their reasoning, it is important to note that these interpretations directly informed their combinatorial thinking. Specifically, participants' interpretations shaped their understanding of sets of outcomes and their counting processes, as reflected in their alignment with either Jamie's or Lucas's approach.

Interpretation 1: Kittens as Identical

Unconscious assumptions. In solving counting problems, personal assumptions often play a significant role in shaping how individuals interpret and solve problems. The following excerpt illustrates this well.

> *Shawn:* I could immediately understand Jamie's answer because it matched my initial thinking. I found Lucas's answer very perplexing until I discussed it with my friend. He mentioned that the kittens could be considered unique or interchangeable. That is when I realized that I had been making the assumption that the kittens were interchangeable without even consciously making that choice. By thinking of the kittens as unique, I could then begin to understand Lucas's answer.

Shawn's explanation highlights an important aspect of subjective combinatorics: the role of unconscious assumptions in interpreting the problem. Initially, Shawn found Jamie's approach to the problem intuitive because it aligned with his own interpretation that kittens are identical. This assumption was made without explicit awareness. It was only after discussing the problem with a friend that Shawn recognized this underlying assumption and acknowledged that kittens could also be seen as unique. Shawn's experience underscores how unconscious biases towards viewing items as identical or unique can significantly influence students' combinatorial thinking.

Interpretation 2: Kittens as Unique

Real-world experiences. While all participants' responses suggest they agree people are inherently unique, some extend this perspective to kittens, recognizing their unique attributes.

> *Max*: Jamie was assuming that the kittens were not unique. The kittens, like the children, are different, so Jamie's expression does not account for all the permutations of different children holding different kittens.

Max challenged Jamie's assumption by likening kittens to children, rejecting the idea that they can be considered identical, and emphasizing that each kitten, like each child, should be considered unique. This perspective is echoed by Heather, who supports Lucas's interpretation by emphasizing that kittens have unique markings, sizes, and personalities, much like humans.

> *Heather*: I agree with Lucas. Kittens have both unique markings, sizes, and personalities therefore it is fair to treat them as unique objects. Humans are similarly typically considered unique objects. Therefore, we are ordering one set of unique objects onto another set of unique objects.

Heather extended this idea further by noting that the problem involves matching one set of unique objects (kittens) to another (humans), reinforcing the importance of recognizing these individual attributes in her combinatorial reasoning.

Matthew's explanation links real-world experiences and combinatorial thinking.

> *Matthew*: When thinking about this question, Lucas appears to have an image of 10 distinct kittens that are up for adoption. This is a fair assumption, since each kitten would naturally be different. A typical animal shelter that offers kittens for adoption would have kittens that already have their own names, and a personalized description for each kitten before they are put up for adoption. During the process of acquiring a kitten, a person also usually chooses a kitten based on a number of factors such as their personality, gender, or compatibility with other animals, thus making each choice unique.

Matthew highlighted the realistic context of an animal shelter to emphasize the assumption of unique kittens. He drew a parallel between the counting problem and the real-world scenario of adopting kittens, where each kitten typically has a distinct name and description. This real-life context supports the idea that each kitten is perceived as unique, similar to how they are treated in actual adoption settings. Matthew's explanation illustrates how real-life contexts can shape students' assumptions in combinatorial reasoning.

Dual Interpretation: Kittens Could Be Either

Personal and mathematical connections. While the earlier discussion highlights the influence of real-life contexts on interpreting the uniqueness of kittens, the following excerpt explores how personal experiences in combinatorics and emotional connections can simultaneously lead to seeing kittens as both identical and unique. This dual interpretation highlights the complex interplay between combinatorial experiences and personal experiences in shaping one's approach to combinatorial problems.

Heather: Most math questions are set up so that if there are 10 kittens all must be distributed unless otherwise stated thus people tend to compare to other previous examples and will assume all kittens must be distributed. Also when discussing the adoption of kittens most people have an emotional preference to having them all adopted out. The confusion as to whether kittens are unique or not may either stem from a comparison to other math examples where objects are frequently treated as identical unless otherwise stated or from their experience with kittens and how they picture the scenario. For example, most people who have previously adopted a kitten and picture this scenario as 7 people going to an agency meeting the kittens and then going home with one or two kittens will know that going home with kitten 1 instead of kitten 2 could feel drastically different for that person. However, if the person is picturing a scenario where an adoption agency is just going to deliver kittens they have never met it might not matter which one you get since you never met kitten and kitten 1 is still a kitten you get to play with or perhaps the person has never met a kitten before and is unaware of their unique personalities, markings and sizes.

Heather's assumption that all kittens must be distributed and might be treated as identical stems from her experience with combinatorial problems. This reflects how her past experiences in combinatorics have shaped her initial subjective interpretation of the problem. However, she also noted that real-life experiences and emotional preference with kittens can influence students' interpretations, leading them to see the kittens as either identical or unique, depending on how they picture the scenario.

Level of detail. While Heather's explanation brings attention to how mathematical experience and personal experience both contribute to a dual interpretation, the following excerpt further explores how the level of detail and personal connection can shift one's interpretation.

Shawn: If I want to categorize something as "bird", I am probably only looking to see if it has a beak and wings. If I want to categorize something as a wood duck, I now have to consider the size, the colouration of the feathers, the body shape, and the habitat. The word kitten is a high level category. It can easily lead to thinking of kittens as generic and interchangeable. Whether one particular person thinks of them as interchangeable or unique probably depends on how they feel about cats in general, and whether those ten cats are physically in front of them. I initially approached the problem seeing the kittens as interchangeable, but if I had to choose a pet from a specific group of kittens, I would have a preference for which one I wanted, meaning that I felt that the kittens were unique.

Shawn's explanation touches on how the level of specificity in categorization can influence whether one perceives objects as interchangeable or unique. This suggests that how one frames the problem—whether focusing on broad categories or specific details—can shape the subjective interpretation of the elements involved. Shawn's shifting perspective—from seeing kittens as generic to recognizing their uniqueness based on situational factors—illustrates how subjective interpretations can evolve as more context or personal connection is applied. Similarly, the following excerpt contrasts how different levels of detail in viewing the kittens can lead to different interpretations.

Dmytro: If Lucas views kittens as complex with different colours, personalities, genders, etc. then in his eyes kittens aren't just kittens. Each one is complex enough in that they should be distinguished from one another. Where Jamie may view kittens as just kittens. More on a macro level like they are all just one species.

Dmytro's explanation highlights the varying levels of complexity with which individuals might perceive and categorize objects, such as kittens, in combinatorial problems. His distinction between viewing kittens as a homogeneous group versus recognizing their unique attributes underscores how subjective judgment influences whether objects are seen as interchangeable or unique. This analysis suggests that the level of detail one applies to a problem can significantly shift the outcome of their reasoning.

Discussion and Conclusion

In this paper, I introduce *subjective combinatorics*, with the goal of providing language to describe different interpretations involved in students' combinatorial thinking. As discussed in the introduction, in recent years, the mathematics education research community has increasingly focused on addressing students' underlying conceptualizations of combinatorial ideas. This study addresses subjectivity in students' combinatorial thinking, thereby filling a gap in the mathematics education research on the area of combinatorics.

To explore subjective combinatorics, I examined how participants attended to a counting problem that allowed for distinct interpretations. The study focused on two main aspects: the restrictions participants generated while engaging with counting problems and the impact of their interpretations on their combinatorial thinking. In particular, this study addressed the following research questions: *How does subjectivity affect students' combinatorial thinking? How do students generate restrictions as they solve and evaluate counting problems that are susceptible to be considered subjectively?*

In addressing the research questions participants were presented with a counting problem which highlighted students' disagreements regarding solutions, drew participants into a situation where they faced varied interpretations. The task encouraged participants to engage with the numerical expressions/formulas component of Lockwood's model. The variation in interpretations—whether treating kittens as identical or distinct—affected how participants made sense of the suggested answers. This variation demonstrated how different conceptualizations of the problem influenced their counting processes and considerations of sets of outcomes. The results highlight how different conceptualizations of the problem influence students' combinatorial thinking. Furthermore, the results indicate that participants' interpretations of the set of outcomes were significantly influenced by unconscious assumptions, real-world experiences, personal and mathematical connections, and the level of detail considered. The findings illustrate how these factors shaped students' views on the uniqueness or interchangeability of objects in combinatorial problems. This underscores the importance of considering subjective factors when analyzing students' counting activities, as these factors can lead to diverse and sometimes conflicting interpretations of the same problem.

This study reveals the subjective nature of students' combinatorial thinking and the significant impact of personal context on their interpretations. Recognizing how these subjective factors affect students' combinatorial reasoning can offer valuable insights for educators. This understanding can lead to more effective teaching strategies that consider the diverse and personal ways students engage with counting problems. Lastly, the focus on a specific type of combinatorial problem may not capture all aspects of subjectivity in students' combinatorial thinking. Future research could benefit from exploring subjectivity across a broader range of combinatorial problems to gain deeper insights into students' combinatorial thinking. Additionally, future research might explore approaches to formulating combinatorial problems that reduce subjectivity, potentially leading to more consistent interpretations of students' combinatorial thinking.

Utilizing Video Resources in Undergraduate Mathematics Classes: A Systematic Review Research Synthesis

Catherine Dennis
University of New Hampshire

The increased use of educational technology has raised questions about technology equity in mathematics education research and pedagogy. This paper provides a subset of findings from a larger systematic review, which aims to investigate literature on equity and personal device use in undergraduate mathematics courses from 2009-2023. For the systematic review, literature was searched and screened for information on personal device access, utilization, and outcomes. This paper reports on the subset of findings specific to the utilization of video resources in mathematics classes. Through the synthesis process variable information regarding student outcomes and student perceptions of use was pulled from 82 studies. Findings suggest that the use of video resources correlates to either higher academic outcomes or no difference in academic outcomes. Additionally, student perceptions suggest that video resources can afford an equitable educational experience in a variety of ways, but elements of distraction and communication can serve as limitations.

Keywords: research synthesis, personal devices, video resources, technology

Technology use in the teaching and learning experience has become more ubiquitous since the turn of the century (Meehan & Halmun, 2016), especially in the form of utilizing personal devices, such as laptops, tablets, or smartphones (Galanek et al., 2018). Mathematics education scholars have raised questions about the implications of personal device use in terms of equitable education. To investigate the research on equity and technology in the literature Hennesey & Dunham (2008) published a research synthesis, *Equity and use of Educational Technology in Mathematics.* The results suggested individual students' access to technological devices varied by household and utilization proficiencies differed by identity traits, such as gender. Hennessy and Dunham concluded that a variety of factors are intertwined into answering questions involving equity and device use, including levels of access and how the technology is being integrated into the mathematics curriculum.

Since the publication of Hennessy and Dunham's 2008 research synthesis technology use in the classroom has undoubtably changed over time. For example, during the early 2000s home and school technology access was limited (Swain & Pearson, 2002). However, personal devices have become more commonplace in society at large over the last two decades. A new population of students, known as *digital natives*, are now navigating higher education with a variety of life experiences involving technology (Filippi & Agarwal, 2017; Galanek et al., 2018). This shift in the undergraduate population, as well as the gap in time since the last research synthesis, motivated a large systematic review project analyzing more recent literature on personal device access, utilization, and outcomes for undergraduate mathematics students. The results for this paper focus on a subset of the systematic review results, utilization of mathematics video resources on personal devices. Utilization is synthesized in terms of both student perceptions of the video resources and the relationship to student outcomes.

Framework

Fennema's (1990) equity framework, accommodated by Hennessy & Dunham (2008) for technology-specific research, was used in this review. This framework navigates literature on equity and technology in mathematics with three lenses: access, utilization, and outcomes. The access component explores mathematics students' access to personal devices and the affordances and barrier that may exist around device access. Personal device utilization encompasses the differing uses of personal devices and their affordances and limitations in mathematics. The multitude of resources available through personal devices have the potential to accommodate a variety of students' learning needs, which is necessary for equitable education (Tan et al., 2019). Student outcomes can also be used as measurable data for statistical analyses in research. This review addressed outcomes in terms of improved learning outcomes and retention rates, both of which are important for investigating equity in education. This paper reports findings using the utilization and outcome portions of the framework.

Research Question

1) In the literature since 2009, what are the results surrounding undergraduate mathematics students' video resource utilization in terms of student perceptions and outcomes?

Methodology

There are four steps in the systematic review methodology: searching, screening, extracting the data, and synthesis & analysis. In order to search and screen the literature inclusion and exclusion criteria must first be created.

Inclusion/Exclusion Criteria

Literature inclusion and exclusion criteria were established through the SPIDER framework (Cooke et al., 2012), which comprises the following elements.

Sample. The sample of interest within the literature is undergraduate students using personal devices in mathematics courses.

Phenomenon of interest. The phenomenon of interest is student access and utilization of personal devices in undergraduate mathematics courses. Personal devices in this review include tablets, computers, and smartphones. Research on calculators is beyond the scope of this review.

Design. This review incorporates qualitative, quantitative, and mixed methods studies through content analysis and Miles & Hubermann's (1994) synthesis methodologies.

Evaluation. Studies were first reviewed to establish the variables for evaluation within access, utilization, and assessment. For the systematic review the access variable was used to evaluate levels of access and barriers to access. Utilization was evaluated in terms of the type of personal device utilization, student perceptions on the device utilization, and the relationship to student outcomes in undergraduate mathematics courses. Outcomes involved both student learning outcomes and retention rates.

Research type. This review included empirical research with quantitative, qualitative, or mixed methods methodologies. Peer reviewed literature and grey literature (dissertations, conference proceedings, etc.) were included and found through the search and snowballing process.

Searching

The goal of the searching process was to find literature involving undergraduate mathematics students' personal device access, utilization, and outcomes. Literature published between 2009-

2023 was searched, to prepare an updated synthesis since Hennessy & Dunham's 2008 publication. ERIC (EBSCO Host), Education Source (EBSCO Host), and The International Journal of STEM Education and PRIMUS, through the University of New Hampshire PRIMO system, were searched to find the 27 foundational studies before snowballing, otherwise known as the start set. The searching methods included Boolean operators with synonyms found either on the ERIC thesaurus or through discussions with colleagues. The search string included four sections, (personal devices) AND (mathematics education) AND (equity) AND (undergraduate students). Each section included a list of synonyms for search terms, separated by OR to find a greater variety of literature.

Screening

Two types of screening were completed for this systematic review: title/abstract screening and full text screening. Studies found through the search terms and systems previously mentioned were screened using the SPIDER framework's inclusion/exclusion criteria. Three rounds of snowballing (forward and backwards) were completed on the 27 foundational studies to find additional literature for inclusion in the systematic review. Through the screening of 17,196 studies, a total of 357 were found to meet all inclusion criteria and were synthesized in the systematic review. The 27 foundational studies in the start set were then reviewed to establish how the literature discusses access, utilization, and outcomes to establish synthesis variables for extraction. For example, studies discussed resources utilization in terms of who assigned or chose the utilization (teacher vs. student choice) and student perceptions of the utilization. Therefore, utilization variables included sub-variables for data extraction of "assigned vs. choice" and a "student perception".

Data Extraction

After establishing the variables of interest within access, utilization, and outcomes, data was extracted from each study using data extraction forms (Briner & Denyer, 2012). Variable data and general literature data, such as country and methodology of research, were extracted to supply some background information on the included studies.

Data Synthesis and Analysis

Synthesizing literature is a process of aggregating the results of multiple studies to establish new knowledge about a phenomenon of interest in the field (Campbell et al., 2003; Denyer & Tranfield, 2009). Literature was first synthesized in this review by looking for common themes or results amongst the data extraction forms. It was then analyzed through cross case data analysis methods and content analysis.

The Miles and Huberman methods involve coding results and establish themes amongst those codes (Dixon-Woods et al., 2004; Miles & Huberman, 1994). This process was used when aggregating and synthesizing results surrounding student perceptions of video utilization. For example, some student perception codes included "Flexibility, mobility, can learn anywhere, helpful for pacing learning, can pause videos, can rewind videos, and can split into smaller learning chunks". Codes were grouped together into the theme "Flexibility and Pacing for Learning". Content analyses were also conducted to count frequences of variable information occurrences amongst the results of each study (White & Marsh, 2006).

Results

Of the 357 studies synthesized for the systematic review project 86 use qualitative methods, 144 used quantitative methods, and 127 used mixed methods. Additionally, studies were conducted in 52 different countries. Through synthesizing and analyzing the studies for this review, six major categories of utilization were found amongst the literature: online learning modality, the flipped classroom, video resources, online homework/practice problems, communication, and additional tool interventions. Please note the results reported in this paper are a subset of the larger results and focus only on the utilization of video resources.

Utilization Perceptions & Outcomes of Video Resources

This section reports results surrounding video resources, from 82 studies, in terms of both student perceptions and student outcomes. Video resources include videos made by the instructor, class recordings, and supplemental videos, such as YouTube or Kahn Academy.

Student perceptions. Student perceptions on the utilization of video resources with personal devices were investigated in 75 studies. Table 1 outlines the different student perceptions and the larger themes that they fit into (underlined). Frequency counts through a content analysis were taken in order to display how many studies reported a given perception, affordance, or limitation. While some studies reported a general liking or positive perception for video resources, counted in the positive perception frequency count, others went further detail about the elements of video resources that students found useful or limiting. A perception, affordance, or limitation was included in the table if it appeared in at least two studies.

Table 1. Student Perceptions of Video Resources

Theme Subcategory/Perception	Study Frequency
Affordances or Positive Perceptions	75
Flexibility and Pacing for Learning	25
Flexibility or Mobility	10
Helpful for Pacing Learning	10
Pausing & Rewinding Features Useful	11
Can Split into Smaller Learning Chunks	3
Modes of Representation and Engagement	8
Visual Aids in Videos	7
Multiple Modes of Representation & Engagement	3
Supplemental Learning	16
Improved Confidence on Prerequisite Knowledge/Closed Learning Gaps	6
Students Found Supplemental Videos Useful	9
Makes Math More Enjoyable	3
Limitations or Negative Perceptions	7
Need for More Communication with Instructor or Other Students	5
Distraction or Lack of Motivation Using Technology	2

Throughout the literature undergraduate students reported both positive and negative perceptions for using video resources for learning mathematics. Positive perceptions include themes of self-pacing and learning flexibility, videos providing multiple forms of representation and engagement for learning, videos affording additional supplements for learning, and videos making mathematics more enjoyable. Negative perceptions included students wanting more direct communication with peers and instructors for collaborative learning and a general lack of motivation or distraction using personal devices to watch mathematics videos.

Student learning outcomes and retention. Student learning outcomes for the systematic review were assessed in one of three ways: better outcomes with device use, no difference in outcomes, or better outcomes with control group (no device use or less frequent device use). Also note that the assessment to measure learning outcomes varied by study. For instance, some used exam scores, while others used final grades. In the review 22 studies investigated video resources and learning outcomes. Some compared video resource use to no resource use, while others looked at frequency of use. Figure 1 shows the frequency of study results in terms of the three possible outcomes.

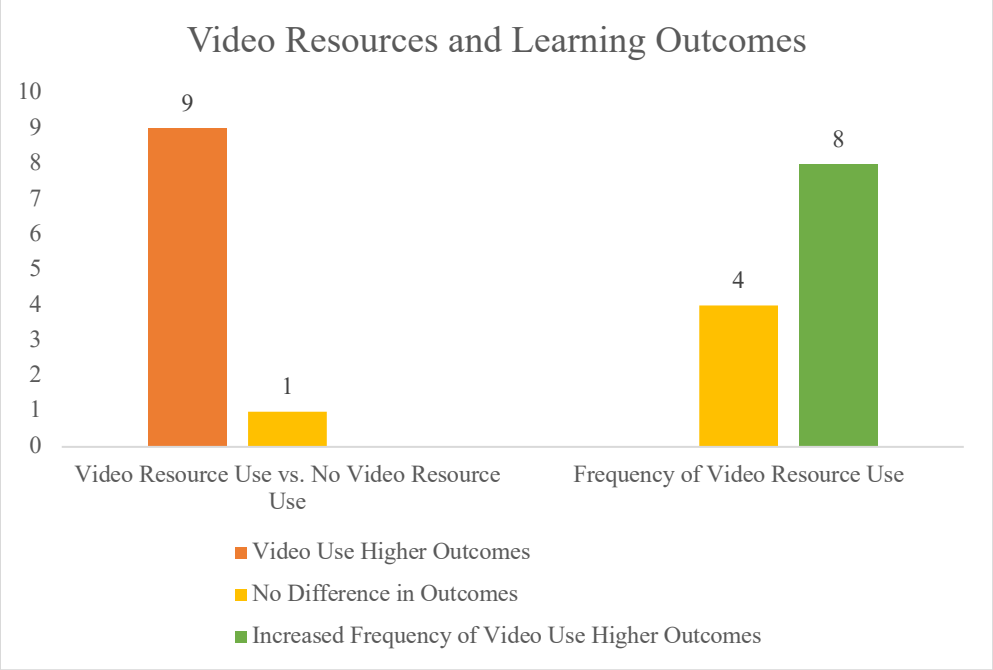

Figure 1. Video Resources and Learning Outcomes Results Amongst Studies

In the studies examined, the results suggested that groups who utilized video resources either had higher academic outcomes or no difference in academic outcomes compared to the control groups. The same was true when comparing the higher frequency use group to the lower frequency use group. Only one study reported on retention rates in relationship to video resource use and suggested that video resource use was related to higher retention rates than the control group, implying that students were more likely to drop out of the course if there were no video resources available for learning in the course.

Discussion

Systematic reviews can afford both scholars and educators a better idea of the existing knowledge within the field and assist with future research and pedagogical choices (Briner & Denyer, 2012). This section will provide an overview of the findings from this part of the larger systematic review, how they may impact the field of mathematics education, and the limitations to the study.

The literature in the systematic review was from 52 countries around the world, suggesting it is an area of interest for scholars at a global level. Additionally, all three empirical methodologies were used amongst the literature: qualitative, quantitative, and mixed methods. These multiple methodologies afforded a variety of data types for synthesis and analysis and suggest there is no one way to investigate personal device use in undergraduate mathematics courses.

Video Resource Utilization

While six categories of utilization were established in the systematic review project, this paper only focused on personal device utilization for video resources. In terms of student perceptions there were more papers reporting positive perceptions or affordances than negative perceptions or limitations. According to the literature, students found video resources useful for flexible, paced learning practices, multiple modes of representation and engagement, such as visual aids, and closing learning gaps. In turn, student participants in the literature reported feeling easily distracted while using personal devices and wished for more live communication with others while learning, which the videos could not provide. Learning outcomes were either higher with video resource interventions or there was no significant difference. These findings are significant for educators when deciding what resources to provide or encourage students to utilize in mathematics learning. Students may be more likely to utilize video resources than others because of the positive perceptions and ability to pace for student agency over learning. The research suggests video resources do not hinder learning outcomes and may even improve them. Additionally, student participants reported many video resource affordances that align with equitable educational practices. The affordance of multiple modes of representation and engagement is beneficial for diverse learning needs, which supports equitable learning practices (Tan et al., 2019). The process of closing learning gaps, reported by students in multiple studies, is equitable because it provides the ability for students to achieve a similar starting line. Students found videos to be beneficial for self-pacing and splitting into smaller learning chunks as well. These student-made learning decisions can promote learner autonomy, a skill known to be necessary for undergraduate learning and career development (Caprara et al., 2008; Zimmerman, 2008).

Given these findings amongst studies, educators may want to include video resources for their mathematics students. By providing supplemental resources that students generally enjoy utilizing, and find useful for learning, pacing, and multiple modes of representation, students may be able to learn mathematics in a more equitable, inclusive way. Furthermore, the review found either no change or improves academic outcomes with video resource use, suggesting that video utilization has the potential to improve mathematical learning. However, the synthesized findings indicate some cautionary measures should be taken, such as still maintaining educator-student communication and being aware of the potential for distraction while on a personal device. Educators may be able to accommodate students' communication needs by opening new avenues for inquiry, such as a discussion board, to assist with questions or concerns that may

arise while watching videos. Additional research can be done to further investigate how to address elements of distraction and focus with personal device use as well.

Limitations

Synthesizing data from studies with multiple methodologies can be difficult in a systematic review (Mays et al., 2001). While the techniques for data synthesis and analysis in this study afforded the ability to aggregate qualitative, quantitative, and mixed methods data, the analysis is not as robust as more rigorous statistical methods, such as meta-analysis. Hence, assumptions made from the findings should be made with caution. The methodology for searching in a systematic review is used to find the most literature possible on a given topic or phenomenon. The process of snowballing was used to find a large variety of research findings and grey literature, but note it is not possible to complete a fully exhaustive search, so other studies on this topic may still exist outside of this review.

Conclusion

This paper includes a subset of findings from a larger systematic review project on personal device use in undergraduate mathematics classes. Literature was searched and screened for evidence of findings involving the three elements of Fennema's (1990) equity framework: access, utilization, and outcomes. Through review synthesis and analysis, results regarding personal device video resource utilization student perceptions and video resource outcomes were discussed. Video resources were utilized in 82 studies, with results regarding both student perceptions and student outcomes. Students reported affordances involving equitable benefits, such as multiple modes of representation, self-pacing, and closed learning gaps. However, students also reported negative perceptions involving elements of distraction and lack of communication. Student learning outcomes were either improved with video resources or no difference was found.

This review is beneficial for both research and pedagogy. Scholars can use the information to further investigate ways to improve upon the limitations reported and find elements of video use that are most beneficial to learning. Educators can use this review to inform decisions around personal device access and utilization within the classroom. The findings suggest a general student liking and perception of usefulness, as well as unchanging or improved academic outcomes. Therefore, providing video resources for student use may be beneficial to both student enjoyment of mathematics courses, as well as mathematical understanding. However, educators should take caution with providing meaningful communication outside of video use, and the potential for distraction.

Acknowledgments

Thank you to Dr. Sheree Sharpe and Dr. Karen Graham for your continued support and assistance with this research project.

Many undergraduate mathematics departments are seeking to improve equity in their programs; however, they may struggle to translate these goals for equity into action. In this study, we used Cultural Historical Activity Theory (CHAT) theory to investigate the evolution of a Networked Improvement Community (NIC) focused on improving equity within their mathematics department, highlighting ways that NIC discourse evolved to support more critical, action-oriented activity. By examining field notes of meetings, documentation (e.g., agendas), interviews, and journal entries from NIC members, we identified key components of the NIC activity system. Our analysis revealed ways that NIC leaders mediated tensions between their object (goals) and implicit discourse norms governing NIC conversations. Specifically, we found that to make progress toward their goals, NIC leaders needed to establish an explicit rule to take certain topics "off the table" in NIC meetings. This rule facilitated discourse that was more action-focused than previously observed.

Keywords: critical transformations, equity, activity system, mathematics

Local data typically show mathematics departments have equity problems: inequitable student outcomes, encompassing not just grades, but course-taking patterns and trajectories, as well as mathematical efficacy and views on the value of mathematics in the world (e.g., Denaro et al., 2022). However, there is little in the way of coherent direction for department members to know what to do to address inequities in mathematics teaching and learning. Indeed, there is no singular "checklist for equity" that can magically "fix" inequities that have deep roots in our culture, educational systems, and institutional systems.

The ACT UP Math project partnered with three mathematics departments to establish networked improvement communities (NICs; Martin et al., 2020) as part of a research-practice partnership designed to help mathematics departments wanting to use data to make critical transformations to address inequities. A NIC is a community of people working toward a common improvement goal, in connection with others across a network. NICs typically are driven by improvement science, iteratively planning and testing improvement ideas through multiple improvement cycles of observation, reflection, planning, and action. NICs are an ideal vehicle for approaching critical transformation efforts; the emphasis across the network is adaptation to local contexts, not replication. For this paper, we focus on the activities of one of the mathematics departments - Tau University as they worked toward critical transformation. In our work (see Hagman et al., 2024), we define making critical transformations as challenging and critiquing the existing systems that create inequitable mathematical experiences.

In seeking to understand the progress of NICs, where "progress" is defined as moving toward the NIC's improvement aim, it can be difficult to tease out the impacts of individual beliefs, collective beliefs, perceived constraints, and systemic constraints. Cultural Historical Activity

Theory (CHAT) provides a valuable lens through which to understand the activities of a NIC (Vygotsky, 1978; Engeström, 1987), particularly to understand change (Turner et al., 2017). Núñez (2021) applied CHAT perspectives to investigate equity-oriented higher education organizational and systemic change; Núñez found the application of CHAT afforded a fine-grained analysis of group activities that delve into cultural practices and how those are sustained or changed over time. CHAT provides a way to understand the roles and values of individuals, while maintaining a focus on the activity system, and allows for interrogating power dynamics and inequities. **Our overarching research question for this study is**: How did the NIC evolve as an activity system during one improvement cycle (from Summer 2023 - Spring 2024) to better support critical transformations?

Methods

Our study methodology is critical ethnography (Palmer & Caldas, 2015). As researchers engaged in a research-practice partnership (Coburn et al., 2021), we are immersed in the data as ethnographic researchers and as participants. Since Fall 2022, we have been working closely with the NICs in our project to better understand their institutional contexts and goals related to critical transformations toward diversity, equity, and inclusion and documenting all interactions.

Data for this study come from a larger project studying three NICs engaged in critical transformation efforts. The focus of this study is on the Tau University NIC, led by three faculty who all teach courses for the mathematics department but have different roles (Natalie, a lecturer; Garrett, a professor of practice and course coordinator; Olivia, a professor and college-level administrator). Tau University is a public, doctoral degree-granting university with high research activity located in the Southern United States. For this study, we draw on the following data sources collected between May 2023 and May 2024 during one improvement cycle of the NIC: individual interviews with NIC leaders (60 min/annual), structured field notes of monthly NIC meetings and planning meetings, NIC member reflective journals (approximately three times per semester), and project documentation (e.g., meeting notes; products from project activities, such as when NIC members reflected in a Google Jamboard about definitions of equity).

The research team, who are regularly observing Tau NIC meetings and facilitating interviews, met weekly over the past year to debrief observations, discuss the goals and challenges of the NIC, and make plans to support the Tau NIC's work. As part of these discussions, we kept notes of research observations as well as themes and storylines present in the efforts of the Tau NIC. One storyline that was consistently present in the NIC data was the shift toward critical transformations in the form of discourse patterns about students at their institution. The Tau NIC leaders were introduced to an anti-deficit framing of students through a presentation from and conversations with our project team, where we drew on the equity-oriented work of Adiredja (Adiredja, 2019; Adiredja & Louie, 2020) and Gutiérrez (2009; 2013). From this point, we kept a comprehensive evidence log of data for instances where Tau NIC members defined critical transformations, described their efforts toward equitable or critical outcomes, or talked about students in their courses or at their institution. After the presentation, NIC members more clearly articulated a goal toward critical transformations and began explicitly addressing their assumptions and language about students in NIC meetings.

Our data analysis consisted of several iterations of analyses, for each data source (e.g., interviews, observation field notes, journals) and for each storyline (e.g., leader goals, discourse about students), similar to narrative coding (Saldaña, 2013). Once we determined that we were viewing the evolution of the Tau NIC as an activity system with the leaders working toward

specific goals via NIC activities, we began to align the NIC's evolution with the seven components of the Cultural Historical Activity Theory framework.

Analytic Framework: Cultural Historical Activity Theory

Cultural Historical Activity Theory (CHAT) is a theory to understand object-oriented activity undertaken by an individual. In other words, a subject's thoughts and actions are directed toward a goal or object; Vygotsky's (1978) initial theory was that the object is realized (as an outcome) through meditating tools/artifacts. Later, CHAT was extended by Engeström (1987) to emphasize the collective nature of object-oriented activity; this work added the components community, rules, and division of labor to the framework (see Figure 1). CHAT can be used to frame how we understand complex, dynamic systems, particularly those that involve tensions and evolve over time (Engeström, 2001). CHAT also examines the history of the activity system and multivoicedness of those involved, emphasizing that the subjects bring various perspectives, interests, and conventions, such as stakeholders in different roles within an educational setting (Hancock & Miller, 2018). We draw upon the second generation CHAT (Engeström, 1987) to examine the activity of the Tau NIC.

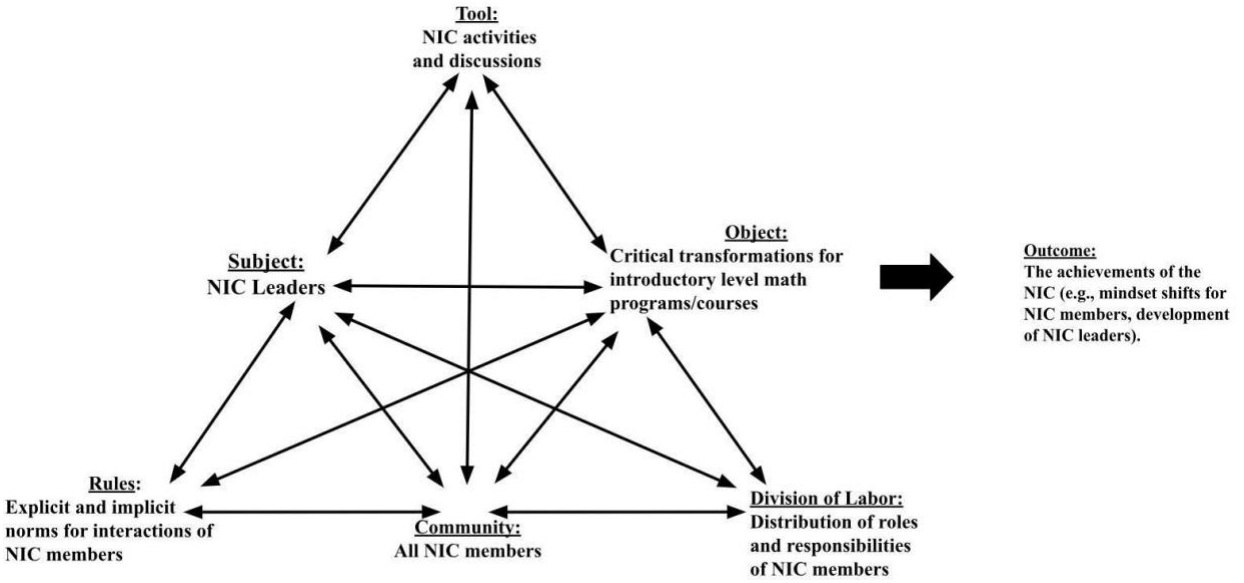

Figure 1. Second Generation CHAT Framework (Engeström, 1987) with Tau NIC activity system components

When applying the CHAT framework as an analytic tool, one of the initial steps is to operationalize the framework by determining what are the subject, object, tools, rules, community, division of labor, and outcomes in the activity system. Figure 1 briefly describes the Tau NIC features we drew upon to determine each CHAT component. The subject, community, and division of labor were operationalized based on observations of NIC planning meetings and artifacts, and our understanding of the formation of the Tau NIC. We operationalized the object, tools, and rules of this activity system based on an in-depth qualitative analysis of journal entries, leader interviews, observational field notes, and (ongoing) outcomes of the NIC within their institution. From this analysis, we identified a significant evolution in the rules of discourse governing the NIC, brought about by tensions between the object of the NIC activity system and the implicit rules governing how NIC members interacted with one another. This evolution supported the NIC's capacity for critical transformation. In the findings section, we describe this evolution in detail.

Findings

In this section, we focus on the NIC leaders' creation of an explicit rule for discourse due to tensions between the goals (object) and implicit rules for discourse established within the NIC's activity system. Based on observations of planning meeting between the three Tau NIC leaders and their journal entries, we identified three primary goals guiding the activities of the NIC:

1. Improve diversity, equity, and inclusion in mathematics at Tau University
2. Improve student experiences in mathematics at Tau University
3. Support mathematics faculty in creating equitable and inclusive experiences at Tau University

Meetings with the ACT UP Math research team in August 2023 equipped leaders with ideas for NIC activities (tools) which could support NIC members in thinking about critical transformations, including promoting an "anti-deficit" perspective of students. Natalie highlighted the importance of this critical language to her goals, "I have learned a lot about my own biases. The biggest impact on my attitude has been the phrase 'students are experts on their own experiences,' rather than just novices in the classroom" (Fall 2023 journal). Similarly, in a Fall 2023 journal entry Olivia wrote, "And a big part of [achieving those goals] is shifting the way that they look at our students, not from a deficit standpoint, but from looking at their student's potential." Thus, for at least one NIC leader, a major goal was to shift faculty mindsets in support of critical change.

Two Relevant Rules for Discourse

The NIC activity system had two rules which we identified as important in understanding the NIC leaders' decision to introduce a more explicit rule governing the NIC's discourse. One rule was that NIC members trust one another and are open to sharing about their experiences. The second rule is that NIC members are allowed to share frustration about students, including a perceived systemic lack of mathematical preparation of the students in their classes. We next describe the formation of these two rules, and the ways in which they supported or inhibited the object of the Tau NIC activity system.

Rule: NIC members trust one another and are open to sharing about their experiences. Evidence from observations indicates that most NIC members were willing to share vulnerable teaching experiences with one another. This was likely supported by the example set by NIC leaders. For example, Garrett often shared his "mistakes" and personal realizations with the group, and we observed Garrett and Natalie intentionally planning what experiences they would share in whole group meetings as a way to model vulnerability with others and ways to question one's practices. This openness often supported the NIC in thinking critically about practices and in working to understand student experiences. However, the level of trust and openness that NIC members felt for each other also supported an implicit rule which at times impeded the object of the NIC, namely a rule that NIC members could share their frustrations. Olivia commented on how the NIC has a "tendency to focus on the negative" in conversations (Tau NIC Planning Meeting - 2023.02.16). Often these frustrations turned to negative comments about students, particularly a perceived lack of preparation for precalculus courses.

Rule: NIC members are allowed to share frustration about students, including a perceived systemic lack of mathematical preparation of the students in their classes. Since the beginning of the NIC, it was apparent that NIC members felt comfortable sharing their frustrations about students, particularly frustrations with their prerequisite mathematical knowledge. We observed multiple occasions of faculty publicly discussing their frustrations during NIC meetings. In the first NIC planning meeting, Garrett expressed being nervous "that

people will just complain about students if there is extra [unplanned] time" during NIC activities (Tau NIC Planning Meeting - 2023.01.19). At first, the NIC leaders seemed to operate as if this was inevitable, and planned around it. For example, in one planning meeting Garrett described how he chose to share data and analysis from his own classroom (mediating tool) to help shift the conversation away from complaining about students:

> I know that whenever faculty get together, we just talk about whatever is bothering us. So we got into that [complaining] and I was like, 'oh I have to get us out of that conversation'. So then I started talking about my data and just sharing my analysis.

In another planning meeting, Garrett shared an additional strategy (mediating tool) for shifting conversations away from complaining: "if it comes to where people start complaining, I will try to have some questions in my pocket." (Tau NIC Planning Meeting - 2023.10.23) In a later meeting, Olivia assured Garrett that she would "jump in" if faculty did start going "off the rails" (Tau NIC Planning Meeting - 2023.11.08). Thus, it seems that the leaders desired to minimize deficit discourse about students, but it was an implicit goal that was not shared with the other NIC members (community). There was also some evidence that NIC leaders felt empathy for faculty members as they shared their frustrations. In his Spring 2024 interview, Garrett described how when "you're in your class, and these things are happening, and then you are in some sort of situation where there's other people with a shared experience, and you want to share - you vent." Garrett felt that this venting was not "necessarily deficit" oriented and stressed the importance of having discussion prompts planned ahead of time so that when instructors "start grumbling" he can move them "forward." In fact, Natalie's observation of her own "venting" and its effects prompted an introduction of a new, explicit rule in the Tau NIC activity system, which we describe below. Garrett was drawing on his experience as a course coordinator when he normalized instructor complaints about students, and also argued that part of the role of facilitating instructor meetings is having explicit strategies or tools (e.g., discussion questions) that can move a group forward. Such tools were used by NIC leaders to shift discourse, but a lack of progress toward critical transformations in the NIC eventually contributed to a desire to make more explicit rules for discourse about students within the NIC activity system.

Explicit Shifts in Discourse: Re-examining What is on the Conversation Table

During Spring 2024, the NIC leaders observed that deficit conversations about students were impeding their ability to reach their goals of critical transformation. In a journal entry, Olivia reflected on the mindset of some NIC members, "I think some of our faculty are still in a space of, it's the students and it's really their problem." She highlighted that at times students are discussed from a deficit viewpoint but continued with a hopeful observation of NIC members, "But I do think that there's some evidence that some of our faculty recognize that there are things that we can do to better support our students, but they're just not really sure how." At this point, shifting discourse about students (within the NIC and among faculty in the department) became a new goal for the NIC leaders and an explicit rule about leaving deficit-oriented conversation "off the table" was shared with the NIC. The following excerpt illustrates how the Tau leaders decided on this rule.

In a planning meeting, the three leaders discussed the structure of their final semester meeting in April 2024. Olivia suggested questions to guide NIC members to consider what they are noticing when viewing data from their classrooms: "What is the problem we're seeing, what are the opportunities we can impact? Maybe strengths? Let's get them thinking about what they've been noticing." Natalie agreed that it would be a good idea to focus on identifying

potential problems. Garrett recalled a conversation with NIC members where he tried to challenge traditional notions and goals in the department about mathematical content and procedures in these courses (e.g., focused on computational fluency). Based on these reflections, the leaders discussed how they should facilitate this conversation in the April NIC meeting:

> *Natalie*: How do we stop focusing on what we can't change, and focus on what we can control?
>
> *Olivia*: Should this conversation take place in a small group?
>
> *Natalie*: Sure
>
> *Olivia*: Then come to the large group; people can vent in the small group, then have a productive conversation in the large group. […]
>
> *Garrett*: What are some potential problems we can actually address that may come up? Obviously I'm focused on changing the computational fluency and thinking everything needs to be this hard. What other problems will come up?
>
> *Natalie:* What we always go back to, is complaining about student prerequisite knowledge. On the one hand, the prereqs don't have to be that hard, on the other hand, they're way too easy.
>
> *Garrett*: Do we want to change their minds on this?

Garrett and Natalie continued to discuss NIC members' and their own views on students' prerequisite knowledge. This exchange ended with Natalie saying "I'm just venting now." In response, Olivia joined the conversation with a suggestion of taking prerequisite knowledge "off the table" for discussion during the April NIC meeting:

> *Olivia*: Ok, these things are off the table for today's conversation. We can't say "we can't do this because of X,Y, Z."
>
> *Natalie*: I like that. We all know that's an issue, let's not talk about that.
>
> *Olivia*: Yeah, and more so, today we're identifying potential areas of places we can consider. Today is about determining the problem that needs to be addressed.
>
> *Natalie*: Then, items off the table: Prerequisite preparation has to be off the table. We all know it's an issue and we have a problem with it.
>
> *Garrett*: Maybe co-construct this list with the NIC members.
>
> *Natalie*: Initially, the other [item] is higher up things we can't change [i.e., trying to make Calculus 1 two semesters long].
>
> *Olivia*: Maybe leave [the list of items off the table] as an open thing, and if they don't say it, then we say it [i.e., we suggest adding it to the list].

In the subsequent Spring 2024 NIC meetings, the Tau leaders established their new rule and worked to navigate conversations away from deficit discourse and toward more productive avenues. Garrett explained, "I don't think it's productive to repeatedly come up with the same challenges." In her interview, Natalie reflected on the impact of their decision to take deficit discourse about students off the table:

> We should focus on what we can fix. Regardless of how you want to label the problem, taking that off the conversation table still didn't remove it completely, but it didn't take up 50% of the conversation, instead 10-15%. I hope the NIC members understand why it was taken off the table. I hope we can train our brains to stop complaining about things we can't fix.

The NIC leaders realized that if their overall goal was to work toward critical transformations in their undergraduate mathematics programs, then they needed a collective, explicitly stated rule to focus on productive areas rather than get bogged down in deficit discourses about students.

Discussion and Conclusion

In institutional or departmental change efforts, there need to be clearly established norms or "rules" for the community of change agents. In the Tau NIC, working toward critical transformations and improving student experiences meant that it was necessary to shift the discourse that was occurring in the meetings and take on an anti-deficit perspective (e.g., Adiredja, 2019). Whereas NIC members collectively viewed students' mathematical preparation as a problem in their introductory mathematics courses, it was not productive to dwell on what students were lacking. Instead, the NIC leaders guided the community to notice students' strengths and attend to challenges they have the agency to address.

The CHAT framework emphasizes the evolution of the NIC through the interaction of the CHAT components, especially the objects, tools, and rules within the community. Viewed through this lens, the object evolved over one year to include a focus on shifting discourse and perspectives about students, and NIC leaders worked to achieve this through the tools of the NIC activities and the established rule of taking specific topics and anti-deficit discourse "off the table" for conversation. CHAT highlights how this shift was a result of observed tensions within the activity system and required clarification of objects and new rules and tools to address the tensions. CHAT was a helpful framework to analyze the multi-voiced activity system, as NIC leaders operated within a community of various stakeholders situated within a large mathematics department at a diverse institution, which complexified the decisions and impacts of their work.

Our work so far has focused on the second generation CHAT framework (Engeström, 1987) to understand the evolution of the NIC as an activity system across one improvement cycle. One of the most prominent shifts in the NIC occurred due to tensions between the object and goals of NIC leaders, and the rules governing discourse within the NIC. Future research could extend by applying third generation CHAT to look at tensions among connected activity systems. Third generation CHAT is better able to consider power dynamics within and across activity systems (Engeström, 2009), along with the inherent tensions involved in negotiating human activities (Sannino et al., 2009). In our case, since ACT UP Math is a research-practice partnership, we plan to examine the research team activity system together with the Tau NIC activity system, and how those systems interact to influence the progression of the NIC activity system. Future work can also apply CHAT to additional NICs – both those within the larger ACT UP Math project and those in other settings.

Finally, one implication of the application of CHAT to understanding NIC evolution is for NIC leaders to explicitly engage NIC members in discussing their activity system as a NIC. Applying a CHAT framework to an activity system or set of activity systems can help system participants see the objects and illuminate what are often implicit rules. Transformation work is more effective when participants are working toward a common goal (Kezar, 2014; Martin et al., 2020), and having a NIC map out their activity system in a CHAT framework can be useful in encouraging conversation about common goals and rules governing collective action.

Using Poetic Transcription to Showcase Multilingual Students' Experiences of Silence in Introductory College Mathematics Education

Colorado State University

In this paper, we explore the role that silence plays in the experiences of multilingual students of color within undergraduate mathematics classes. The poetic narratives presented in this paper focus on exploring the role of silence in students' experiences. While silence often reflects marginalization (e.g., being silenced), it can also function as a mechanism for navigating different spaces, and as a form of resistance. As such, we take an asset-based and anti-deficit framing to explore how silence interacts with students' cultural capitals, including, for example, navigation capital, resistance capital, aspirational capital, and language capital. We use poetic transcription to present students' stories using only their own words.

Keywords: multilingual students, undergraduate mathematics, critical methodologies, poetry

Educational institutions at all levels continue to serve more students who are multilingual learners (henceforth, this term is used to refer to students whose home languages are different from the language used for instruction). For decades, research in K-12 mathematics education has advocated for tending to the care of these students, and the importance of nourishing their home language and culture in their learning of mathematics (Civil, 2009; Gorgorió & Planas, 2001; Moshkovich, 2002; Planas & Setati, 2009). In this paper, we focus on elevating the voices of multilingual students of color by sharing their narratives about introductory college mathematics education using their own words through the process of poetic transcription.

Background and Literature

Language is inherently political and can function, in conjunction with race, to empower some students while marginalizing others (Barwell, 2015; Planas & Civil, 2013). This has been discussed significantly at the K-12 level; however, the same challenges documented in the K-12 literature persist in higher education (Rios, 2024; Hwang, 2023). For example, Rios (2024) found that multilingual students were often positioned by others in deficit-oriented ways, particularly when they are not frequent vocal participants in the classroom. Civil (2014) states that "if most of the communication is expected to be in oral form, this may silence students who are not comfortable speaking up or who have a hard time producing oral explanations" (p. 14). In response, Planas and Civil (2013), Civil (2014), and Rios (2024) challenge deficit narratives about students' participation by emphasizing ways that home languages and prior experiences serve as assets to students' mathematical learning.

Focusing on student assets is an approach research has taken to promote an anti-deficit orientation of multilingual students. This involves recognizing the valuable role that students' cultural capitals can play in their education. In addition to language resources, other cultural capitals include students' families, communities, aspirations, and knowledge about navigating and resisting existing systems that are oppressive (Peleaz et al., 2023; Yosso, 2005). Research

has shown how different forms of capital, rooted in community, are linked to student motivation in pursuing and persisting in their education (e.g., Dilka et al., 2018; Samuelson & Litzler, 2016). Moreover, in Peleaz et al. (2023), the authors discuss the tensions around celebrating 9th-grade multilingual student Layla's strengths, agency, and ability to overcome, without minimizing the structural barriers that are potentially marginalizing to students of color. They state that "while other students may navigate or resist the educational system differently, their relative empowerment does not change the overall reality of oppression" (p. 11).

The growing body of literature examining multilingual students' experience in K-20 mathematics emphasizes the importance of amplifying students' voices and documenting their lived experiences using their own words. For example, Hwang (2023) uses narrative inquiry to explore, in greater depth, the lived experiences of four international, post-secondary students studying mathematics. In her methodological approach, Hwang constructs narratives—using primarily students' own words—to capture each student's experiences studying advanced mathematics.

There is an undercurrent in this body of literature related to silence, and the lack of students' voices, in their experiences. Recognizing and responding to this juxtaposition, this paper aims to showcase the individual experiences of multilingual students of color in undergraduate mathematics classes, especially around silence, while using only their own words via poetic transcription (Glesne, 1997; Prendergast, 2009; Tremaine, 2022). Our methodology builds off of Hwang's (2023) narrative inquiry approach to present multilingual students' experience in undergraduate mathematics. The poetic narratives we present here attend to both the challenges shared related to silence and the cultural capital demonstrated through silence.

Theoretical Perspectives

Asset-based and anti-deficit lenses

Two theoretical lenses guiding this work include asset-based perspectives (emphasizing the resources students bring rather than their deficits) and anti-deficit perspectives (explicitly and intentionally challenging the deficit narratives). Historically, the language resources of multilingual learners have been viewed as obstacles to learning mathematics (Barwell et al., 2016; Setati & Adler, 2000). To shift this narrative, asset-based and anti-deficit perspectives (Adiredja, 2019; Adiredja et al., 2020; Celedón-Pattichis et al., 2018; Harper, 2010) take the firm stance that "all students are capable of reasoning mathematically and that they bring productive resources for learning" (Adiredja et al., 2020, p. 521). In the context of language, these lenses assert that all students are capable of learning and participating meaningfully in the classroom, and that students' language backgrounds enrich their ability to do so. While asset-based perspectives highlight student's strengths and resources, anti-deficit perspectives go a step further to challenge deficit narratives (Adiredja, 2019). This asset-based, anti-deficit approach informs our work by acknowledging that some multilingual students of color may be quieter in the classroom, not due to disengagement, but because they may feel uncomfortable speaking in an environment that lacks diversity and emphasizes vocal participation (Civil, 2014; Rios, 2024). An anti-deficit lens also challenges the "disengaged" narrative by emphasizing alternative ways these students actively engage in their math courses (Rios, 2022).

Cultural Capital Wealth framework

Yosso's (2005) Community Cultural Wealth (CCW) framework exemplifies the transition from a deficit to an asset-based perspective. Specifically, this framework identifies existing resources and capitals that students of color often bring to their college experiences. Although

not typically valued by the dominant culture, these forms of capital originate from students' communities and can play a crucial role in how students of color navigate educational systems and environments. In particular, Yosso's framework identifies six cultural capitals: (1) *linguistic capital,* (2) *resistance capital*, (3) *navigational capital*, (4) *aspirational capital*, (5) *familial capital*, and (6) *social capital*.

In addition to language capital, in this work we focus on resistance and navigational capital. *Resistance capital* represents the knowledge and skills that students of color develop to stand up to inequities and injustices in their daily lives. Similarly, *navigational capital* is the knowledge and skills that students of color develop through constantly navigating spaces that are not designed for them. In this paper, we examine how silence intersects with these two capitals as manifestations of the resources students draw upon when facing potentially harmful experiences.

Perspectives on silence

Finally, we draw upon theoretical perspectives on silence. This literature provides distinct forms of silence: that of being silenced, broader notions of silencing, as well as using silence for navigation, and as an act of resistance. While the first two are clear acts of marginalization, the latter two, though they may happen in conjunction with being marginalized (Peralta et al., 2013), can also be seen as components of students' cultural capital, and related to navigational capital and resistance capital respectively. Silence can be shaped by students' sociopolitical realities (Smith & King, 2018). Silence is intermeshed with the distribution of power, and social roles, among dominant and marginalized groups of people (Mills, 2006; Verma, 2017). For example, the act of silencing—that is, the deliberate or inadvertent suppression of the voices, ideas, or agency of individuals or groups—functions as a way to "exclude", "constrain", and "devalue" others (Mills, 2006, p. 1). Moreover, silence can relate to assimilation, and how certain aspects of people's identities are silenced as a result of the dominant culture, including their language and cultural values (Migliaccio, 2016; Ricketts et al., 2007). At the same time, silence is also a form of communication and can have a specific navigational or resistance function (Verma, 2017; Ellis & Wrightsman, 2024). For example, in Gilmore (1985), African American students in an inner-city school deliberately used silence as a way of shifting the burden of communication back to the teacher, thereby asserting their resistance to the teacher's authoritative role in the classroom. We draw on these perspectives to guide our investigation and discussion of how multilingual students of color experience silencing in their introductory mathematics courses, as well as how they navigate, and resist being silenced.

Research Questions

Drawing from these perspectives, the research questions we explore are: (1) How do multilingual students of color experience silencing in college precalculus and calculus classes? (2) How do these students respond to silencing in college precalculus and calculus classes?

Methods

The data utilized for this paper is part of a larger study aimed at exploring the experiences of multilingual students in precalculus and calculus courses. The study was conducted at a large Hispanic-Serving Institution in the Southwest, which also serves a large population of international students. As part of the study, 28 students were selected to be interviewed, all of whom identified as having a home language other than English. All 28 students were students of

color[1], and although their racialized experiences in mathematics were not the central focus of these interviews, it is an important context that distinguishes their experience from multilingual students from Europe, where accents are often privileged and seen as an indication of education status (Moscovitch, 2007; Rosa & Flores, 2017). Interviews were conducted over Zoom, lasted for 60-90 minutes, and were semi-structured. Interviews were recorded and were transcribed verbatim. As will be detailed below, we identified six of these students to answer our research questions. In the results section, we include a brief introduction to each student.

We use poetic transcription (Glesne, 1997; Prendergast, 2009; Richardson, 2004; Tremaine, 2022) to showcase the stories of multilingual students of color within these courses. Poetic transcription is an arts-based methodological tool that re-presents interviewees' words in the form of a poem; this allows the interviewee's own words to be used to tell their story while also bringing in space for the researcher's interpretation and analysis through choices in poetic juxtaposition. Particularly as we discuss the cultural silencing of multilingual students of color, our research methodology must be one which centers those students' voices; we see re-presenting these students' own words verbatim through intentionally constructed poetry as aligned with this aim.

We developed a process for co-creating poetic representations of students' experiences in undergraduate mathematics. First, the first author identified 10 student interviews that explicitly discussed or related to silence. Four students were initially selected, and we began by individually engaging in poetic transcription using Tremaine's (2022) methodology. After creating poems for two of these students, we paired up to co-create collaborative versions. This proved challenging due to our attachment to our individual drafts.

To address this, we adopted a new approach: two team members would each create individual drafts, while two others would merge them into a cohesive poem by selecting stanzas that told a unified story. The first author then reviewed all the poems to ensure a cohesive voice across the collection. As we refined the process, we eliminated four students' stories after team discussions about their relevance to the theme of silence.

Through this process, we established a set of guidelines for consistency, such as using students' exact phrasing without creating repeated words, removing filler words when necessary, and preserving students' sentence structures. We used italics to indicate direct quotes and combined experiences from both high school and college to create a cohesive narrative. Our approach prioritized methodological rigor while embracing the creative elements of poetry to authentically capture students' experiences with silence.

Results

Qamar: *Not Something I Wanted to Hide*

Qamar (she/her) is a Syrian refugee student who spent the pandemic living in Saudi Arabia, while her college classes were all remote. In her poem, we see her share about two class experiences: first, where a teacher refused to record the video sessions, and so Qamar had to attend that class remotely at 3am her time; second, where her teacher muted Qamar in the video session so that the class could not hear Qamar's contributions, to which Qamar responded by unplugging her audio so the teacher could see that Qamar was attending but not listening.

[1] Drawing from Yosso's (2005) work and terminology, we have chosen to use the term *students of color* to refer to students from racially minoritized communities, based on the U.S. context. We recognize that international students may not be from racially minoritized populations in their home countries and that different countries use different terminologies to describe minoritized populations.

I was like:
Hey Professor,
can you please record the Zoom thing?
I'm not sure I could make it,
it's like really late.
Actually
I will not record this class.
We're actually going to make it more harder for you.
Because you know what?
It's your struggle, you have to deal with it.
We will not record the class.

I speak a different language.
I don't think it shows.
Maybe it shows in certain words.
I'm not sure how that would impact this.
There was definitely some circumstances where
the teacher is treating someone else better.
Ask me all the questions you guys want.

I was asking a question,
and the professor literally muted me.
I'm a good student, I'll do it–
You will not do it.
She'd interrupt me.
I'm not physically muting you,
I'm talking-muting you.

(continued)
Okay.
It's stay silent situation.
It was really belittling,
Rude.
and not welcoming–
I'm not asking any more questions;
that just creates more problems.
It's better to be silent.
I'll stay silent.

I'm a very extroverted student
I usually just want to talk and share–
You're not really welcomed in this class.
Why are you even here?

You know what?
I'm never responding to you;
this will only harm me.
You muted me in your class.
I'm attending
but I'm not really listening.
I did not want to listen to you.

I would literally leave the computer audio
I don't want to hear you anymore.
Your class is not even valuable to me.
I'm in the class but I don't want to hear you.
She definitely could see that
And it was not something I wanted to hide.
I didn't even apologize.

We use italics and formatting in this poem to illustrate different voices, though all of the words were spoken by Qamar during her interview. This structure conveys a back-and-forth dialogue between Qamar (represented by italics and left justified) and her teachers (represented by italics and right justified), with reflection from Qamar in regular font. While this dialogue is a poetic transcription of Qamar's reflections from two different class experiences, the juxtaposition emphasizes Qamar's desire to be a "good student" who was working hard to attend class and engage, but feeling shut out and treated differently than other students. By the end of this poem, we see Qamar stand up to her teacher by choosing to literally silence her teacher by turning off the audio feed from class (which was conveyed back to the teacher) - an act of resistance for which Qamar "didn't even apologize."

Suveer: *The Switch Just Turns On*

Suveer (he/him) is an international student from India who majored in computer science and took Calculus II.

I am always myself.
Most of the time I use Hindi to talk to myself.
I just use American English, sometimes.
Your mind automatically switches to the Hindi mode for conversation.
We sometimes may use Hinglish.

Everything is English;
the resources are all in English.
Nothing is in Hindi.
My mind would be a bit confused initially:
Oh my God
Why are you doing this?
It is so awkward
But then it is our teacher
and you can't really disobey.

I don't talk a lot.
Every student knows English.
The switch just turns on.
But I won't say I was uncomfortable
or I felt really strange.
I just bend myself into the surrounding;
I have to adapt to the thing that is with me.
It happens automatically.

(continued)
It's not like
I'm calling upon
a second personality within me.
It's just habituated,
it's there in me.
I am being myself.
I have that background of watching American films,
superhero films, and all of that.
So I am being myself.

Being bilingual doesn't make things better in the class.
Classroom exams, homework assignments–
no, not particularly there is an advantage of being bilingual.
But when I'm talking to myself,
studying math,
then I use Hindi.
That is one essential part
I won't give that up.

Italics is also used in Suveer's poem to portray the voice in Suveer's mind that felt "confused initially" by the lack of Hindi used in his math classes. While this voice is still part of Suveer and not meant to portray a second person as in Qamar's poem, this poetic structure helps to highlight the "second personality within" Suveer that can "bend' and "adapt" to the English-only mathematics class. He relates his ability to adapt (or one may say assimilate) to the expectations and norms of his math classes to his "background of watching American films", and so he asserts that this adaptation version is still him "being [him]self." The poem ends with Suveer naming "one essential part" of himself that he "won't give up": talking to himself about math in Hindi.

Discussion

Our poetic narratives explored multilingual students of color experiencing silencing in college precalculus and calculus classes and highlight how these students respond to silencing. Several students described explicit acts of verbal silencing, carried out by others' lack of engagement with their questions and contributions. For example, Qamar details being explicitly silenced by her teacher, via muting her on Zoom, when she asks questions in class. She notices that other students frequently ask questions and do not receive the same treatment.

Beyond sharing these students' stories of silencing while using their own words, the poetic narratives reveal three different responses: (1) becoming silent, (2) intentionally using silence as a navigational tool, and (3) using cultural capital, sometimes through silence, to manage and resist marginalizing experiences in the classroom.

We see instances where students become silent in the face of explicit actions by others that are meant to silence their voices, ideas, or identities. Qamar says "It's better to be silent. I'll stay silent." Qamar refers to these as "stay silent" situations. Qamar's poem exemplifies how the silence instructors or peers might see in the classroom is not necessarily indicative of disengagement, but rather a response to marginalization within the classroom.

We also see examples that demonstrate students' agency to intentionally use silence as a navigational tool, allowing them to more comfortably maneuver within the classroom environment. For instance, Suveer describes code switching as a way he silences his home language to navigate the classroom. Suveer recognizes that the math classroom is a place for speaking English, and navigating this space requires turning on his internal English "switch", "bending" himself into the "surroundings". Although he feels like he can "be himself" and does not feel "uncomfortable" speaking English, Suveer shares that he does not "talk a lot" in class. These students' narratives highlight the way that silence can still include speaking, allowing them to still engage in some of the mathematical discussions in class while silencing aspects of their experience - their home language (Fivush, 2010).

In recognizing silence as a form of navigational capital, we are pushing back on the narrative that multilingual students are quiet because they are not interested, not engaged in learning, or not capable of communicating with sufficient fluency in English to maintain mathematical discussions. Instead, we showcase how students' "silent" responses to the silencing around them can be tactical, and that their participation should not be interpreted in a deficit way. We offer their narratives and our reframing as an explicit counter-story to the discourse of multilingual students' silence.

Finally, students' narratives exemplify a third response to silencing: using cultural capital, sometimes through silence, to manage and resist marginalizing experiences in the classroom. Qamar describes agentively using silence as a form of resistance. Recognizing that her teacher's behaviors are harmful to her, Qamar intentionally disconnects her computer audio during her online class and decides: "I'm never responding to you". Moreover, she chooses this form of silent resistance, knowing that it is a visible act that she was not trying to hide from her instructor. This skill of knowing how to resist is an asset that Qamar brings to the classroom and allowed her to exist in a harmful space in ways that mitigated this harm.

Our work shares (counter) narratives in the form of poetic re-presentations of multilingual students of colors' experiences of silence within undergraduate mathematics. These poems allow us, as researchers, to share students' stories in a way that conveys more of their human experience and preserve the emotion of these experiences, and we offer our methodology to support more such work. These poems also teach us, as college instructors, to view students' participation (or lack of participation) in our classes with a different lens, and specifically with an anti-deficit lens. We join other scholars (e.g. Boistrup & Samuelsson, 2018; Hinestroza, 2020) in calling other teachers in to recognize how silence can be used as a tactical resource in students' mathematical sense making, and to encourage instructors to recognize and disrupt the harmful ways other students or they themselves may be silencing their multilingual peers or students.

The implications for students and teachers of educational digital tool design have thus far been under-examined. We find it important to problematize and bring attention to relationships between the explicit or hidden choices of digital tool designers and implications for the possible learning taking place with the tool. Exploring one aspect of these relationships, we examined extant digital tools within the undergraduate mathematics curricula. Grounding our analysis in Piaget's genetic epistemology, we took on the perspective of the epistemic user and identified features of extant digital tools that hold implications for the learner-user experience. With this we generate initial categories that contribute to a user-oriented phase of a framework for digital tool design and discuss implications for further research.

Keywords: digital tools, digital task design, undergraduate student learning

Digital tools can be leveraged in a wide variety of contexts ranging from asynchronous learning environments, in-class digitally supported activities used by individuals or groups, discussion-orienting didactic objects (Thompson, 2002), or tools to be used throughout a curriculum. Designers of educational digital tools engage in unique task design, at times facing different constraints than those of traditional in-class or at-home task-design. For instance, digital tools are necessarily contextualized within software constraints, and designers have varying levels of control over user-interface and visual design features that can enhance or constrain the user experience. These decisions, made implicitly or explicitly by the designer, all have the potential to orient the user towards learning goals set by the designer or to potentially obscure the underlying intended mathematical content.

Not yet directly addressed within the literature on digital tools is the relationship between designer choices and the experiences of users engaging educational tools. The broad aim of our research agenda is to highlight this relationship and infer implications for users. Pursuant of this goal, we analyzed a variety of extant digital tools (e.g. "micro-worlds", online interactive textbooks, educational games, computational tools, etc.) to infer features of the tools that might constrain or afford users' experiences for learning. We address the following research question: *What design features of specialized interactive digital tools might enhance or constrain the learning of users engaging with the tools?* We provide initial explanatory and operationalizable constructs in the form of digital tool features that demonstrate the relationship between design choices and the user experience.

Literature and Theory

This report is part of a larger project exploring educational *digital tool* design. By *digital tool*, we mean an instantiation of a digital technology created within a specific software for the purpose of student use in learning (Margolis et al., 2025). We aim to provide a framework for designers of undergraduate mathematical digital tools, enabling them to approach tool design with attention tool features that might constrain or afford users' progress towards established

learning goals. We think of this design process as unfolding in two phases: 1) a macro-orienting phase in which the designer situates possible digital tools within *design space*, and 2) a micro-orienting phase in which the designer makes tool-level design choices, continually de-centering to consider the implications of the choices for users (Margolis et al., 2025).

This conceptualization of the design process draws from Yerushalmy's (2005) notion of a *design space* for interactive digital mathematics textbooks, which she broke down according to "forms of interaction", "interdependency of diagrams and text", and "forms of represented data" (Yerushalmy, 2005). We adopt our own notion of a design space to all digital tools and think of the space as variations in the spectra of *specialized to generalized*, *interactive to inert*, and *dynamic to static* (Margolis et al., 2025). For the purpose of this report, we analyze extant tools from undergraduate mathematics curricula that are specialized (e.g. supporting a specific learning trajectory) and interactive (e.g. users manipulate controls and receive feedback). Our analysis attends to features of tool-level design choices that impact the experience of the epistemic user.

Situating Within the Literature

Thus far, the literature on digital tool design includes well-investigated but siloed regions of design space, such as micro-worlds (Kaput, 1992), didactic objects (Thompson, 2002), videos, or projects like TELMA (Bottino & Kynigos, 2009) or ReMath (Artigue & Mariotti, 2014). When not siloed, much of the literature also takes broad framings of the digital tool use that foreground the interplay between the student, teacher, tool, and situated social or pedagogical environment (Leung & Bolite-Frant, 2015). While these silos are of value, to our knowledge links have not yet been made between design decisions, the user experience, and the learning taking place.

In a recent review of the literature on digital tool design, Leung and Bolite-Frant (2015) described a still extant gap between our knowledge of "...how to use a tool and how the tool usage leads to mathematics concept development." (p. 207). They cautioned that without more careful attention to tool use and students' cognition, "…the use of tools may result in epistemological and didactical obstacles for students, depriving them from reaching the desired or intended mathematical knowledge." (p. 207). They concluded that no theory yet exists that productively encompasses "tool-based task design", which is a gap that we intend to remedy.

Other authors have problematized the interplay between pedagogical intention and design. Bottino & Kynigos (2009) consider the pedagogical intentions of digital tools as inseparable from the tools itself. Our work aligns with this general conception of digital tool design, and we intend to generate features of design informed by foregrounding the user experiences and the possible hindering or supporting of users' achievement of the designers' pedagogical goals.

Theoretical Framing

For this paper, we foreground the experience of the epistemic user of digital tools. The user engages with the digital tool to complete an activity or to learn a mathematical idea within an undergraduate mathematics setting. For space, we will consider only individual student-users, leaving other scenarios such as groups of student-users or teacher-users for future work.

With this in mind, we take a radical constructivist framing (Glasersfeld, 1995) of the user, who learns through interaction with the digital tool. The epistemic user takes actions within the digital tool, receives and interprets feedback from the digital tool, and imputes and develops mathematical meanings from their tool engagement via assimilations to and accommodations of schemes of meaning (Piaget, 1971) for which the inscriptions or visualizations within the digital tool are figurative material for their re-presentations. Within this epistemological framing of

users' experiences with these tools, in analysis we consider the epistemic student's digital and mental actions using the tool and inferences possible from assimilations, abstractions and generalizations (ibid) resulting from their interaction with the digital tool.

Similarly, while our analysis primarily considers the user perspective, we find it also important to note that extant digital tools for mathematical learning were necessarily created in the context of the (however broad or specific) pedagogical goals of the designer. We consider that when designing a digital tool to meet some learning objective, the designer is making explicit or implicit conjectures about how students' interactions are going to support particular ways of reasoning. While we can reasonably establish the pedagogical underpinnings of some digital tools designed with respect to curricula that well-define hypothetical learning trajectories and targeted ways of thinking, such as quantitative and co-variational reasoning (Thompson & Carlson, 2017), we foreground our analysis on the features of the tools made for such curricula.

Methodology

The primary goal of this initial analysis was to examine extant digital tools from the perspective of a user. Because of the magnitude of digital tools publicly available, we sought digital tools that would likely generate theoretical user-oriented insights, rather than attempting to survey or descriptively analyze the breadth of tools available. As such, we drew from our own diverse libraries of tools, tools that we were aware of from active curricula or research projects, and tools submitted via survey. All tools discussed are masked, and in our results we generically describe features of the tools and give general diagrams of the tools' layouts and controls. This masking is to analytically describe and explain features of tools without being read as passing undue judgment on any one digital tool or a collection of digital tools.

Analysis

Our analysis attends centrally to observable features of extant digital tools as they might matter for the actions, feedback, and potential meaning-making of the epistemic student. This involves critically examining tools by taking on the perspective of a user. Our approach is analogous to prior work taking radical constructivist framings of exam items from the perspective of "users" (i.e. the students taking the exams) (Tallman, Reed, Oehrtman, & Carlson, 2021; Reed, Tallman, Oehrtman, & Carlson, 2021). Analyzing exam items for the purpose of identifying features by which one might assess mathematical understanding, Tallman and colleagues considered the mental activity necessary for the epistemic test-taker to successfully answer the exam item. They identified reasonable requirements on mental activity and thusly inferring features of items that reasonably assessed particular mathematical meanings. In doing so, the authors foregrounded: 1) the problem contexts, 2) the relative complexity of the various mental actions and inferences necessary to successfully complete the prompt, 3) the mathematical modeling required to establish quantities relevant to the problem, 4) the necessity of the student to make strategic decisions at the onset of solving the problem, 5) and other necessary mental actions taken by an epistemic user (Tallman et al., 2021; Reed et al., 2021).

We take a similar approach, in that we consider the epistemic user of digital tools, analyze the tools with respect to the actions and inferences from feedback reasonably necessary for use of the digital tool to achieve an objective, or for mathematical meaning making. Such analyses, independent of knowledge of the designer intention, are important, as how users might perceive or engage with the tools might drastically differ from how designers intend tools to be used.

After engaging in individual analyses, the team met to discuss the salient features of tools for supporting or constraining meaning-making. We report on some of the features that emerged

from our analysis and give examples that problematize the need for a greater dialogue around the interplay between design choices, learning goals, and the user experience.

Results

We will elaborate the emergent features of two primary types of tools that fall within the interactive and specialized regions of design space. In this analysis, we highlight the features of *complexity, signaling,* and *goal-orienting feedback.*

Dynamic Interactive and Specialized Tools

We first discuss digital tools of interest that are also dynamic (e.g. "micro-worlds" (Kaput, 1992)). This particular design subspace tends to contain tools that display at least one or more non-symbolic representations of mathematical quantities and give the user some means of dynamically altering the state of the representations as well as any linked textual or symbolic information related to the mathematical representation. We attend to features that help delineate similar tools with respect to the student experience and discuss then ways that these features extend less dynamic, but still interactive and specialized tools.

The first collection of tools come from curricula that intentionally leverage dynamic tools to promote quantitative and covariational reasoning in pre-calculus and calculus. We examined tools promoting quantitative meanings for Riemann Sums and definite integration by appeal to applied contexts. As masked stand-ins for the common design elements of these tools, we will use hypothetical digital tools that we refer to as the *Hydrostatic Force Tools*.

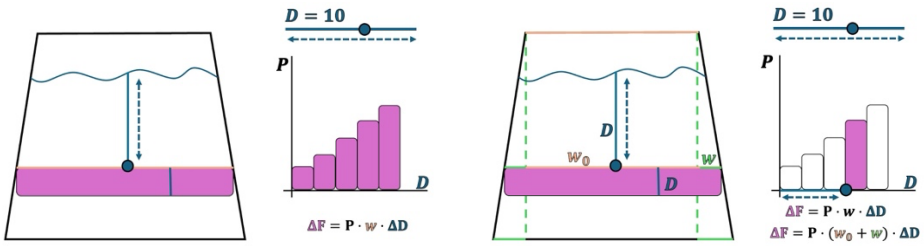

Figure 1. Variations on Hydrostatic Force Tools

These masked tools use hydrostatic force on a dam as the central context for definite integration. Figure 1 depicts variation in the typical layout of such tools and gives representations of the common design choices for control elements, feedback elements, and stylistic elements of the *Hydrostatic Force Tools*. As depicted Figure 1, common to these tools were contextual representations of the quantitative relationships relevant to defining a definite integral (seen on the left), a separate but linked representation (typically graphical) on the right, symbolic or numerical representations of the quantitative relationships at selected states, and one or more control elements (sliders) that the user could manipulate. The masked task for these tools asked students to come up with a Riemann Sum or definite integral that would calculate the hydrostatic force on the depicted dam. Some tools would be implemented as didactic objects, others as formative asynchronous quizzes, and others as supports for in-class group work.

Two important features that emerged from analysis of these tools are *complexity* and *signaling*. *Complexity* relates tool controls to the types and levels of feedback given in response to control change. *Signaling* refers to stylization of the perceptual features of the digital tool with the potential to highlight information or make connections between representations. Many Hydrostatic Force Tools employed color to signal links between multiple in-tool representations

of quantities. In Figures 1a and 1b, each representation for depth (e.g. graphical, contextual, symbolic, and slider) is colored blue. Similarly, force representations are colored pink, and width representations are colored orange (and green). Moreso in Figure 1b, contextual and graphical representations of the local force quantities are signaled when the slider varies. As the local representation of force moves throughout the dam, the rectangle at the associated depth is singularly colored pink. Conceptualized as dynamic supports for students' quantitative and covariational reasoning, signaling was a key design feature of these tools that served the purpose of not only emphasizing the key quantities in the modeling process, but also linking the representations of the quantities within the tool amidst variation of the independent quantity.

Complexity was also a distinguishing feature of these tools. Figure 2a depicts one tool in our data with higher complexity, in a way that potentially hindered present signaling. There were multiple sliders in the tool, each controlling possible variation in the setup of a Riemann Sum such as interval size, sample point location, interval location, and interval number. Many of these control elements influence each other, including the interval number and interval size being interrelated, and the sample location impacting all approximation representations at once. With this higher complexity, particularly the interrelatedness of the control variables, the user must attend to numerous feedback elements at once when altering the value of any number of sliders.

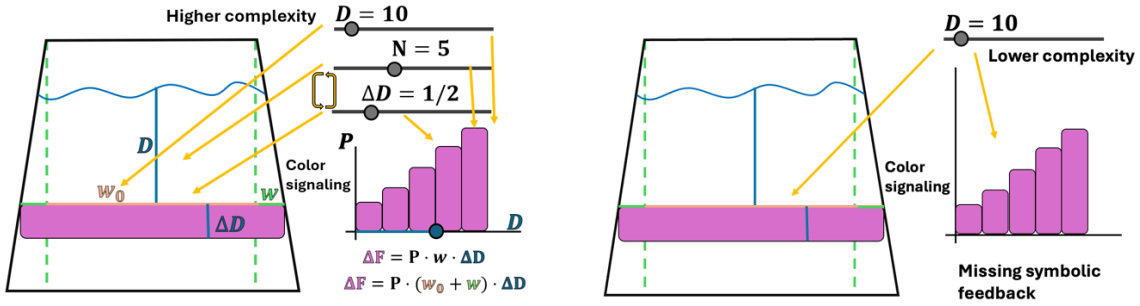

Figure 2. Tools with higher and lower complexity

This feedback variation was across representations and across other control elements. This adds mental actions necessary for a user to infer the important quantitative relationships in the accumulation process, potentially distracting from color-based signaling taking place within the tool. Contrastingly, Figure 1b has lower complexity, hides certain feedback elements, and contains similar intentional signaling. Each slider directly alters only one aspect of each representation, increasing the signaling potential to a user intentionally varying the control elements. Moreover, the symbolic feedback is hidden, reducing the amount of information that the user might observe at any one time, and increasing the weight of the color-based signaling.

River Swimmer Tools

We now broaden the design subspace by including digital tools that share features with Hydrostatic Force Tools but are more static. Such tools are largely text-based and highly scaffolded, centering on singular vector or trigonometric problems. Our masked hypothetical tool is called the *River Swimmer Tool*, involving velocity vectors and correction trajectory angles. The following directions and problem statement are placed at the top of the webpage: ***Directions*** *Use the interactive application below to visualize the problem and guide you through the process of solving. You may choose your own path to the solution.* ***Problem:*** *A swimmer wants to cross a river that is 120 meters wide. The river's current flows at a speed of 1.5 m/s parallel to the riverbanks. The swimmer can swim at a speed of 2 m/s in still water. The swimmer wishes to*

reach the point directly across the river from the starting point. What angle relative to the riverbank should the swimmer aim for in order to reach the point directly across?

This is followed only by a single statement and dropdown menu:

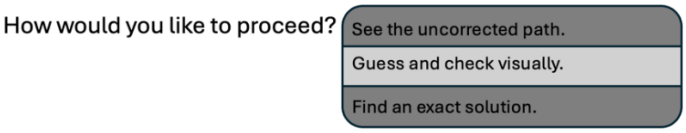

Figure 3. Branch Choices for the River Swimmer Tool

If the first option is selected, the user is presented with a simple dynamic diagram with three points: one for the starting location, another for the intended destination, and a third representing the path of the swimmer. Pressing the "GO" button in the diagram causes the swimmer point to move diagonally away from the starting point, downstream of the intended destination. Choosing the second option provides a similar interactive element.

The third option in the dropdown menu provides a sequence of steps, containing boxes in which users provides numerical data (pertaining to angles, directions, and coordinates) and the boxes give immediate feedback based on the entry. More dropdown menus then provide further branching opportunities. Each option in Figure 3 creates one of three main branches in which the user progressively acts, receives feedback, and is provided more branch options. For example, on one branch the user can choose between solving the problem via a vector table or solving via drawing a triangle, with either choice creating a new sub-branch of activities. Certain paths also contain minimalistic diagrams, such as an unlabeled triangle for the triangle solution path.

This digital tool leverages a branching mechanism, guarded by dropdown menus, as an effective means of reducing complexity. The user not only interacts with one branch at one time, but also only one activity within the branch at any one time. The more static design of the tool provides the user with clear singular feedback from any one action taken within the tool. Even more unique to the design of this tool, the hiding of further steps along any branch contrasts similarly set up tools in which information is not hidden, but the action of scrolling (rather than option selection) is the mechanism for progress through a task.

The River Swimmer Tool made less use of color-based signaling, instead signaling in ways different from the Hydrostatic Force Tools. As much of the tool was text-based, textual stylization such as italicization, bolding, and fully capitalized words were implemented to emphasize tool instructions, to call attention to situational considerations such as units, or to draw attention to optional tool features such as drop-down hint boxes.

One feature of this digital tool not present in the Hydrostatic Force Tools was explicit feedback provided in response to user actions that informed the user whether the input or action advanced them towards (or away from) completion of a goal. For instance, users received "Red X" (incorrect) or "Green Check" (correct) feedback for angle measure, magnitude, and vector coordinate inputs. Further, textual feedback given at the end of certain branches similarly oriented users to other branches that might yield more accurate results. Much feedback of this type had the function of explicitly guiding users to a final answer. Each step, including the optional step of guessing and checking, was accompanied by written and/or symbolic affirmations (e.g. "Yes! We want to use sine for the vertical component.") or formative guidance (e.g. "Consider how a negative angle would affect the path of the swimmer in this problem."). We call this feature of the digital tool *goal-orienting feedback*. Key to this feature is an explicit tool function of providing actionable feedback, indicating that the user is closer to or farther from

achieving a goal. *Goal-orienting feedback* was less present in Hydrostatic Force Tools, though it was identified in some. We interpret that rather than directly in the tool itself, any goal-orienting feedback intended for the Hydrostatic Force Tools would be given by an instructor.

Discussion and Conclusion

In this report we examined extant digital tools, attending to design features that hold implications for the user experience in the context of learning. We now discuss implications of the features for user learning and conclude with future directions for this avenue of research.

Complexity, signaling, and goal-orienting feedback all interact with each other and contribute to the barriers or supports for user learning. Use of a digital tool with high complexity of the kind seen in Figure 2a would require the user to strategically vary individual controls attending to interrelationships between the controls inferred from systematic variation, to then infer the particular quantity represented by individual controls, to then infer the quantitative operations that construct hydrostatic force. This complexity might obscure extant signaling, and in the absence of explicit goal-orienting feedback within the tool users might need to spend a substantial amount of time engaging with the tool itself before being enabled to make the necessary abstractions to the underlying mathematics. This is not to say that increasing the need for user observation and inference is a constraint for every task. In fact, there are plenty of curricular contexts in which a higher need for inference is an intentional design element.

In contrast, River Swimmer Tools were heavily scaffolded, and complexity was lessened by restricting viewable and actionable tool elements, ensuring that users were only tasked with one small component of the larger problem solving at any one time. High volume of goal-orienting feedback densely distributed across the tool provided users with more explicit indications that their actions brought them closer to or farther from the task goals. This requires less inference on part of the student, and more heavily guides users towards goal achievement, such that the task can be entirely achieved within the tool. This lessening of user inference is not suitable for all tasks, however, and in particular removes much of the need for guidance from an instructor.

As such, the three features identified from our results allow for analysis of digital tools of varying types such that one might build initial hypothetical models of interactions taken by the epistemic student, as well as the constraining or affording of learning by use of the tool. Moreover, these features also enable us to distinguish (and perhaps eventually establish) design choices for supporting students in ways unique to the location of tools within design space and unique to the designer's goals. While our features were applied across disparate tool types, we were also able to speak into the tool-specific design elements in relation to the features. In other words, reducing complexity in a static environment might be different from complexity in a dynamic environment, and tools residing in similar regions of design space might have unique design components that contribute to a feature such as complexity.

Such constructs can be incorporated into a process of design-based research on digital tools, wherein theoretical analyses of newly-built tools might provide initial models for the learning taking place by use of the tool. Such models can then be refined through observation of actual user engagement with the tool. Considering categories such as these in the process of tool design can be an important perpetual act of de-centering by designers. Further work from which more similar features might emerge will contribute to an eventual process for iterative design of digital tools that is informed by the thinking of users, thus enhancing their impact. Future work will also include interviews with designers and interview observation of students' use of these tools in clinical learning environments.

Developing Pre-Service Elementary Teachers' Conceptions of Place Value Through Coursework

Katherine E. Burkett, North Carolina State University
Rachel Abel, North Carolina State University
Erin E. Krupa, North Carolina State University

This study investigates how instruction in the base-8 number system in a Calculus Course for pre-service elementary teachers (PSTs), affects PSTs' conceptual understanding of place value. Despite the importance of number sense and numerical operations in the K-12 curriculum, research shows that many PSTs struggle to grasp place value conceptually, often focusing on procedural rather than conceptual knowledge. This study uses a convergent mixed-methodology approach with quantitative pre- and post-tests and qualitative clinical interviews to analyze PSTs' understanding of place value after instruction in base-8. Findings suggest that instruction in base-8 improves the sophistication of PSTs' place value conceptions, though verbalizing that understanding remains a challenge for some. These results highlight the need for a focus on both conceptual understanding and consistent language use in undergraduate teacher preparation programs.

Keywords: pre-service elementary teachers, content knowledge, place value, undergraduate mathematics

The concept of number sense and operations is one that permeates all levels of K-12 mathematics curriculum in the United States (National Governors Association & Council of Chief State School Officers, 2010). As such, it is imperative for elementary school students to develop proficiency with number sense and numerical operations (Kilpatrick et al., 2001). Despite its clear importance, research suggests that undergraduate pre-service elementary teachers (PSTs) struggle to understand numerical operations and place value at a conceptual level (e.g. Southwell & Penglase, 2005; Thanheiser, 2009b).

Often PSTs are proficient in carrying out algorithms for numerical operations, but struggle to conceptually explain the algorithm or why it works (Ball, 1989; Ma, 1999; Thanheiser, 2009b). These struggles are sometimes left unresolved even by the end of PSTs' undergraduate teacher preparation program (Thanheiser, 2009b). Fortunately, some research suggests that studying alternate numeration systems can deepen PSTs' conceptual knowledge of place value (e.g. Yackel et al., 2007; McCain, 2013; Thanheiser et al., 2013a; Thanheiser & Melhuish, 2019). The purpose of this study is to analyze PSTs' conceptual understanding of place value after in-depth instruction on alternative numeration systems and basic operations in the base-8 number system.

Literature Review

PSTs often exhibit a calculational perception of mathematics (Thompson et al., 1994; McClain, 2003) and see the discipline as simply "memorization of basic facts, rules, and procedure[s]" (Simonsen & Teppo, 1999, p. 517). This perception can lead PSTs to engage with arithmetic operations on multi-digit numbers as surface-level manipulations of algorithms (McClain, 2003; Tirosh & Graeber, 1989). While the procedural treatment of standard algorithms may be a natural consequence of years of use, the tendency to focus on procedural aspects of algorithms over conceptual understanding persists when PSTs are introduced to novel alternative algorithms (Harkness & Thomas, 2008; Lo et al., 2008; Nugent, 2007). It is common for PSTs to conflate procedural accuracy and conceptual understanding of the underlying mathematics (Graeber, 1999). As such, while PSTs typically have no problems executing the

standard arithmetic algorithms, they struggle to justify why they work (Ball, 1989; Ma, 1999; Thanheiser, 2009b). Southwell & Penglase (2005) argue that some misconceptions around arithmetic algorithms originate from a lack of conceptual understanding of place value. Upon entering undergraduate teacher preparation programs, Thanheiser (2009a) found PSTs often hold incorrect conceptions of place value, which can persist through their undergraduate education (Thanheiser & Philip, 2012; Thanheiser et al., 2013b; Thanheiser, 2009b).

Research suggests that studying alternative numeration systems can help correct these misconceptions and deepen PSTs' conceptual understanding of place value. Thanheiser & Melhuish (2019) designed an instructional sequence to highlight the three key features of the base-10 number system - grouping, having a base, and place value - by studying other numeration systems without these features (e.g., tally & Egyptian). Their findings suggest that coupling this approach with the study of arithmetic algorithms using the Mayan numeration system (a foreign system possessing the three key features previously listed), left PSTs with a more robust understanding of place value in the base-10 number system (Thanheiser & Melhuish, 2019). Other research supports the idea that the study of algorithms in alternate numeration systems can help PSTs develop their conceptual understanding of arithmetic algorithms (McCain, 2003), place value (Thanheiser, 2015), number relationships, and grouping strategies (Yackel et al., 2007).

Given the promising results that engaging PSTs in instruction of alternative numeration systems has on their conceptions of place value, this study adds to that body of work by operationalizing an established framework for categorizing PSTs' conceptions of place value (Thanheiser, 2009b) to evaluate the efficacy of in-depth instruction on the base-8 number system and use of the standard arithmetic algorithms within that system to increase the sophistication of PSTs' conceptions of place value. In this instructional unit, PSTs learn how to count, represent numbers, add, subtract, and multiply in base-8 to experience and illuminate elementary students' struggles with place value when learning arithmetic algorithms for the first time. The features of the base-8 number system are identical to that of base-10 with the exception of the base, much closer than numeration systems such as the Mayan numeration system, providing familiarity to PSTs while also forcing attention to be on place value as this is the sole featural difference between the two systems. Specifically, this study aims to answer the following research questions:

1. Does studying arithmetic in base-8 increase the sophistication of PSTs' conceptions of place value with statistical significance?
2. To what extent do the qualitative findings converge or diverge with quantitative findings?

Conceptual Framework

For this study, we apply Thanheiser's (2009b) framework for the categorization of place value conceptions. Thanheiser's framework (2009b) was developed from interviews conducted with 15 undergraduate PSTs before their first undergraduate mathematics course. Participants engaged in two clinical interviews over four weeks. During these interviews, they were given problems to solve. This led to Thanheiser (2009b) developing four groups to categorize PSTs' conceptions of place value. The framework was created to "build on aspects of the framework for two-digit numbers (Fuson et al., 1997) and extend them to numbers of three or more digits on the basis of the results of [the] study" (Thanheiser, 2009b, p. 261). The framework is summarized in Table 1. It is important to note that the conceptions are listed in order from least sophisticated to most sophisticated and that the first two are incorrect conceptions, while the

final two are correct conceptions (Thanheiser, 2009b).

Table 1. Explanations of Place Value Conceptions held by PSTs

Conception Held
Concatenated digits only. PSTs holding this conception conceive of all the digits in terms of only ones (e.g., 548 would be 5 ones, 4 ones, and 8 ones).
Concatenated digits plus. PSTs with this conception conceive of at least one of the digits in the number in terms of an incorrect unit type at least some of the time. They therefore struggle when relating the values of the digits in a number to one another. A PST may correctly conceive of groups of 100 ones for a digit in the hundreds place but incorrectly conceive of one for the tens place (e.g., 389 would be seen as 300 ones, 8 ones, and 9 ones).
Groups of ones. PSTs with this conception reliably conceive of all digits in terms of groups of ones; 389 would be 300 ones, 80 ones, and 9 ones. PSTs holding the conception do not conceive of the digits in terms of reference units.
Reference units. PSTs with this conception reliably* conceive of the reference units for each digit in the number and can relate the reference units to one another; in 389, the 3 can be seen as 3 hundreds or 30 tens or 300 ones, and the 8 can be seen as 8 tens or 80 ones.
**Reliably* in these definitions means that after the PSTs were first able to draw on a conception in their explanations in a context, they continued to do so in that context.

Note. Adapted from Thanheiser (2009b, p. 263).

Methods

This study followed a convergent mixed-methodological design (Creswell & Clark, 2017). Quantitative secondary data was collected from students in the form of a base-10 pre- and post-test completed as part of the work required for their undergraduate mathematics course. Additionally, clinical interviews were used for qualitative analysis to further elicit student thinking and validate results (Creswell & Clark, 2017).

Participants

This study was conducted on elementary PSTs (n=37) at a large southeastern university in the spring semester of 2024. Participants were second-semester freshmen enrolled in a calculus course specifically designed for PSTs. The calculus curriculum for this course includes a unit on alternate numeration systems and arithmetic in base-8. These systems included the tally system, the Mayan system, the Egyptian system, and more. Students spent the next two weeks studying arithmetic in base-8. In particular, students relearned how to count, add, subtract, and multiply in base-8. The first author served as the instructor for the mathematics course. Throughout instruction, emphasis was placed on the concept of place value and what each digit represents.

Data Collection

Students were given a paper-pencil pre-test prior to any instruction. Immediately following the instructional sequence described above, students were given the same assessment as a post-

test. The assessment was adapted from the instrument used by Thanheiser (2010) to classify elementary PSTs' conceptions of place value by level of sophistication. As such, its intent was to measure the participants' demonstrated level of sophistication of place value conception. The pre- and post-tests of students who consented to participate (n=43) were used for analysis and any participants missing either a pre- or post-test (n=6) were excluded.

A subset of five students participated in a clinical interview (Hunting, 1997) to explore their conceptions of place value. However, two of the students interviewed were participants missing pre- and post-test data that were excluded, resulting in three interviews for analysis. Interviews were conducted by the second author at the end of the spring semester, approximately three months after instruction. During the interview, participants were asked to verbally explain their thinking as they solved one addition, one subtraction, one multiplication, and one division problem in base-10. Interviews were semi-structured (Maher & Sigley, 2014) and students were asked probing questions throughout the interview to elicit their thinking (Hunting, 1997).

Each interview lasted about 30 minutes and was conducted in person. Interviews were recorded via Zoom and the students' work was completed on an iPad with its screen shared to the Zoom meeting. In this way, both the participants and their work were recorded simultaneously. Transcripts of the interviews were created with screenshots of participant work for data analysis.

Data Analysis

Analysis occurred at the end of the semester after all data collection was complete, in line with a convergent mixed methodology design (Creswell & Clark, 2017). This allowed participants to remain unknown to the instructor until the conclusion of the course. Thus, the quantitative and qualitative data were analyzed concurrently as separate data sets.

Quantitative analysis. A scoring system that built upon the levels of Thanheisers' (2009b) framework (0 - *irrelevant,* 1 - *concatenated digits,* 2 - *concatenated digits plus,* 3 - *groups of ones,* 4 - *attempt at reference units,* 5 - *reference units*) was used to assign a score to each question on each pre- and post-test. Authors scored all pre- and post-tests individually with a high percent agreement (79.72%) and met to resolve disagreements. A final average pre-and post-test score was calculated for each student and used for statistical analysis. SAS Studio was used to run paired *t*-tests to determine if there were statistically significant differences between student pre- and post-test scores.

Qualitative analysis. Each interview (n=3) was transcribed and coded for instances of each type of place value conception. Since the primary goal of the study was to analyze PSTs' conceptions of place value, moments where participants were discussing place value were identified within the transcripts and assigned a conception type using Thanheiser's (2009b) levels of sophistication as an a priori framework (Miles et al., 2018). It is worth noting that Thanheiser's levels are intended to describe how PSTs *reliably* conceive of place value; however, throughout coding, the levels were used to describe *individual* instances of place value conceptions. Authors coded independently and met to establish agreement.

Data integration. After initial analysis of quantitative and qualitative data was complete, qualitative data was transformed to quantitative data (Creswell & Clark, 2017) by counting the frequency of instances in which participants displayed each type of conception. Frequencies were then used to calculate percentages to identify what portion of the time participants used each conception. For the participants with both interview and pre-post data (n=3), the post-test scores were compared with the frequency of each conception they displayed in clinical interviews. This comparison was conducted in line with convergent mixed-methodology design

principles (Creswell & Clark, 2017) to corroborate results and provide more insight into participants' conceptions of place value.

Findings

This section presents the findings from analyzing the pre- and post-tests and the interview transcripts. It is important to note that, while reliably demonstrating the same kind of conception is a cornerstone of Thanheiser's (2009b) conception categorization, in this study, every instance of place value conception used by each participant has been counted and categorized.

Quantitative Findings

To answer research question 1, participant pre-test averages (μ=2.00, σ=0.94) on the base-10 assessment were compared with post-test averages (μ=2.89, σ=0.91) in a paired t-test. Results indicate that the mean level of sophistication displayed for participants on the post-test was statistically significantly higher compared to the pre-test and had a large effect size (t=7.00, p<0.0001, d=1.15). This suggests that PSTs' level of sophistication of place value conceptions improved after instruction on arithmetic in base-8.

Qualitative Findings

The percentages of frequencies with which each interviewed participant demonstrated each conception in their interviews are displayed in Table 2 along with their base-10 post-test average and gain score. Note that the Concatenated Digits Plus code was only applied for instances where participants used both Concatenated Digits and a correct conception (either Groups-of-Ones or Reference Units) within the same sentence. As shown in the table, results of the clinical interview analysis are in line with the results of the post-test for both Student 1 and 2. Student 3's interview, on the other hand, was not necessarily consistent with their post-test score.

Table 2. Integrated Qualitative and Quantitative Results

Percentages of Each Conception, Post-Test Scores, & Gain						
Participant	Concatenated Digits	Concatenated Digits Plus	Groups-of-Ones	Reference Units	Post-Test Scores	Gain Scores
Student 1	16.13	6.45	29.03	48.39	4.6	1.6
Student 2	63.16	0.00	15.79	21.05	2.8	1.2
Student 3	46.43	7.14	28.57	17.86	4	0.6
Total	38.46	5.13	25.64	30.77		

Student 1 scored high on the post-test (μ=4.6 out of 5), demonstrated a correct conception of place value over three-quarters of the time in her clinical interview (77.42% of all instances), and showed the most sophisticated conception (Reference Units) almost half of the time (48.39%). For example, Student 1 used Reference Units language when she tackled the task of subtracting 40 from 10 (see the left-most picture in Figure 1), to describe extracting a group of one hundred from the hundreds place, augmenting the tens place to be 110 minus 40, stating, "So I take one of the 100 groups, making that 500, and then adding a one in front of the tens, since it would be 10 groups of 10." Student 1 is able to refer to numbers by their groups and change that language to

reflect the place value she was working with, a group of 100 becomes 10 groups of 10. After regrouping, when Student 1 performed the subtraction in the same figure, she switched to using a Groups-of-Ones conception. When subtracting 40 from 10, Student 1 explained her reasoning as, "Technically, it's a hundred…and then I'm putting it over here, which would make it…110 minus 40 instead of 20 minus 40." This differs from referring to the numbers as four tens or 11 groups of ten but is still correct.

The results are similarly aligned for Student 2 who scored relatively low on the base-10 post-test (μ=2.8 out of 5) and demonstrated incorrect conceptions of place value over half of the time in her clinical interview (63.16%). For example, when Student 2 subtracted 40 from 10, she used a Concatenated Digits level of conception. Explaining her steps in the middle picture of Figure 1, Student 2 said, "Then we are going to use this 10 and subtract 4, and that would be 6. Then I do 6 minus 2, just like earlier, to get 4," explaining the steps as if she were dealing with the one's place rather than the ten's or hundred's place.

For Student 3, the quantitative and qualitative results were misaligned. The post-test score was high for Student 3 (μ=4 out of 5). However, she demonstrated correct conceptions of place value less than half of the time (46.43%) and her most frequently demonstrated conception was Concatenated Digits (46.43%). To describe multiplying 700 with three in the third picture of Figure 1, Student 3 explained, "So then, when we multiply 7 times 3, you're getting what was essentially 2,100." The beginning of this statement, referring to each number as seven and three shows the use of a Concatenated Digits level of thinking, yet then recognizing that the multiplication actually yields 2,100 employs a Groups-of-Ones level of thinking. This is one example of an instance coded as a Concatenated Digits Plus conception. The contradictory use of language will be examined further in the discussion section.

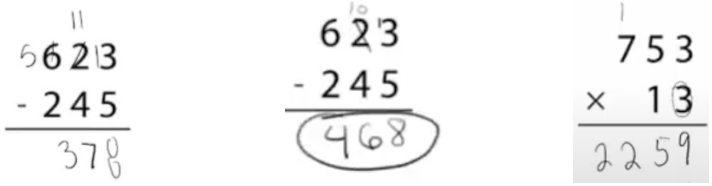

Figure 1. Student Examples of Conceptions: Student 1 on Left Using both Reference Units and Groups-of-Ones, Student 2 in Middle Using Concatenated Digits, Student 3 on Right Using Concatenated Digits Plus

Discussion

The findings suggest that the study of arithmetic algorithms in base-8 has a statistically significant impact on PSTs' level of sophistication of place value conception. However, with an average gain score of 0.89 points, the small amount of gain suggests that engaging in arithmetic in base-8 may not be sufficient to drastically change PSTs' conceptions of place value. While the pre- and post-tests offer insight into the change in the thought process of students before and after engaging in arithmetic algorithms in base-8, they also provide only a snapshot of student thinking. The interviews with a select number of participants gave greater insight into students' understanding of place value as they approached arithmetic operations. The close alignment of qualitative and quantitative findings from Students 1 and 2 provides further support for this improvement.

The misalignment of quantitative and qualitative data from Student 3 highlights an interesting additional consideration. During her interview, Student 3 switched between correct and incorrect language within single statements in a way that could be more confusing than consistently using a single conception - even an incorrect one. For example, when multiplying 700 and 3, she explained "when we multiply 7 times 3, you're getting what was essentially

2,100." For a student who has just learned 7 times 3 is 21, not 2,100, this can be more difficult than either using Groups-of-Ones language - "700 times 3, which is 2,100" - or Concatenated Digits language - "7 times 3, which is 21." It is clear from the post-test scores that Student 3 conceptually understands place value; however, she demonstrated difficulty with the consistency of language use while explaining problems in real time. This highlights the importance of having PSTs practice verbally explaining arithmetic operations using correct language. Though studying arithmetic in an alternative numeration system may deepen PSTs' understanding of place value and arithmetic algorithms, that does not guarantee they are able to verbalize that understanding to their future students.

An interesting finding that emerged from the interview data was students' response to re-learning arithmetic and place value in base-8. For example, Student 2 referenced that the instructional unit had changed her understanding of place value and that previously, for "all problems in base-10, [she'd] learned to just accept it as it is" and that carrying out algorithms in base-8 had "tricked her brain" in a way. Similarly, Student 3 reflected that "I did not have that basic understanding of place value going into this class… you know I would have never told you that when you multiply this 3 and this 1 [referring to a double-digit multiplication problem], you're multiplying 3 times 10". Additionally, Student 1 indicated that after "relearning addition, subtraction, [and] multiplication… it made me kind of understand why that stuff works more so". Student 1 also explained how she was able to easily transfer her learning in base-8 to base-10: "When I was having trouble, thinking… as soon as you hit eight, that's actually one-zero because it's one group of 8. I was like, okay, well, in tens when you hit 10, that's one group of [the base]". It is possible that the nature of base-8 and its similarity to the base-10 system made it easier for the PSTs to develop a conceptual understanding of place value and to disrupt the automatic procedural nature of their thoughts surrounding operation algorithms within base-10.

Limitations

This study was limited by a sample size that, while large enough to produce statistically meaningful quantitative results, was still small. Additionally, the involvement of the first author instructing the course naturally introduces the chance for bias in the results. The post-test was given immediately after the participants had engaged in the base-8 unit and interviews were conducted within the same semester. While the base-8 unit clearly changed the way participants described arithmetic operations, whether these changes are sustained remains to be seen. Finally, whether base-8 instruction is more beneficial than less familiar systems, such as the Mayan or Egyptian system, would require further study.

Conclusion

This study highlights the positive impact of studying arithmetic in the base-8 system on PSTs' conceptual understanding of place value. While the instructional unit successfully improved participants' level of sophistication of place value conception, the variation in individual results underscores the complexity of this learning process. Some participants exhibited strong conceptual understanding, yet struggled to consistently verbalize their thinking, emphasizing the need for more focus on clear communication of mathematical concepts. Future research should further investigate the long-term effects of learning alternative numeration systems on both conceptual comprehension and the ability to articulate mathematical reasoning.

Students' Actions Related to Complex Exponents

Matt F. Park
Virginia Tech

Interest has been growing in how students learn concepts in complex analysis (Troup, 2015; Hancock, 2019). A concept generalized in complex analysis is exponents and logarithms, yet little is written on how students leverage their existing knowledge to the complex case. In this paper, I present data from task-based interviews via the lens of APOS theory to present two students who leveraged their knowledge of real-valued exponential and logarithmic operations to varying degrees. I present data from a single question asking them to compare the magnitude of complex numbers and argue that their schemas for the two subjects were separate.

Keywords: Complex Analysis, Exponents, APOS Theory

Many studies concerning how students understand exponential or logarithmic operations and functions have looked at how students generalize the domains of exponents from natural numbers to rational numbers (Elstak, 2007; Williams, 2011). In the context of complex analysis, there is a notion of raising a complex number to a complex power, defined as $z^w = e^{(w \cdot Log(z))}$, where $e^{a+bi} = e^a(cos\ (b) + i \cdot sin\ (b))$, and Log(z) denotes an inverse of e^z. At the time of writing, there is yet a study on how students understand such expressions, either from the literature on learning of exponents & logarithms or learning of complex analysis.

In this study, I extend studies on exponents and complex analysis that used APOS theory (Pitta-Pantazi et al. 2007, Tabaghi, 2007). Foundational among these studies is that from Danenhower (2000) which touches on the theme of Thinking Real, Doing Complex (TℝDℂ). Extending his work, along with that from Troup (2015, 2019), Hancock (2018, 2019), and Soto (2014, 2016), I investigate the question "How do students leverage their knowledge of real-valued exponential operations to reason about the complex analog?"

Theoretical Framework and Literature Review

Next, I briefly review APOS Theory and the studies related to the learning of complex analysis, exponents, and logarithms situated within it.

APOS Theory

The four constructs of actions, processes, objects, and schemas constitute the basis of APOS theory. APOS theory, as described by Asiala et al. (1997) is concerned with the construction of schemas and mental objects, and the theory posits that objects are the result of sufficient reflection of processes or the thematization of schemas. According to Asiala et al. (1997), an action "is a transformation of objects which is perceived by the individual as being at least someone external," a process is the result of reflective abstraction on an action or the reversal of an existing process, and an object is a result of either "when an individual reflects on operations applied to a particular process, becomes aware of the process as a totality, realizes that actions or processes can act on it, and can construct such transformations" or schemas via "thematization," which is defined as a schema's inclusion in other schemas.

Dubinsky (1991) and Asiala et al. (1997) define a schema: as a "coherent collection of objects and processes," (p. 166) and argue that the main concern of math education researchers should be the construction of schemas. Although a schema is internal to the individual, Dubinsky (1991) highlights the idea of genetic decomposition as "detailed descriptions of schemas in terms

of these mental constructions" as "a way of organizing hypotheses about how learning mathematical concepts can take place" (p. 182). Although schemas, objects, and processes aren't possible to directly observe by outsiders, Dubinsky (1991) describes them as the entry point for reflective abstraction.

Exponents

Some of the earliest studies around exponents and logarithms were from Confrey (1994), Confrey & Smith (1995), and Weber (2002). The primary contribution of Confrey (1994) and Confrey & Smith (1995) is the theoretical notion of the splitting world and covariation as a means to productively understand the exponential function. Weber (2002) reports on the result of a teaching experiment primarily through the lens of APOS theory. He also uses Sfard's notion of reification and Sfard's postulation that structural understanding is "necessary to reason about mathematical concepts" (p. 1020) His test group was found to be able to "use their conceptual knowledge to reconstruct" exponent and logarithm rules. (p. 1025) Like Confrey (1994) and Confrey & Smith (1995), Weber finds that the idea of exponents as iterated multiplication is an insufficient model for generalizing to non-natural numbers.

Pitta-Pantazi et al. (2007) identify three levels of understanding exponents within APOS theory via written questionnaires and semi-structured interviews. The interviews consisted of asking students to compare the magnitude of exponential expressions. The first level they identify corresponds to "the pre-conceptual stage at which students are getting used to certain computational operations on the exponents with natural numbers," or an action understanding of exponents. The second level "corresponds to the operational stage at which students use the familiar processes on exponents with new kinds of numbers such as rational numbers," or is characterized by generalizing valid bases. In the case of rational numbers, it can also be seen as a coordination of applying exponents on the numerator and denominator. The third and final one "corresponds to the restructured stage at which students recognize exponents as a mathematical object" (p. 309). Here, "object" is used in the sense of APOS theory.

Complex Analysis

Danenhower's (2000, 2006) work is foundational to contemporary investigations into students' learning of complex analysis and is situated within a framework of radical constructivism and APOS theory. His primary hypothesis distinguishes the vector, cartesian, and polar forms of complex numbers and conjectures that students will have difficulty moving between these forms.

One part of his dissertation focused on the "multirepresentations of complex numbers" (p. 109), which is also how he thematizes his findings (p. 110). One of these themes was "Shifting Representations," which refers to how students change the representations of complex numbers to expedite (iterated) multiplication, division, or addition/subtraction. In such context, Danenhower describes four stages of understanding complex fractions in terms of APOS theory, the last one being "the ability to indicate when to shift representations" from "our conception of complex fractions" (p. 124). He also presents the following criteria for each stage of the theory.

Table 1. Danenhower's (2000, p. 125) findings on simplifying positive integer powers of complex fractions in APOS theory

Action	"Concerned with the details of the realizing algorithm for each problem. Applies algorithms routinely and apparently without thought of other

	possibilities (absence of evidence of a thought process leading to a decision to perform the calculations that were undertaken by the student)."
Process	"Shifts to the polar representation at some point, but is still primarily concerned with the details of the simplification. Possibly uses some "short cuts", e.g., uses (a + ib)(a - ib) = $a^2 + b^2$ without calculation. Generally fluent technique, i.e., is able to do the simplification correctly with few obstacles. Shows that they are doing the calculations by decision, rather than because 'it is what you do in this kind of problem'".
Object	"Uses prior knowledge freely. Indicates consideration of more than one method of solution. Uses geometry to aid calculations. Freely modifies realizing algorithm or polar method to save work."

Similar findings regarding Shifting Representations would be replicated by Panaoura et al. (2006), Karakok et al. (2014), and Soto-Johnson & Troup (2014). Panaoura et al. (2006) found that "the identification of two distinct clusters of pupils revealed that there are two fundamentally different perspectives from which complex numbers are viewed and approached: the algebraic and the geometric approach" (p. 700). Soto-Johnson & Troup (2014) found that algebraic and geometric reasoning decreased as time went on with a bias toward algebra.

Data and Methods

This paper draws on a wider data set concerning how students understand the complex exponent and logarithm for a pilot study. In this paper, I mainly look at responses to questions concerning exponents based on items from Pitta-Pantazi et al. (2007) which looked at comparing the magnitude of exponential expressions, as well as responses to earlier questions based on those from Danenhower (2000) which give further context to their responses.

Research Design

Participants and Setting: Two participants, Monk and Thomas, were recruited from an American R1 university. These students were currently enrolled in an undergraduate complex analysis course and recruited with the aid of their instructor. The study was structured to have each participant participate in two individual interviews and two paired interviews, totaling six interviews, but this paper reports only data from the individual interviews.

Instrument: Complex exponents can be understood to require a coordination of three actions to achieve an object-level understanding: complex multiplication, the complex exponential function, and the complex logarithm, and so the item I present requires coordination of these actions. This paper reports on the result of a specific question based on Pitta-Pantazi (2007): Given expressions a, b, c, compare them in terms of "<," ">" or "=." The expressions were as follows:

1. $|(2e^{i\pi/4})^3|, |(2e^{i\pi/4})^4|, |(2e^{i\pi/4})^5|$
2. $|(-1+i)^{3+i}|, |(-1+i)^{4+i}|, |(-1+i)^{5+i}|$
3. $|(-1+i)^{3+i}|, |(-1+i)^{3+2i}|, |(-1+i)^{3+3i}|$

These items came after the participants calculated the following: $\frac{-2+2i}{(1+i)^3}$, $-\frac{8}{(\sqrt{3}+i)^6}$, $(3\sqrt{2}+3\sqrt{2}i)^{\frac{1}{2}}$, $i^i, i^{2i}, 3i^{1+i}, (-(1+i)^{-5-3i})$, as it contextualizes their behavior for the three items and

gave them opportunities to interiorize their relevant actions into a process for taking complex powers. Some of these items were chosen due to their use by Danenhower (2000).

Analysis

Although there were similarities between the two participants, there were also differences in how they reasoned about these three problems to such an extent that they reached different conclusions for question 3. Thomas deduced the sequence was decreasing while Monk deduced it was increasing. To understand how Monk and Thomas compared the magnitudes of exponential expressions, it is necessary to understand how they computed exponentials.

Calculating Real Exponents

Common between both participants was their strategy in computing the factors with purely real exponents. When faced with an exponential term in the denominator, they immediately multiplied by some power of the conjugate. To simplify $\frac{-2+2i}{(1+i)^3}$, they multiplied by $\frac{(1-i)^3}{(1-i)^3}$, and similarly, for the second they multiplied by $\frac{(\sqrt{3}-i)^6}{(\sqrt{3}-i)^6}$. And then when calculating the square root, $(3\sqrt{2}+3\sqrt{2}i)^{\frac{1}{2}}$, Monk deferred to the definition of $z^w = e^{w\cdot log(z)}$, writing $e^{\frac{1}{2}log(3\sqrt{2}+3\sqrt{2}i)}$, and then eventually simplified to $e^{\frac{1}{2}ln(6)}(cos\,(\frac{\pi}{4}) + i\,sin\,(\frac{\pi}{4}))$. In contrast, Thomas drew a picture of the vector $(3\sqrt{2}+3\sqrt{2}i)$ in the complex plane and reasoned that "the square root should stay on the same line, because the angle is retained... and the modulus is greater than 1 so the length should be shortened." Then he started to reason with the Pythagorean theorem, concluding "I wouldn't know how to expand it otherwise."

According to Danenhower (2000), they operated at an action-level understanding of complex numbers, characterized by their reliance on algebraic definitions and manipulation. Their responses to the square roots are stronger evidence of this claim, where according to Pitta-Pantazi (2007), they were operating on a Level 1 understanding of fractional exponents with a complex base. Monk relied solely on an algebraic calculation, and although Thomas attempted to use geometric reasoning to calculate the square root, he was ultimately unsuccessful and incorrectly stated that taking square roots leaves angles unchanged. So there was also a lack of evidence that complex multiplication was reversed for either participant. Thomas' assumption that square roots stay on the same line is possibly an instance of the TRDC phenomenon. Thus, I conclude they have not achieved a robust process understanding of complex multiplication in general but were working with a process understanding of algebraic complex multiplication.

Calculating Complex Exponents

Monk: When tasked with calculating $3i^{1+i}$, Monk immediately deferred to the definition by writing $e((1+i)(Log(3i)))=e(Log(3i))e(iLog(3i))$.[1] When asked how he got the second term, Monk described a mental calculation of distributing the Log(3i) term and using the established property of $e^{z+w}=e^z e^w$. He continued to simplify by writing 3ie(iLog(3i)), using the inverse relationship between logarithm and exponent, and tried to "do [Log(3i)] in my head," subsequently simplifying to 3ie(i(ln(3)+iπ), and finally to 3e(-π)i(cos(ln(3))+i·s(ln(3))). In this inscription, "s(ln(3))" stands for "sin(ln(3))."

When asked for another means of calculation, he checked if the value he calculated prior would match with the identity $3i\cdot(3i)^i$ as an instance of the conjectured rule $a^{z+w}=a^z a^w$. He

[1] At this point, Monk stopped writing exponential expressions with the power above the base, hence the change in style.

simplified $3i\cdot(3i)^i$ into $3i\cdot3^i i^i$ using another conjectured rule that $(ab)^z=a^zb^z$, and used his past work to replace i^i with e(-π/2). Then, he replaced 3^i with e(iLog(3)) and had a final answer of 3e(-π/2)i(c(ln(3))+is(ln(3))). He recognized that these two expressions were not equal, due to a different factor of e(-π) and e(-π/2), but corrected it after the researcher pointed out that the argument of 3i is not π, but π/2. After this, he concluded that the rule $a^{z+w}=a^za^w$ was valid.

He immediately used this rule in calculating $(-(1+i)^{-5-3i})$, after first distributing the negative sign. By reducing the calculation to $(-1-i)^{-5}(-1-i)^{-3i}$, he looked to simplify the term $(-1-i)^{-3i}$, again by using the definition of complex exponents. He rewrote it as e(-3iLog(-1-i)) and then as $e(-3i(\ln\sqrt{2}-\frac{3\pi}{4}i))$, and then by distribution of the -3i term, arrived at a final answer of $-(1+i)^{-5}e(-\frac{9\pi}{4})e(-3i(\ln\sqrt{2}))$.

His performance demonstrated a strong action understanding of complex multiplication, but as evidenced by his calculation of the square root, he has not reversed iterated multiplication. His initial claim that the argument of $3i$ as π reveals his attempt to conceive of the logarithm as a process, and his adoption of the rule $a^{z+w}=a^za^w$ indicated that he was attempting to coordinate the processes of exponentiation with real power and with complex powers into a single process.

Thomas: When tasked with calculating $3i^{i+1}$, Thomas first wrote the definition $e^{(i+1)Log(3i)}$ and replaced Log(3i) with the definition, giving $e^{(i+1)(ln|3i|+i\cdot Arg(3i))}$, then replaced the magnitude and argument functions with their outputs, giving a final expression of $e^{(i+1)(ln(3)+i\frac{\pi}{2})}$, saying "honestly, I would leave it at just that." I asked if there was an alternate way to write it. Thomas proceeded by using the conjectured rule that $(ab)^z=a^zb^z$, transforming the calculation to $3^{i+1}\cdot i^{i+1}$ He wrote both factors in terms of the definition, similar to how he did with his first calculation. Because Arg(3)=ln(|i|)=0, he got the expression $e^{(i+1)ln(3)}e^{(i+1)(i\frac{\pi}{2})}$. Next, he distributed and used an exponent rule simultaneously to get the expression, $e^{iln(3)}e^{ln(3)}e^{-\frac{\pi}{2}}e^{i\frac{\pi}{2}}$ identifying the outermost terms as rotations and the inner terms as scalars. He then identified that $e^{i\frac{\pi}{2}}$ is a 90-degree rotation, and is therefore equal to i, and substituted, giving a final answer of $ie^{iln(3)+ln(3)-\frac{\pi}{2}}$. The final question I asked about this calculation was if it said anything about the final angle and magnitude. He "could simplify a bit more" using the inverse relationship between ln(x) and the exponential function, resulting in the expression "$3ie-\frac{\pi}{2}3^i$ but "in terms of angles I can't say much," and indicated that the magnitude could be read as a product of "all the scalars here," referring to 3i, $e-\frac{\pi}{2}$, and 3^i. There was no clear evidence if he thought of 3^i as a scalar, or just the 3.

When calculating $(-(1+i)^{-5-3i})$, Thomas again used the definition of z^w, writing $e^{(-5-3i)Log(-1-i),}$ and then the definition of the logarithm, writing $e^{(-5-3i)(ln|-1-i|+i\cdot Arg(-1-i))}$. Although he instantly calculated |-1-i| as $\sqrt{2}$, he drew out the argument to get $\frac{3\pi}{4}$, "because φ is between -π and π." He again did a multiplication and exponent rule simultaneously to get $e^{-5ln\sqrt{2}}e^{-i\frac{15\pi}{4}}e^{-3iln\sqrt{2}}e^{\frac{9\pi}{4}}$. Finally, using the inverse relationship between the exponential and logarithm, he got a final answer of $(\sqrt{2}\ \ )^5(\sqrt{2}+\sqrt{2}i)(\sqrt{2})^{3i}(\sqrt{2}+\sqrt{2}i)$, and commented that he would not know how to simplify $(\sqrt{2})^{3i}$, and that the furthest he could go in simplifying would be to identify the real and complex parts.

The simultaneity of operations indicates a process understanding of finding the magnitude and angle of a complex number, although these two processes did not appear to be coordinated

into a process for calculating logarithms. Thomas also demonstrated a process understanding of complex multiplication but continued to rely on an action understanding of taking complex powers via the constant execution of a standard algorithm.

Comparing Magnitudes of Exponential Expressions

Question 1: per the framework described by Danenhower (2000). By this, I mean that both Thomas and Monk identified that the polar form of a complex number has an independent magnitude and angle component and that for the question, they only needed to isolate the magnitude. This is the "free modification" that is characteristic of an object-level understanding. Consistent with prior data, they both treated integer exponents as iterated multiplication. I infer this because they both alluded to notions of stretching and rotating and did not use the general definition of complex exponentials in their calculations. According to Thomas "the $e^{i\theta}$, that's always just going to be 1," and according to Monk, "This (referring to terms of the form $e^{i\theta}$) is just going to be our spinny component, so it'll just go away." They reasoned that because the base had a magnitude of 2, taking higher integer powers caused the sequence to increase.

Question 2: The second question caused the participants to think aloud the most out of the three as they used the techniques they developed for Question 2 for Question 3. Thomas used his prior observed method for computing $(-1+i)^{3+i}$, concluding that "the things that affect our length" were the terms $e^{3\ln(\sqrt{2})}e^{\frac{-3\pi}{4}}$, upon which he concluded that the sequence was increasing. Upon further questioning, he went back and forth between each factor determining the magnitude or only one. Initially, he thought that the increase of the real component of the exponent affected only the first term, but likely due to both factors having a 3, he changed his process to have each 3 increment by 1, resulting in this chain of expressions: $e^{3\ln(\sqrt{2})}e^{\frac{-3\pi}{4}}$,$e^{4\ln(\sqrt{2})}e^{-\pi}$,$e^{5\ln(\sqrt{2})}e^{\frac{-5\pi}{4}}$. However, he eventually realized that the second term of each expression corresponded to the angle of the base, which stayed constant, and was able to settle on a conclusion that the sequence was increasing. Notably, despite the length of the interview and his continued practice in calculating logarithms, he was still careful to write out the definition of logarithms to calculate his final answer. From this, it is evident that his thinking at that point relied on a mix of actions and processes, as he consistently deferred to the definition of logarithms, and kept track of each quantity so he would not have to redo the other calculations.

Monk operated with a different understanding of Question 2. He explicitly used the assumption that $z^{a+b}=z^a z^b$, and likely implicitly used the assumption that $|zw|=|z||w|$. Hence his sole focus on the term $(-1+i)^3$, ignoring $(-1+i)^i$, possibly because it was a common factor in all three terms. After calculating $(-1+i)^3$ as $2(i+1)$, he reasoned that higher powers would increase the magnitude, verbalizing the magnitude of each, concluding that the sequence is increasing. Essentially, he identified the consequential calculations to attend to and reduced it to a question about iterated multiplication of real numbers.

Question 3: Thomas approached Question 3 with his usual approach of decomposing each operation into its definition. However, once he arrived at the term $e^{(3+i)(ln|-1+i|+i\frac{3\pi}{4})}$, he replaced the (3+i) term with a variable, (3+ai), "since we're changing the coefficient in front of the i." He proceeded to distribute and use a power law to get $e^{3ln\sqrt{2}} \cdot e^{i\frac{9\pi}{4}} \cdot e^{ai \cdot ln\sqrt{2}} \cdot e^{\frac{-3 \cdot a \cdot \pi}{4}}$. After simplifying each term, he identified that "the main thing here that's changing is this $\frac{3 \cdot a \cdot \pi}{4}$." Although the third term also has an a inside of it, he reasoned that "this one's also going to be an angle, and we're just dealing with the modulus here… we know that we can split the modulus up

across products, so $[e^{a \cdot i \cdot ln\sqrt{2}}]$ is equivalent to 1." He also noted that $e^{i\frac{9\pi}{4}} = \frac{\sqrt{2}}{2} + i\frac{\sqrt{2}}{2}$ "because of periodicity, we can subtract 2π from it." He concluded that because "our thing that's changing is $e^{\frac{-3 \cdot a \cdot \pi}{4}}$, so a larger a means our overall quantity is decreasing" and concluded that the sequence is decreasing. There is evidence here that Thomas is operating with an object-level understanding of complex exponentiation, given that he established a useful form of the numbers he was working with and used a variable to reason about the problem. He developed an algorithm for this question and realized exponentiation as a function, corresponding to object-level understanding in Danenhower's (2000) and Pitta-Pantazi et al.'s (2007) frameworks. The question possibly made him generalize his schema of functions to accommodate complex exponents, as he first led me to believe that he would calculate each term individually.

Monk's initial reaction was that "$[(-1+i)^3]$ will give us $2\sqrt{2}$ and $[i]$ is going to spin it each time." From this, I infer that he knew immediately that $|-1+i| = \sqrt{2}$, and that cubing it would give it a magnitude of $2\sqrt{2}$. I also infer that he was breaking up the calculation into $|(-1+i)^3| \cdot |(-1+i)^i|$ This is further evidenced by his next move where he looked at the second term, and wrote $2\sqrt{2}|(-1+i)^{i+i}|$. He then broke $(-1+i)^{i+i}$ into $(-1+i)^i \cdot (-1+i)^{i+i}$, after which he said "and that's just taking your vector and spinning it so the magnitude isn't going to change, so it's just going to square itself." In this utterance, he partly associates purely imaginary powers with rotations. Next, he said, "Well, this is going to be a squared magnitude," referring to his inscription of $(-1+i)^{i+i}(-1+i)^{i+i}$ "And because the magnitude of that is $-1+i$ is $\sqrt{2}$ because that's not less than 1" he concluded that the sequence was increasing. However, the magnitude of $(-1+i)^i$ is approximately 0.09, which would instead lead him to conclude the sequence was decreasing.

I conclude that Monk demonstrated a process understanding of complex multiplication and complex exponents with integer coefficients, given his instant claim that the magnitude of $(-1+i)^i$ was greater than 1. This is possibly an instance of the TℝDℂ phenomenon as described by Hancock (2018) where he described participants "extending real intuition to the complex setting erroneously," (p. 392) the intuition being that a complex number with magnitude greater than 1 raised to a power with magnitude greater than or equal to 1 will have magnitude greater than 1.

Discussion and Conclusion

In extending research on student understanding of complex analysis, I replicated the finding of Shifting Representations as found by Danenhower (2000), Panaoura et al. (2006), Karakok et al. (2014), and Soto-Johnson & Troup (2014) in how the participants tackled their calculations of complex exponentials. My participants chose the representations to use for a given question based on either its initial representation, or its representation in the definition of the complex exponential. They rarely experimented to see if alternate representations would be useful.

Because they only used familiar rules after they established their plausibility, participants seemed hesitant to leverage their knowledge of real-valued exponents and logarithms, instead reasoning from the definition. Only toward the end were instances of TℝDℂ seen explicitly. It is possible that during the experiment, the schemas related to complex and real exponents were separate, and the participants were actively generalizing both into a more general schema. Additional analysis of their performance on other items will need to be done to make definite conclusions, but this works toward a more complete understanding of the TℝDℂ phenomenon.

Implications From Interviews of and About International Students and Researchers

Matt F. Park
Virginia Tech

Following the work by Shultz et al. (2023), I present data related to surveys and interviews of math education researchers from underrepresented cultures in the wider literature. I present findings related to constructs they deem important in math education and have not seen widely represented in current research.

Keywords: International Students, Equity

Long ago in ancient India, there was a group of blind monks. One day, they learned that something had come to their village. Only able to touch the object, one thought it to be a thick snake, another a large fan. When the third touched it, he determined it to be a leathery barricade, and the fourth concluded it was a tree trunk. The last concluded it was a curved spear. This is The Parable of the Blind Monks and the Elephant, which illustrates the variety of conclusions that people can arrive at despite studying the same phenomenon. Even if math education research might be a well-defined area of study, different researchers may view the nature of math education, teaching, and learning quite differently. So wider adoption of differing, even contradictory viewpoints, can help paint a more holistic picture of any topic of interest, including math education.

In this paper, I present data from a preliminary investigation into the cultural differences that math education researchers from non-American backgrounds notice in math education spaces. When I use the term "math education spaces," I refer to math classrooms and math education research. This paper reports on the specific research question "What attitudes toward mathematical learning do scholars identify as important and underrepresented?" To work toward an answer to this question, I started by looking at the experience of researchers who came to the US as international students. Due to survey responses, I expanded my view to include anyone who might fall outside the dominant, White culture of the United States. The scope of the participants' experiences ranges from learning or teaching in an American math classroom to conducting research in a math education setting. In this paper, I present a wide variety of sentiments, opinions, and judgments of the current state of mathematics education research based on the lived experiences of a similarly wide variety of researchers and graduate students.

Theoretical Framework

Just as the theoretical frameworks we use are inherently influenced by their authors, sometimes quite explicitly in the case of individuals like Vygotsky and the cultural influence of Soviet Marxism (see Fu (1997) for his commitment to furthering the Marxist project) researchers also bring their own biases and influences to their work. It is not only the implicit biases and beliefs of American and European researchers that are worth examining but also of outside the Anglosphere, especially as non-Western education and math researchers and instructors continue to work in the West and international students continue to be a significant (and changing) demographic of college math classrooms. We must also ask if we allow international students to bring their frameworks to their professional work and if we allow their influence to perpetuate throughout the field.

For this paper, I draw upon Sfard & Prusak's notion of identity and draw a parallel to their belief that "the notion of identity is a perfect candidate for the role of 'the missing link' in the [researchers'] story of the complex dialectic between learning [about mathematics education] and its [American] context." They define identity as "collections of stories about persons or, more specifically, as those narratives about individuals that are reifying, endorsable, and significant." Key to this idea is the distinction between Actual and Designated Identity, where "actual" identity is characterized by how the individual understands themselves and "designated" identity is how they imagine themselves in the future. Sfard and Prusak (2005) argue that one's education is how one realizes one's Designated Identity starting from one's Actual Identity. In the context of this study, this means that one's understanding of American classrooms starting from outside the United States shapes one's designated identity as a math education researcher.

Literature Review

In their paper on the role of mathematical identity in math education research, Sfard and Prusak (2005) report on a study of Prusak (2003) comparing the learning outcomes of national Israeli students and Soviet-Israeli immigrants, both of Jewish religious backgrounds. While the outcomes of each group were comparable in terms of overall success, the methods each group of students employed were not. Sfard and Prusak argue that the identity of the students is powerful enough to explain the different study methods. The Israeli students saw mathematics as a way to further their career prospects, and the Soviet immigrant students instead saw mastery of mathematics as important to becoming "full-fledged as a human being" (p. 20). That is, they saw mathematical mastery as having inherent value.

Shultz et al. (2023) investigated how Hispanic serving institutions enact culturally relevant pedagogy (CRP) in the sense of Ladson-Billings (1995). They found two barriers to enacting CRP: a reluctance to discuss various aspects of identity (racial, gender, ethnic) and a belief that "mathematics is culture-free" (p. 503). They linked the various attitudes and instructors' reluctance toward implementing CRP to their identity. For example, one Korean instructor guessed that shallow cultural references in word problems would be more insulting than inviting based on how he imagined references to various aspects of Korean popular culture. They found that despite both barriers, instructors generally enacted aspects of CRP in their classes. To address these barriers, they call on the field to "take more risks in conversation and invite a more diverse range of people to the undergraduate mathematics community" (p. 486). As RUME researchers are part of the undergraduate mathematics community, this call applies here as well.

In summary, Sfard and Prusak (2005) linked identity to how math students understand the experience of mathematical instruction, and Shultz et al. (2023) did a similar investigation, except with instructors instead of students. In this work, we link identity to how education researchers understand the experience of mathematical instruction.

Methods

To begin to understand the cultural influences that international students of math and math education bring to their work, I sent out a survey primarily aimed at students who started their math education in the United States as immigrants or international students and recruited conference attendees as participants. Recruitment took place in person and online.

Participants filled out an initial survey consisting of demographic questions and two main questions: 1. What are some things in math education that you feel are important but are underrepresented in Western math education research? 2. Briefly describe American cultural practices or attitudes regarding teaching and learning that initially surprised you. Participants

were also asked if they would participate in a follow-up interview, of which 8 agreed. Interviews were semi-structured and lasted for 45 to 60 minutes. Interview participants were all relatively new to math education research, either as graduate students, postdocs, or established scholars who have recently started math education research. Transcripts were edited for clarity.

After cleaning up the transcripts, I engaged in a thematic analysis (Braun and Clarke, 2006) to identify common themes between the survey and interviews. The thematic analysis consisted of two rounds of coding. The first identified answers that expanded upon what was asked in the initial survey. The second round identified common themes between the questions. Although a common finding that I will discuss later is the importance of ethnic identity, I will discuss them in general terms to protect anonymity, thus cultural origin will be discussed only when necessary. It would be overly ambitious to sketch out an entire theory of attitudes toward math education or to think that a handful of interviews can provide enough material to even do so. As such, the results are meant to illustrate the diversity of opinions even within a small dataset.

The interview participants consisted of 2 Central Americans, 1 South Asian, 1 West Asian, 1 North Asian, 2 Southeast Asians, and 1 East Asian. This demographic information is based on self-reported data but generalized to grant wider anonymity. A limitation was my inability to collect interview data from large groups such as Africans, Hindus, or Chinese. Furthermore, because there was only a single researcher involved in coding, there is no measure of inter-reliability.

Results

After organizing my findings, multiple themes appeared: the cognitive aspect of mathematical learning, the social aspect of mathematical learning, and the American mathematical practices in a global context. All these reflect some facets of math education that the participants do not see reflected in their work, either as researchers, instructors, or students.

Cognitive Nature of Math Learning

One cultural difference participants noticed regarding the cognitive aspect of mathematical learning was the emphasis on calculations and memorization. One survey response described an "arbitrary distinction between procedural and conceptual mathematics," and another wrote about the importance of not only memory, but also rhythm in mathematical learning, and that "reciting math orally often uses rhythm."

Two interview participants went into greater detail about the importance of mastering calculations. Both discussed how the use of calculators was discouraged in their upbringing outside the United States. When asked how such practices affected their mathematical education, one said "I felt like if I learned by doing things by hand I understand things better." Another discussed how achieving algorithmic competency helps achieve "mastery" and importantly, move beyond memorization, "deeper understanding," and "critical thinking."

These respondents placed large importance on memorization and algorithmic competency in their personal theory of mathematical learning and see that Western research largely marginalizes it. It is unlikely they can use it in their professional theories. Although the interviewers rarely cited existing research on why strong procedural knowledge advances one's conceptual knowledge, one survey response has insight into that "mathematical ideas and justifications underpin every algorithm and procedure."

Relatedly, one participant discussed how some of her work's results described different attitudes among students regarding the usefulness of lectures. Of note was an international student who deeply enjoyed lectures. In summary, some researchers come to the United States

placing importance on what is typically deemed “rote” or “passive” methods of learning mathematics, and the research they are exposed to does not align with such attitudes.

Social Aspect of Mathematical Learning

There were more findings based on reactions to American classrooms, typically in higher education, as many of the participants first came to the United States as graduate students. However, some reactions were rooted in coming to the United States as children.

Attitudes Toward and of Teachers: Americans' broad cultural attitudes toward teachers and the teaching profession stood out to many participants. In describing the teacher education program from overseas, one participant said the “teacher education program is really small and [back home], being a teacher is really competitive. It is still crazy competitive. In the United States, we can't really imagine it.” A similar difference was backed by another participant from a completely different culture, who said that American teachers “do not get treated like professionals and often don't see themselves as professionals practicing a profession.” Other participants discussed how this broad societal attitude toward teaching manifested in students. One participant wrote about the surprise of “how little authority teachers hold in teaching and learning in America” and the independence of students, even though “the student-teacher ratio was a lot higher in my culture.” This comparative lack of authority was reinforced by another survey response which described seeing students “talking back to the teacher” as a culture shock. These culture shocks impacted participants’ learning as well as their work as instructors. One self-described Middle Eastern researcher who first came to the United States after college described the culture as “very different” and the adjustments they needed to make when teaching American students. “We were the ones that were always guilty if we didn't know anything. And here it was, it was like the exact opposite.” The participant discussed more on how in her upbringing, the onus fell on the student to motivate their own learning, and how they had to adapt to the shift of such responsibility onto the instructor.

Classroom Dynamics: When participants discussed topics related to the wider classroom dynamics, they made their ethnic, religious, or cultural background the most explicit.

Learning as a Community: One theme that appeared in one Southeast and one South Asian culture is the idea of Learning as a Community. I offer a broad, initial definition as a culture where students, particularly higher-performing ones, have an obligation to ensure their classmates understand the material. One participant described it as follows:

> “A sort of idea where it can't just be me who's learning something. Like if I'm in a classroom as a student, I can't be the only person learning because I'll feel bad. Because I want other people to also pass. The idea that somebody has to fail does not cohere with my mind. It doesn't make sense in my head like somebody has to fail. Cause it's sort of like, it takes a village to pass. And so for me, I'm definitely the type to try to study and learn and work with people, regardless of the fact that I can handle it by myself. Sometimes I take the position of a teacher.”

Moreover, this idea of Learning as a Community stood out to the participant as a noticeable absence from the American classrooms he was in, and he differentiated it from ideas such as “active learning” or “inquiry-based learning.” Another participant from a similar cultural background considers a similar phenomenon part of his initial motivation to pursue math education research. He described how, due to his relatively higher performance in his math courses even in high school, his classmates sought help from him, forming a “helper” identity and sparking an interest in math education. The first participant attributes this to how

"individualism" is characterized in their culture, where it is not the individual person that is prioritized, but the individual family unit, and how it is practiced. He said, "Constantly when I was going up… we would get told, ask your big sister, ask your big brother or like make sure they help your little brother, make sure to help your cousin."

The emphasis on relying on others and making oneself reliable to others seemed to extend to a classroom setting and impacted the participant's theory of classroom dynamics. This awareness of how one's knowledge can help their classmates was present in another interview in a completely different religious context.

> "In Islam, there's a lot of emphasis on learning about how the world works, how the universe works…the other thing is like when I'm learning something, I feel like this is something important I'm doing. It has an impact. I can help other people. If I learn something I can help other people to learn."

The participants, with their varied backgrounds, described a variety of perspectives on the nature of mathematical authority and how it is exercised in and beyond the classroom varied among participants, but a common theme was the larger responsibility of students to themselves and each other.

Closeness and Caring Relations: Another difference was how participants characterized "caring" in American instruction. Some participants elevated the caring of their own culture over the aspects of American culture they experienced. One preferred to characterize it as a distinct construct using the Spanish equivalent of "Cariño." In her Hispanic culture, she characterized "Cariño" as "this value placed on being friendly and loving and caring, like this caring warm quality." She described how it was a prominent feature of teachers from her experience teaching at an overwhelmingly Hispanic secondary school, as this extended to how the teachers treated their students "Like calling them my child… Like there's a lot more like mothering or fathering I think that goes into that role that you wouldn't see" in other cultures. Other participants partially validated this by discussing how they understood "caring" instructors from their cultural backgrounds.

One participant with an Asian background compared his experience in the United States with two Asian professors. Although both taught "traditionally" either in mindset or instructional practices, he saw different levels of caring between the two. One was "incredible in terms of he was a caring guy" and although "he would do the lecture, make stuff really hard, he really wanted you to work hard for his class and he was super." He attributed this partially to this professor's flexibility, such as working with him for longer than expected, and even at night. Compared to another professor "he wasn't as caring. There was an instance that I asked them a question after class. And he said to me 'You should just practice more. You don't understand.' And he just left." Another participant discussed availability in terms of the expectations for teachers in her home country. Although students were expected to be in school for more than 12 hours a day, so were teachers. She characterized the instructors who adhered to the same schedule as their students as "really passionate." While neither the teacher nor the student was in class every moment of the day, teachers were expected to be available similar to "office hours." This same participant also described having minimal connection with her American professors and felt a lack of caring on the side of their professors.

Situating American Culture in a Global Context

Finally, the participants' perspectives help put different aspects of American society into greater context. One of these is Americans' beliefs about people's capacity for mathematical

learning, especially in children. One participant described how the math content in the United States seemed a year behind what she was used to in her original country and how returning home left her unequipped for her school. Another described her experience as an instructor. In her home country, high school students in math regularly graduate with integral calculus, which required an adjustment to teaching what she considered high school material at a college.

Another finding is that the current diversity and equity research paradigm does not align with how non-European American researchers understand diversity. Participants do not encounter much work regarding Middle Eastern and North African, Asian, religious minority, or even White ethnic cultures. Some discussed their motivation to seek out Critical Race studies related to their cultural background in other departments, and the wider discourse on diversity seemed alienating, and overwhelmingly shaped by White researchers with "little room for opinion from those who are non-white, non-American."

The participants' opinions on diversity differed from the more dominant racial discourse. Aside from an implicit desire to see their culture represented in the wider discourse, some were also interested in more granular factors such as linguistic, ideological, religious, and ethnic diversity. One rooted their interests based on their culture where multiple indigenous languages existed in a classroom where everyone was taught their country's national language. For example, studies about linguistically diverse classrooms in America might also benefit by drawing from frameworks drafted by those with upbringings from multilingual societies. More broadly, there might be a place for frameworks that illustrate American attitudes as foundational rather than as a reaction, as the former is the perspective of these researchers. Others placed specific importance on their ethnic background on their Actual Identity, as there were instances of individuals from Southeast and East Asia identifying not as Asian, but as their specific ethnicity. This was alongside an interest in cultural differences among White Americans. Thus, the investigation of the link between identity and attitudes should not be relegated to just non-American, non-White researchers, or even restricted to a single White identity, as there is potential interest in the relationship between White ethnic identities and math education. In general, the field can benefit from a closer inspection of these ethnic identity.

There were also different attitudes regarding the inclusion of women in academic spaces. One woman described avoiding the sexism of her home country as part of her preference for working in the United States. Another described her understanding of her place in academia as rooted in her culture. "[There's] a very conservative mindset, but then there are Muslim scholars who are women. When we date back to the beginning of Islam. One of the wives of the Prophet was a scholar and she just devoted her life to education." Further investigation concluded that she was likely referring to Aisha, who became of renewed interest among Arab scholars in the 20th century (Elsadda, 2001).

Discussion and Conclusion

I end this paper with a brief discussion on counterstories. Solórzano and Yosso (2002) describe one kind which counters majoritarian stories, and another in the sense of Ikemoto (1997) which is not "created as a direct response to majoritarian stories" (p. 32). This final quote regarding the beginning of Islam could be an instance of the former. It could be a counter-story within the context of Islam, not the Christian one that dominates North American culture. Alternatively, it could be a counterstory within an Islamic context.

My findings may well be instances or parts of counter-stories that can exist outside the context of the majoritarian paradigm. Regarding authority relations, there are similarities to authority relationships as described by Amit and Fried (2005) as a development of Weber's

(1947) framework, as well as near-peer mentoring (Stringer, 2024). It would be inaccurate to describe these frameworks as wholly inappropriate for characterizing the dynamics that have been described. However, non-Western perspectives can likely enrich current authority frameworks by providing another foundation. For example, unlike the frameworks from Amit and Fried (2005) or Hackenberg (2010), it does not need to be surprising that students would see each other as an authority by supposing such dynamics from first principles, as might be the case for Confucian frameworks.

Similarly, my findings illustrate two distinct notions of "caring," one as a construct related to immediate, present behavior and another related to availability. These notions have been expanded on mostly outside of the Western European tradition. Lomei (2023) offers a more concrete definition of "Cariño" as "the manifestation of caring grounded in Latino cultural values" (p. 20). Her work is designed as "a departure from a universalistic conception of care and makes an intentional departure from Eurocentric views of what care might entail" (p. 21). and it remained until her work produced a workable framework to recognize cariño in predominantly Hispanic classrooms, and its absence can be felt in other studies. For example, Hufferd-Ackles et. al's (2004) study about the classroom culture of a predominantly Hispanic classroom arguably captures "cariño" from the teacher in a salient way, yet they could not recognize it. A Korean researcher, Ye Ryung Chun, worked to capture the second notion of caring. In her dissertation (2007), she acknowledges the concept of "chuk eun ji shim" which is instead related to the idea of "how to care in situations where we almost do not want to care" (p. 106). In her estimation, this dimension of obligation is absent from Noddings' work. Both these researchers shed light on conceptualizations of caring outside an American perspective and corroborate claims from the participants that such ideas are outside the current mainstream of math education research.

Conclusion

The diversity of opinions I found demonstrates the large diversity of perspectives among non-European American researchers. One does not necessarily need to conclude that the differences researchers notice between their culture and the dominant math education and research culture indicate definitive neglect of such concepts. To do so outright would downplay the contributions of scholars who have contributed in these ways. That said, the data demonstrates an opportunity to leverage the unique perspectives of international researchers working in America, as many of their personal theories of mathematics education were shaped outside a strong Western influence. They can help Western researchers have a more holistic perspective of math education as these researchers demonstrate the capacity to embody multiple cultural paradigms in a single researcher. More generally, future frameworks should not be responses to the dominant culture of the United States, but ones developed outside of it.

The variety and cultural salience of the responses raise questions for the field going forward such as: How can we understand and situate existing frameworks in relation to the cultural identity of their original authors? Explicit awareness of an author's cultural identity does not inhibit the adoption of their frameworks. For example, Lev Vygotsky worked within the Marxist tradition (Fu, 1997) but his theories were eventually adopted by those in a capitalist society. So should work from scholars like Lomei or Chun be restricted to only Latino or Korean contexts? Our field has always applied learning theories to cultural environments distinct from cultures where said theories were initially developed, so I propose not.

Mathematics education scholars have asserted that proof can be viewed as a unique genre of communication with specific norms and conventions. Further, some have argued that these norms and conventions are gendered and may dissuade women from participating in advanced mathematics. However, these assertions for the most part have not been investigated empirically. In this proposal, we systematically analyze the linguistic features of 90 proofs from 15 textbooks in advanced undergraduate mathematics. Key findings include that many feminine ways of communication rarely occur in proofs, including hedges, references to emotions, and intensive adverbs. Some masculine ways of communication, including the use of directives, are common in undergraduate proofs. Implications of this research are discussed.

Keywords: Gender; Genre; Linguistics; Proof

Mathematical proof plays a vital role in advanced mathematics. Proof is the dominant means of justification in advanced undergraduate mathematics classes and testing students' ability to prove statements is a primary means of assessing students' performance in those courses. For this reason, proof serves as a gatekeeper to studying advanced mathematics and participating in the community of professional mathematicians. Students who do not master the practice of proving will neither succeed in their advanced undergraduate mathematics courses nor be invited to study mathematics further.

There are several reasons for why reading and writing proofs is challenging for university mathematics students (see Stylianides et al., 2017, for a review of this literature). In this paper, we focus on one particular source of difficulty: to read and write proofs, undergraduate mathematics students must work with a new genre of academic writing. In recent years, several scholars have remarked that proof can be viewed as rhetorical genre (Bowers & Küchle, 2020; Lew & Mejía-Ramos, 2019; Selden & Selden, 2013). There are a number of norms and conventions in proof writing that seem unique to this genre and are not present in most other forms of discourse. For instance, mathematics educators claim that proofs usually do not use the "I" pronoun (Burton & Morgan, 2000; Dawkins & Weber, 2017). Lew and Mejía-Ramos (2019) demonstrated that students are not aware of these norms, and they speculate that this may contribute to students' difficulties in engaging with proof. We note, however, that the norms and conventions of proof described in the mathematics education literature are usually not based on empirical studies on how proof are written. Rather, authors commonly justify their claims by referencing their own experience, or by citing other scholars who have made similar assertions. One contribution of this report is to provide an empirical study exploring trends on how 90 proofs are written in undergraduate textbooks.

Scholars have further asserted that the norms and conventions of proving may lead to inequities and discourage students from underrepresented populations from participating in advanced mathematics (e.g., Brown, 2018; Tanswell & Rittberg, 2020; Minggi, et al., 2021). In

particular, some scholars claim that proof may represent a masculinized way of communicating (Keith, 1988; Mendick, 2006), since proofs are impersonal and directive. If true, this can dissuade women from participating in advanced mathematics, as there is a larger gap between the norms of proof writing and the way that women would ordinarily communicate in natural settings (c.f., Tanswell & Rittberg, 2020). However, claims that proof is indeed a masculine form of communication are in need of empirical support. In this paper, we investigate this hypothesis by analyzing 90 proofs from undergraduate textbooks.

Related Literature and Framing

Like Selden and Selden (2013) and Bowers and Küchle (2020), Dawkins and Weber (2017) assert that proof is a genre where proofs are expected to adhere to specific norms. Dawkins and Weber argue that these norms are not arbitrary. Rather, these norms are in place for epistemological reasons. These norms support axiological virtues of the discipline of mathematics and facilitate the epistemological aims of the intended audience for these proofs.

Dawkins and Weber (2017) first assert that mathematicians desire that mathematical truth be *a priori* and objective, corroborating Ernest's (1995) claim that mathematicians have absolutists views where their knowledge claims are correct, universal, and incorrigible since they flow from firm foundations via deductive logic. Two norms associated with this value are that justifications must be traced to stipulated definitions, and that justification should be deductive and not allow for rebuttals (c.f., Inglis et al., 2007). This leads proofs to be written as chains of deductions. As Pedemonte (2007) summarizes: "[W]ithin proofs, the steps are connected by a 'recycling process' (Duval 1992–1993): the conclusion of one step serves as an input condition to the next step" (p. 24).

Dawkins and Weber (2017) further argue that "mathematical knowledge and justification should be independent of (non-mathematical) contexts, including time and author" (p. 129). This points to a common refrain that proofs aim to conceal the author and render them without a human element (e.g., Burton & Morgan, 2000). Further, proofs are "addressed to a universal audience" (Pedemonte, 2007, p. 27). This leads to the norm that references to the personal experiences of the author are omitted, including the process used to generate the proof and even the pronoun "I".

A final epistemological virtue mentioned by Dawkins and Weber (2017) is that proofs should be written to enhance understanding. Proofs are written in a brief and clear style so that mathematicians can recognize the overarching structure of the proof and recognize their key ideas. To avoid getting bogged down in logical minutia, routine details from a proof are omitted, and the proofs do not contain redundancy (Selden & Selden, 2013). We note here that this sparse writing style might not actually increase comprehensibility, especially for students. Logically compact statements can be difficult to parse, and "routine" details might not be obvious for a student to supply (see Minggi et al., 2021).

Gendered Communication

Women and men tend to communicate differently. In Table 1, we present Mulac et al.'s (2001) synthesis of the documented significant differences between male and female communication. As can be seen from Table 1, the literature reveals that men are more likely to use directives and judgmental adjectives in their communication and women are more likely to express uncertainty, add hedges, or use intensive adverbs. With Table 1 in mind, our research questions are: (R1) To what extent do proofs in advanced undergraduate mathematics textbooks

contain the 18 language features described in Table 1 and (R2) Which masculine features are common in proofs in advanced undergraduate mathematics textbooks, and which feminine features are absent?

Table 1. Features of Language Found in Empirical Studies (Mulac et al., 2001) where M: male features, F: female features; X: mixed results from empirical studies.

Language Variable [1]	Definition
Questions (X)	But not including directives in question form
Tag questions (F)	An assertion that is followed by a question asking for support
Directives (M)	Telling another person what to do
Negations (F)	A statement of what something is not
Sentence initial adverbials (F)	Answers the questions: how, when, or where? regarding the main clause [why and how long]
Oppositions (F)	Retracting a statement and posing one with an opposite meaning
Judgmental adjectives (M)	Indicating personal evaluations rather than merely description
Uncertainty verbs (F)	Verb phrases indicating lack of certainty or assuredness
Progressive verbs (X)	Verbs presented in the "-ing" form
Intensive adverbs (F)	Adverbs such as "really" or "so"
Hedges (F)	Modifiers that indicate lack of confidence in, or diminished assuredness of, the statement
Justifiers (X)	A reason is given for a previous statement
References to emotion (F)	Any mention of an emotion or feeling
References to quantity (M)	References to an amount or quantity
Locatives (M)	Usually indicating the location or position of objects
Personal pronouns (X)	Words that stand for beings
"I" references (M)	First person singular pronoun in the subjective case
Fillers (X)	Words or phrases used without apparent semantic intent

1 We do not report on two categories from the framework: elliptical sentences (due to lack of consensus in coder team) and dependent clauses (due to their common appearance across all types of texts Rafajlovičová, 2013).

To avoid misinterpretation, we wish to emphasize two points. First, Table 1 represents broad trends in the differences between how men or boys and women or girls communicate, but these are only statistical trends, and do not tell us how a particular individual will communicate. There are doubtlessly specific females who will frequently use directives and specific males who will avoid them. Second, Table 1 does not specify *why* males and females communicate differently. We agree with Mulac et al. (2001), gender can be understood as a culture in which communication is learned and practiced. That is, "much of what people know about interpersonal communication is learned from same-sex peers during the ages of 5 to 15 years," and therefore particular cultural elements, including language and communication, are developed within same-sex groups. Of course, power, societal ideologies, and ambient cultural trends likely shape how children learn to communicate in their formative years. We also note that this empirical synthesis only allows for exploration related to binary gender identities.

Methods

To explore the nature of language in proof textbooks, we selected the five most used books at the undergraduate level for each of: Introduction to Proof, Abstract Algebra, and Analysis. To identify these books, we used the analysis by David & Zazkis (2020) for Introduction to Proof, Melhuish (2015) for Abstract Algebra, and use the Open Syllabus (2023) project to identify Analysis textbooks. Based on a power analysis (80%) to capture a 0.5 effect size (f) with 15 groups (reflecting 15 textbooks), a sample size of 90 was needed to detect medium differences between books. In this paper, we focus primarily on overarching trends, but this will allow for more detailed analysis in the future.

We selected six proofs per textbook. We selected these six proofs as follows. For each textbook, we set n equal to the total page count divided by 6. We went to page n, and proceeding backwards, identified the first proof. We then repeated this process for $2n$, $3n$, $4n$, $5n$, and $6n$, thus collecting six proofs that span the textbook. Each proof was then coded using the linguistic features in Table 1. This began with a common coding of eight proofs in a pilot to develop a shared understanding of codes. After initial coding, the team met to discuss questions, inconsistencies, and to come to a consensus on how each code was applied. At this point, a revised primary coding was finalized for each proof and is reported below.

Results

Many of the linguistic features we analyzed were consistent across proofs. Table 2 provides an overview of the frequencies of the different features.

Table 2. Frequencies of Features in Proofs Analysis where) where M: male features, F: female features; X: mixed results from empirical studies (Mulac et al., 2001).

Language Variable	Proofs with This Feature (n=90)	Instances of This Feature
Questions (X)	0	0
Tag questions (F)	0	0
Directives (M)	78	209
Negations (F)	26	54
Sentence initial adverbials (F)	90	626
Oppositions (F)	4	5
Judgmental adjectives (M)	23	40
Uncertainty verbs (F)	2	2
Progressive verbs (X)	38	83
Intensive adverbs (F)	10	13
Hedges (F)	3	3
Justifiers (X)	27	41
References to emotion (F)	1	1
References to quantity (M)	46	198
Locatives (M)	18	46
Personal pronouns (X)	76	323
“I” references (M)	0	0
Fillers (X)	0	0

To organize the remainder of the results discussion, we suggest three distinct types of features: necessary, arbitrary, and epistemological. We borrow the distinction between arbitrary

and necessary from Hewitt (1999) but delineate between the two slightly differently. A necessary feature is one necessitated by the mathematical content involved in the proof. We then make a distinction between two types of non-necessary features: arbitrary and epistemological. An epistemological feature is one rooted in the way knowledge is established by the mathematical community. We use arbitrary feature for one that does not link to a particular content need or means of knowledge generation. Both epistemological and arbitrary features are reflective of convention, but as noted by Kontorovich and Zazkis (2017) convention choices are meaningful in the discipline.

Necessary Content-Based Linguistic Features

Some linguistics in proof are what we refer to as *content-based features*. Many proofs had references to quantity (n=46) and locatives (n=18) , which seem unavoidable in mathematical domains that concern number and space. Arguably, negations are a content-based feature as well. The negations that we observed in the proofs for the most part concerned proofs by contradiction.

Epistemological Linguistic Features

In many cases, we could relate the presence or absence of some linguistic features to epistemological values such as those described in Dawkins and Weber (2017). We refer to these linguistic features as *epistemological features.* For instance, across all 90 proofs, there were three instances of hedges, two instances of uncertainty verbs, and no tag questions. Each of these three linguistic features was described as more common in feminine communication. The absence of these linguistic features is consistent with the view that proofs should provide certainty. There was only one reference to emotion across the entire data set, which also has been found to be a feminine way of communicating. This finding is consistent with the content of proofs being independent of the author or the reader (in particular, the emotional reactions or states of the authors or readers).

The use of the "I" pronoun is found to be a masculine way of speaking. Both Burton and Morgan (2000) and Dawkins and Weber (2017) assert that the "I" pronoun is rarely used in proofs, with Dawkins and Weber (2017) speculating that this norm is in place so that proofs are independent of their author. We found support for the norm to avoid the "I" pronoun; none of the 90 proofs used this pronoun. The "we" pronoun was used frequently, accounting for all 323 personal pronouns in the proofs. Although the use of personal pronouns was not distinctly masculine or feminine, we found that the "we" pronoun was often used to give directives (e.g., "We observe…"), and as a "royal we". So, this may still nonetheless may represent a depersonalized and masculine form of communication (see Weber, 2023, for more discussion). Interestingly, Hungerford (2012) did not use the word "we" in any of the six proofs that we analyzed, suggesting that the use of "we" may be a stylistic choice by the author.

In contrast, we were surprised to see judgmental adjectives (a masculine way of communicating) were present in 23 of the 90 proofs that we analyzed with statements such as "we merely have to show..." or "it is obvious that…" This would seem to go against upholding the value that proofs are independent of the authors who wrote them.

Arguably other features that may align with the values of the discipline and knowledge generation include the frequency of "sentence initial adverbials" (found in every proof on average 7 times) and "justifiers" (found in 27 proofs, 41 times). Justifiers provide a reason for a fact after it is presented. These were unexpectedly low. Sentence initial adverbials serve to connect a new state from the prior. The justification in proof is often found *before* a statement,

and thus not meeting the justifier definition. That is, these justifications are found in the initial sentence adverbials which often look like "Thus" or "By theorem X." We note that these features align with the deductive logic that underscores proofs. Each line follows deductively from the previous illustrating the recycling process suggested by Pedemonte (2007).

We also note progressive verbs were not found commonly amongst the proofs; another feature found more often in how women communicate. Thirty-eight of the 90 proofs contained progressive verbs. These are action verbs that end in "ing." We suggest this again aligns with epistemological features as truth is not established via the problem-solving process (Dawkins & Weber, 2017) and therefore active verbs would be uncommon in the final product.

Arbitrary Linguistic Features

Some of the linguistic trends that we observed appeared to us to be independent of the content being studied and did not appear to support an epistemological value. We refer to such features as arbitrary linguistic features. Intensive adverbs, a feminine form of communication, were infrequent in the proofs that we surveyed. We found only 13 intensive adverbs appearing in 10 proofs. We suggest that proofs tend towards brevity and words that do not serve to provide additional meaning are not commonly found. We also suspect this desire for brevity may account for the breach of the objective value because statements like determining something is "obvious" often serve the purpose of reducing the amount of information needed to be shared.

Directives, a masculine form of communication, were common in the proofs that we observed. A total of 209 directives appeared in 78 of the 90 proofs that we surveyed. We discuss directives as an arbitrary feature because they do not necessarily connect to the deductive argument development of knowledge. Sometimes they serve the role of introducing notation (e.g., "let x be a...") while other times serve to draw attention to information (e.g., "note ..."). Directives are one of the few features that have been empirically studied. Inglis and Tanswell (in press) found that imperatives where common in mathematicians' proofs on the mathematical archive, and Weber (2023) illustrated how directives (which he labeled "instructions") were frequently used in graduate set theory textbooks. Our results corroborate these findings in undergraduate mathematics textbooks.

Discussion

A number of mathematics educators have speculated on the nature of the genre of proof (e.g., Bowers & Küchle, 2020; Selden & Selden, 2013). However, empirical analysis of the linguistic features of proofs in advanced undergraduate mathematics courses is uncommon. Table 2 reveals several trends based on 90 proofs in 15 textbooks that we analyzed. In many cases, our results corroborated the claims made by other scholars, such as proofs rarely use the "I" pronoun. In other cases, we documented (perhaps not surprising) trends in proofs, such as the lack of hedges, uncertainty adverbs, and intensive adverbs. Finally, there was the curious finding that judgmental adjectives appeared in 23 proofs. This warrants further analysis.

Our findings also indicate several linguistic features of proofs that are representative of masculine ways of communicating. These include the lack of tag questions, uncertainty verbs, hedges, intensive adverbs, and references to emotion, the frequent use of directives, references to number, and locatives, and the occasional use of judgmental adjectives. We note that not every masculine linguistic feature of communication from the literature was common in the proofs that we analyzed. In particular, the pronoun "I", a masculine form of communication, was not present in any of the 90 proofs that we coded.

This raises the question, do proofs need to contain masculine linguistic features and avoid feminine linguistic features? Our current analysis is speculative. It amounts to us asking whether proofs need to have the linguistic features that they do, and can we imagine presenting proofs of the same content in different ways. We cannot see how the content-based linguistic features that proofs have can change. Much of mathematics concerns numbers, quantities, and location, and as such, proofs will often have references to quantity and locatives. It is easier to imagine altering the arbitrary linguistic features. For instance, one can add intensive adverbs to a proof without changing its content, and one can write proofs in a way that does not direct the reader to perform actions. What we coded as epistemological linguistic features present a more interesting case. It is true that avoiding reference to emotion may uphold the value that proofs are independent of author, and avoiding hedges and uncertainty may uphold the value that mathematical results can be known with certainty. However, as noted by Ernest (1995), these epistemological values themselves may be masculine. He suggests:

> There is a radical view that the kind of popular image of mathematics described above serves conservative interests in the mathematics community and in society in general. For if mathematics is viewed as difficult, cold, abstract, ultra-rational, important and largely masculine, then it offers access most easily to those who feel a sense of ownership of mathematics, of the associated values of western culture and of the educational system in general (p. 454).

He further references the work of Gillian (1982) which argues that women and men have differed values in their development where, women are more likely to have values that are, "relationships, connections, empathy, caring, feelings and intuition, and tends to holistic and human-centred" (p. 454). This is contrasted with a separated view where men are more likely to have values that emphasize, "rules, abstraction, objectification, impersonality, unfeelingness, dispassionate reason and analysis, and tends to be atomistic and thing-centred in focus" (p. 454). If this assertion is accurate, then the proof features aligning with epistemological values may need to be interrogated for the way they encode gendered and power dynamics. For example, one can imagine proof norms where the author is allowed to express an emotional state (surprise at a non-intuitive result, or frustration that a particular proof approach is difficult). Further, while proofs must employ deductive reasoning, we can imagine proofs where the author acknowledges that they are not absolutely certain that they carried out each deductive step correctly. Mathematicians offer these types of hedges in their ordinary discourse around proofs (Weber, Mejía-Ramos, & Volpe, 2022), so we can imagine permitting them to do so within the proof itself.

We have demonstrated that proofs in undergraduate mathematics frequently possess linguistic features that are associated with masculine forms of communication. Bowers and Küchle (2020) noted that genres have a power dimension and may play an exclusionary role. It is therefore reasonable to conjecture that the linguistic norms around proof writing may serve to exclude students (Keith, 1988). This suggests two lines of future research. The first is seeing how these linguistic norms encourage or discourage participation in the practice of proving, particularly in gendered ways. Would women, nonbinary individuals, (or even men) be more comfortable in writing proofs in ways that did not adhere to the masculine norms of proving? The second is more explorative and involves designing classrooms that re-imagine proof discourse.

Exploring Undergraduate Mathematics Students' Math Identities Using Sentiment Analysis: Affordances and Precautions

Victoria Delaney
San Diego State University

Megan Selbach-Allen
Harvard University

Students' identities, orientations, and experiences in mathematics courses shape their participation and longevity in the discipline. Yet, undergraduate mathematics instructors do not often integrate pedagogy or curricula that help them build knowledge of their students' math identities. We believe that in many math courses this is a problem of time and scale. We propose that language processing methods can help alleviate this tension by giving instructors a baseline understanding of their students' math identities. In this study, we applied sentiment analysis to 28 mathematics "origin stories" written by undergraduate pre-calculus students. We compared the predictions from four language models with qualitative codes applied by two mathematics education researchers. We conclude this paper by discussing the strengths and limitations of sentiment analysis in our data, and discuss implications for undergraduate mathematics researchers and practitioners who may wish to apply these methods to their work.

Keywords: math identity, sentiment analysis, mixed methods, math instruction

Research has demonstrated the importance of *math identity*, how students see themselves in relationship to mathematics, as doers of mathematics, and their ability to persist in mathematics courses (Boaler, 2002; Cribbs et al., 2016). When mathematics instructors attend to students' math identities with culturally sustaining pedagogy, scaffolding curricula, or creating supportive course infrastructure, they can help students persist by diminishing issues of power and authority historically present in mathematics. However, an important first step in teaching responsively to students' math identities is building knowledge of students. While small class sizes make this a tractable task in K-12, organizational arrangements in undergraduate education pose difficulties for many teachers who wish to know their students' math identities. Undergraduate mathematics courses often enroll hundreds of students, and many instructors serve in a lecturer role. Even by incorporating pedagogical best practices that scale well to lectures, building knowledge of students' mathematics identities remains an intractable challenge. Furthermore, from a research perspective, undergraduate students' math identities are difficult to study at scale with qualitative methods that require humans to apply and agree upon qualitative codes.

To address these challenges, we explore the potential of using *sentiment analysis*, a technique from natural language processing, using community college mathematics students' math origin stories. Though limited to affect, sentiment analysis can give teachers a first glimpse at their students' positive/negative valences with respect to mathematics. We then investigate the limitations of sentiment analysis by comparing predictions from four language models to qualitative affective codes applied by the researchers. Our goal is to explore the extent, if at all, sentiment analysis can aid mathematics instructors and researchers in building knowledge of students' math identities (particularly in large math courses). We ask:

1. How accurately can sentiment analysis predict students' affect in math origin stories?
2. What limits exist for studying students' math identities with sentiment analysis?

Theoretical Framework

Math identity refers to "the ways that students think about themselves in relation to mathematics" including "a person's beliefs, attitudes, emotions, and dispositions about mathematics and [their] resulting motivation and approach to learning and using mathematics knowledge" (Froschl & Sprung, 2016, p. 1). Building and acting upon knowledge of undergraduate students' math identities can impact students' perceptions of their ability to succeed in mathematics. Incorporating math identity requires teachers to inquire about students' math histories and interrogate students' ongoing tensions in seeing themselves as agentic doers and persistors in mathematics. Research has presented several strategies that can aid teachers build knowledge of students' math identities and histories. For instance, Nasir and colleagues advocate for making explicit the relationship between mathematics knowledge, students' cultures, and identities (2008). Rubel and Chu (2012) found that utilizing students' math histories as a starting point for enacting instruction led to increased participation and improved problem-solving skills among underrepresented minority students. However, both of these studies were conducted in K-12. It is unclear how the strategies presented in these studies would be implemented in larger undergraduate mathematics courses.

Implementing pedagogy based on students' math identities is significantly more challenging in large undergraduate mathematics courses. Hornsby and Osman (2014) highlight that the sheer size of lecture halls and high student-to-teacher ratios often impede instructors' abilities to know their students personally. This conclusion is echoed by Cooper and Robinson (2000), who note that large class sizes can hinder the development of a classroom community that is conducive for students to share their personal mathematical experiences. Furthermore, Jaworski et al. (2017) point out that the diverse backgrounds of students in large lectures make it challenging to address all individual math identities effectively. To mitigate these issues, some researchers have suggested using technology to collect data on students' math histories (e.g., Cotner et al., 2013), or using active learning pedagogies during lecture, such as group problem-solving, that could give students opportunities to share aspects of their math identity with peers (Freeman et al., 2014). However, these strategies require time investment and pedagogical knowledge, which may not always be available in large, traditional collegiate mathematics departments.

Sentiment Analysis in Mathematics Education

Although limited to affect, sentiment analysis could give mathematics instructors and researchers initial signals about students' math identities. *Sentiment analysis* is a supervised machine learning technique that has been used in social science research to study emotions and affect in large text-based data sets (Thelwall & Buckley, 2013). Within sentiment analysis, language models make inferences on input text by weighting linguistic features that are likely associated with affect (e.g., "great," "fail," or "!") towards a positive or negative prediction. An input text assigned a "positive" prediction, for example, represents the model's inference that features extracted from the input text align most strongly with patterns associated with positive sentiment, based on the data that the language model was trained upon. In the case of mathematics identity, sentiment analysis can be applied to predict the positive/negative valence in students' writing samples about math identity, which could give suggestions about how students perceive their past and present experiences in mathematics courses.

To date, sentiment analysis has been applied in mathematics education research to analyze pieces of student writing *after* mathematics courses have been completed. For instance, Crossley and colleagues (2018) used sentiment analysis on students' emails to an emotional support

"Genie" (intelligent agent) to study correlations between students' math identities and K-6 mathematics assessment scores. Other studies in higher education have used sentiment analysis to study students' dispositions in end-of-course reviews (Bringula et al., 2022; Hew et al., 2020). However, as large language models are now available to consumers, we believe that these tools may afford mathematics instructors and researchers opportunities to study students' math identities vis-à-vis writing artifacts produced *before* and throughout mathematics courses. Our goal is to study the affordances and limitations of this method with texts about math identities.

Context and Methods

The participants in this study are part of a larger research project in a community college undergraduate mathematics course sequence. The course sequence contains one semester of pre-calculus and one semester of calculus, taught by the same instructor. Students are STEM majors in a cohort pursuing 4-year degrees. Many come from diverse linguistic, cultural, and educational backgrounds and have had mixed experiences in mathematics prior to the study.

The second author requested that the instructor give students a "math origin story" assignment at the beginning of the semester. Here, we consider "math origin story" to be roughly equivalent to other math identity activities (e.g., "mathography," "math autobiography," and "math history"). 28 students submitted math origin stories. The prompt for this assignment was:

> "…Write a short paper (approximately 300 - 500 words) OR make a media recording (audio or video, 3-5 minutes) and talk about your experiences of mathematics [before this class]. Describe the ways that any important experiences you had made you feel about math and how they shaped your learning of math. You can draw from formal or informal experiences, in the home, school, or any other setting. Maybe you had conversations with a family member that was important to you? If you were fortunate, you may have had an amazing teacher or perhaps you were unfortunate enough to have had a negative learning experience. Be descriptive, this is not an academic paper, it is a chance for you to share your math history and for me to learn more about you and your relationship with math."

Data Analysis

To determine the usefulness of sentiment analysis from the perspective of college mathematics researchers and educators, we analyzed the data using mixed methods. First, both researchers individually coded students' math origin stories for positive, negative, and neutral sentiment at the level of the entire math origin story. Next, we met collectively to agree on sentiment codes and resolve outstanding disagreements (Cornish et al., 2016). Drawing from research on math identity, we placed importance on students' statements that described their relationship to mathematics, such as "I am excited by the idea of doing mathematics," or "Using mathematics, I see myself as a future engineer." We placed less emphasis, although still took into account, sentiments about students' experiences with individual mathematics subjects or teachers unless the description indicated a transformation about their relationship with mathematics (e.g., "After taking Ms. G's class, I no longer see myself as a mathematician."). Table 1 shows criteria that we used to assign positive, negative, and neutral sentiments with examples from the data.

Table 1. Qualitative sentiment codes applied by the researchers.

Sentiment	Description	Example from Data

Positive	The text indicates affirmative behavior and/or thoughts in relationship to math identity, such as self-affirmation, seeing oneself as a doer of math or persisting in math. When positive and negative sentiments exist, positive sentiment is stronger.	"...I did notice at an early age that math was something that came natural to me even though I didn't apply myself as much." (Student 6)
Neutral	The text does not indicate sentiment direction, or, is not about the subject's math identity.	"The next math class I took was algebra 2." (Student 3)
Negative	The text indicates disaffirming behavior and/or thoughts in relationship to math identity, such as poor experiences, not seeing oneself as a doer of math or not persisting in the discipline. In the case of positive and negative sentiment, the negative sentiment is stronger.	"There were very few instances in math where I felt that what I was currently learning was genuinely …something that would … help me." (Student 17)

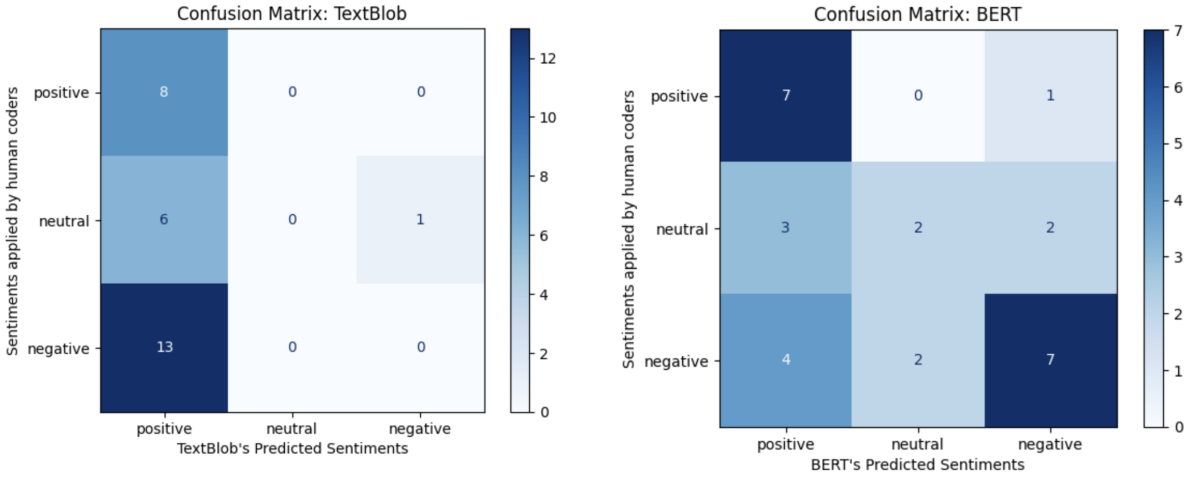
Both researchers held at least six years of teaching and research experience in mathematics education that informed how we conceived of math identity in undergraduate mathematics. The first author taught statistics and calculus for seven years in high school, and the second author taught calculus for nine years in higher education. Both authors taught mathematics to populations of students who have indicated complex relationships with "doing math."

After we applied sentiment codes, the first author pre-processed the text in students' math origin stories to ensure students' stories were compatible with the language models (Haddi et al., 2013). All program-specific acronyms were converted to their full name to reduce the likelihood that the language model would incorrectly infer alternative linguistic meanings. Then the corpus of words was spell-checked, and some words were edited for clarity (e.g., "highschool" was converted to "high school"). Any non-math symbols were removed from the data.

The first author then compiled a corpus of data containing students' origin stories to be analyzed at the level of each story. Sentiment analysis was performed with four language models: TextBlob, a python language processing package chosen for its accessibility; BERT, selected as a former state-of-the-art model for language inference tasks; GPT-4, chosen because it is a current state-of-the-art large language model accessible to consumers for free, and GPT-4o (ver. Sept. '24), selected because it is a current state-of-the-art large language model available to consumers (via OpenAI's API) for a monthly subscription fee. We then analyzed the nature of the errors each model made with confusion matrices and examined patterns of misclassified sentiments. The first author then created a new data corpus with all math identities misclassified by the highest performing model, at the level of individual sentences. We then performed sentiment analysis again with the highest performing language model.

Results

We present the findings from our study by research question. First, we give aggregate performance by each language model; then we analyze the sentiment of misclassified examples to further investigate differences between machine and human-applied sentiments.



RQ1: How accurately can sentiment analysis predict students' affect in math origin stories?

Table 2 shows the performance accuracy of the four language models. While most models performed poorly (and Textblob performed worse than random guessing), GPT-4o's 82.19% accuracy is close to what is considered to be state-of-the-art performance (about 90%) among language interpretation tasks in English at the time of this writing.

Table 2. Sentiment analysis prediction accuracy.

Model	Python TextBlob	BERT	GPT-4	GPT-4o
% Accuracy	28.57%	57.14%	64.28%	82.14%

Figure 1 shows four confusion matrices that demonstrate how each model differed in sentiment predictions from the sentiment codes we applied as human researchers. Counts along the top-left, bottom-right diagonal indicate math stories where the model predicted the same sentiment as we did. All other areas of the confusion matrices indicate classification errors. For instance, TextBlob's low accuracy was almost entirely due to the fact that 27 out of 28 predictions were "positive," whereas we only labeled eight math origin stories as positive. On the other hand, GPT-4o's errors are due to predictions of neutral sentiment on positive math origin stories. We explore these misclassified results in detail in the second portion of the findings.

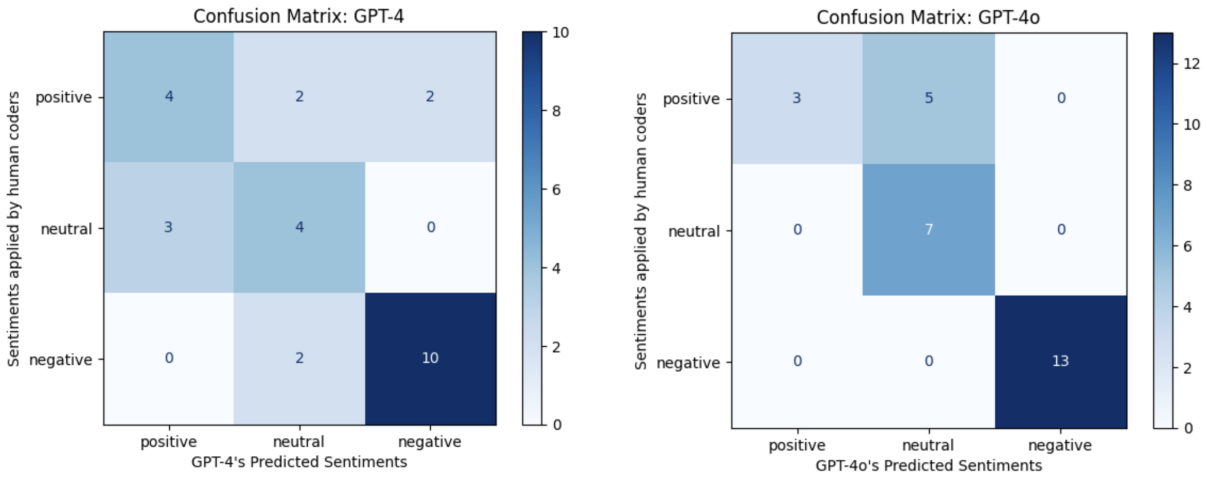


Figure 1. Confusion matrices for each language model.

RQ2: What limits exist for studying students' math identities with sentiment analysis?

We compared the sentiments of the misclassified math origin stories from GPT-4o by sentence to better understand why misclassifications occurred. Figure 2 shows the relative frequencies of positive, neutral, and negative sentiments among the 83 sentences in stories of five students whose positive sentiment was misclassified as "neutral." Results show that GPT-4o classified math origin stories as "neutral" if the ratio of positive to negative sentences was within ~20%. We examined misclassified data for common themes, and found three key distinctions.

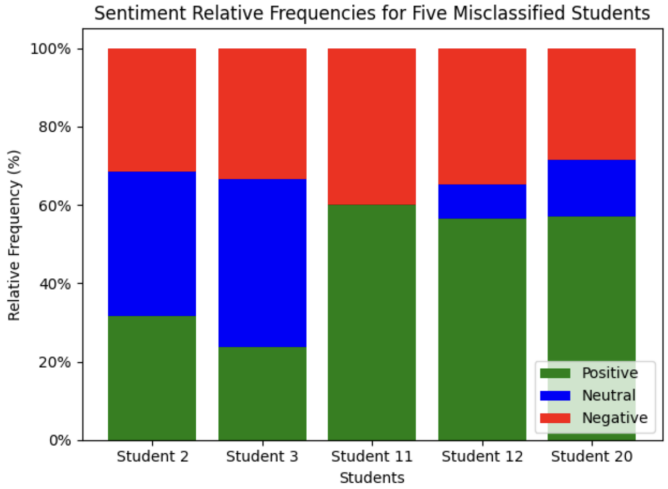

Figure 2. Relative frequencies of sentiments in five misclassified math origin stories.

Theme 1: Math identity in mixed sentiments. Sentences with higher word count frequently contained both positive and negative sentiment. In some cases, GPT-4o classified these sentiments as "neutral." For example, student 20 wrote: "As soon as the semester was over, I immediately dropped [math] class and became a teacher's assistant for my cooking teacher." We inferred that GPT-4o predicted "neutral" because "Dropped the class" is a negative sentiment and "became a teacher's assistant" is positive. However, as mathematics educators, we believed that dropping a mathematics course was more consequential for students' persistence in math,

and therefore was more closely related to the student's math identity than becoming a teaching assistant for a cooking class. We therefore rated this sentence, and others like it, as "negative."

Theme 2: Attribution of sentiments. Unlike human raters, GPT-4o did not seem to weight sentences that referred to individuals other than the student author with less importance. For instance, student 12 wrote, "The most important person to my journey understanding math is my mom. She was always very good at math and knew most things." GPT-4o rated both sentences with positive sentiment. We agreed; however, we did not believe these sentences were as closely related to the students' own math identity, as they described the mother's ability to know and do mathematics. We rated these statements as "neutral" because they described another person.

Theme 3: Prioritization of sentiments that directly described students' math identity. All sentences seemed to be weighted equally by GPT-4o toward the overall sentiment prediction of the math origin stories, regardless of the subject-matter within the sentence. It appeared that the model tried to give an "average" sentiment prediction in neutral cases. For instance, student 3's story contained five positively-classified sentiments, nine neutrally-classified sentiments, and seven negatively-classified sentiments, and was given a "neutral" label. We show a portion of student 3's story below, *italicizing* negative sentences and **boldfacing** positive sentiments:

> "…*My algebra 2 class was a joke. My teacher retired and we did not have a teacher for the rest of the year. We changed substitute teachers and I learned nothing.* The next math I took was pre-calculus. *I would always skip class so I really didn't learn anything during the last 2 years of math.* During all my high school math I have had nothing crazy or anything important enough to remember. *My math classes shaped me to know the basic understanding of math but did not prepare me to thrive.* **Even though I had poor math experience it does not scare me or deter me from becoming a computer science major and I am excited to complete calculus and move on to future maths."**

Since Student 3 described their overall relationship with math as positive in the final sentence, and indicated that they wished to study more math (indicating persistence), we labeled their math origin story as positive, despite the student's description of negative past experiences.

Discussion

Performing sentiment analysis on a class of community college mathematics undergraduates gave us insights about the affordances and limitations of the methodology for both researchers and practitioners. Although GPT-4o underestimated the amount of positive math origin stories, it accurately predicted negative stories. This implies that state-of-the-art language models could potentially assist researchers and teachers to determine how many students express negative affect toward math early in the term, affording opportunities to provide instructional interventions proactively. Of course, sentiment analysis is not instructors' only potential tool for assessing the affective dimensions (McLeod, 1992) of students' math identities. Kaspersen and colleagues (2017) constructed a validated survey to measure math identity in STEM students. We note that the underlying data sources that support surveys (student questionnaires) and sentiment analysis (math origin stories), as well as students' relationships to those data sources, are structurally different from each other. We are curious to explore the measurability affordances of surveys versus sentiment analysis in math identity research in future work.

Furthermore, sentiment analysis by sentence demonstrates that instructional interventions can go beyond mathematics performance and address common themes in students' math identities

such as challenging teachers or struggles to understand math concepts. Doing so could signal to students that their teacher is receptive to negative sentiments about mathematics, and will help students persist in mathematics regardless (Cribbs et al., 2016).

We explored sentiment analysis on students' math identities as a proof-of-concept methodology with a small sample intentionally. Our goal was to unpack the nuances of misclassified sentiments and make conjectures about how human mathematics researchers weigh linguistic features and assign labels in comparison with machines. In future work, we aim to explore this methodology at scale. We also wish to investigate how, if at all, knowing students' math sentiments at the beginning of the course impacts instructors' pedagogical decisions.

In the meantime, we recommend that instructors and researchers wishing to experiment with sentiment analysis and math identity begin their inspections of the data with neurally-labeled sentiments. Throughout this analysis, we learned that "neutral" can mask "mixed" or "nuanced" statements about math identity, which was the case for Student 3. Yet, a balance of "good" and "bad" math experiences does not imply neutrality in one's math identity. Humans apply their own weights to past experiences to determine their present relationship and future aspirations when seeing themselves as doers of mathematics. Our students deserve culturally-responsive instructors and researchers that understand the mixed nature of students' sentiment toward math.

Enacting Care in a Community College Math Classroom: A Case Study

Megan Selbach-Allen
Harvard University

Victoria Delaney
San Diego State University

Too often college mathematics classes become a gatekeeper that pushes students off of STEM pathways. This study looks at an example of a community college mathematics instructor who appears to be successful in supporting students to stay on a STEM pathway through creation of a warm, caring classroom environment. Using the lenses of a caring relation and a teacher as a 'warm demander' this case study examines what pedagogical practices he used to create and sustain this environment. We illustrate in the findings how the instructor used his emotional intelligence and skill in relating to students to sustain a caring, warm classroom. He also incorporates metamessages and 'off-topic' talk in his classroom which demonstrate care to students. This case study serves as a beginning point in thinking about the social and emotional work of teaching and we end by proposing a model for caring instruction in community college mathematics classrooms.

Keywords: Community College Math, Care, Pedagogical Practices, Equity

The study of Science, Technology, Engineering, and Mathematics (STEM) disciplines is often seen as an avenue to good jobs and a requirement for many in the modern workforce of the 21st century. Politicians and business leaders regularly lament the lack of qualified students prepared to fill these roles. Unfortunately, STEM fields also continue to be a place where historical inequity around race, gender, and socio-economic status also continues to persist.

At the undergraduate level, mathematics is often the subject that determines whether students begin or continue these majors. Students are required to pass through the calculus sequence before they can access other higher-level classes in their desired major. Studies have shown that many students who drop the subject are not less prepared or capable but cite a negative experience in their early classes (Rasmussen & Ellis, 2013). Work over the last few decades has examined how to teach these disciplines better and has shown the effectiveness of active and inquiry-based learning for improving results for all students (Freeman et al., 2014; Hassi & Laursen, 2015; Laursen et al., 2014). However, a few studies have shown that discrimination can still exist in active learning classrooms and impact the experiences of students from marginalized groups (Ernest et al., 2019; Johnson et al., 2020).

In further understanding how to address the issues of inequity, researchers have also pointed to the value of focusing on community college contexts (Sitomer et al., 2012). While community colleges educate a disproportionate share of students from backgrounds underrepresented in STEM fields, they are also understudied in comparison to 4-year university contexts (Mesa et al., 2014). In a 2019 study, Nabb and Murawska found that community college instructors identified care as an important component of their jobs. This case study provides a detailed examination of what care may look like in the context of a successful community college mathematics program. The research question of focus for this report is: What pedagogical practices characterize care in a community college math classroom?

Theoretical Framework

In defining care, we draw on the work of Nel Noddings and her definition of care as a caring relation (Noddings, 2013). Noddings' definition of care importantly distinguishes the caring

relation from a definition of caring as a virtue simply dependent on the orientation of the individual in the role of 'carer'. The caring relation only exists if the 'carer' offers care and the care is acknowledged or received by the individual to whom it is directed, the 'cared-for' (Noddings, 1999).

This relational definition of caring offers important additional considerations in the enactment of caring. If caring is defined in the relationship built between the teacher and student, the experience of the student and how they respond to their teacher's acts of care is an important factor in determining whether the teacher was in fact 'caring.' This need for a relation means that there may sometimes be structural factors at play that could prevent a recipient from receiving the care intended, such as in a large class where an instructor is not able to build relationships with all students. Beyond structural factors, the instructor's cultural knowledge or skills, such as emotional intelligence, might limit or enhance an instructor's ability to enact care that is felt by their students. The enactment of this type of relationship with students relies on a skill set that many community college and undergraduate instructors have never been trained in. Caring in this definition requires judgment, awareness, and nuance to enact in ways equitable toward all students (Noddings, 1999).

Noddings' work on care is limited in that it does not provide specific guidance on what care looks like in educational arrangements (Roberts, 2009). Multiple scholars have also noted a lack of engagement with the impact of race and racism in the contexts of care, such as educational settings, that Noddings addressed in her work (Patterson et al., 2008; Thompson, 1998). We believe it is important to address these limitations, and so make use of Noddings' framework in connection with the idea of a 'warm demander' bringing in race conscious, critical perspectives.

Kleinfeld (1975) identified two characteristics that appeared to separate effective from ineffective teachers. The first characteristic, which she deemed the most important, was teachers' ability to "create a climate of emotional warmth that dissipates students' fears in the classroom and fulfills their expectations of highly personalized relationships" (p. 318). The second was, "teacher's ability to resolve his own ambivalent feelings about the legitimacy of his educational goals and express his concern for the village students, not by passive sympathy, but by demanding a high quality of academic work" (p. 318). This framework is important to pair with Noddings caring relation because it points to the importance of maintaining high academic standards while also creating warm environments. It adds more context to the caring relation that must be felt. Care in this context is not just creating "a climate of emotional warmth" but also communicating to students that you believe they are capable of academic success and pushing them to work hard toward achieving at high levels.

This framework also helps us bridge the gap between a caring relation and pedagogical practices. To define practices we look to social practice theory and the work of Reckwitz (2002), who defined a 'practice' in the social theory sense as a "routinized type of behaviour which consists of several elements, interconnected to one [an]other" (p. 249). This definition casts practices in the realm of actions that may be driven by mental processes, beliefs and learning but is enacted day to day through the actions taken. In the case of teaching these practices are a unit of study or focus, but whose existence depends on the interplay of beliefs, learning, emotions, social context and background of the individual engaging in the 'practice.' In the case of teaching, pedagogical 'practices' can take the form of instructional lectures or actions to facilitate student engagement in the classroom. Taking a more expansive view on the work of teaching to include motivating and engaging students in the discipline of study, pedagogical practices also include efforts to build relationships with students and help them develop a sense

of belonging and identity in the field. This study with extensive time in the classroom and interviews with the instructor and students allows for detailed examination of the pedagogical practices engaged in by the instructor.

Study Context and Methods

Study Participants

Students. The classroom population reflects the demographics of the school and the broader California Bay Area where it is located. In Fall of 2021, around 40% of the students identified as Asian and 20% as Latinx, the two largest demographic groups. While the racial and ethnic makeup of the class was similar to the school demographics, it was considerably more male, over 70%, and younger, 85% of students were 19 years or younger than the school as a whole. These differences likely reflect that the focus of the program was students interested in engineering or computer science, which are fields that skew male and included the introductory math sequence, so the majority of the students were in their first year of community college and came directly from high school.

Instructor. The instructor who is the focus of study, Professor O[1], is an experienced faculty member at the college with over 20 years of experience teaching mathematics at the school. Furthermore, he has been an instructor for the program of study for all 9 years of its existence. While Professor O identifies himself demographically as a white male, an important aspect of his orientation to teaching is how he identifies with his students. Professor O is a first-generation college student and describes himself as a bad student in high school. He is also a community college graduate himself. This shared experience provides him with important insight into his students' struggles and likely supports his ability to be highly empathetic towards them.

STEM-Core Model

The class is a part of a program initially started with funding from an NSF grant, STEM-Core. The STEM-Core model creates a cohort of students, who follow an accelerated math course sequence and stay together for one year. This study was conducted in the 9th year of the program at this school and is no longer supported with NSF funding.

Site implementation

This particular program was chosen for study because students are broadly succeeding at high rates. Students are prepared to pursue a STEM major and ultimately go on to complete 4-year degrees in STEM and find jobs in the field. Institutional data shows that students have a higher pass rate in Pre-Calculus 1 and 2 and Calculus 1 than the college as a whole. Historically, 64% of students who started the program in Algebra II reached Calculus 1 within one year, compared to the statewide average of 16% of students who start in algebra reaching calculus (Mejia et al., 2016). Furthermore, when students do struggle and drop or fail classes, they re-enroll in the classes at higher rates demonstrating resilience.

Analytic Methods

The study makes use of a case study design with the instructor and a single cohort of students serving as the case under study. This design was chosen because it allows for a fine-grained and

[1] All names are pseudonyms

detailed description of the environment. The first author spent a full year in the class, attending classes and documenting observations through fieldnotes. During the spring semester videos were also recorded. In addition to class observations, interviews were conducted with students and the instructor to understand their perspectives and experiences. The complexity of the environment and constructs of interest lend to the need to consider depth over breadth in this study and makes it particularly well-suited for an ethnographic case study methodology (Merriam & Tisdell, 2015). This need for deep understanding of a complex environment leads naturally to adopting a case study design for this work (Starman, 2013).

The fieldnotes and student interviews were coded with a priori codes based upon the 'warm demander' (Kleinfeld, 1975) and caring relation frameworks and observations of the classroom (Saldaña, 2021). Adjustments were made to each codebook to allow for analysis of the interviews to focus on students' description of the instructors' actions and their experiences in the class while the codebook for the fieldnotes was focused on observable behaviors in the classroom. After initial coding, the excerpts were pulled out and a thematic analysis conducted to develop descriptive categories for the codes (Clarke & Braun, 2017).

Results

Coding of field notes and interviews showed the practices breaking down into three broad categories: active learning, warm language and meta messages, and off-topic talk. The combination of both data sources allowed for important triangulation of observable actions in the classroom, conversations with the instructor to understand his intent, and hearing from students to understand their experiences.

Active learning

The instructor extensively made use of pedagogical practices associated with active learning. The most common code that appeared in the data was 'students relating to each other'. This code was driven by the frequent turn-and-talks initiated by the instructor. A turn-and-talk occurred when Professor O paused his lesson and told the students to check-in with one another on what he just shared or to ask them to attempt the next step in the problem. The frequency of these turn-and-talks led to a very active classroom, with around 8-15 turn-and-talks per a 110-minute class period. Professor O intentionally initiated interaction among students, occasionally telling students to stop working if he felt the class had gotten too focused on working individually and say, "Everyone needs to stop writing and talk to the person next to them." (FN 27 Oct)

An outcome of his push for regular student to student engagement, is that students appeared to start engaging with one another apart from the turn-and-talks. In interviews, students shared how they had built relationships with another in the class because they were pushed to interact. One student contrasted this experience with a previous instructor who did not push students to talk in these moments. He appreciated how Professor O pushed students to talk when necessary. Since talking with one another was normal, students started to talk together before class, or during breaks. Another strategy Professor O employed was structuring his long class with "working breaks" and "group quizzes" to encourage students to engage in math problems together. In interviews students used words like "community" in describing their experience in the class.

Students using one another as a source of knowledge would also often overlap with Professor O's use of turn-and-talk. He would make requests like, "I need everyone to pick up their calculator to attempt to do this calculation in your calculator and when you get the answer share

it with the person sitting next to you." (FN 13 Oct) This push to check with each other helped demonstrate to students that in working together they could build confidence in their answers. In addition to having students check in with one another, Professor O would also regularly solicit ideas from the class and make use of their ideas. He very intentionally encouraged students to challenge each other to make sure they understood what the other person was thinking and use necessary tools when it made sense. This environment of encouraging struggle aligned well with the second most common code from the field notes: a supportive learning environment.

Warm Language and Meta Messages

Professor O also appeared to use language intentionally for initiating the turn-and-talks. He regularly used language and phrasing that is not common in college math classrooms. Phrases like, "check in with the person next to you and say, 'I care about you and I want to make sure you are doing okay' say it" (FN 27 Sept) as the initiation for a turn-and-talk when he wanted students to check in with one another about whether they were understanding the next step in solving a problem. Another prompt he would use frames the need for each student to check-in with their neighbor to ensure the other person was understanding, "check with the person next to you to make sure they understand." (FN 22 Sept) Sometimes this statement was followed up with the rejoinder, "no one gets left behind". His phrasing for turn-and-talks brought the language of care into the classroom and emphasized that students are not only responsible for their own learning, but they are part of a community where everyone is learning. When interviewed 10 of 13 students made comments that explicitly addressed their comfort in the classroom.

He also often made comments and initiated discussions to push students to engage in productive learning behaviors. In talking about watching the videos before class he said, "If you come to class confused you will leave class not confused. If you come to class not confused because you have not watched any of the videos or done any work, you will leave confused." (FN 11 Oct) With this statement he is simultaneously pushing students to watch the classroom videos ahead of time and encouraging them that if they are confused after watching the videos then that is normal and where he wants them to be. He is also reinforcing to them that they have some agency about how confused they are, based on their behavior/choices to watch the videos.

Normalizing struggle also showed up in a number of small ways through comments from Professor O and norms he set in the class. This came up in the initiation of turn-and-talks with "explain to the person next to you what I just said, 'I know you understand but they were confused.'" Everyone in the class is simultaneously being identified as the person that understands but also the neighbor that is confused. He would sometimes take a moment in class to acknowledge, "that it might be overwhelming right now but by the time you get to the exam it will be okay." (FN 27 Oct). This acknowledgement did not mean that he was going to cover less material or slow the class substantially because that would not be possible with the requirements of material to be covered, but it made space for emotion and feeling and served as an acknowledgment of what many students might be feeling. Messages like this one about studying and learning were common supplements to the mathematics content in this classroom.

Students also commented about how Professor O handled mistakes in ways that helped them see their mistakes as part of the learning process. One student Zara commented, "every time I've made a mistake, it was more just like, oh no, it's fine. This is the actual answer and this is how we're supposed to do it. Just remember that for next time. And I was like, okay. Not that big of a deal." Messages like this were interspersed with regular, micro growth mindset messages he

gave by encouraging students that their brain was growing when they made a mistake in class, and struggle is a normal part of the learning process.

Off-topic Talk

Professor O regularly took the time to address relevant issues for the students that were not directly related to mathematics, which we coded as "off-topic talk." These topics could range from broad educational and career goals and skills to mental health and university resources. He would often connect these topics to aspects of the class. On several occasions he mentioned vaccine clinics for both COVID and flu vaccines that were being hosted by the school. (FN Oct 11) When talking about the flu vaccine he commented to students about how getting the flu at the wrong time can really mess up your academic plan and encouraged students to get vaccinated.

In addition to health-related issues, he would occasionally address topics that he felt were important even if they were completely disconnected from mathematics such as Banned Book Week and the connections between book bans and racial issues in the U.S. Professor O did not generally address race explicitly in class, although he would regularly wear t-shirts with messages around racial, gender, LGBTQ and immigration equity issues. However, in this case, Professor O made use of the moment to name and address his racial identity and share support for work that would allow him to better understand other people's experiences. In interviews several students share how these comments demonstrated to them Professor O's awareness of structural inequities and made them more comfortable approaching him when they had an issue.

Professor O regularly connected what students were learning to their future careers and educational trajectories. He would often share about the importance of internships and creating resumes to apply to those internships because, "you aren't going to put a math topic on your resume, so that is why you need to make sure that you are doing clubs and activities." (FN Sept 6) He pushed students to attend information sessions about various internships they were eligible for and supported them through the application process. Professor O also used these opportunities to help offer perspective to students on what they were working towards, "no one is here because the one thing missing in your life is trig identities, but you are all here to get a job and internships will help with that." (FN Oct 27)

Professor O also took time out of class to invite two speakers from the counselor's office and host a 'field trip' to the school's Transfer Day so the students could engage with schools they would be interested in attending in the future. All of these conversations communicated to students that Professor O had a bigger picture in mind when he was teaching them math. He wanted them to learn the content in his class but ultimately to use it as a stepping stone for careers in their desired fields.

Interviews with students confirmed that they received his inclusion of these outside as helpful, caring actions. In interviews (9 of 13) shared how Professor O cared about them and would support them in various ways, beyond just learning mathematics. Several students explicitly connected his discussion of non-math or 'off-topic' content as an indicator of his caring about them.

Discussion and Limitations

These findings illustrate that while one area of practice related directly to content, active learning, the other two involved engagement and work not directly related to the curricular content of the course. From this case study, we propose a framework of caring instruction in a

community college mathematics classroom. The major components of the framework are: *relationships*, *holistic support,* and *active learning*. *Active learning* has been discussed extensively in math education literature and shown to be effective in increasing student success and learning. (Deslauriers et al., 2019; Freeman et al., 2014). However, some studies have also shown that it alone may not be able to address all the challenges and equity gaps that exist in the mathematics classroom (Johnson et al., 2020). In this case, *active learning* appears essential to enabling the other portions of the framework because without space to engage in mathematical conversations and interact with other students and the instructor, the other pieces are not possible. However, *active learning* alone does not equate to caring instruction.

The data from this study reveal that *relationships* are a fundamental driver of success in this math classroom. Students felt like they had access to a warm relationship with their instructor who knew their name and cared about them as people. Professor O worked to cultivate opportunities and encouraged students to develop *relationships* with one another. The richness of these *relationships* and normalization of mistakes and struggle in the classroom appears to have improved students' sense of their ability to belong in and succeed in mathematics as shown by their comments in interviews.

Finally, the *relationships* are also intertwined with the *holistic support* offered in this classroom through the inclusion of 'off-topic' material such as health information, school transfer fairs and various speakers sharing about resources on campus. These discussions helped show students that their instructor cared about them as people beyond just being math students in his class, which helped build trust and enable *relationships*. This broader, *holistic support* also helped to even the playing field by making explicit aspects of the education experience that are often part of the hidden curriculum and not revealed to first generation and low-income students.

While not addressed in this paper, it is important to note that in the background of these three pieces: *relationships*, *holistic support,* and *active learning*, are the challenges of implementing these ideas with students, which requires critical consciousness and emotional intelligence. It is important for instructors to be aware of systemic inequity and the realities of position, power, and privilege when they are working with diverse groups of students (Rubel, 2017). They need to understand that certain groups of students may be less comfortable in their classroom or may have a different experience because of their identity or social positioning. At the same time, instructors need to be careful not only to rely on broad generalization or stereotypes but instead know how to engage with the wide variety of students they teach and meet each student where they are. Such work requires a high degree of emotional intelligence.

This case study involves only a single instructor and class, which means it can only serve as a starting point. An important next step for this work is the observation and study of other successful instructors to see if and how these pieces show up in those classrooms as well. An active classroom appears to be a necessary foundation for enacting care, but it alone does not appear to be sufficient. We need to build capacity for the social and emotional work of teaching in college math classrooms. Instructors need support in learning how to enact care in their classrooms for all their students. Community college math instructors know care is an important part of good teaching (Nabb & Murawska, 2019) but not all know how to enact care. This work shows the need to support teachers to move beyond an orientation of care, but to caring relations that are received by students. We as a community of educators and researchers need to think about how we can create learning environments that are truly welcoming and supportive for all students.

Floating in a Most Peculiar Way: The Role of Feedback in a Playful Calculus Task

Robert Ely

Dru Horne
University of Georgia

Sohei Yasuda
University of Georgia

Anna Bloodworth
University of Georgia

We created and piloted a playful calculus-based activity called Major Tom with preservice secondary mathematics teachers over two classroom sessions. Players create sequences of jetpack boosts (accelerations), controlling an astronaut's movements to arrive at a pick-up location at a particular time. The learning goal was for students to draw upon and enhance their knowledge of integration to determine velocities and displacements. We found that the imprecision of the system's feedback inhibited the students' productive use of their formal calculus knowledge, while on the other hand an instructor-led structured discussion about velocity graphs supported it. Neither of these features of the playful math environment much affected the students' playfulness, but a third feature, the opportunity to create and solve your own challenges, fostered significantly increased play and laughter. This contributes to our broader goal of how to elicit play with undergraduates while simultaneously engaging and building their formal mathematics knowledge.

Keywords: velocity, integral, calculus, play, acceleration

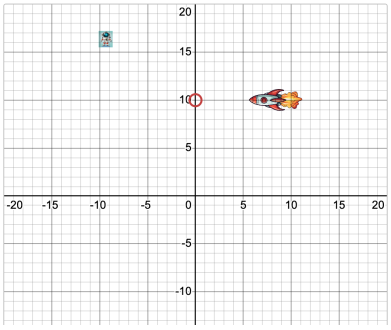
Mathematical play is beneficial for students. It can improve enjoyment and engagement (Plass et al., 2013), increase equitable access to mathematics (Widman et al., 2019), and help students develop creativity and a disposition for innovation (Barab et al., 2010; Gresalfi et al., 2018). It has also been shown to support mathematical learning and reasoning at the elementary and middle-school levels (e.g., Edo & Deulofeu, 2006; Jasien & Horn, 2018; Levine et al., 2012). However, there are still significant gaps in our knowledge of how play can support learning, particularly at the undergraduate level. The aim of our work is to support undergraduate students' mathematical play while at the same time meaningfully leveraging their formal mathematics knowledge. We consider this kind of "productive" playful engagement to be an interaction between the task(s), student(s), and the teacher's implementation. We use the term *playful math* to describe the elements of classroom activities and environments that facilitate mathematical play. To investigate this broader question, we studied students engaging in playful math activities in an undergraduate class. Our research questions for this study are: (1) What features of the playful math environment supported or constrained students' productive use of their formal mathematics knowledge? (2) What features of the playful math environment supported or constrained students' mathematical play?

Background and Framing

Our two-part definition of mathematical play is grounded in the traits of a person's behavior and experience that are considered foundational in the literature. Firstly, mathematical play entails *agency in exploration* and *self-selection of goals or subgoals*. A person experiences freedom and control over their activity, including how they explore and the goals they select (Holton et al., 2001; Gresalfi et al., 2018). Exploration is essential (Mason, 2019) and often accompanied by unexpected outcomes (Davis, 1996). Goals are inherent to play (Huizinga,

1955) and can emerge and change as play proceeds (Jasien & Horn, 2022, Radke & Ma, 2018). Secondly, mathematical play entails *immersion* and *enjoyment*. People who play are highly engaged (Gresalfi et al., 2018) and may exhibit a state of flow (Csíkszentmihályi, 1990). They find pleasure in their activity and experience it as being worthwhile for its own sake (Su, 2017).

This definition highlights a tension that arises when mathematical play is used to support learning in classroom environments. Students with high agency might pursue goals that have little to do with the teacher's learning goals. Pyle and Danniels (2017) view play-based learning to be situated in a continuum, where the activity ranges from student-directed to teacher-directed. In more teacher-directed play, the broad goals can be prescribed if students have significant leeway in the subgoals and actions they can take to pursue them. This type of continuum provides a way to situate playful math activities at the undergraduate level also, where a teacher may direct students to engage with formal mathematics while still playing.



We have identified six design principles for playful math activities (see Ellis, et al., in press): (1) foster understanding of specific mathematical ideas; (2) enable free exploration within constraints; (3) engender anticipation within the task; (4) provide a method for intrinsic feedback; (5) offer meaningful challenge while still being feasible; and (6) allow the student to act as both designer and player. For this study, we considered what the students did with the intrinsic feedback they received from the task environment. A student experiences intrinsic feedback in direct correspondence to their actions, rather than as mediated by a teacher or some other extrinsic source. Students can increasingly come to anticipate the results of their actions in the environment when they are able to use their mathematical understanding to simulate and predict the experience first (Tzur, 2007). The feedback students receive can therefore inform their mental models and anticipated actions and outcomes, rather than just allowing for reactive adjustments to their actions. For example, Williams-Pierce et al. (2024) studied a case in which students programmed a robot to navigate a path and received perceptual feedback when the robot missed the mark. Because the students had developed and used a quantitative model while doing the programming, they anticipated the path and were able to interpret the feedback in light of their model, productively engaging with their prior mathematics knowledge.

Methods

We collected data with 16 secondary pre-service teachers (PSTs) at a public university in the southeast United States. The PSTs had taken at least two calculus courses and were enrolled in an algebraic reasoning content course. They formed 8 pairs, and each pair engaged in two playful activities on an iPad over four sessions. We collected audio and screen recordings of each pair's work as well as any written work not captured by the iPad. This report is based on the engagement of one PST pair, Audrey and Penny (pseudonyms), in one of these activities called *Major Tom*. *Major Tom* (Figure 1) consists of 6 tasks whose common objective is to move the astronaut ten miles "north" in space, from (0, 0) to (0, 10), in 10 minutes by adjusting "boosts" (accelerations). The PSTs entered magnitudes, angles, and durations of the boosts, hit Play, and the system showed the astronaut's motion. The system also provided quantitative feedback (time and fuel usage during the first session, position also during the second session). The activity's introduction read: "You are floating in space, at the origin. In 10 minutes, the spaceship will swing by the pick-up point ten miles 'north' of you. Can you be there at the right time? Your jetpack can give you a boost if you open its valve, in any direction you want. At each moment, the valve setting determines the acceleration you experience (in mi/min^2) at that moment. Change the table to make whatever sequence of valve settings you want."

On successive screens are follow-up tasks. Task 2 requires Tom to be stationary at the pick-

up point. Task 3 introduces a fuel gauge (a valve setting of n for m seconds uses nm kg of fuel), and requires the use of specific amounts of fuel. In Task 4, an asteroid blocks the way, so Tom cannot stay on the y-axis. In Task 5, boosts can now include variables. In Task 6 you design your own challenges, which you solve in Task 7. *Major Tom* satisfies our design principles, allowing PSTs to select and explore their own goals, use feedback to reflect on their solution strategies, and design challenges. To save space we will use a shortened notation for inputs. For instance, the sequence of two boosts in Figure 1 would be written as {1, 90°, 0, 2} and {2, 180°, 4, 5}.

Minutes: 9.192
Position: (-9.384,16.384)

Play

Valve setting	Angle	Time Begin	Time End
1	90	0	2
2	180	4	5
0	0	0	0
0	0	0	0

Figure 1. Major Tom Activity.

We intended the *Major Tom* activity to promote an understanding of the relationship between position, velocity, and acceleration in terms of derivatives and integrals. For instance, suppose a PST tried out one boost {1, 90°, 0, 2} followed by Tom coasting the rest of the way from $t = 2$ to 10. One can mathematically model Tom's velocity, whose derivative is the acceleration $a(t) = \begin{cases} 1, & 0 \le t \le 2 \\ 0, & 2 < t \le 10 \end{cases}$, to get $v(t) = \begin{cases} t, & 0 \le t \le 2 \\ 2, & 2 \le t \le 10 \end{cases}$. One could then find the total displacement by integration, either by reasoning with areas under the velocity graph or symbolically as $\int_0^{10} v(t)dt = \frac{1}{2}t^2|_0^2 + 16 = 18$ miles. These models could support PSTs to get exact answers and examine more phenomena such as minimizing fuel usage or going in non-vertical directions. The PSTs engaged with *Major Tom* in two 75-minute sessions.

This is part of a larger study, so we adopted an existing coding scheme to describe the characteristics of mathematical play (Ellis et al., in press) as well as developed emergent codes to investigate the PSTs' cognitive engagement with a particular emphasis on their use of feedback. Part of the existing scheme relevant to this report concerns the characteristics of playful engagement, in which we distinguished moment phenomena from task phenomena. Moment phenomena are discrete instances of experience or behavior, and include *competitive fun*, *feeling proud*, *enjoyment*, *taking on authority*, and *laugh* (as evidence of enjoyment). Task phenomena reflect an outcome of the PSTs' engagement with a task as a whole, and include *investment*, *immersion*, *agency* in goal exploration or accomplishment, and *perseverance*. We coded the transcripts independently, discussing and resolving any disagreements to refine and establish a common understanding of the codes during weekly meetings. Once we developed a stable coding system, Authors 2 and 4 then re-coded the data corpus with the final system.

Results

Features influencing PST's productive use of their formal mathematics knowledge (RQ 1)

In the first session, the PSTs worked in pairs on Tasks 1-7. They did not always clearly distinguish between acceleration and velocity, and many had difficulties drawing on calculus concepts to try to produce exact solutions. At the beginning of the second session, the first author

therefore led a structured discussion on constructing a velocity graph from a sequence of unidirectional accelerations (i.e., parallel to the y-axis) and discussed what the graph informs about displacement. The PSTs then revisited the tasks from the first session and solved new challenges they created. In examining what supported and constrained the PSTs' use of formal mathematics, we found two features. One is the imprecision of the program's feedback, which acted as a hindrance; the other is the structured discussion, which acted as a support.

A hindrance: Imprecise feedback from the system. The program's imprecise feedback hindered Audrey and Penny's productive use of their formal knowledge. We initially programmed *Major Tom* with a relaxed success condition: the spaceship would stop if Tom was less than 1 mile from the pick-up point (0, 10) at time $t = 10$ minutes, and would otherwise cruise past without stopping. Furthermore, the screen did not show a position readout for Tom. For the second session we added the position readout and shrunk the window of success to 0.1 mile. In this section we illustrate how this imprecise feedback in the first session diverted Audrey and Penny from drawing on the derivative/integral relationships between acceleration, velocity, and displacement to determine exact displacements for Tom.

On Task 1, Audrey and Penny started with the values seeded in the table and changed them one at a time for five tries, to understand the system. They then tried just one boost: {1, 90°, 0, 2}. When this took Tom too far, they tried {1, 90°, 0, 1}. With this, the spaceship stopped, with Tom at (0, 9.5) at time 10 (although the exact position was hard to discern). They considered this a success and moved on to Task 2, at no point using symbolic or numeric calculation. On Task 2, Audrey and Penny kept the same first line in their table, but added a second boost: {1, 90°, 0, 1}, {-1, 0°, 9, 10}. Tom veered at the end, so they corrected the angle from 0° to 90° and tried again. This time Tom stopped at (0, 9), short of the pick-up point. They kept making small adjustments, six different times, and eventually solved the problem with {1, 90°, 0, 1}, {-2, 90°, 9.5, 10}. The alert reader may calculate that this solution puts Tom at (0, 9.25) at $t = 10$, which is short of (0, 10), yet the program considered this close enough and the spaceship stopped.

Audrey and Penny continued to almost exclusively rely on this repeated guess-check-adjust method for the rest of the first session. They experienced success each time after multiple tries, never attaining an exact answer of (0, 10) at time 10. On Task 3 they used exactly 3kg of fuel with {1, 90°, 0, 1.5}, {-1, 90°, 1.5, 2}, {-2, 90°, 9.5, 10}, ending with Tom at (0, 9.75). On Task 4, with an asteroid in the way at (0, 5), they adapted their previous approaches to split the journey into two parts, and after many adjustments ended up with an approximation that got the spaceship to stop: {2, 45°, 0, 1}, {-2, 45°, 4, 5}, {2, 140°, 5, 6}, {-2, 140°, 8.8, 10}. They did not appeal to a mathematical model, never calculating anything with $\sqrt{2}$ or using a symmetric 135° angle to try for an exact solution. On Task 5, they were asked to use some variable non-constant valve settings (and still avoiding the asteroid at (0, 5)). The aim was to push the PSTs to reason with integrals to calculate displacements when the accelerations were non-constant (and thus required calculus). Penny did briefly start by writing some calculus symbolism, "ds^2/d^2t," but she quickly abandoned this approach and instead decided to adapt their solution from the previous task, inputting {4x, 45°, 0, 1}, {-4(x-4), 45°, 4, 5}, {4(x-5), 140°, 5, 6}, {-4(x-9), 140°, 9, 10}. She explained to Audrey, "We want our average acceleration for one minute to be 1, which means it should be 2x." Thus, an acceleration of 4x over the time interval $x = 0$ to 1 would average to 2, so she assumed that replacing every 2 with 4x would not affect the displacement.

Penny conflated some aspects of velocity with acceleration here. If the *velocity* were 4x, it could be averaged to 2 over this time interval without changing the total displacement, but the same is not true when the *acceleration* is 4x. The displacement s over one minute is 2/3 when

$\frac{d^2s}{dx^2} = 4x$ and 1 when $\frac{d^2s}{dx^2} = 2$. This difference, accumulated over their four small time intervals, put Tom a bit beyond (0, 10) when the spaceship came by. But because Major Tom was within 1 mile of the target, it stopped anyway. Audrey and Penny made further adjustments to get Tom visibly closer to (0, 10), but, like before, they moved to the next task without getting an exact answer. Getting an exact answer was unimportant to them, as it was not necessary to make the spaceship stop. This laxity of feedback thus allowed Audrey and Penny to avoid confronting a conceptual issue about the relationship between acceleration, velocity, and displacement.

A support: Structured discussion. During the beginning of the second session, the PSTs discussed how the area under the curve (i.e., between the graph and the time axis) represented the total distance traveled. This discussion supported Audrey and Penny's productive use of their formal mathematics knowledge. They proceeded to engage with the activity very differently when they revisited the tasks from the previous session, including the challenges they had invented. They no longer conflated acceleration and velocity. For each task they drew a velocity graph, and they consistently interpreted the accelerations as the slopes of this graph, recognizing acceleration to be the derivative of velocity. They interpreted Tom's total displacement as the definite integral of the graph. An example is in Figure 2, which shows Penny's mathematical model of her solution to Task 2, where Tom must be stationary at (0, 10) at $t = 10$. This allowed them to calculate inputs to yield an exact solution which they could then test with the system, instead of repeatedly guessing, checking, and adjusting as they did in the first session.

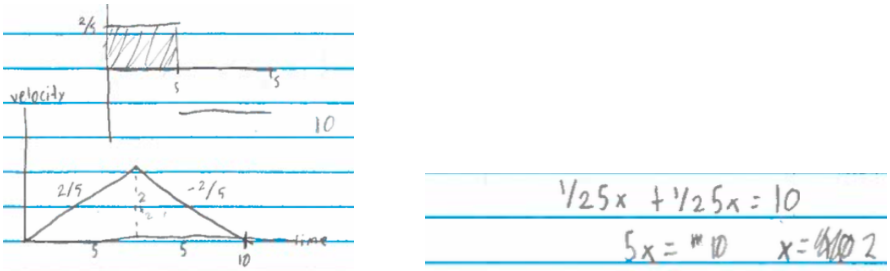


Figure 2. Penny's velocity graph model for solving Task 2, second session: {2/5, 90°, 0, 5}, {-2/5, 90°, 5, 10}.

Velocity graphing also helped the PSTs use their calculus knowledge to create new scenarios. For instance, they invented this challenge: "Major Tom needs to go to (0, 15) to pick up some space litter but still needs to get to the rocket. Figure out how he can do this and be stationary at the pick-up point at least one minute early." They used a velocity graph with negative area (Figure 3) to calculate a solution: {5/3, 90°, 0, 3}, {-5/3, 90°, 3, 6}, {-20/9, 90°, 6, 7.5}, {20/9, 90°, 7.5, 9}. Penny initially calculated a solution that she found to be incorrect when she checked it on *Major Tom.* Seeing Tom miss the mark, she said, "Oh wait, no, no, no, I see what I did. I see what I did. So, I made the area of this [the negative region] ten. It's supposed to be five." Then she said, "This is why I like having this [the program] to check. I wouldn't have realized I did it wrong." Thus, the velocity graph model not only helped them solve the problem, but also helped them interpret and resolve perturbing feedback from the system.

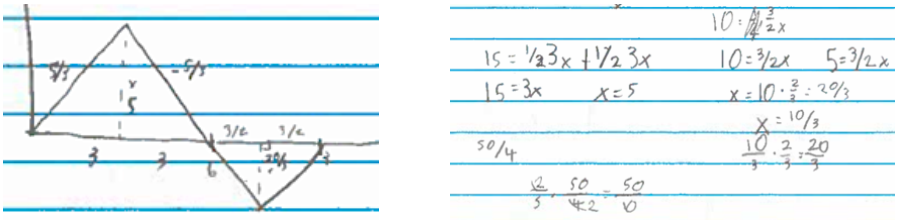

Figure 3. Penny's model for solving their invented challenge, second session.

Features Influencing Mathematical Play (RQ 2)

To investigate the features of the environment that may have influenced mathematical play, we considered the incidence of our moment and task codes. *Competitive fun* occurred when the PSTs demonstrated excitement about their challenges, *feeling proud* occurred when they showed pride in their work, *enjoyment* occurred when they demonstrated enthusiasm (further evidence of this was through the *laugh* code), and we coded *authority* when seeing either PST take on that role. We coded for *investment* when the PSTs showed that they cared about their work or the task's outcome. Evidence for *immersion* included the PSTs ignoring distractions and lacking awareness of time passing. *Agency* occurred when the PSTs demonstrated autonomy in choosing a strategy or posing their own problem, and we coded for *perseverance* when we found evidence of the PSTs voluntarily persisting through difficulty.

Audrey and Penny did demonstrate evidence of mathematical play. Across both days they engaged in a total of 14 tasks, spending on average eight and a half minutes per task (although there was great variation across the tasks). Considering the moment phenomena, competitive fun occurred 0.8 times per task on average, feeling proud 1.6 times, enjoyment 1.1 times, taking on authority 0.6 times, and laugh occurred 6.2 times. The task phenomena codes we either applied zero or one time per task. Out of the 14 tasks, we found evidence for investment during 8 of the tasks, immersion during 2 tasks, agency during 10 tasks, and perseverance during 5 tasks. In considering whether the imprecise feedback influenced Audrey and Penny's mathematical play, we noted that it was a feature of every task, and thus the presence of mathematical play phenomena suggest that it did not prevent them from playful engagement. However, some aspects of mathematical play were minimal, such as immersion, taking on authority, and experiencing a sense of competitive fun. To examine the potential effect of the structured discussion, we compared the incidence of mathematical play prior to and after the discussion. Audrey and Penny solved 8 tasks prior to the discussion and 6 tasks after. The length of time they spent per task was slightly more prior (9.2 minutes) than after (7.4 minutes). If the structured discussion affected the PSTs' playful engagement, we would expect to see a noticeable difference in the average incidence per task prior to the discussion compared to after. Except for the laugh code, we did not see any meaningful difference in the moment phenomena. Two phenomena decreased slightly (competitive fun and feeling proud), and two increased slightly (enjoyment and authority). Laughter, however, did decrease noticeably, occurring 7.4 times per task on average prior to the structured discussion and only 4.7 times per task on average after. The students made more verbal expressions of enjoyment after the discussion, but they laughed less. Considering the task phenomena, we saw a slight decrease in the incidence of investment and perseverance and a slight increase in the incidence of immersion. Agency, however, doubled, occurring for only half the tasks prior to the structured discussion and for every task after. It may be that Audrey and Penny experienced greater agency having gained an appreciation for the utility of velocity graphing, derivative, and integral to tackle the challenges.

We then returned to the data to see whether there were any features of the task / instructional environment that *did* influence the PSTs' playful engagement. We found one feature, which was the creation and solution of their own challenges. Audrey and Penny solved nine regular tasks (in which they solved a problem given to them), two "make a challenge" tasks, and three "solve your own challenge" tasks. Figure 4 shows the average number of moment and task phenomena per task for the regular tasks compared to the make-a-challenge and solve-your-challenge tasks. One caveat is that the task time differed significantly, which would affect the incidence of

moment codes (but not task codes). Audrey and Penny spent longer on average on the regular tasks compared to the make a challenge tasks (5.9 minutes versus 3.3 minutes), and they spent a whopping 19.4 minutes on average when solving their own challenges. Thus, there was more time to observe and code moment phenomena during the solve your challenge tasks. This accounts for the large discrepancy of laugh codes, for instance. However, it is interesting to observe that the PSTs laughed 7.5 times per task when making a challenge compared to 2.3 times per regular task, despite make-a-challenge tasks being shorter. Moreover, when we consider task phenomena, which are not swayed by task length, we still saw greater levels of investment, immersion, and perseverance when solving their own challenges. It appears that having the agency to design and solve problems of their choice was meaningful for Audrey and Penny, and it enabled them to take ownership in their work and invest in the outcome of their activity.

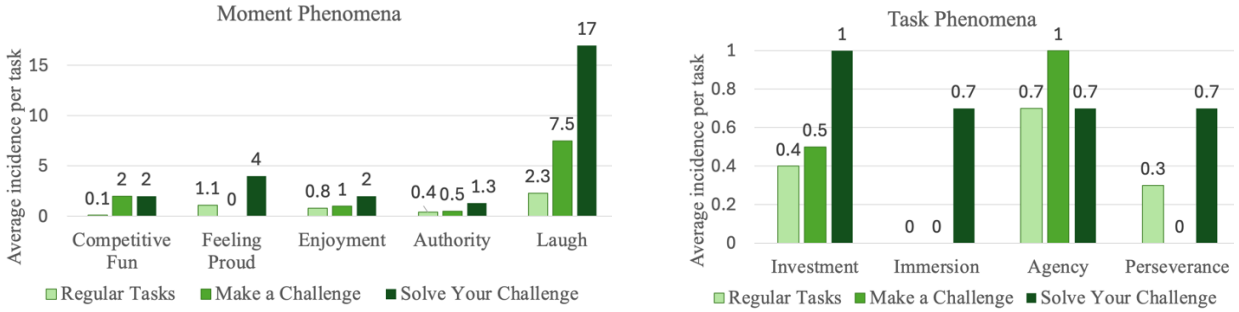

Figure 4. Comparison of mathematical play phenomena across task types.

Discussion

Our findings with Audrey and Penny playing with the *Major Tom* activity provide detail that can augment our design principles for playful math tasks. One of those principles is to provide a method for intrinsic feedback. This case indicates that it is worth considering whether this feedback is also precise and quantitative enough to be reasonably guess-and-check-proof. This can help to necessitate (or at least to not allow the students to easily avoid) the engagement of formal math knowledge. The feedback can then bear on their mental models, not just on their immediate actions. The design factor of allowing students to act as both designer and player was certainly reinforced for these students, for whom inventing and solving their own challenges was propitious for play. Our findings also reinforce the design factor of fostering understanding of specific mathematical ideas. In particular, it illustrates that there need not be a trade-off between play and engagement with formal mathematics; the teacher-directed discussion supported the latter without diminishing the former or dampening student agency.

As we reported on just one pair of students, we do not wish to make any general claims from them, but rather to note that they reveal how various features of a playful math environment can function. Since other students may be hindered and helped by different factors, based on their dispositions and knowledge, we aim to continue studying this question in the context of other playful activities in other undergraduate mathematics classrooms.

Calculus I Students' Logical Reasoning About the Definition of Continuity of Function

Orly Buchbinder
University of New Hampshire

Meaghan Allen
University of New Hampshire

We examine undergraduate calculus students' reasoning about the continuity of a function at a point. The study was conducted in the context of an NSF-funded project that supported the redesign of Calculus I recitations at a large public university. One aspect of the reform effort involved introducing conceptually rich, collaborative activities into Calculus recitations. One such activity focused on the concept of continuity at a point, with one particular task probing students' understanding of the definition of continuity at a point using true-false statements. Data from 84 student in-class worksheets were analyzed with a focus on the type of reasoning students used to respond to these questions. The results reveal a variety of graphical, logical, example-based, and rules-based strategies.

Keywords: Continuity at a point, Limits, Calculus learning, Logical reasoning

The concepts of limits and continuity are fundamental to calculus, yet they present many challenges for students to understand practically and conceptually (e.g., Amatangelo, 2013; Bezuidenhout, 2001; Denbel, 2014; Williams, 1991). Some researchers locate these challenges in the procedures-oriented emphases that are prevalent in many calculus textbooks (Bezuidenhout, 2001), while others suggest that students' challenges may reflect the historical, mathematical, and psychological complexity inherent in these concepts (Juter, 2006; Tall & Katz, 2014). Consequently, many studies focused on revealing various types of students' conceptions and misconceptions about limits and continuity. Our study seeks to add to this literature. In particular, we examine how first-year Calculus students reason about the definition of continuity at a point as they learn about this concept in an authentic classroom setting.

The study was conducted in the context of an NSF-funded project aimed at improving the teaching of Calculus. The enacted changes included using more conceptually oriented tasks, which students solved by working in small groups during the recitations. This context constitutes an authentic learning setting where students, after attending a lecture on continuity, work together to solidify their understanding of this concept. Learning construction is expected to be characterized by students expressing incorrect or incomplete ideas, drawing on prior knowledge and naïve conceptions that may or may not apply to the mathematical situation at hand. Within this learning situation, we explore the research question: *How do students reason about the definition of continuity at a point, and what types of justifications do they use to make sense of this definition*?

Literature Review and Theoretical Background

Definition of Continuity at a Point

The formal definition of continuity at a point states that a function f is continuous at a point c, in its domain, if for every $\varepsilon > 0$ there exist a $\delta > 0$ such that if $|x - c| < \delta$, then $|f(x) - f(c)| < \varepsilon$. This definition is rarely introduced to first-year Calculus students. Instead, a more intuitive definition is commonly used: a function f is continuous at a point c if $\lim_{x \to c} f(x) = f(c)$. While this definition relies on notation and concepts that are more familiar to students, it has some non-obvious challenges. First, it is often written as a conditional rather than

a bi-conditional statement, which may affect how students interpret and apply the definition in practice. Second, $\lim_{x\to c} f(x) = f(c)$ implies that a function is defined at a point c, and the limit $\lim_{x\to c} f(x)$ exists. Thus, some textbooks, introduce a *criterion* for determining if a function is continuous at a point c, comprised of three rules: (1) $f(c)$ is defined, (2) $\lim_{x\to c} f(x)$ exists, and (3) $\lim_{x\to c} f(x) = f(c)$. This three-rule structure streamlines the procedure for determining if a given function is continuous at a point, but complicates the logical structure of the definition. Let V (value), L (limit), and E (equal) represent propositions corresponding to the three rules above, and C (continuity) the conclusion. Then the definition of continuity at a point has a logical form of $(V \wedge L \wedge E) \Leftrightarrow C$. The criterion for continuity at a point is the direction $(V \wedge L \wedge E) \Rightarrow C$, while the contrapositive $(\neg C \Rightarrow (\neg V) \vee (\neg L) \vee (\neg E))$ represents the property of a function being not continuous at a point. While first-year Calculus students are not expected to unpack this complex logical structure, they may be expected to use it flexibly and implicitly when solving problems. For example, students must understand that a function can be discontinuous at a point, even if it is both defined at that point and has a finite limit at that point.

Students' Reasoning about Continuity at a Point

The concepts of limit and continuity are closely related to each other and are the core of differential Calculus. However, they pose persistent difficulties to learners (Núñez, et al., 1999; Oehrtman, 2009; Tall & Vinner, 1981). Studies distinguish between how students evaluate limits and continuity at a point (often utilizing algorithmic, procedural approach) vs. how students interpret them conceptually (Amatangelo, 2013; Bezuidenhout, 2001; Denbel, 2014).

When reasoning about limits and continuity, students rarely rely on the formal definition, even if they are familiar with it, but rather on what Tall and Vinner (1981) call a personal concept image – a collection of all mental images, words, metaphors, and associations a student has developed about a particular mathematical concept. Thus, students may interpret continuity using intuitive, dynamic images of graphs that can be drawn without lifting a pen or interpret limits using the language of movement, e.g., "getting close." Such reasoning is associated with a dynamic conception of limits and continuity and can lead to either correct or incorrect conclusions (Núñez, et al., 1999; Oehrtman, 2009; Przenioslo, 2004). For example, Denbel (2014), found that pre-engineering students often viewed limits as "unreachable" or "approximations", and many mistakenly believed that if the limit exists at a point, then the function is continuous at that point. Similar misconceptions were observed among first-year Calculus students in South Africa (Bezuidenhout, 2001) and Sweden (Juter, 2006).

Amatangelo (2013) identified four common misconceptions related to limits and continuity at a point: (1) a function defined at a point implies continuity at that point, (2) the limit value is equivalent to the function value at a point, (3) the existence of a limit implies continuity, and (4) a limit at a point necessitates discontinuity. That study involved over 800 students and revealed that these misconceptions were prevalent and persistent until students took advanced calculus courses like Multivariate Calculus or Theory of Analysis.

Logical Reasoning

As mentioned above, interpreting the definition of continuity at a point requires (possibly implicit) reasoning with logical operators of conjunction ("and"), disjunctions ("or"), and negation. Most first-year calculus students have not received explicit training in mathematical logic. Thus, their conceptions of logical principles are rooted in everyday language that often

misaligns with conventional mathematics (Epp, 2003). For example, students tend to interpret disjunctions as exclusive rather than inclusive "or" (Dawkins & Cook, 2017) and confuse between the statement and its converse (Durand-Guerrier, 2003). Additionally, negations and reasoning with contrapositives have been shown to be challenging for students (Buchbinder & McCrone, 2019; Brown, 2018; Yopp, 2020). While the logical form of a statement may affect how it is interpreted, some psychologists argue that people mainly reason by analyzing the *semantic* content of the statements: by forming and mentally manipulating mental representations of that content (Johnson-Laird & Byrne, 2002; Oaksford & Chater, 2002). Bringing back the notions of concept image and dynamic reasoning, this may imply that when interpreting the definition of continuity at a point, students form mental images of continuous and discontinuous functions and mentally manipulate them to arrive at certain conclusions.

Method

This study is a part of the larger, NSF-funded project that focused on reforming the teaching and learning of STEM gateway courses, particularly courses in the Calculus sequence, at a large public university in the northeast of the USA. The reform efforts involved re-envisioning of Calculus I recitations by introducing conceptually rich activities, active-learning strategies such as collaborative problem-solving (CBMS, 2016), and introducing learning assistants (LAs) alongside graduate teaching assistants (GTAs) to support student group work. Calculus I is taught in the lecture-recitation format. Large lectures (~120 students) are taught by a faculty member, and coordinated recitation sections of about 20 students each are led by GTAs.

Data Collection

The data for this study were collected in Spring 2023 during one of the first recitations of the semester. The topic of the activity was the continuity of functions. We focused on the task, modified from Straumanis et al. (2013), that probed students' understanding of the definition of continuity at a point by asking students to respond to five true-false statements (Figure 1).

Given five statements. For each statement, decide if it is true or false. For each false statement, provide a counterexample: sketch a graph of a function showing that the statement is false. Then, use another representation: a table, a symbolic equation, and/or words to explain why the graph you sketched disproves the statement.

1. If $\lim_{x\to c} f(x) = f(c)$ then f is continuous at $x = c$.
2. If f is not continuous at $x = c$, then $f(c) \neq \lim_{x\to c} f(x)$.
3. If f is not continuous at $x = c$, then $f(c)$ is undefined.
4. If f is not continuous at $x = c$, then $\lim_{x\to c} f(x)$ does not exist.
5. If f is not continuous at $x = c$, then either $f(c)$ is undefined, or $\lim_{x\to c} f(x)$ does not exist.

Figure 1. Definition of Continuity at a Point Task

Item (1) is a true statement, which is an abbreviated version of a semiformal definition of continuity at a point. The hypothesis $\lim_{x\to c} f(x) = f(c)$ suggests that both the limit at point *c* and the value of the function at point *c* exist and are equal to each other, and therefore, the function is continuous at *c*. Item (2) is the contrapositive of item (1) and is logically equivalent to it, thus it is also true. Items (3-5) contain false statements comprised of the elements of the contrapositive; the conclusion of item (5) is a combination of items (3) and (4).

Data Analysis

To analyze the data—students' written responses to the task—we used open coding (Patton, 2002), informed by the literature described in the theoretical background section. While we noted whether students responded correctly or not to each question, our main focus was on the reasoning they used to justify their responses. The following questions guided our analysis: Did the student's explanation rely on graphs, words, or both? If graphs were used, what kinds of graphs were they? If discontinuities were mentioned (verbally or graphically), what kinds of discontinuities were they? Were their reasoning strategies rule-based, or did they reason about the semantic meaning of the statements (or both)? Were students' justifications logically sound (did they reach valid conclusions based on true premises)? If logical mistakes were made, what was the nature of these mistakes?

Students' work for each item (Figure 1) was tagged and grouped in different ways according to the answers to these questions. Next, we examined trends in data across all five sub-questions. Due to space constraints, in this paper, we report mainly on the phenomena identified in student responses to individual items, followed by a discussion of general outcomes about students' reasoning about the definition of function's continuity at a point. Before describing the results, we emphasize that our goal in this analysis was not to make any assertions about students' conceptions or cognitive processes. Rather, we seek to understand how students reason about the definition of continuity at a point and how they justify their thinking.

Results

Overall, students were relatively successful in responding to all items in Figure 1.

Item 1, which presents a definition of continuity at a point had a 100% success rate. Four out of 84 students initially selected "false" but crossed it and wrote "true," possibly after discussing it with their peers. Most students' justifications (52) mentioned the definition of continuity at a point in some way. Of those, 17 students re-formulated the definition of continuity in their own words (e.g., "the function is continuous because the limit and the function value agree at a point"). 11 students wrote that the statement is true based on the "three rules of continuity" and stated these rules. We interpret these responses as rules-based reasoning. 19 students drew graphs of continuous functions in their responses, but only one student explained how their graph relates to the statement at hand. It seems that in these cases, the graphs served as illustrations, and students may not rely on these graphs to reason about the meaning of the statement, especially if they recognized it as a definition of continuity at a point.

11 students mentioned that given the statement, there cannot be any discontinuity at $x = c$ and therefore, the function was continuous at $x = c$. This is an attempt to apply contrapositive reasoning, where the negation of the conclusion implies the negation of the condition, or "eliminating counterexamples" (Yopp, 2020). While this reasoning could be valid, most students did not specify how they knew that there were no discontinuities, but some mentioned the different types of discontinuities they learned (hole/removable, jump, infinite).

Six students exhibited a "defined = continuous" misconception, previously identified in the literature (e.g., Amatangelo, 2013). For example, one student wrote: "If we are able to plug c into the function $f(x)$ then it must be continuous because it can approach that limit."

One student claimed that statement 1 is true unless the function and the limit are both undefined and therefore "equal DNE." The student seems to treat the acronym *DNE* (does not exist) as a number, which can be equal to another DNE "number," resulting in an equality

$\lim_{x \to c} f(x) = DNE = f(c)$. The student realized that a function cannot be continuous in such a situation but thought it implies that equality is true and should be treated as an exception.

Although this was a singular occurrence, it indicates the ambiguity of notation and a potential misinterpretation of what DNE stands for (undefined for a function and does not exist for a limit) and that the acronyms cannot be treated or equated as numbers.

Item 2 is a contrapositive of item 1. Despite the high success rate (80 students correctly responded "true"), the analysis suggests that it was a much more difficult item to comprehend compared to item 1. Of the students who correctly determined the statement was true, 11 merely restated it as their explanation. 23 students mentioned at least one rule of continuity. Of those, seven claimed that "if a function is discontinuous at a point c, it means it is undefined at that point," and three students said that "it means that $\lim_{x \to c} f(x)$ does not exist." Possibly, the students were showing different ways in which a function can be discontinuous, but it can also indicate a limited concept image of discontinuity, with students overlooking other ways in which a function can be discontinuous at a point. For example, one student wrote: "It is not continuous at $f(c)$ then that means there's a jump or stop somewhere, meaning the limit can't exist."

31 students drew at least one discontinuous graph in their explanation. Of those students, 24 drew a graph of a function with a hole or a removable discontinuity, while some students drew multiple graphs with different types of discontinuities. While these were correct discontinuous graphs, it is unclear whether students considered them as illustrations of where the statement is true or if they attempted to "prove" the statement with specific examples of discontinuous functions, thus exhibiting example-based reasoning (Rissland, 1999; Watson & Mason, 2006).

Rather than examining discontinuities, 21 out of 84 students used a rules-based approach. Working from the three-rule criterion of continuity, these students explained that since the function was discontinuous at $x = c$, it must not satisfy one of the three rules of continuity at that point. While this is a potentially productive approach, some students interpreted it narrowly, identifying specific rules that would be broken.

When students mentioned all three rules of continuity at a point, they seemed to struggle with negating their conjunction. For example, one student wrote: "Because the rule of continuous function does not allow $\lim_{x \to c} f(x) \neq f(c)$ to be continuous, all rules can be proven to be untrue." The student could be wrongly assuming that all three continuity rules must be simultaneously false or merely using "all" in the sense of "any" — a common confusion (Epp, 1999).

Six students justified statement 2 by proving its converse: If $f(c) \neq \lim_{x \to c} f(x)$, then the function is not continuous. Since definitions are true, biconditional statements, the students reached the right conclusion, even by using a logically problematic approach.

Items 3 and 4 are both false. Students performed well on both, using similar reasoning and exhibiting similar challenges. Most students (57 for item 3, and 53 for item 4) drew graphs showing counterexamples to justify their reasoning. Of these students, most (37 of 57 for item 3 and 38 of 53 for item 4) drew a graph of a function with a removable discontinuity at $x = c$. For item 3, these students drew graphs of functions where $f(c)$ was defined, and for item 4 $f(c)$ was not defined. Other students (33 for item 3, and 29 for item 4) mentioned different types of discontinuities which would constitute a correct counterexample to this statement. Similarly with the graphs, most of these students (24 for item 3, and 29 for item 4) mentioned removable discontinuities to prove this statement false. Overall, very few of the common misconceptions suggested in the literature appeared in these explanations.

Item 5 was the one the students found most challenging compared to other statements. 71 out of 84 students correctly responded "false," with 14 of them initially choosing the option "true". Many students noticed that item 5 is a combination of items 3 and 4 and used that in their justifications. They did this in a variety of ways, not always correctly. Most students either explicitly referred to or re-drew the graphs they used to disprove items 3 and 4: a graph of a discontinuous function with a hole (showing $f(c)$ undefined) or jump discontinuity with $f(c)$ defined but undefined or non-existing limit. The challenge appeared in making conclusions based on these examples. 11 out of 84 students incorrectly inferred from these graphs that the statement was true, not realizing they were "proving" the statement with supportive examples.

One possible reason for these types of responses could be students' limited concept image of discontinuity, restricted to only certain types, while a removable discontinuity would constitute a valid counterexample. Indeed, the majority of correct arguments relied on graphs with removable discontinuity, like Figure 2, where the student explained that "The graphed function is not continuous because $f(c) \neq \lim_{x\to c} f(x)$, but both $f(c)$ and $\lim_{x\to c} f(x)$ exists."

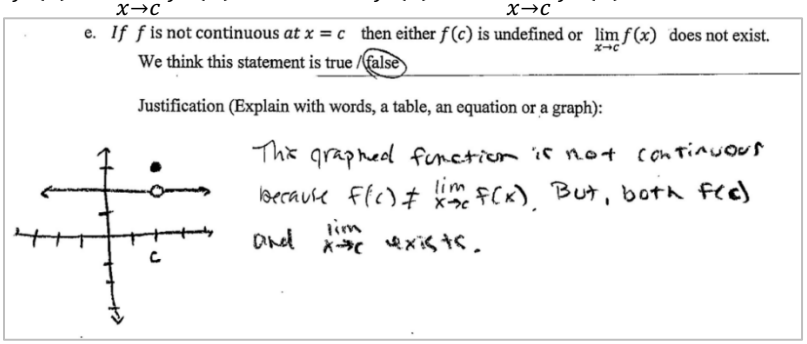

Figure 2. Correct response to item 5: a counterexample of removable discontinuity

Another explanation for incorrect conclusions about discontinuous functions whose graphs contain holes or jump discontinuities could be that the students were attempting to evaluate the converse of statement 5. That is, looking at graphs where the conclusion is false and inferring the function is not continuous. Whether this is the case or not was not always clear from written responses, but the argument in Figure 3a supports the assumption about evaluating the converse.

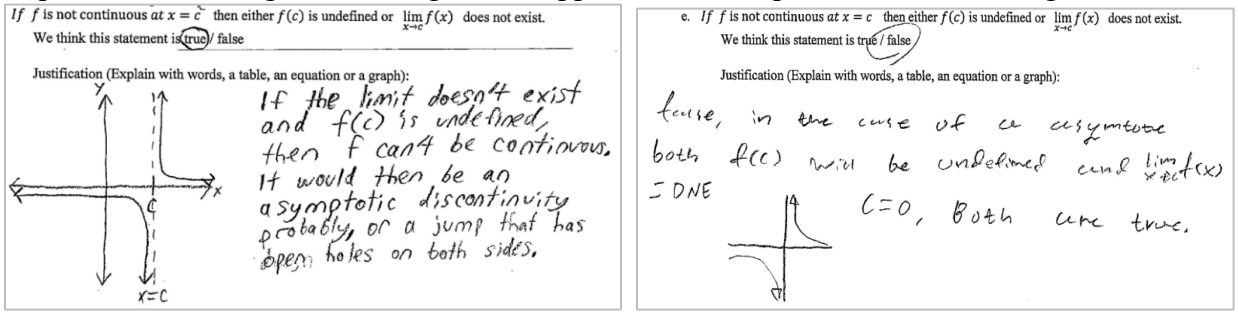

Figure 3. Different incorrect inferences from an asymptotic discontinuity. 3a (right): Evaluating the converse to "prove" the statement. 3b (left): Relying on exclusive disjunction to "disprove" the statement.

The student gave an example where both parts of the conclusion are true: "The limit doesn't exist, and $f(c)$ is undefined" but inferred that the hypothesis must be true also: "then f can't be continuous." Note that in the argument in Figure 3a, the student used "and" instead of "or." This was another recurring issue of students' difficulties with disjunction. Figure 3b shows one of the four instances of arguments where students attempted to disprove the statement by drawing a graph of a function with an asymptotic discontinuity at $x = c$ and explaining that the statement is

false because "Both $f(c)$ is undefined and $\lim_{x\to c} f\ (x) = DNE$." These students interpreted the disjunction as inclusive rather than exclusive and asserted that they found a counterexample where both parts of the statement's conclusion were true. Whereas in fact, such an example supports the statement. Challenges with negating disjunction, interpreting its meaning, or confusing it with conjunction led to 10 instances of incorrect reasoning on item 5.

Another example of this challenge appeared when students did not rely on graphs but on three continuity rules. This reasoning involved students claiming that the statement is false because: "All three rules need to be untrue in order for a function to be not continuous. This [statement] only specifies two of the three [rules]". Similar to the examples above, this argument shows a rigid application of continuity rules, but contrary to those examples, this is a clear invalid negation of the disjunction. It is also interesting to note that only 10 students mentioned $\lim_{x\to c} f\ (x) \neq f(c)$ in their answer to item 5 in some way, whereas in the previous items, students relied more heavily on the three rules of continuity.

Discussion and Scientific Significance of the Study

The results reported herein shed light on the variety of ways in which students reason about the definition of continuity at a point – an important concept of introductory Calculus. The results reveal that item 1, which presents a definition of continuity at a point, had a 100% success rate, while item 5—an incomplete contrapositive—had the lowest success rate. Some of the students' responses align with the common misconceptions identified in the literature, like conflating $f(c)$ defined or $\lim_{x\to c} f\ (x)$ with continuity (Amatangelo, 2013; Denbel; 2014; Juter, 2006). However, most of the reasoning challenges in our study were related to logical reasoning, especially the negation of the intersection of the three continuity rules ($\neg(V \wedge L \wedge E) \equiv (\neg V) \vee (\neg L) \vee (\neg E)$), interpreting the contrapositive and disjunctions (Brown, 2018; Dawkins & Cook, 2017; Yopp, 2020). Students' responses suggest that as the logical structure of the statement became more complex, it became more difficult for students to apply continuity rules in a rote way. It forced students to attend to the logical and semantic meaning of the statements, challenging their emergent understanding of the definition of continuity. Thus, students relied heavily on examples: graphs of discontinuous functions but often struggled to make inferences from these examples. Having limited example space (Watson & Mason, 2005) or a limited concept image of discontinuities (Tall & Vinner, 1981) often negatively affected students' reasoning. However, even when correct examples were used, drawing correct logical inferences from them was often challenging. This concurs with prior studies showing similar challenges in other mathematical contexts, like concluding the statement is true based on several examples or proving (or disproving) the converse (e.g., Buchbinder & Zaslavsky, 2019; Rissland, 1999).

The authentic context of the study, where students work in groups trying to make sense of the definition, distinguishes our study from previously reported in the literature, making for a unique contribution and capturing student thinking during concept construction. Focusing on written responses allowed us to analyze a rather large data set, but since our analysis is limited to written responses, we could not probe student thinking further. This seems critical since some of the students' responses were rather surprising. We intend to explore them more closely in the future.

Students' Connections About Equivalence Across Contexts: Substitution and Known vs. Own Equivalences

April Paige Richardson
Oklahoma State University

The concept of equivalence is fundamental to problem-solving in mathematics. Particularly, an oft-utilized feature of equivalence is substitution, in which the mathematics doer replaces one object with an equivalent object. Equivalence in general, and substitution in particular, have been identified as common threads that can tie together different areas of mathematics, but do students notice these connections in their own mathematics? In this paper, I report on task-based clinical interviews with students exploring the commonalities they identify among tasks implicitly involving equivalence relations. In particular, I discuss themes that students explicitly identified as relevant when answering the interview tasks: (1) substitution equivalence and (2) a distinction between students using a known equivalence for substitution or introducing their own equivalence.

Keywords: equivalence, substitution, actor-oriented, student-generated connections

Equivalence has two fundamental uses throughout mathematics: it is used to express the *sameness* of mathematical objects as well as their *interchangeability*. In fact, Liang (2021) proposed that equivalence "can be used as a thread to connect mathematical concepts and topics," but that much "remains to be done to analyze the nature of equivalence and substitution in different contexts, and in developing suitable tasks to provide students […] with opportunities to enrich their understandings of these ideas" (Liang, 2021, p. 43). Studies have extensively examined the substitutive aspect of equivalence with respect to equality, but it remains to be seen how the substitutive aspect of equivalence is conceptualized by students when working with non-equality equivalence relations, and moreover if students see these ideas as related across contexts. Thus, for this study I sought to answer the following research question: *What connections do undergraduate students identify among tasks involving equivalence relations?*

Background & Theoretical Framework

Actor-oriented Perspective

To examine whether students identified any commonalities across tasks involving equivalence in various forms, I adopted the actor-oriented perspective. This perspective was appropriate because my purpose was to "[inquire] into what types of common features students might perceive across cases" (Ellis et al., 2007, p. 227). Under this perspective, Lockwood (2011) defines a *researcher-generated connection* as a connection inferred by the researcher, i.e., "a connection that was not verbally articulated or borne out in some external activity" (p. 311) by the student, and a *student-generated connection* is one in which a student explicitly articulates or demonstrates that they view a particular connection. Student-generated connections are important to study because they are the connections that students are consciously aware off, thus students may more intentionally attend to or rely on them in their problem solving. In short, this framework provides researchers with an opportunity to examine what *students* see as relevant when identifying similarities between their current and past mathematical activity. Lockwood (2011) characterizes types of student-generated connections as:

- *elaborated* or *unelaborated* connections, where the former refers to connections in which the student explains what prompted them to draw a connection, and the latter refers to when students mention a connection but do not expound upon what led them to make this connection;
- *conventional* or *unconventional* connections, where the former "occur when students make connections to problems that may conventionally be considered isomorphic to the problem at hand" (p. 311), and the latter "occur when students relate situations that an expert or observer might not find mathematically isomorphic" (p. 312); and
- *referent type*, meaning the types of objects students draw connections to, including particular problems, problem types, and strategies or techniques for solving problems.

My work builds upon the existing work of Cook et al. (2022) and Richardson et al. (2024)—who presented *researcher-generated* views of the key commonalities in reasoning about equivalence across contexts—by examining students' views on the commonalities they attend to and identify when reasoning about equivalence across contexts.

Substitution Equivalence

Researchers have posited that a desirable conception of equality is a relational one, i.e., a recognition that equal mathematical objects have the same value (e.g., Baroody & Ginsburg, 1983; Jones & Pratt, 2012; Kieran & Martínez-Hernández, 2022). An elaborated, *full relational* conception of equality has been proposed as more completely capturing the nature of equivalence, which involves recognizing the sameness of mathematical objects and that one object can be substituted for an equivalent object (Carpenter et al., 2003; Jones et al., 2012; Jones & Pratt, 2012; Molina et al., 2009; Tirpáková et al., 2023). In particular, for the symbolic representation $x = y$, the sameness component would manifest as x "is the same as" y and the substitutive component would manifest as x "can be exchanged for" y (Jones, 2008, p. 154). I use the *sameness* and *substitutive* aspects as similarly applying to equivalence, whereby objects related by some equivalence relation have the properties that they are the same with respect to some property of interest and they can be freely substituted for one another.

Tirpáková et al. (2023) elaborated on the idea of substitution equivalence by introducing the idea of students' *own equivalences* to describe when students define an arbitrary equivalence for the purpose of using substitution in mathematics. This is contrasted with what I call *known equivalences*, which are equivalences that students do not define themselves and are instead recalled, proven to be true, or created via a sequence of appropriate transformations. For example, substitution of 0.5 with $\frac{1}{2}$ in simplification of the expression $\frac{2}{3} + 0.5 + \frac{3}{4} - \frac{4}{9}$ would be the use of a *known equivalence* because it is based on the numeric equality of the objects in question. Contrarily, using substitution of variables $u = 2x$ to rewrite the integral $\int_0^{\sqrt{\pi}} 2x \sin(x^2)\, dx$ as $\int_0^{\pi} \sin(u)\, du$ would be considered an *own equivalence* because it is an arbitrary, albeit convenient, replacement introduced by the mathematics doer and is not based on some known, given or discovered property of the given mathematical objects.

Introducing an *own equivalence*, such as in the integration example above, is important because it involves attending to the structure of the given problem without changing its content mathematically. Tirpáková et al. (2023) emphasize the importance of students' own equivalences as they can be introduced strategically to make the intended calculations more efficient or easier to perform. Moreover, Tirpáková et al. (2023) assert that "perceiving structure of the given equation allows the students to effectively connect their various knowledge of mathematics by

using appropriate substitution," and that by defining their *own equivalences*, students "can transform an unknown task into a task that they are already able to solve" (p. 486).

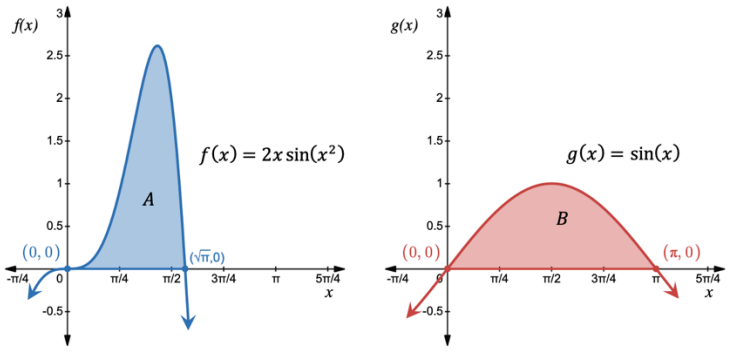
While the idea of substitution has been studied extensively as it relates to equality of expressions, this work has been done primarily at the level of researcher-generated connections, and it remains to be seen what findings are also applicable in more general instances of non-equality equivalence. Thus, my work addresses a gap in the literature by investigating the commonalities students identify in how they view equivalence (in particular, substitution equivalence) across contexts.

Methods

Data Collection and Task Design

I conducted task-based clinical interviews (Clement, 2000) with 16 students who were either currently enrolled in or had recently completed the last course in a three-course calculus sequence. Each student participated in an individual interview lasting between 90 and 120 minutes. Students' written work was recorded on a digital whiteboard iPad application and synced with an audio recording of the interview.

I selected this population of students because they would have had prior exposure to the mathematics required to complete each interview task, but they would not yet have been exposed to formal notions of equivalence relations. I conducted task-based clinical interviews because the purpose of a such an interview is to capture students' genuine interactions with the task setting in order to understand how they reason about a concept in the moment. My goal was to learn about students' current understandings of mathematical ideas—with the hope that the given tasks would elicit students mentioning ideas of equivalence or substitution—without deliberately influencing changes in students' thinking.



Task 1:	Simplify the following expression: $\frac{2}{3} + 0.5 + \frac{3}{4} - \frac{4}{9}$
Task 2:	Simplify the following expression: $\sin(2400°) + \cos(1110°) + \tan(585°)$
Task 3:	Show that the two shaded areas in the graphs below are equal: 
Task 4:	Solve the following equation on the set of real numbers: $\frac{x\sqrt[3]{x}-16}{\sqrt[3]{x^2}-4} - \frac{\sqrt[3]{x^2}-1}{\sqrt[3]{x}+1} = 17$

Figure 1. Tasks administered during the interviews.

The interview tasks (Figure 1) were selected because they could each be completed by using some form of substitution to make the given task simpler to execute, but the tasks involved

different contexts and slightly different notions of equivalence. For example, in Task 1, each term can be substituted with an equivalent fraction so that every term has a common denominator, and each original term is numerically equal to its substituted term (e.g., $\frac{2}{3} = \frac{24}{36}$). In Task 2, each angle can be substituted with its coterminal angle in the interval $[\mathbf{0}, \mathbf{2}\boldsymbol{\pi})$, and while these angles are not numerically equal (e.g., $\mathbf{585}° \neq \mathbf{225}°$), they are equivalent in the sense that they share the same position on the unit circle and thus would produce the same value when used as the argument for given trigonometric functions. The interview tasks also involved different notions of substitution. For example, the substitution discussed above for Task 1 would be considered using a *known equivalence* because it involves substituting one number for another which is known to be equal. Contrarily, the example of introducing $\boldsymbol{u}$-substitution to rewrite an integral (discussed in the "Substitution Equivalence" Section) for Task 3 would be considered using an *own equivalence*.

Data Analysis

The audio for each interview was transcribed verbatim and then coded using Clement's (2000) cycles of interpretive analysis. I focused on ideas that students mentioned repetitively throughout the interview and across tasks because I wanted to investigate what features of the tasks and their solutions that students deemed as relevant across a variety of contexts. In particular, I was interested in whether the students identified anything pertaining to equivalence.

I distinguished between what I deemed as common ideas that students appeared to recognize across tasks (*researcher-generated connections*) and what students *explicitly* mentioned as being common or similar across tasks (*student-generated connections*). That is, instances labeled as researcher-generated connections could have been connections that the students *implicitly* recognized but did not *explicitly* identify as being connections across tasks in their utterances or writing, i.e., there was not sufficient evidence to show that students did in fact see these as connections across tasks. Thus, connections classified as researcher-generated have the potential to be commonalities that students identify across tasks but are simply not made explicit by the students. In the results, I provide examples of explicit, student-generated connections; I used Lockwood's (2011) framework for categorizing the types of student-generated connections. While I was interested in all types of connections that appeared in the data, in the results I provide two examples of elaborated, conventional student-generated connections.

Results

I will now discuss two particular connections that students identified during their interviews. For brevity, I discuss selected excerpts from two participants: Jackson and Alex (pseudonyms). I consider these to be prototypical examples that are illustrative of the commonalities identified across contexts by multiple interview participants: *substitution equivalence* as a problem-solving strategy and the difference between *known* and *own equivalences*.

Student-generated Connection: Substitution Equivalence

Jackson identified his use of *substitution*—i.e., replacing one mathematical object with an equivalent one—as part of his strategy for answering several of the interview tasks. As evidence, Jackson continually referenced how he would "exchange" or "interchange" equivalent elements for the purposes of changing the given task into a "more convenient" format throughout multiple interview tasks. In particular, he expressed that he viewed equivalence as a necessary condition for being able to freely substitute mathematical objects.

In his work on the first task, Jackson simplified the expression by first writing each term as a fraction, then finding common denominators pairwise and simplifying left-to-right. He wrote 4/6 and 3/6 in place of 2/3 and 0.5, respectively. He then justified this step of his work by saying:

> *Jackson*: That ratio would be the same if you had 6 things and you picked 4 out of that. It's like the same ratio, but 4/6 was just more convenient to work with than 2/3 is. **And since they're the same thing, you can just interchange them.**

That is, Jackson used the idea of substitution as a solution strategy because he "interchange[d]" the fractions 2/3 and 4/6 and expressed that he knew this was allowed mathematically because "they're the same thing."

On the second task, Jackson subtracted the highest multiple of 360° that he could from each angle to convert into a coterminal angle between 0° and 360°. He then used the unit circle to read off or calculate the desired trigonometric values. When asked to justify his work, Jackson explained:

> *Jackson*: So if it's anything more than 360 you can just do, um, your starting number minus 360 because that'll take out the unnecessary rotation and then just give you the exact, like angle that you're looking for because **if it was 30 or if it was 390 those are the same thing because they both lead to the same spot.** […] And then whatever I'm finally left with, that's what gives me my angle that I can use.

He then clarified that he viewed *sameness* of angles in terms of their position on the unit circle, and expressed that this sameness allowed him to substitute one angle for another for the purposes of this task:

> *Jackson*: **For two angles to be the same on the unit circle they have to have the same end coordinates.**
>
> *Interviewer*: Okay. […] So as long as two angles […] have the same end coordinates, what happens?
>
> *Jackson*: **Then they can be exchanged** […] within trigonometric functions.

Similar to the first task, on the second task Jackson explained his process of "exchang[ing]" one object with an equivalent one that would yield the same end result as the original presentation of the task. In the first task this equivalence condition was numeric equality, whereas in the second task this equivalence condition was position on the unit circle. However, in both cases, Jackson expressed that this equivalence condition allowed him to substitute one element for an equivalent one and still preserve the solution to the original task. Moreover, Jackson was careful to clarify that his equivalence condition for Task 2 allowed him to exchange angles specifically "within trigonometric functions."

Until this point, I had viewed Jackson's use of substitution as a *researcher-generated connection*, because although Jackson was continually mentioning the same ideas of using substitution across tasks, he did not explicitly state that he did in fact view these uses of substitution as being instances of one unified idea. However, after completing all the interview tasks, Jackson summarized his work by saying, "**If two things are equal, then you can substitute them**, or like interchange them with whatever's more convenient." He expressed that in hindsight he recognized that he used substitution on every interview task:

> *Jackson*: But like, if it's the same thing, you can exchange it with something else and that makes it a lot easier. And that's kind of like one of the core [ideas] of math I guess because you use it like a lot more than you would think. Like **I used it for every problem on this without realizing it**, like, yeah.
>
> *Interviewer*: And you used what on every problem on this?

Jackson: Uh, just like **exchanging a different form of what I'm working with if it's more convenient to work with it in that form.**

Because of Jackson's repeated identification of substitution as a strategy for turning a given task into a "more convenient" form, as well as this substitution being allowed as long as the objects being substituted are "equal" within the given context, and Jackson's recognition that these were ideas he used on every task, I claim that Jackson viewed substitution equivalence as a strategy connection across the interview tasks.

Student-generated Connection: Known Equivalences and Own Equivalences

Alex elaborated on a difference between using a *known equivalence* versus defining his *own equivalence* to make substitutions that resulted in the task being easier to complete. I classified Alex as having made a *student-generated connection* because he explicitly discussed how different types of substitution manifested across tasks.

Alex used the metaphor of putting a "mask" on a complicated part of a task in order to temporarily ignore a complicated part and make the task easier to understand. He identified that this "masking" of part of a task was allowed as long as it was temporary, i.e., it is undone at some point before the task is completely answered. On Task 3, Alex applied this metaphor to the process of integration via *u*-substitution. He began the problem by writing the integral $\int_0^{\sqrt{\pi}} 2x\, sin(x^2)\, dx$ to represent the first desired area A, and then used *u*-substitution to evaluate this integral.

Alex: So for that process, that is, um, *u*-substitution, and that is a process of simplifying complex integrals to make them easier to calculate. Um, so the way that works in my brain is I think of it like **taking the difficult parts and putting a mask over them. So they're still there, but you don't have to look at them.** Um, so you can compute it without dealing with the complicated parts of those, **and then once you're done with that, you can take the mask off and put back the parts that you need to.**

Alex then clarified that that in the integral $\int_0^{\sqrt{\pi}} 2x\, sin(x^2)\, dx$, he used u as the "mask" for x^2 and then used his *own equivalence* $u = x^2$ to determine that du should be the "mask" for $2x\, dx$. When asked how the "masked" integral $\int_0^{\pi} sin(u)\, du$ compared to the original integral he wrote, Alex said that the integrands were "not *perfectly* equal because if you were to just say, um, $2x\, sin(x^2)$ is equal to $sin(u)$, that wouldn't be right." However, he then clarified that this substitution was appropriate as long as the substitution $u = x^2$ was made explicit and the final answer for the task was given in terms of the original variable *x* instead of the chosen variable *u*.

Furthermore, Alex expressed that he saw the type of substitution used on Task 3 as a different type of substitution than he had used on other Tasks. For example, when comparing Task 3 to Task 1, Alex said:

Alex: **But that's not a mask that's more switching it,** like the same way as 0.5 and ½ [from Task 1] are equal because that gets you straight to the answer. You don't have to backtrack to get back to the same […] terms that you were in. […] Um, because I can't solve it in terms of *u*. It has to be solved in terms of *x*.

In this excerpt, Alex identified that the substitution of 1/2 for 0.5 in Task 1 would "[get] you straight to the answer," whereas in Task 3, after the substitution of $u = x^2$ was made, he would "have to backtrack" or undo his substitution in order to solve the task in terms of the original variable *x*.

Alex explicitly stated that substitution was a strategy he used across multiple interview tasks, and that some type of equivalence was a necessary condition for these substitutions. In fact, Alex went so far as to say that he used some form of substitution on *every* interview task. However, Alex additionally contrasted problem types by distinguishing between the different ways that equivalence allowed him to use substitution, i.e., using an equivalence that was already known versus one that he introduced himself:

> *Alex*: Um, so while for all of these, **you do need to interchange and you do need to, um, like set them equal to something else to be able to solve the problem**, for u-substitution it's necessary to be a mask because you have to be able to take part of that mask off afterwards and be able to plug part of the original part back in. **Whereas for the other ones, you don't have to so it doesn't really need to be a mask, it just needs to be like they're the same in like equivalency, the same in nature.** Um, I think of it as a mask because it still means that there's something behind it instead of being replaced by an equivalent term.

I interpret Alex's use of the phrase "equivalent term" in the last sentence to refer specifically to *known equivalences*. Thus Alex is distinguishing between substitution with his *own equivalences* where there is "something behind" the substitution and he needs to "take […] that mask off" before finishing the task and substitution with *known equivalences* that he can use freely without needing to undo or account for these substitutions later in his problem-solving process.

Discussion

My findings address a gap in the current literature in several ways. First, my work extends the work of previous researchers by shifting the attention from the commonalities that *researchers* identify in students' utterances and work across contexts (e.g., Cook et al., 2022; Richardson et al., 2024) to focus on what *students* explicitly identify as being common across contexts. In particular, Jackson's interview provides evidence that *substitution equivalence* is a commonality that students identified across contexts, and Alex's metaphor of using a "mask" for temporary replacements provides evidence that students identified a distinction between using *known equivalences* or introducing their *own equivalences*. I reiterate that Jackson and Alex were not the only students who explicitly identified these connections, nor were the instances documented here the only connections that students made. Rather, these excerpts provide examples to illustrate that these students made elaborated, conventional connections consistent with what researchers agree is important for students to attend to when their work involves equivalence.

Future research building upon this work could examine the ways in which students' conscious attention to these connections affects their problem-solving. Work can be done exploring the affordances and constraints of students' explicit attention to substitution equivalence and known vs. own equivalences, and how students can leverage their awareness of these ideas in learning new mathematical concepts. As a potential instructional implication, introducing *own equivalences* as a problem-solving method can help student students to turn a complicated problem into one they know how to solve in contexts other than integration by u-substitution (e.g., in Task 4, temporarily replacing $\sqrt[3]{x}$ with a placeholder, or "mask" variable).

Enacting Active Learning in Calculus: How One Graduate Teaching Assistant's Instruction Shifted with an Experienced Learning Assistant's Support

Lauren Sager
University of New Hampshire

Rebecca Butler
University of New Hampshire

This study explores the changes in a graduate student teaching assistant (GTA)'s teaching actions over two semesters in an active learning Calculus I course. Cole, a GTA with little teaching experience and no prior experience with active learning, was paired with an experienced undergraduate learning assistant (LA) in his second semester teaching in a purposefully designed active learning-based Calculus I course. Cole's teaching actions varied more when paired with the experienced LA, including short periods of lecture and classroom discussion with the facilitation of group work. This case study provides insight into how an experienced undergraduate LA can be an agent of change in an active learning-oriented classroom.

Keywords: Active Learning, Calculus, Teaching Practices, Graduate Teaching Assistants, Undergraduate Learning Assistants

At the undergraduate level, introductory Calculus is typically a core requirement for degree programs across science, technology, engineering, and mathematics (STEM) disciplines. However, Calculus can act as a barrier to students' continuation in such programs, with many students who fail calculus ultimately leaving STEM majors (Smith & Funk, 2021). Because of this relationship, many are concerned with the currently high rates of student drop, withdrawal, or failure from calculus courses (Bressoud & Rasmussen, 2015).

Previous research suggests that active learning is an effective means of lowering DWF rates (students who receive a D, F or withdraw from the course) in Calculus courses (Bressoud & Rasmussen, 2015; Freeman et al., 2014) and cultivating more positive attitudes toward STEM subjects (Tutal & Yazar, 2022).While active learning is conceptualized in many ways (Ting et al., 2023), we offer the following literature-based definition to guide our work: active learning is marked by a learning environment which provides meaningful opportunities for all students to learn mathematics, by incorporating engagement with cognitively demanding mathematical tasks, and instructor facilitation of collaborative learning opportunities, including the promotion of both small and whole-group discussions (CBMS, 2016).

Due to its documented success in cultivating positive content-related and affective outcomes for students, university administrators and faculty within mathematics departments are interested in transforming large-lecture introductory Calculus courses to include active learning practices. Practically, the transformation of such courses requires "buy-in" from a number of individuals, including course instructors and graduate teaching assistants (GTAs) who are responsible for the teaching of the course. For instructors, the implementation of active learning can require construction of high-level tasks to engage students, moderation of classroom discussions, and facilitation of group work, which are distinct from the skills required to teach traditional, lecture-based courses. At larger universities, many Calculus courses rely on the teaching of graduate students, either as instructor of record or as a recitation section instructor. These GTAs often have scant teaching experience, speaking generally. They also typically have little experience with active learning as a student, meaning that they have few examples to emulate when asked to teach in active ways. Consequently, recent efforts have been made to create and provide

professional development to GTAs regarding the implementation of active learning and other evidence-based strategies (Deshler et al., 2015), but still little is understood about GTAs' teaching practices and their development.

Motivated by this under-researched topic, we conducted a previous study (Sager et al., 2023), in which we examined the conceptions and teaching actions of a group of Calculus GTAs with varying levels of background in teaching and experience with active learning. We found that more experienced GTAs tended to scaffold their small-group work time with short bursts of class discussion and content review, while less experienced GTAs tended not to incorporate such scaffolding. One GTA from this study, Cole, had had little previous teaching experience and no experience with active learning, and showed little scaffolding of his group-work time during his first semester implementing active learning. However, our research team noticed significant qualitative differences in his classroom environment during his second semester as a GTA when he was paired with an undergraduate Learning Assistant (LA) who had ample experience teaching and learning in the active learning environment at the university. In this current study, we specify these noticed differences, asking: how do Cole's teaching actions and perspectives on active learning shift as he gains experience with different LAs in an active learning Calculus I course, and how are these shifts related to the actions and perspectives of the LAs? Cole's case contributes to our understanding of GTA professional development in the active learning context by showing how GTAs development and the broader classroom environment can be impacted by LAs.

Literature Review

The important role of GTAs in the introductory STEM experiences of university students has led to increased interest in professional development (PD) programs for GTAs (Braley, et al., 2023). PD programs allow GTAs to interact with student-centered and evidence-based practices, such as active learning (Archie et al., 2022, Deshler et al., 2015). Many GTAs have little to no teaching experience, and have not experienced student-centered teaching in a classroom, which leads to limited confidence in implementing these strategies in their own classrooms (Deshler et al., 2015). Additionally, while GTAs may believe students learn best through active learning or other student-centered strategies, they often do not act on this belief, instead teaching how they were taught (Patrick, et al., 2021). GTAs also need a way to gain the pedagogical content knowledge and knowledge of student thinking central to effective teaching (Kung & Speer, 2009). The research on graduate students' background and their implementation of student-centered learning strategies is sparse.

While GTAs can act as facilitators of active learning in large-lecture courses, an additional approach to facilitation is through the incorporation of undergraduate LAs into the course structure. An LA is an undergraduate student who has successfully passed the course previously and returns to aid in the teaching of that course, typically by facilitating discussion amongst small groups of students. In addition to their time in the classroom, LAs also typically participate in a pedagogy course and meet weekly with instructors to discuss course content. While much of the research around the LA model of instruction has focused on ascertaining the benefits to both students and LAs involved in this instructional model (Barrasso et al., 2021), recent efforts have centered on aspects of departmental change, since this was an original goal guiding the design of this model (Otero et al., 2010). In particular, the nature of LA-faculty partnerships in the instruction of LA-supported courses has been of interest. Faculty members working with LAs have reported improvements to their course designs, including increased emphasis on active learning classroom activities, and that LAs present them with new pedagogical perspectives (Hill

et al., 2024; McHenry et al., 2010). Others have begun to conceptualize how these faculty-LA relationships impact course design and particular instantiations of the LA instructional model (Davenport et al., 2017; Karch et al., 2024). While the literature suggests that these faculty-LA relationships influence both instructors' professional development and the design of the course, the impacts of LAs' relations to other members of the instructional team remain largely unexplored. Our study contributes to this area by exploring the relationship between a GTA and LA, detailing the impacts of this relationship on classroom instruction and this instructor's conceptions of teaching and learning.

Data and Analytic Frameworks

This case study takes place within a larger project focused on improving introductory STEM courses at a large research university in the Northeastern US. One component of the project was the introduction of active learning into the Calculus I course. The course follows a lecture-recitation structure, where the students meet with a faculty member for a lecture section (of approximately 120 students) three days a week, and with a GTA in recitation section (of approximately 20 students) the other two days. Undergraduate LAs were introduced within the recitation sections to support group learning, an integral part of the active learning incorporated into Calculus I recitations.

To promote active learning, a new recitation structure was suggested to GTAs: a short introduction, followed by small group work, and whole class discussion. GTAs were given autonomy to adapt the suggested structure to fit their classroom. At the beginning of each semester, the course team (faculty instructors, GTAs and LAs) met with project team members to discuss the active learning and recitation structure, ask questions, and give and receive advice about best practices. In addition, all first-year TAs in the mathematics and statistics department are required to take a full year course discussing pedagogy and other topics pertaining to GTAs' teaching, including active learning. Similarly, the LAs are required to take a pedagogy course designed for peer coaches. Both LAs and TAs also meet with their peers and course instructors weekly to discuss upcoming course topics, but also to share feedback and suggestions related to course activities.

This case study focuses on one GTA: Cole. Cole was a beginning Ph.D. student in statistics and served as a GTA in this active-learning recitation during the Spring 2023 and Fall 2023 semesters. During his first semester as a GTA in the active learning context, Cole taught with an LA named Ann, a second-year mechanical engineering major who was a novice LA. However, during the Fall 2023 semester, Cole worked with an LA named Fran, a junior environmental engineering major who had been a mathematics LA for the three previous semesters.

In this study, we focus on the case of Cole because the research team noticed significant qualitative differences in Cole's classroom between these two semesters, with many of these differences seeming to be initiated or introduced by the LA, Fran, in the second semester. While Cole's Spring 2023 classroom practices and conceptions of teaching were analyzed in a previous study (Sager et al., 2023), here we examine how Cole's actions and conceptions change over time, connecting these changes to his relationship with Fran. The data for this case study includes 360-degree video recordings of Cole's recitation sections across the Spring 2023 and Fall 2023 semesters and as well as two interviews with Cole (one from the end of each semester) and one end-of-semester interview with each LA. Video recordings were conducted during six recitation sections each semester consisting of class sessions in which students worked on researcher-designed, conceptually-oriented activities. The semi-structured interviews with Cole focused on his perception of, experience with, and use of active learning. The LAs' interviews

we also semi-structured, but included stimulated recall, with each LA reflecting on video clips of their interactions with small groups and discussing their general thoughts on mathematics teaching in this context.

In order to capture the actions of Cole, Ann, Fran, and the students in the classroom, the Classroom Observation Protocol for Undergraduate STEM (COPUS) (Lund et al., 2015) was used to code the recitation video recordings. COPUS is an observation framework which applies codes for instructor and student actions to every 2-minute interval of the recording. Traditionally, COPUS is used to categorize an instructor's teaching (e.g., lecture-based or active), specifically for the purposes of professional development. However, we leverage COPUS as an analytic tool to provide a snapshot of recitations across the semester. For more information about COPUS and codes in the framework, see Lund et al. (2015). Two recitation recordings were chosen for each semester – one from the first third of the semester, and one from the last third, based upon the availability within the data set. The content of the early semester activities was the same for both semesters (continuity), while the content of late semester activity was different for the two semesters (antiderivatives and logarithmic differentiation, respectively). Nevertheless, each recording took place during the implementation of researcher-designed, conceptually oriented activities. Each classroom recording was coded by two members of the research team resulting in an interrater reliability of 92% and disagreements were discussed until a consensus was reached. The codes for Cole, the LAs, (Figure 1) and students (Figure 2) were aggregated over the two recordings for each semester in order to provide a profile of the classroom over the entire semester.

The GTA and TA interviews provided context and background to the GTA and LA relationship and Cole's actions in the classroom. Interviews were coded using open and thematic coding to capture the changes in Cole's definition of active learning and the GTA and LA relationship in the classroom (Miles et al., 2018; Strauss & Corbin, 1998).

Results

In this section, we compare the classroom actions of Cole, the LAs, and the students during Cole's first and second semesters as GTA in Calculus I. While Cole's actions and perceptions during the Spring 2023 semester are more extensively detailed in Sager et al. (2023), we provide an overview here to contextualize our new analysis of his LAs' actions, their perceptions, as well as his evolving conceptions and practices in the Fall 2023 semester. We illuminate the changes that occurred when Cole worked with an experienced learning assistant.

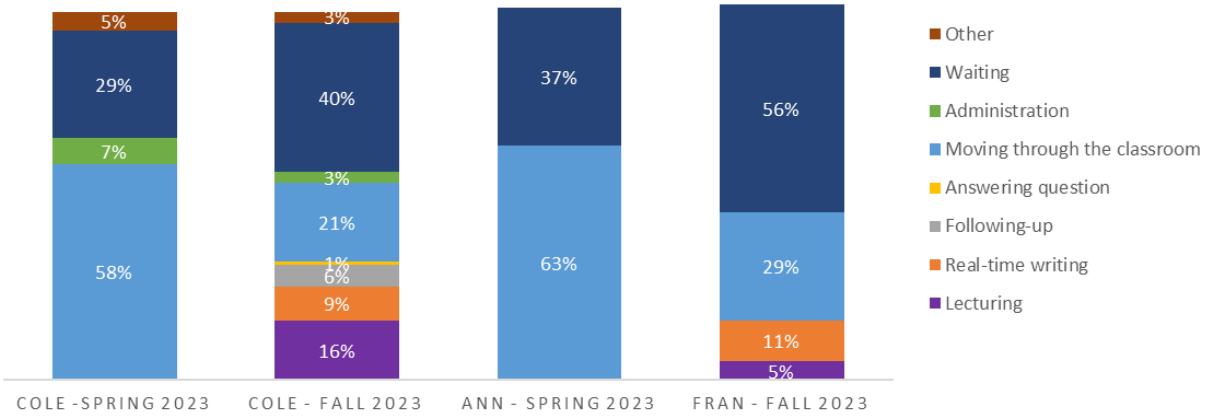

Figure 1. Instructional actions of Cole and his learning assistants.

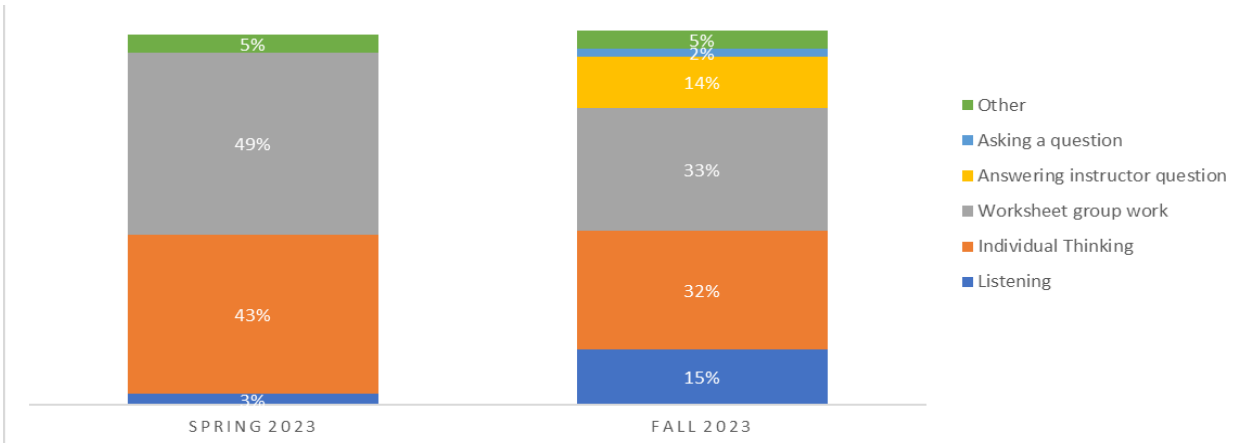

Figure 2. Classroom actions of students in Cole's classrooms.

Cole was a first-year Ph.D. student in statistics in Spring 2023, when he first acted as a teaching assistant for Calculus I. At this time, he was in his second semester of teaching as a graduate student, having taught precalculus without an LA or conceptually oriented activities in his first semester. His only teaching experience before entering the Ph.D. program was as a virtual one-on-one tutor in a program for gifted elementary students. He reported no previous experience with active learning as a teacher or a student. He "barely asked [his] teacher a question" as a student, and he would "pretty much work alone."

In contrast to his own experience as a student, Cole's working definition of active learning during the Spring 2023 semester, his first time teaching in an active learning setting, was "engagement." He believed that "most of [the] students would just copy paste notes and just leave it there. So, they learn nothing, but they think they learned a lot." Engagement and interaction were his antidote to the "copy paste" mentality of students. His actions in Spring 2023 from Figure 1 reflected his emphasis on interaction with the students -- 58% of his classroom actions were m*oving and guiding*. *Moving and guiding* was coded when the instructor moves around the classroom, interacting with students working on the activity individually or in groups. Cole's emphasis on allowing students to engage with the activity was also reflected in the student actions from Spring 2023 as well (Figure 2), as 92% of their actions were either *group work* or *individual work*.

Cole described himself as a "tutor" in his first semester as a Calculus I GTA – his first semester in a purposefully-designed course using group work and active learning. The lack of any *lecturing*, *follow-up* or *real-time writing* in his actions corroborates this description. He described that his role in the classroom was to "learn if [students] are active, thinking or learning or not ... I definitely will walk around so I'll ... check their work." In contrast, he described how students from his previous semester without active learning would "just listen to me and then copy what I wrote on a board," and characterized himself as a "lecturer." His "tutor" status was also reflected through an abundance of *waiting* codes. Because he viewed himself as a tutor, he waited for students to ask for assistance.

Ann acted similarly to Cole in the 2023 semester. In Figure 1, we see that Ann spent her time in recitation either interacting with groups (63% of her COPUS codes were *moving and guiding*) or *waiting* to interact with students (37% of her COPUS codes were *waiting*). While she spent a significant proportion of her time *waiting* to assist students, she explained in her interview that this was because, as a novice LA, it took her some time to "get more comfortable with the students" and be able to "go out of my comfort zone and initiate questions with the students". Additionally, her primary engagement in *moving and guiding* is consistent with the

responsibilities of an LA in this context as they were primarily facilitators of small group discussion. It is also consistent with her description of her role as an LA, as she stated her role is "answering questions" and acting as a "second brain" for Cole. That is, as a recent learner in the course, she provided a "second way to think about" course content and reported that Cole often sought her advice when addressing student questions, saying "when he felt like he couldn't answer it that well, he would come to me and ask, can you explain this?". From Ann's description, we see Cole's disposition toward collaboration with his LA, with Cole actively enlisting the expertise of his LA as a recent Calculus learner.

While Ann's actions of *waiting* and *moving and guiding* were consistent with and typical of the responsibilities of an LA in this environment, Fran showed more variation in her classroom actions. We see that Fran also engaged in *writing on the board* (11% of her COPUS codes) and *lecturing* students (5% of her COPUS codes). *Writing on the board* included instances when Fran would work out a solution at the chalkboard at the front of the room, walking through the steps of the problem by soliciting these steps from students around the room. She also briefly lectured about course content, explaining general concepts to students. Like Ann, these actions were consistent with her description of her classroom role, saying:

> "[Cole] and I work really well together. I feel like we pretty much have the same role. He obviously is grading the homework and stuff like that. And towards the end of class, if there's an overall concept announcement or we want to go over L'Hospital or something, he'll do that as the TA. But working in the classroom, we pretty much do the same thing"

In contrast to Ann, who viewed herself as more of an assistant to Cole, Fran viewed herself and Cole as having nearly identical roles. This alternate view was rooted in Fran's previous LA experience, since she previously worked with an experienced GTA who supported her in taking on a more active role, saying this GTA made her "feel like another TA in the class". While Fran had a higher proportion of *waiting* codes than Ann, this is attributable to both a smaller class size in Fran's semester (i.e., there were fewer students to engage with) and the increase in Cole's actions related to whole-class engagement. Overall, we see that Fran's previous experience as an LA paired with a supportive and experienced GTA, empowered her to take on a more active role in her teaching with Cole.

We see in Figure 1 that Cole's actions in the classroom changed when working with Fran. In addition to the *moving-guiding* and *waiting* codes, 16% of his COPUS codes were *lecturing*, and 9% were *writing on the board*. We notice that Fran also includes *lecturing* and *writing* with the *moving and guiding* and *waiting* expected from an LA facilitating group work. Often, Cole built upon Fran's engagement of the whole class, adding a short explanation (*lecture*) addressed to the class, or to *follow up* (6% of his COPUS codes) on a student question or problem from the activity. While Cole, like Fran, had a high proportion of *waiting*, the class was smaller and more independent in their group work, leading to less time where Cole and Fran were working with the groups.

Cole's perception of his role in the classroom also changed after working with Fran. In his interview at the end of the Fall 2023 semester, he talked about how he had "transferred [himself] from the teacher to the guide" and pointed out that his new goal was to "mix these things together." He sought to combine the "lecturer" of his first semester of teaching with the "tutor" of Spring 2023. His classroom actions indicate that he was successful in meeting this goal. His students' actions are also much more varied in Fall 2023: only 65% of their actions are either *group work* or *individual thinking* on the activity, compared to 92% in Spring 2023. In accordance with Cole's change to include more *lecturing*, 31% of their actions are *listening,*

answering instructor questions or *asking questions*. Some of the *other* codes for students include a student writing an answer on the board and explaining the problem to the class, a contrast to the *other* codes in Spring 2023, when the *other* codes were exclusively for off-task students or packing up to leave class.

When asked what advice he had for GTAs implementing active learning in the future, his response was that they should "learn from [Fran]." He mentions that she is "able to teach on the stage" and also adept at "teaching everything to the students". That is, Cole learned from Fran's example how to incorporate appropriate scaffolding through whole-class engagement into his teaching in the active setting. Cole and Fran take a similar role in the classroom, with Fran diverging from the traditional role of an LA, and Cole welcoming and assimilating her teaching actions.

Discussion

Cole's teaching actions changed dramatically in his second semester of leading an active learning recitation for Calculus I. In his first semester, he took the relatively passive role of a "tutor", spending a significant amount of time waiting for questions and interacting directly with the groups. His only interaction with the whole class was administrative in nature – giving directions or reminders. His LA, Ann, used similar actions, implementing the standard role of a learning assistant. When working with Fran the following semester, he incorporated more lecture and class discussions into his recitation. This more varied set of teaching moves led to more engagement with students, and by Cole's own definition, more active learning.

While we cannot point to any single reason for this change, Cole and Fran both describe their relationship as an important aspect of the classroom dynamic. Cole was going into his second semester in an active learning facilitation role, while Fran was in her fourth semester as a learning assistant. Fran was given the opportunity to take on more responsibility than a traditional LA, and Cole varied his teaching actions in a similar way to her. Cole cited Fran as an inspirational figure for teaching, indicating that she impacted him through their time working together.

While including LAs in a course is often viewed as a professional development experience for LAs themselves, we offer evidence that this relationship can be bidirectional, with LAs also acting as model teachers for the instructors with whom they work. Experienced LAs can be agents of change in promoting practical active learning teaching actions in the classroom. Our study has practical implications for GTA professional development programs, showing how novice GTAs can be supported by the presence of LAs in their classrooms and suggests that GTAs can benefit from real-time illustrations of pedagogy in their institutional contexts. Likewise, our results carry implications for LAs' pedagogy courses, showing that such courses should support LAs in confidently enacting innovative teaching techniques.

Overall, we emphasize that the collaboration between LAs and instructors, especially when they differ in experience, fosters a mutually beneficial professional growth process. This partnership can also enhance the implementation of active learning practices in more scaffolded ways. Our findings suggest that expanding LA programs and integrating them more closely into GTA professional development can play a critical role in advancing teaching effectiveness in higher education.
