This study arose as part of an ongoing project exploring the activity of authoritative assessment in a semester-long inquiry-oriented abstract algebra class, using video data collected by the fourth author. While developing this theoretical construct, we identified several instances of student questioning which caused debate as to whether the utterance made by the student was authoring or assessing an idea.

In line with the AAA framework, we analyzed segments, stretches of classroom activity possessing consistent mathematical focus and participatory structure. We focused specifically on segments in which students' activity included posing questions to develop inductively a theory of questioning as an authoritative activity. We identified a question as any utterance that requested information of some kind. To determine the influence of students' questioning on the overall authority relations within a segment, we attended to not only the mathematical content of their questioning but also the source of that content. We asked, "Whose idea is the subject of the question? What mathematical contribution does it make? Does the contribution become the focus of classroom discourse?" Using the method of constant comparison (Corbin & Strauss, 2015) to develop and refine our definitions, we first made the distinction between questioning activity that contributes new mathematics to the discourse and that which does not. For instance, we differentiated questions regarding a previously spoken idea, uttered by the teacher or another

classmate from those about a student's own ideas. This distinction between questions that clarify and those that contribute does not value one type over the other, but rather foregrounds the public mathematical activity involved so that the influence of these interactions on the classroom authority relation can begin to be understood. Within these two types, distinctions arose in the data that warranted further development into two subcategories for each type, dependent on the scope of the mathematical activity involved. We develop our classification below.

Findings

In this section, we present preliminary findings in the form of four types of questioning that arose throughout the semester, describing how students' questioning garnered them authority for authorship, animation, and assessment. Figure 1 summarizes our classification.

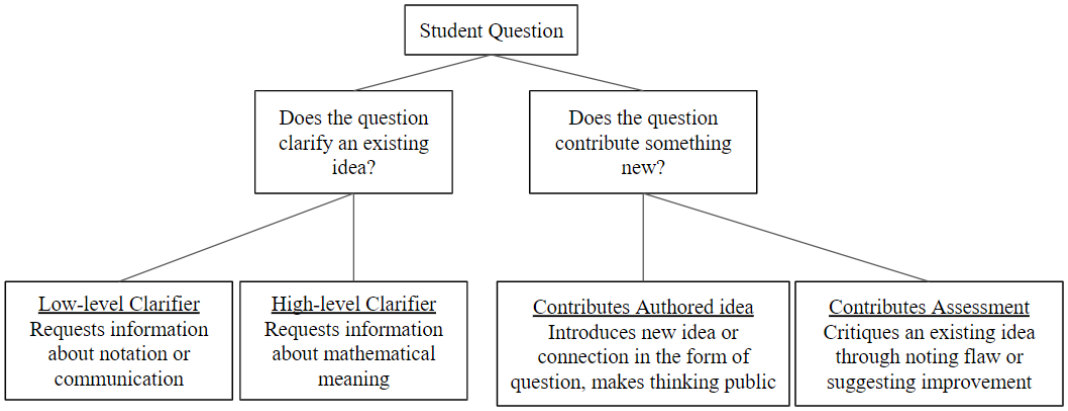

Figure 1. Classification of Student Questions as authoritative activities.

Clarifying Questions

Students regularly asked questions which aimed to clarify an element of the classroom discourse. We saw a distinction between questions that clarified notation and questions that clarified mathematical content. In the first type, which we designated low-level clarifiers, the question asked serves to clarify the visual and audible communication of mathematics, rather than the creation of it. These questions attend to notation or vocabulary within the class discourse and generally are not mathematically substantial. For example, when the teacher had finished presenting a proof, a student asked, "Is that the letter U or V used to represent that set?" Questions like this are focused on an aspect of communication rather than the mathematical content itself. While we see it as likely that this student was engaging in meaningful sense-making of the teacher's proof during this interaction, such activity was not publicly available and so did not contribute to the authority relation of the classroom beyond simple animation, i.e., the student's utterance garnered authority to animate an existing idea through speaking.

On the other hand, we also saw students ask clarifying questions that attended to the meaning of the mathematical content at hand. These questions, which we called high-level clarifiers, made students' reasoning about the mathematics public, usually by alluding to a new idea or connection. For example, while the class was investigating why a non-trivial homomorphism from the group of rotations of the square into the integers (Z) could not be constructed, the following interaction occurred:

Ella: Could you do equivalency classes instead?

Teacher: The problem is that I'm mapping to Z.

Ella: Not Z mod 4?

Teacher: Yeah, right? So I can't map to equivalence classes because the elements here aren't equivalence classes.

Ella's question suggests attention to the operation-preserving property of a group homomorphism and an attempt to rectify the issue. While the utterance was posed as a clarifying question about whether the codomain can be changed to preserve the operation between groups, the question also served as a vehicle for an idea. We saw activities like this as being more mathematically substantial than a low-level clarifier because they involve public student reasoning in ways that questions aimed to clarify simple communication often do not. However, while high-level clarifiers contained new ideas or perspectives, these did not become the focal idea of the conversation in a way consistent with authorship authority. Therefore, for both types of clarifying questions, students had authority for animating the mathematics through speaking.

Contributing Questions

In some cases, students posed questions that indicated an existing idea or belief and requested the teacher's judgement to verify. When this happened, we saw the student's question as contributing an authored idea. To exemplify this, we present the following exchange where Levi and Cammie ask about another student's solution on the board.

Levi: Does it hold that like, we don't have to check any elements in H? So if you checked the coset {a, b, d} to make sure that the left and right are equal, we don't have to do that because H is a group so any left- or right-product of d and H is gonna be in there?

Teacher: Yeah, if H is a subgroup, then I know it's closed, so I don't have to check any of the things in there when I'm checking my left- and right-cosets. Yeah?

Cammie: So for cH you could also use eH or fH?

Teacher: Yes, I could use any name I wanted for this.

In the course of asking his question, Levi introduces the idea that the closure property of the subgroup H simplifies the process of constructing cosets and explains his reasoning. The novelty of Levi's idea together with the public justification for the thinking within the question earned credit for authorship because the question was substantive enough to become the focal mathematical idea of the segment.

Although Cammie's question displays some reasoning about the choice of coset representatives, we see this question as a high-level clarifier rather than a contributing question because she appeals to an idea authored in a previous discussion by the teacher. Observe that Levi's question authored mathematics while Cammie's question animated existing mathematics through speaking. We see similarity between Cammie's question in this excerpt and Ella's high-level clarifier in the last section because neither student elaborates on nor justifies their thinking, though both clearly demonstrate sense-making of the mathematics at hand.

Another kind of contribution that arose through students' questioning activity came in the form of authoritative assessment. Questions that *contributed an assessment* typically contained a critique of an authored idea through noting a flaw or suggesting an improvement. In the following example, a student's question about a proof the teacher has presented does both.

Justin: Why do we need to do eH? Why can't we just do H times gH?

Teacher: I could've done H●gH.

Justin: Right.

Teacher: Yeah. Because H is the identity coset, it's the same name as eH. And I didn't use that e for anything. I was trying to highlight for you guys that this was the identity.

Consistent with our framing of assessment, we noted that the teacher's response to Justin's question defended her choice of notation when she said, "I was trying to highlight for you guys that this was the identity," indicating that the question was playing the role of a public critique within the discussion.

Implicit within Justin's question is an attention to the technique of proof-writing, with some implicit regard to whether it is more appropriate to express the idea of multiplying by the identity coset using fewer symbols. Viewing proof-writing as a cultural adaptation to the discourse of mathematicians provides a potential reason for why Justin would phrase this critique as a question; perhaps he experiences some uncertainty about whether mathematicians would find his expression more appropriate. As the teacher points out, his technically-more-concise statement has the potential to obscure for someone reading the proof that the coset used is in fact the identity. This discussion, though subtle, arises from Justin's critique and contributes something of mathematical importance to the discourse, so we see his question as a way of taking up the authority to assess the teacher's mathematics.

Discussion

In our preliminary work, we have seen how student questioning activity may move beyond authority for animation to become authority for authoring or assessing mathematics. Rather than treating all questions as students appealing to the authority of the teacher for authorship or assessment, we attend to the public nature of students' questions and the mathematical activity involved in formulating and communicating them to parse ways that students' questioning creates an authority relation. In viewing questioning as an authoritative mathematical activity, we expand the scope of possible outcomes in interactions when students question and explore the boundaries between animation and authorship.

We distinguished Ella's high-level clarifying question from Levi's contributing question in our analysis because Levi's question became the mathematical focus of the segment while Ella's did not, although both involved the students bringing their own mathematical ideas into the class discourse. In this example, the difference between a high-level clarifier and a contributing question lies in two places: the mathematical scope of the segment and the teacher's response to the question, how it was taken up or developed. Levi's question occurred in a segment where the classroom activity was narrowly focused on students asking questions after the presentation of the teacher's proof, so the introduction and justification of a new idea garnered Levi authority for authorship. In contrast, Ella's question occurred during a rich discussion of a particular example, so her idea had less influence in the context of the broader conversation. Similarly, the teacher's respective responses to Ella and Levi influenced the way the authority relation in each segment was created. The teacher validated Levi's thinking and formalized the language used, indicating that Levi was leveraging the properties of a subgroup rather than a group. In response to Ella, the teacher pointed out a flaw in Ella's suggestion. In both cases, the teacher took up authority to assess the students' ideas. We wonder whether this is consistently the case: does the teacher's (or other students') response determine the authoritative nature of students' questions?

Questioning is not the only activity during which the authority relation can shift from animating to authoring or assessing mathematics. While we looked at questioning in this preliminary analysis, we wonder about the circumstances required for such a shift when students are engaged in other classroom mathematical activities like validating proofs, writing mathematics publicly on the board, or working together in small groups. Knowing where this boundary lies in these varying contexts may further illuminate how authority relations are formed across activities.

Converging Paths: A Survey of Calculus Students' Course Experiences

Joe Champion
Boise State University

Brinley Stringer
Boise State University

Amanda Willoughby
Boise State University

Rachael Welder
Boise State University

This preliminary study reports on a brief survey of students' course experiences in introductory university calculus. In particular, we compared the responses of students who took precalculus and calculus at the same institution with those who took precalculus in high school or other settings. Findings highlight significant differences in students' reported calculus experiences between the two groups of interest, which indicates areas for improved alignment of course structures in undergraduate precalculus and calculus, especially around academic support. Building on this initial study, the data are being used to inform efforts to improve instruction and curriculum of both precalculus and calculus courses at the research site, starting with a new pilot calculus course in Spring 2025.

Keywords: calculus, precalculus, affective experiences

Calculus is widely recognized as a challenging course in the undergraduate curriculum that often serves as a barrier for students pursuing STEM majors (e.g., Steen, 1988; Chen & Soldner, 2013). The combinations of barriers to STEM achievement are formidable, with only 35% of high school seniors who intended to pursue a STEM major earning an undergraduate STEM degree (Seymore & Hewitt, 1997). Yet, despite longtime efforts to improve retainment of students in the STEM pipeline, undergraduate programs continue to struggle with attrition. For example, Chen and Soldner (2013) found that 48% of students pursuing bachelor's degrees and 69% of those pursuing associate degrees in STEM switched to a non-STEM field or left college without a degree.

STEM attrition is particularly pronounced among students from historically marginalized and underrepresented groups, including students identifying as ethnic minorities and women. Treisman (1992) noted that ethnic minority students often face higher barriers in STEM courses, while Ellis and colleagues (2016) reported that women are one and a half times more likely to leave the STEM pipeline after experiencing Calculus I than their male peers. Additionally, Chen and Soldner (2013) found that students attending less selective colleges were more likely to leave STEM fields compared to their peers at highly selective institutions. Increasingly, undergraduate educators have focused on the role of early coursework and institutional support for high quality resources to support student success in calculus and precalculus courses.

Calls for improved student outcomes in calculus have led to many small and large reforms, including curriculum and assessment overhauls to focus more on student engagement and essential understandings, and the integration of innovative teaching methods, often including technology-enhancements, inquiry-based activities, and adaptive learning systems (Bressoud et al. 2015; Rassmussen et. al. 2019). The good news is that research indicates that the instructional methods used in calculus courses can have a significant impact on student outcomes. For example, a recent landmark randomized trial by Kramer and colleagues (2023) demonstrated that active learning techniques that involve students more directly in the learning process results in improved grades and a deeper student understanding of calculus concepts. Similarly, Freeman

and colleagues (2014) observed positive outcomes of active learning approaches in courses in other STEM disciplines. Yet, despite these advancements, traditional lecture-based instruction remains the primary mode of instruction in many undergraduate calculus classes (Rasmussen et al., 2019).

Sonnert and Sadler (2015) observed significant declines in students' attitudes and desire to continue in mathematics after completing an introductory college calculus course. While taking and excelling in advanced math courses in high school had a strong positive effect on students, completing a precalculus or calculus course in college did not show the same impact, highlighting a disconnect in the transition from high school to college mathematics. Students' experiences in college calculus courses seem to play a crucial role in declining affect (Sonnet & Sandler, 2015) and persistence in the subject (Rasmussen & Ellis, 2013). Notably, Rasmussen and Ellis (2013) reported that 31.4% of students who initially intended to progress from Calculus I to Calculus II, but chose not to do so, cited their experiences in Calculus I as a major factor in their decision. Similarly, Ellis and colleagues (2014) found that students' perceptions of their calculus courses, including the pedagogies they experienced, played a critical role in their decision to (dis)continue studying mathematics. Unfortunately, the characteristics of calculus courses that have been identified as most strongly correlated with maintaining confidence, enjoyment of mathematics, and desire to continue in STEM fields–such as slower pacing, smaller class sizes, more qualified instructors, and more student-centered pedagogies–are more prevalent in high school classrooms than in college settings (Bressoud, 2015).

Though calculus is a central junction in the STEM pipeline, it is necessary to investigate the (dis)continuous experience that students face while both preparing for, and enrolling in, calculus courses. Existing literature that has examined curricular and pedagogical aspects of precalculus to calculus transitions (e.g., Apkarian et al. 2018; Voigt et al. 2019; Wade et al. 2023) highlights a lack of consistency. However, there is a gap in the literature emphasizing the affective experiences of students as they navigate the precalculus-calculus corridor of the STEM pipeline.

In this preliminary report, we investigated student-reported survey data on their experiences in a Calculus I class and how it relates to their other class experiences. We pay special attention to the group of students who completed precalculus courses prior to enrolling at the university research site compared to those students who completed precalculus at the same university in which they took calculus. We hope results of the study can spark conversation about the importance of alignment between course structures in college-level precalculus and calculus courses with those of high school precalculus settings. The guiding question is, "**How can students' reported experiences in university calculus classes inform better alignment of curriculum and instruction of precalculus and calculus courses?**"

Methods

The institutional setting is important to this study. Mountain State University (pseudonym) is a large public university in the western United States. Students typically enroll shortly after graduating from high school in the local or nearby state. Admission is minimally selective (~85% acceptance rate). The undergraduate student body is typical of many mid-to-large U.S. public research universities, including many first generation students (~35%) and students eligible for federal financial aid (~50%). Calculus classes are typically taught by full-time lecturers and adjunct faculty who specialize in lower-level undergraduate mathematics teaching. The calculus curriculum has many of the features of reform calculus programs, including technology-assisted assessment, frequent low stakes individual and small-group assessments, and a focus on applications. Most applied tasks center around physical contexts typical of

introductory engineering and physics courses. Course coordination is moderate, with a schedule of topics, homework, and exams provided on an opt-in basis among instructors, but daily instructional methods vary. Success rates, as measured by the percentage of registered students who earn a letter grade of A, B, or C, have improved in recent years, averaging about 70%, with considerable variability across instructors.

A recent institutional emphasis on first year student experience and retention highlighted calculus as one of a small number of STEM courses targeted for improved equity in student outcomes, and a task force within the department was established to address potential improvements in the course. This study is part of those efforts.

Precalculus courses at MSU are designed for students who are admitted to the university without sufficient preparation for calculus, with very robust systems for supporting student success. The courses are taught by different faculty in a separate unit from the mathematics department using a hybrid of flipped-classroom and emporium formats centered around building students' mathematics self-efficacy (Bandura, 1997). Class sizes are similar to calculus (about 40 students each), but classes are much more coordinated. In all sections, students spend several hours per week in an online program that helps reinforce procedural knowledge, while class time is a mix of small group activities and individualized work time for students to reinforce conceptual knowledge with their instructor available to answer questions. The model has resulted in high success rates (consistently around 80%), and MSU has received two recent national awards highlighting the positive impacts of precalculus systems on student success and retention outcomes (APLU, 2023; NCCU, 2023).

The primary data source for this observational study was an abridged version of the end-of-course student survey from the large MAA National Study of College Calculus (Bressoud et al., 2015). We distributed the survey by email to all 905 students who registered for calculus at MSU during fall or spring of the 2023-2024 academic year, yielding a sample of N = 190 student responses (response rate = 21%). As a preliminary study focused on informing alignment of precalculus and calculus courses, the primary groups of interest were students who reported completing their precalculus courses at MSU (43%) versus those who reported completing precalculus in all "Other" (57%) settings (high school = 49%, two-year or community college = 6%, others = 2%). We computed comparative descriptive statistics of students' reported calculus course experiences in these two groups, emphasizing indications of similarities and differences.

Results

Overall, students who took precalculus at MSU tended to report lower letter grade attainment in their first calculus course (A = 37%, B = 37%, 19%, D/F/W = 13%) compared to those who took precalculus in Other settings (A = 53%, B = 23%, C = 17%, D/F/W = 7%), χ^2 (3) = 14.2, $p < .01$. Similarly, students who took precalculus at MSU tended to report lower levels of agreement on survey items about math enjoyment (MSU = 71%, Other = 86%), confidence (MSU = 61%, Other = 78%), and preparation for calculus (MSU = 53%, Other = 65%). Details are shown in Figure 1.

In questions about their experience of calculus course quality (see Figure 2), students who took precalculus at MSU tended to report lower agreement with survey items about the course increasing their interest in mathematics (MSU = 43%, Other = 55%), getting the support they needed to succeed (MSU = 54%, Other = 80%), and wishing more courses were taught like their calculus course (MSU = 51%, Other = 64%) In addition, students who took precalculus at MSU reported feeling more frequently "lost and unable to keep up" in calculus (MSU = 42%, Other = 26%), although they reported asking questions (MSU = 47%, Other = 35%) and learning through

peer interaction (MSU = 67%, Other = 65%) with similar distributions in their calculus courses (see Figure 3).

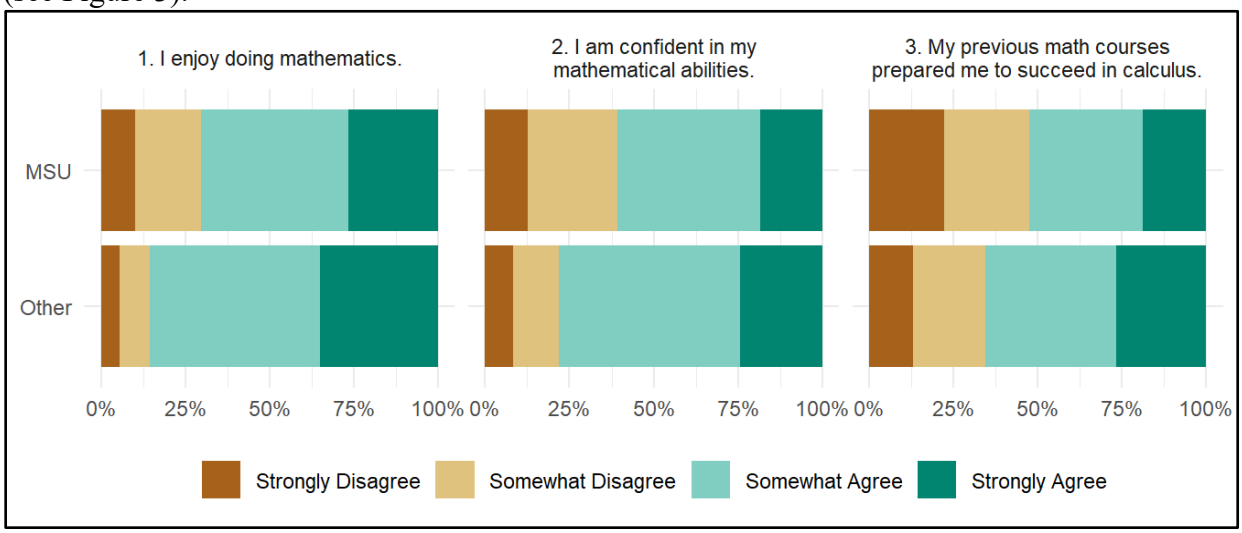

Figure 1. Indicators of calculus students' reported mathematics identity.

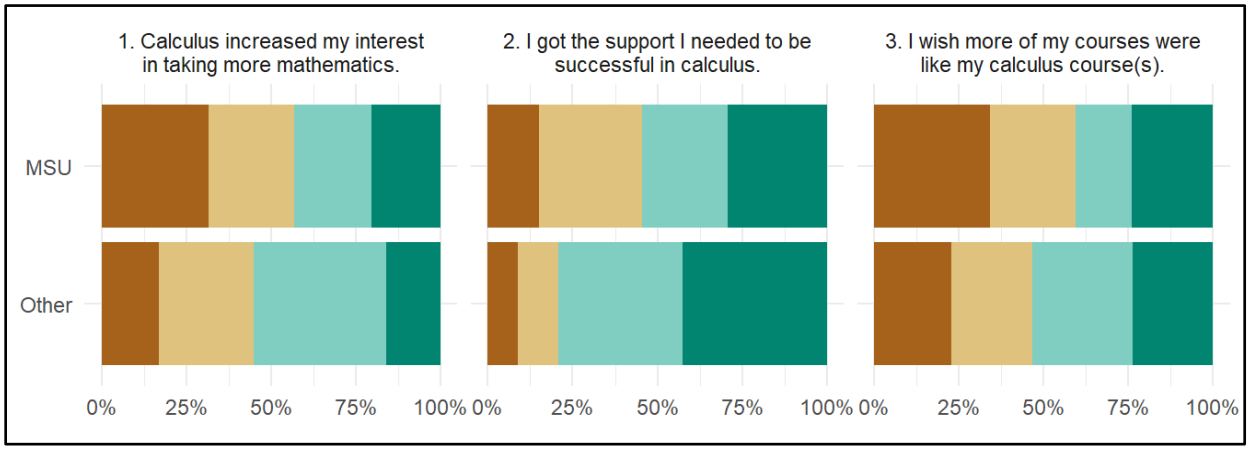

Figure 2. Indicators of calculus students' perceptions of calculus course quality.

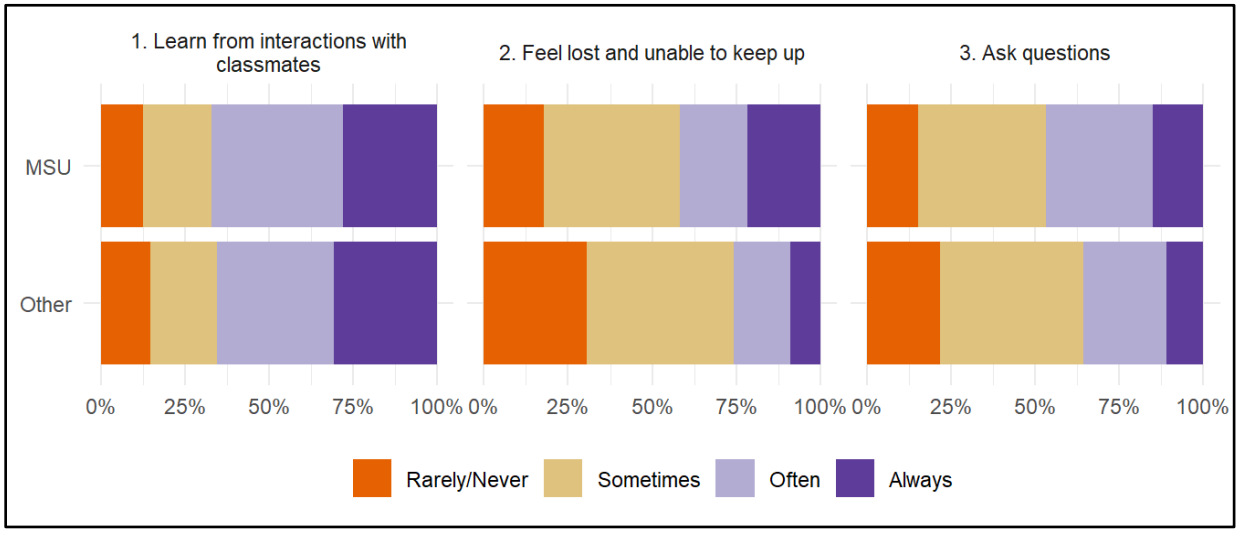

Figure 3. Indicators of calculus students' experiences of calculus instruction.

Discussion

The distributions observed in our survey of students' course experiences suggest substantial differences in the calculus experiences of students who completed precalculus at MSU compared to students who completed precalculus in another setting (typically high school). There is a consistent pattern of students who took precalculus at MSU reporting lower perceptions of instructional quality and support for their learning. This is particularly surprising given that the precalculus course at MSU has been designed to foster student self-efficacy and has garnered national attention for its impacts in supporting student success and retention efforts across the institution.

The results from this study are only observational, thus it is difficult to discern the cause(s) of the observed differences. Nonetheless, the disparities suggest room for improvement in better aligning precalculus and calculus transitions at the university level. More broadly, the results highlight a need for more research into localized, contextual factors which may impact students' affective experiences in calculus and other undergraduate mathematics courses which are taken in sequence at MSU, and all institutions of higher education.

We anticipate that attending to vertical alignment of sequenced courses, especially in terms of instructional methods, assessment strategies, and other course design features could positively affect students' perceptions of course quality. To test this idea, we are currently building a pilot calculus class that aligns with the structure of precalculus classes at MSU to see if there are any differences in student's reported experiences in such a course. This course will launch in the Spring 2025 semester. In addition to survey data, we hope to follow up with focus group interviews with students to better understand their experiences in transitioning from precalculus to calculus. This data will help inform cycles of design research to help improve the pilot calculus class, and other changes to create more consistency in this portion of the STEM pipeline.

Questions for Audience

As a preliminary study, we are particularly interested in the perspectives of other undergraduate mathematics education researchers and university teaching faculty. We want students to experience cohesive, well-designed undergraduate courses, and recognize that the challenges of offering high quality calculus course experiences are widespread. Thus, we welcome input from colleagues about interpreting the survey data, in the context of the scholarship of teaching and learning at the undergraduate level. In particular, we are interested in conversing about the following questions:

1. What changes to calculus might lead to better course experiences for both students who took precalculus at the same university and those who took precalculus in other settings?
2. Which aspects of course design are most important to align across university precalculus and calculus courses?
3. What other aspects of students' calculus course experiences are most important to consider in the context of precalculus?
4. How might we effectively facilitate cross-course collaboration about course design between undergraduate calculus and precalculus instructors? What are the barriers and drivers?

Use of WeBWorK as an Online Homework System as it Relates to Student Mathematical Identity

Anna Marie Bergman
Fort Lewis College

Colton Sawyer
Regis University

This study explores how WeBWorK, an online homework system, influences student mathematical identity, with a special focus on students at a Native American-serving institution. Mathematical identity refers to beliefs, attitudes, and emotions toward mathematics, impacting motivation and learning. Through an online survey we gathered insight on student perceptions of WeBWorK's role in shaping four identity dimensions: self-efficacy, understanding, confidence, and persistence. Results reveal significant differences in student perceptions compared to prior studies, with survey participants showing lower engagement across these dimensions. Preliminary analysis suggests that WeBWorK may not equally support the mathematical identities of all students, particularly those from minority or first-generation backgrounds. This research contributes to understanding how web-based homework systems affect diverse student populations, providing insights for improving such systems to foster mathematical engagement and identity development.

Keywords: WeBWorK, online homework, mathematical identity

Introduction

In an increasingly technology-heavy world, many institutions of higher education are turning to the use of web-based homework (WBH) to allow for more time to be spent on material outside of class, which may be correlated to increases in student achievement (Cooper et al., 2006**;** Kehoe, 2010). Several types of WBH platforms exist and are used nationwide to supplement or replace traditional homework systems (Kehoe, 2010), including the open-source platform WeBWorK. From the perspective of the instructor, WBH has clear educational benefits, ranging from instantaneous feedback on assignments, an increase in understanding of the material, more consistent time spent studying, and leveling access across general and diverse populations of students (Boudreaux et al., 2022), as well as the economic benefit and objective nature of the system for large class sizes (Wood & Bhute, 2019). Furthermore, use of WBH allows additional time for students to develop a sense of their mathematical identity (Fernandez et al., 2024).

Mathematical identity here refers to a person's beliefs, attitudes, emotions, and dispositions about mathematics and their resulting motivation and approach to learning and using mathematics knowledge (Fernandez et al., 2024; Martin, 2000). There are a myriad of recent studies focused on how WBH affects mathematical identity in STEM minority populations (e.g., girls and women [Fernandez et al., 2024] and race [Nguyen et al., 2006]). Our study contributes to this important effort by looking at how the use of a particular WBH, WeBWorK, affects aspects of students' mathematical identity sorted by demographics including race (with a particular focus on Native American/Alaska Native students) and first-generation status. Our research question is: *How do student perceptions of their engagement with WeBWorK relate to different attributes of their mathematical identity? Moreover, how do these perceptions change with differing student demographics?*

Background

Student interaction with WBH systems has increased and has been particularly well-documented in the past 10 years (Dorko, 2020; Dorko et al., 2023; Hauk & Segalla, 2019; Kehoe, 2010; Serhan, 2019; Valdez & Maderal, 2021). Hauk & Segalla (2005) acknowledge WBH is "only a support tool…and [replaces] the unevenly implemented pedagogical interaction of homework grading with a uniform method of feedback" (p. 233). However, WBH systems are suggested to be at least as effective, if not more effective, than traditional written homework (Boudreaux et al., 2022; Hauk & Segalla, 2005; Wood & Bhute, 2019). Student perceptions of the value of WBH relate to a more positive learning experience in the classroom (Serhan, 2019). Furthermore, perception of the use of WBH is significantly correlated to motivation toward mathematical learning (Valdez & Maderal, 2021). Here, mathematical learning can be placed within the larger context of mathematical identity.

Considering attitudes toward aspects of WBH under the lens of mathematical identity can help us understand how a student may develop individual and group membership within a mathematical community (Cribbs et al., 2015). Mathematical identity is often used as a means for understanding student engagement with the subject (Black et al., 2010). This engagement often translates to growth of a student's conception of self, which has been found to be connected to their choice-making and performance at advanced levels (Mendick, 2006). Some researchers even claim that identity is crucial to the belief that one can be a creative participant in mathematics as a social practice (Boaler & Greeno, 2000).

For our study we will consider four facets of mathematical identity: self-efficacy, learning/understanding, confidence, and persistence. In particular, self-efficacy through a mathematical identity lens refers to a person's internal beliefs about their capabilities to produce levels of performance that allow them to exercise influence over events that affect their lives (Brenner et al., 2017) and their success in a mathematics classroom. Here, we ask how student engagement with WeBWorK relates to different aspects of a student's mathematical identity. As such we are interested in how these aspects relate across demographic axes such as first-generation and minority (with a specific focus on Native American/Alaska Native students) statuses.

Methods

For this study we administered an online survey to students at a public bachelors granting Native American-serving nontribal institution which we've given the pseudonym, Mountain College. The survey focused on student engagement with the web-based homework platform WeBWorK. WeBWorK is an open-source homework system supported by the Mathematical Association of America and the National Science Foundation. Created in 1996, WeBWorK describes itself as an open-source online homework system for STEM courses with an Open Problem Library of over 35,000 homework problems (WeBWorK, n.d.). At the time of the survey, WeBWorK was being used in all math classes at Mountain College from College Algebra, through the calculus sequence, and beyond in courses such as linear algebra and differential equations. WeBWorK had also been used for a number of previous terms.

Mountain College is located in the Southwestern United States serving a diverse student population. The majority of the student body identify in a minority race category (54%), with 27% of the total population as Native American or Alaska Native students. There is also a high percentage of first-generation college students (44%).

Overall the survey consisted of twenty five 5-scale Likert questions and five open responses covering four domains: accessibility, attitudes and engagement, mathematical identity, and

community. For this preliminary report, we will be focusing on the results pertaining to mathematical identity. There were six survey questions aimed at student engagement with WeBWorK and mathematical identity which can be seen in Table 1 below. All questions were asked on a 5-point Likert scale from 1-Strongly Agree to 5-Strongly Disagree. Whenever possible the wording of the questions matched questions used in previous investigations reported in the literature. These questions are identified in Table 1.

Table 1. Survey questions relating WeBWorK to students' mathematical identity

	Survey Question	Dimension of Identity
Q1	Given any WeBWorK problem I could start to answer it, or at least part of it, right away.	Self-efficacy
Q2[a]	Doing my homework using WeBWorK enhanced my learning of mathematics.	Learning/Understanding
Q3	Using WeBWorK has helped me understand material in other courses.	Learning/Understanding
Q4[a]	The use of WeBWorK has helped me develop confidence in doing mathematics.	Confidence
Q5[a]	Solving questions using WeBWorK prepared me for the paper-based class exams in the class.	Confidence
Q6	Doing homework using WeBWorK discouraged me to take more math classes.	Persistence

[a] (Serhan, 2019)

The survey was administered in Spring of 2024 inviting all Mountain College students with experience with WeBWorK at Mountain College to participate. In total we received 109 responses, 97 of which responded to all six of the identity questions. These 97 responses will be analyzed using primarily quantitative methods, specifically through a series of t-tests. Quantitative analysis will include descriptive statistics, comparing our means to results in existing literature, comparing means of individual questions sorted by various demographics, and exploring the correlation within and between the identity-focused questions and other dimensions captured by the survey.

Results

Of the 97 complete responses, 55% of students identified as a minority with 32% identifying as Native American/Alaska Native. Furthermore, nearly 31% (30.9) of the respondents identified as first-generation college students. Therefore, we can say the demographics of our survey participants are representative of the demographics of the student body of Mountain College.

Mountain College Compared to Previous Findings

Comparing the survey results from Mountain College to preexisting results found in literature yielded significant findings. Half of the questions focused on identity were taken from previous studies and their results are listed in Table 2 below.

Table 2. Means for survey questions relating WeBWorK to student mathematical identity

	Survey Question	Previous Findings	Survey Results
Q1	Given any WeBWorK problem I could start to answer it, or at least part of it, right away.	*N/A*	2.3
Q2	Doing my homework using WeBWorK enhanced my learning of mathematics.	*2.4*[a]	2.8**
Q3	Using WeBWorK has helped me understand material in other courses.	*N/A*	3.6
Q4	The use of WeBWorK has helped me develop confidence in doing mathematics.	*2.4*[a]	3.1**
Q5	Solving questions using WeBWorK prepared me for the paper-based class exams in the class.	*2.3*[a]	3.2**
Q6	Doing homework using WeBWorK discouraged me to take more math classes.	*N/A*	2.8

[a](Sehran, 2019) Note: Literature results were recalibrated to accommodate for a reverse-scoring Likert scale
** indicates a p-value less than 0.001

Every question that had a previously reported mean was found to be statistically significant compared to previous findings. For each of the questions a one-sample t-test was run using the mean from the literature. Our analysis found statistical evidence that Mountain College students' average scores not only differed from the previously reported average scores but were lower than all the previous findings. Note that since the Likert scales were presented with 1-Strongly Agree and 5-Strongly Disagree, a higher mean value indicates stronger disagreement with the question statement. A series of one sample t-tests with alpha = 0.05, two-tailed, were used and each difference of means was found to be statistically significant yielding $p<0.001$. These results suggest that at Mountain College WeBWorK may be supporting students' mathematical identity less than at other institutions.

Mountain College Findings by Demographic Group

Table 3 contains results from our survey data. Participant self-reported race is separated into three categories: white, non-minority identifying (White), n = 45; Native American/Alaska Native (NA/AN), n = 31; and non-NA/AN minority (Other), n = 16. Non-responses to the race demographic question (n = 5) were not included in the table or analysis. First-generation status is separated into two categories: (Yes), n = 30; and (No), n = 65. Non-responses to the first-generation demographic question (n = 2) are not included in the table or analysis.

Table 3. Results for survey questions broken out by student demographics

Survey Means by Demographic Groups					
Survey Question	Overall Mean	Race		First-Generation	
Question 1	2.2	White	2.2	Yes	2.2
		NA/AN	2.2	No	2.4
		Other	2.5		
Question 2	2.8	White	2.8	Yes	2.9
		NA/AN	2.7	No	2.8
		Other	2.6		
Question 3	3.6	White	3.6	Yes	3.5
		NA/AN	3.5	No	3.6
		Other	3.4		
Question 4	3.1	White	3.1	Yes	3.1
		NA/AN	3.1	No	3.2
		Other	3.0		
Question 5	3.2	White	3.1	Yes	3.3
		NA/AN	3.2	No	3.2
		Other	3.1		
Question 6	2.8	White	2.9	Yes	2.7
		NA/AN	2.8	No	2.9
		Other	3.1		

A preliminary series of one-way ANOVA tests have been run to explore differences within question responses between demographic groups within questions and thus far no statistical differences have been found. Furthermore, the p-values related to race ranged from 0.323 to 0.785 whereas the p-values related to first generation status ranged from 0.259 to 0.936.

In the presentation we will continue reporting on our analysis including a conversation focused on the correlation between the identity questions and also how the responses to the identity questions correlated with the other dimensions captured in the survey.

Discussion and Implications

In our preliminary analysis, we are noticing that while student responses at Mountain College are statistically different from previous studies, there is very little difference in survey responses based on categories within and across race and first-generation status. This invites questions about considering the data through a different lens. As such, we are considering analyzing the survey results through breaking down responses into cohorts based on both the types of classes taken and initial mathematics course placement. Furthermore, we ask how this free resource might work for development of student mathematical identity.

Student Conceptualizations of Confidence Interval Attributes

The Pennsylvania State University

Interval estimation has become one of the preferred means for communicating the statistical findings of a study. Students, and even experienced professionals, often misinterpret frequentist confidence intervals. As part of the broader study in which this work is situated, we developed an instrument to assess undergraduate students' statistical literacy surrounding confidence intervals. We conducted think-aloud interviews with six students who had recently completed an introductory statistics course. In this work, we qualitatively capture the meanings that students construct about attributes of confidence intervals to inform the results from the instrument. We use grounded theory to model how students conceptualize attributes of confidence intervals and propose evidence of interactions between interrelated ways of thinking. For this paper, we focus on one student's conceptualizations about the confidence level and error attributes of confidence intervals to illustrate our modeling process in detail.

Keywords: confidence intervals, grounded theory, interaction effects, statistics education

Introduction

Hypothesis testing is often presented as a rote multi-step procedure (Horton, 2015; Lock et al., 2017). This training has led many research communities to falsely believe that only statistically significant results are meaningful. The standards adopted by entire disciplines that require statistically significant results for publication perpetuate this belief. As a result, researchers strive to achieve statistical significance, which can lead, and has led, to research malpractice (Collins, 1984; Wasserstein et al., 2019).

Moreover, the outcomes from hypothesis testing are frequently misinterpreted by students and professionals (Hoekstra et al., 2014). Interval estimation has been proposed as a more acceptable alternative since confidence intervals are accessible, readily display the precision of the interval construction method, and are not restricted to a specific null hypothesis (Hoekstra et al., 2014, 2018; Kaplan & Roland, 2022a). However, individuals treat confidence intervals like significance testing when they focus on whether the null value falls in the interval (Wasserstein et al., 2019). As such, it is insufficient for just the *presentation* of the findings to shift from a p-value to a confidence interval; the *interpretation* of the findings must shift as well from that of desiring statistical significance to that of desiring transparency of results. More broadly, there must be a shift from procedural treatment of statistical tools towards building and working with deep, productive meanings and exhibiting quantitative reasoning (Hatfield et al., 2022). Thus, studying individuals' understanding of confidence intervals is imperative.

Literature Review

Individuals, even experienced researchers, grossly misinterpret confidence intervals (Hatfield, 2024; Hoekstra et al., 2014, 2018; Roland & Kaplan, 2022; Saldanha et al., 2024). In fact, even statisticians and authors of introductory statistics textbooks disagree regarding how to

interpret a frequentist confidence interval (Hoekstra et al., 2018; Kaplan & Roland, 2022a). These misinterpretations are worsened by the ambiguity surrounding the word 'confidence' (Kaplan & Roland, 2022a, 2022b). Morey et al. expand upon these misinterpretations of confidence intervals by identifying the most common confidence fallacies: fundamental confidence fallacy, precision fallacy, likelihood fallacy, and fallacy of acceptance. They describe these misinterpretations as fallacies since they are in opposition to Neyman's theory of confidence intervals (Morey et al., 2016). The fundamental confidence fallacy deals with making probability claims about the resulting confidence interval. These claims reference the probability or confidence that any realized interval contains the parameter (Hoekstra et al., 2018; Saldanha et al., 2024). These claims place the confidence in one particular interval, rather than the method where it rightfully belongs (Hoekstra et al., 2014, 2018; Saldanha et al., 2024). The precision fallacy deals with belief about precision based on the width of the confidence interval (Hoekstra et al., 2018; Morey et al., 2016). The precision fallacy manifests itself in the belief that a narrow interval gives more knowledge or suggests that the statistic is a better estimate of the parameter.

The likelihood fallacy is thinking that the confidence interval presents a set of reasonable or plausible values for the parameter. If a value falls inside the interval, it is reasonable, otherwise it is unreasonable (Hoekstra et al., 2018; Morey et al., 2016). Thoughts that align with the likelihood fallacy include assigning probability to individual values or thinking that values in the interval are more likely values for the parameter (Saldanha et al., 2024). When interpreting a confidence interval, individuals naturally want to accept a set of values, which is known as the fallacy of acceptance (Hoekstra et al., 2018; Mayo & Spanos, 2006; Morey et al., 2016). Accepting a value as the true parameter because it falls in the interval is an indicator of the fallacy of acceptance. Other problematic meanings of confidence intervals include believing the interval is a descriptive statistic (Hoekstra et al., 2014), is a set of reasonable values for individual cases (Hatfield, 2024) or for the sample statistic (Kaplan & Roland, 2022b).

After discussing some problematic meanings, we now present a productive meaning of confidence intervals. A person with such meaning would view the process of constructing a confidence interval as entailing randomness, leading to variation in the resulting intervals when the process is repeated. They would also have the ability to conceptualize and articulate the distinction between the procedures for, and results from, obtaining a sample and constructing a confidence interval (Hatfield, 2024). Therefore, in a productive interpretation, the confidence is in the method, not in a particular interval, and there is recognition of uncertainty involved in the process (Saldanha et al., 2024).

There are a few assessments in the statistics education literature to measure understanding of confidence intervals (delMas et al., 2006, 2007). For example, the Comprehensive Assessment of Outcomes in Statistics (CAOS) measures statistical literacy, reasoning and thinking on major topics covered in the introductory statistics curriculum, including confidence intervals (delMas et al., 2007). Conventional practices in assessment development resemble a one-factor-at-a-time design in which each item assesses one idea at a time, independent of the other ideas (see delMas et al., 2007; Sabbag et al., 2015; Ziegler, 2014). From a cognitive perspective, ideas do not necessarily develop in isolation of each other. Rather individuals often coordinate multiple ideas; thus, evaluating the interactions between multiple ideas is crucial (Thompson et al., 2014).

Methods

The work we present here is part of a larger project which investigates students' statistical literacy surrounding confidence intervals after an introductory course. In an on-going feasibility

study, we are developing, validating, and analyzing an instrument to evaluate interactions among attributes of confidence intervals. This paper intends to provide qualitative insight into the instrument by addressing the following research question in support of these broader aims: How do undergraduate students conceptualize, and coordinate their meanings for, confidence level and error in the context of confidence intervals?

Drawing upon the literature (e.g., Hatfield, 2024; Hoekstra et al., 2018; Lock et al., 2017) and our own expertise, we identified several attributes of confidence intervals that are often taught in an introductory course: confidence level, error, sample size, p-value, and method. For this paper, we focus on the first two attributes. We operationalize confidence level as the proportion of times the process of constructing a confidence interval results in an interval that captures the parameter of interest (i.e., success rate) and error as a measure of variability associated with the data and with the sample statistics.

Theoretical Perspective

In this study, we adopt an interpretivist epistemology, in particular, radical constructivism (Stinson, 2020), which we use to guide the formation of models of student conceptualizations about attributes of confidence intervals. We consider knowledge to be constructed by students based on their interactions and experiences, both in life and in the classroom (Stinson, 2020; Thompson, 2008; von Glasersfeld, 1995). A radical constructivist approach acknowledges that students construct different meanings or ways of thinking (Goldin, 2000), reflecting student autonomy.

Interview Protocol

Cognitive interviews are used for a multitude of purposes in mathematics and statistics education (Clement, 2000; Goldin, 2000; Theobold et al., 2023). One benefit is that they are useful for observing students' mathematical/statistical thinking processes and approaches (Case & Jacobbe, 2018; Clement, 2000; Goldin, 2000). In this study, we conducted think-aloud interviews with six students who recently completed an introductory statistics course. We interviewed these students separately, on Zoom, for one hour. We asked students to read and discuss their thinking aloud as they interacted with our items. As needed, we asked follow-up questions. We audio recorded the interviews to obtain detailed transcripts.

Data Analysis

To model how students thought about confidence intervals, we used grounded theory. Grounded theory is a qualitative method for deriving a theory to describe a phenomenon of interest in a manner that reasonably stems from the observed data and has a clearly outlined scope of generalizability (Strauss & Corbin, 1990). We used a generative approach in that we developed our codes/theories based on students' demonstrated thinking about confidence level and error rather than having a priori hypotheses about the meanings students have for these attributes (Clement, 2000). To start, we read the transcripts and flagged sections (sentences, paragraphs) corresponding to each of the five attributes. Starting with the confidence level attribute, we identified codes (concepts) for each section to represent the thinking that students conveyed. We drew upon existing literature and our understanding of students' statements as a basis for our theoretical sensitivity and to inform the open coding process (Strauss & Corbin, 1990). Examples of our codes include: confidence level refers to confidence in the method, fundamental confidence fallacy, confidence level is a success/capture rate, articulates the

normatively accepted relationship between confidence level and interval width. We grouped (categorized) the codes for each student to create higher order descriptions, encompassing multiple concepts (Strauss & Corbin, 1990). We developed a list of defining properties for each category by iteratively revisiting the original sections and making note of instances which supported (or not) the proposed relationship. Elaborating on the nature of this variation enabled us to construct a more nuanced theory describing the phenomenon of interest (Strauss & Corbin, 1990). For this paper, we focus on just one student (whom we call S3) to illustrate in depth how we model students' conceptualizations about the confidence level and error attributes.

Results

Consider the following excerpt from S3 which is part of an exchange on why they chose a provided option that indicated the width of a 90% confidence interval is narrower than that of a 95% confidence interval (for the same sample) because it has a smaller multiplier (critical z-score), leading to a smaller margin of error. This particular excerpt demonstrates S3's meaning for confidence level: "I'm pretty sure we always just kind of grab multipliers off a table so…I don't really remember…I don't know a whole lot about actually calculating it…based on like confidence." From this excerpt, we observe that S3 has a meaning consistent with a procedural acquisition of the multiplier. This excerpt, along with others coded similarly, lead us to believe that S3 has a meaning consistent with a formulaic treatment of confidence intervals. By this we mean that an individual has an understanding of confidence intervals as a formulaic calculation on individual components. Although this meaning allows S3 to articulate the normatively accepted relationship between confidence level and multiplier (as confidence level increases, the multiplier increases in magnitude), this meaning makes it difficult for S3 to determine how intervals with the *same* confidence level, but constructed using different methods, would differ. Moreover, the following excerpt is in response to an item that asks students to explain, if 100 students replicate a given study, how many of the 100 resulting 90% confidence intervals are expected to capture the parameter of interest. This excerpt reveals that S3 has a meaning for confidence level that is consistent with how we operationalized it:

> Alright so the method in this question method in this case is one we're 90% confident in so…therefore, we would *expect*…for every 100 intervals we would. Well, we would simply multiply the number of intervals by the...rate of correct of a…rate of expected correct, of a[n] expected capture…which would be 90.

Here S3 appears to imagine carrying out a process to produce multiple intervals. Further, S3 connects the confidence level to the notion of a success rate (how many intervals capture the true value). Taking the two instances together, S3 appears to coordinate a repeatable calculational process and anticipated success of the results. This thinking supports S3 in articulating the normatively accepted relationship between confidence level and interval width (as confidence level increases, interval width increases) and meanings for confidence.

Consider the following exchange between S3 and the interviewer on a multiple-choice item that demonstrates S3's meaning for error:

> *S3:* Using the empirical rule, the 95% confidence interval for the mean difference in plant heights would take the following form [statistic $\pm$ measure of error expression]. Okay, the empirical rule...in other words 68, 95, 99 point…something.
>
> *Interviewer:* Mhm 7.

S3: Yeah, yeah one standard error...captures about 68%, 2 standard errors captures 95%. So multiplier is 2 should be 2 in this case. So that…(5 second pause)…okay, margin of error. Right. You said margin of error is the…the radius right? That's what I said. So.

Interviewer: Everything to the right of the plus or minus sign.

S3: Yeah, yeah, exactly. So that's the 2…so…so in other words, that would be…that's the result of multiplying the multiplier and the standard error.

From this exchange, we observe that S3 conveys the margin of error as being a distance for the interval, specifically, a radius, and getting the error via a product of components. There is still a formulaic aspect to S3's meaning for error. S3 routinely comes back to the multiplication aspect as well as the Empirical Rule. While S3 can articulate error as a distance quantity, they tend to focus more on the calculations of and with error than articulating any underlying quantitative relationships involving error. Even so, S3 is able to articulate the normatively accepted relationship between standard error and interval width (as standard error decreases, interval width decreases) but lacks sureness in their meaning of error terms apart from the formulas. We note that S3 conveys that the standard error is a property of the data instead of the statistic, and they imagine deviation as referring to differences between the intervals.

When discussing both confidence level *and* error, S3 appears to coordinate their meanings. Consider the following excerpt from S3 which details their reasoning on a multiple-choice item assessing how the standard error and margin of error for a 90% and 95% bootstrap confidence interval (constructed using the same bootstrapped sampling distribution) would compare:

> So standard error is that a property of the? That's I kinda wanna say standard error is a property of the data itself? So I don't think that would differ between the two methods [method of constructing a 90%, 95% confidence interval] but the margin of error *should* differ because that's a matter of how much leeway we give ourselves, how much confidence we're willing to sacrifice.

S3 appears to use their meaning of confidence level as the method's success rate, and their meaning of standard error as a property of the data, to construct a meaning for error that no longer has the distance aspect previously mentioned. Rather, this meaning for error is in-line with the colloquial use of the word error, as in the interval has the property of making mistakes.

Discussion

A consistent meaning that students appear to have is a formulaic treatment of confidence intervals. It would be of interest to study whether a formulaic approach is an efficient way to solve the respective items and/or whether this meaning is influenced by the presentation of the general formula for a confidence interval throughout the instrument. Moreover, S3's conceptualizations of confidence level and error display the interactions between their ways of thinking about these attributes of confidence intervals. This preliminary evidence of interactions among attributes of confidence intervals justifies the need to efficiently estimate these interaction effects and indicates instances of quantitative reasoning (Hatfield et al., 2022) and potentially covariational reasoning (Carlson et al., 2002; Thompson & Carlson, 2017; Zieffler & Garfield, 2009). There is further insight to be gleaned on this front as we have five other students for whom we can model their conceptualizations of the confidence level and error attributes. We also have three additional attributes of confidence intervals (sample size, p-value, method) to analyze. By understanding how students coordinate meanings for attributes related to confidence intervals, instructors can achieve greater clarity on what changes are needed in curriculum or assessment to foster statistical literacy on the topic of confidence intervals.

When Different Conceptions Hold Together: A Case of a Student's Coordinate Systems and Graph Reasoning

Robert Knurek
University of Colorado Denver

Heather Lynn Johnson
University of Colorado Denver

Teo Paoletti
University of Delaware

We report on a qualitative case study of a college algebra student, Jamie, who exhibited multiple conceptions of coordinate systems (Lee et al., 2020) and forms of graph reasoning (Johnson et al., 2020) during a single task-based interview. Our analysis of Jamie's graph sketches and interactions with digital tools during the interview highlighted connections between her quantitative reasoning and conceptions of graphs. Specifically, Jamie's conception of a quantitative coordinate system was closely linked to her reasoning about changing attributes and their relationships, whereas her conception of a spatial coordinate system was closely linked to her reasoning about the physical motion within the dynamic situation. Jamie's case speaks to the complexity of students' quantitative reasoning and illustrates the interconnectedness of their conceptions of coordinate systems and graph reasoning.

Keywords: undergraduate education, technology, quantitative reasoning, graphing conceptions

Sketching graphs is a productive way for students to represent and reason about relationships between attributes in dynamic situations (Carlson et al., 2002; Thompson & Carlson, 2017). However, the effectiveness of this activity is closely tied to students' underlying conceptions of coordinate systems (Lee et al., 2020) and their graph reasoning (Johnson et al., 2020). Emerging research suggests a potential interconnection between these constructs (Johnson et al., 2024; Paoletti et al., 2022). Our goal for this qualitative case study (Stake, 2000) was to analyze a college algebra student's conceptions of coordinate systems alongside their graph reasoning. This study seeks to delve deeper into the relationship between these constructs by exploring the question: What is the nature of students' conceptions of coordinate systems and graph reasoning within digital graphing tasks involving dynamic situations?

Background

Quantitative and Covariational Reasoning

To frame our study, we draw on Thompson's (1994, 2011) theory of quantitative reasoning. According to Thompson, students conceive of attributes of objects as quantities when they consider them to be measurable. When students conceive of relationships between attributes that are capable of varying simultaneously with one another, they are engaging in covariational reasoning (Thompson & Carlson, 2017). For example, consider a situation in which a toy car travels at a constant speed around a traffic cone (Figure 1). Given this dynamic situation, a student may conceive of the toy car's total distance traveled and distance from the cone as attributes that are possible to measure, thereby conceiving of them as quantities. If the student were to conceive of a relationship between these attributes in which they vary simultaneously with one another, then they would be engaging in covariational reasoning.

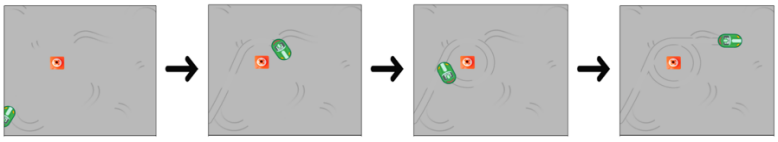

Figure 1. Toy Car Dynamic Situation.

Spatial and Quantitative Coordinate Systems

Lee et al. (2020) distinguished between two kinds of coordinate systems that students may conceive of when representing a situation: spatial and quantitative. A student conceives of a *spatial coordinate system* when they mentally overlay a coordinate system onto a physical or imagined space to determine relative locations within that space. For example, given the dynamic situation in Figure 1, a student may conceive of a spatial coordinate system by imagining a collection of points representing the toy car's position at different moments in time and sketch a graph resembling the toy car's path through the physical space.

A student conceives of a *quantitative coordinate system* when they extract and coordinate quantities from a situation to represent the quantities and the relationship between them in a new space, such as a Cartesian plane. For example, given the same situation, another student may disembed the toy car's distance traveled and distance from the cone, then plot these quantities on a graph with total distance traveled represented on the x-axis and distance from the cone represented on the y-axis. In doing so, the resulting graph would be representing the relationship between the two quantities. Lee et al.'s (2020) distinction offers a framework for analyzing students' conceptions of graphical representations in various contexts.

Graph Reasoning

Johnson et al. (2020) developed a graph reasoning framework to characterize students' conceptions of graphs. The framework includes four broad types of reasoning that encompass students' reasoning about quantities, relationships, and observable aspects of dynamic situations. The first two types of reasoning, *Covariation* and *Variation*, refer to evidence of students' gross coordination of values and gross variation (Thompson & Carlson, 2017). For example, if a student is tasked with sketching a graph of the toy car dynamic situation (Figure 1), they might say, "the distance from the cone decreases at first as the total distance traveled continues to increase, so the graph should start by going down". This response would serve as evidence of Covariation per Johnson et al.'s (2020) framework, as they are attending to the gross change in both attributes. If they only mention the change in one attribute (i.e., "the total distance traveled continues to increase"), their response would serve as evidence of Variation. The third type of reasoning, *Motion*, refers to evidence of students' reasoning about physical motion embedded in dynamic situations (Kerslake, 1977). For example, a student reasoning at a level of Motion might say, "the toy car moves at a constant speed, so the graph should be linear." The fourth type of reasoning, *Iconic*, refers to evidence of students' reasoning about physical features that comprise a dynamic situation (Leinhardt et al., 1990). For example, a student reasoning at a level of Iconic might sketch a graph resembling the path of the toy car, saying, "the toy car's path forms a circle around the cone, so the graph should have a circle too." Johnson et al.'s (2020) framework distinguishes between these four unique ways in which students may conceive of graphs.

Methods

We report on a qualitative case study (Stake, 2005) of a college algebra student, Jamie (pseudonym), who participated in a series of task-based interviews (Goldin, 2000). This study is part of the first author's dissertation, a collective case study conducted as part of a larger National Science Foundation funded project aimed at promoting students' mathematical reasoning by engaging with tasks called "techtivities." Housed in the Desmos Classroom (www.desmos.com), techtivities are interactive tasks based on video animations designed to engage students in quantitative reasoning (Johnson et al., 2020).

The Toy Car Techtivity

In the Toy Car techtivity, students watch an animation of a toy car traveling at a constant speed around a cone (Figure 1). They are asked to consider two attributes: the toy car's total distance traveled and distance from the cone. Next, students are to represent changes in these attributes by dragging "Axis Sliders" along the axes of a Cartesian plane as the animation plays. Students are to sketch a graph relating the two attributes before watching an animation of a computer-generated graph that shows the accurate graphical representation of the relationship.

Data Collection and Analysis

We used purposeful sampling (Gliner et al., 2017) to select Jamie (pseudonym), a college algebra student interested in participating in our study after seeing an announcement posted by her instructor on our behalf. Drawing on teaching experiment methodology (Steffe & Thompson, 2000), the teacher-researcher (TR) conducted exploratory teaching in a series of online task-based interviews (Goldin, 2000), in which Jamie completed four different techtivities. The TR used semi-structured protocols during the interviews.

We analyzed each interview using Wolcott's (1994) description, analysis, and interpretation framework. In the description phase, we documented everything observed during the interviews. In the analysis phase, we inferred Jamie's reasoning based on her actions and utterances. Finally, in the interpretation phase, we connected our findings to related literature, including frameworks from Lee et al. (2020) and Johnson et al. (2020).

Results

Our analysis of Jamie's third interview, during which she completed the Toy Car techtivity, revealed that she demonstrated evidence of multiple conceptions of coordinate systems (Lee et al., 2020) and forms of graph reasoning (Johnson et al., 2020). Through sketches and slider movements, Jamie displayed these constructs in a way that was agentic and meaningful to her.

Conceiving of Attributes as Quantities

Jamie's responses and drawings at the beginning of the techtivity serve as evidence of her conceiving of the toy car's total distance traveled and distance from the cone as quantities (Thompson, 1994, 2011). When the TR asked Jamie to describe the toy car's distance traveled, Jamie traced the entire path of the car with a sketch tool and said, "As the car's moving, he's getting further in distance." When the TR asked Jamie to describe the toy car's distance from the cone, Jamie drew a straight line between the toy car and the cone and said, "The distance is that, but if he's like in this area [puts cursor near the cone], the distance from the cone is way shorter."

Representing Different Aspects of the Situation with Sliders

Jamie dragged the horizontal Axis Slider (intended to represent Distance Traveled) from left to right along the x-axis as the toy car traveled. She followed this up by saying, "I just kept moving my slider until it basically stopped moving, and I tried to go at the same speed." This response, along with her previous description of distance traveled ("As the car's moving, he's getting further in distance"), demonstrate evidence of Variation and suggest that Jamie used the slider to represent the change in the toy car's distance traveled using the horizontal slider.

Next, Jamie dragged the vertical Axis Slider (intended to represent Distance from Cone) upwards along the y-axis as the car traveled towards the cone, downwards along the y-axis as the car traveled around the right side of the cone, and then upwards again as the car traveled around

the left side of the cone and continued away from the cone (Figure 2). She went on to describe her slider movements:

> So I assumed since [the slider] was in the middle of the graph, that it would want me to go back down when it did that little loop. So that's what made me move it. Like that's what made me move [the slider] down and then go back up 'cause it does do a little circle.

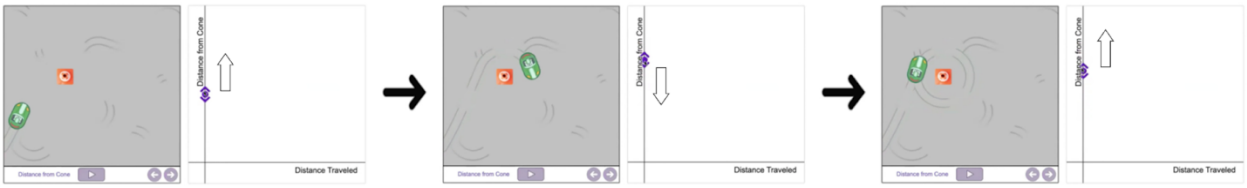

Figure 2. Jamie's Movements with the Vertical Axis Slider (Distance from Cone).

Jamie's movements with the vertical Axis Slider suggest that she was representing spatial aspects of the dynamic situation. She appeared to use the slider to match the toy car's vertical displacement from the bottom of the screen. Jamie's response shows evidence of Motion, as she is describing how her movements with the slider were meant to match the position of the toy car.

Demonstrating Different Conceptions

Jamie proceeded to sketch a graph on the Cartesian plane (Figure 3). The TR asked Jamie to describe her sketch, and she proceeded to talk about different sections of her graph.

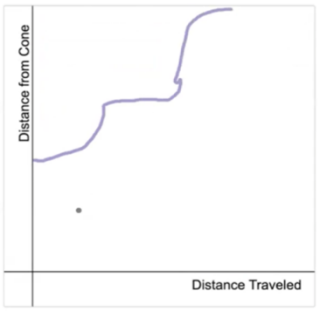

Figure 3. Jamie's Graph Sketch.

> *Jamie*: Yeah I feel like it might be going up, and then possibly, like I don't know if a graph could do this, but plateau out and then like all the way up.
>
> *TR:* And can you talk more about that plateau?
>
> *Jamie:* The plateau is when it's in the circle when it's staying at that one point, but the distance is still moving. So that's why I drew that there. And then after once it gets out of that circle, the distance from the cone goes back up along with the distance traveled.

Jamie's responses highlight multiple forms of graph reasoning. Her first comment, "it might be going up," demonstrates evidence of Motion, as she is attending to the movement of the car in space. Her second comment, "the distance from the cone goes back up along with the distance traveled," demonstrates evidence of Covariation, as she is describing the relationship between attributes.

Jamie proceeded to the last part of the techtivity and watched an animation of the computer-generated graph. When the TR asked Jamie for her initial reaction to the graph, she talked about the difference in how the computer treated the attribute on the y-axis.

> With their graph, they moved that dot down and then they go back up. I didn't think to move it down because when I did my graph, when I did the little move thingies, I more followed the car. Like the car's going up, so I'm going up. And then when the car came back around, I stayed and then I went back up.

Jamie's responses indicate that she situated her original graph (Figure 3) in a coordinate system containing both quantitative and spatial components. The left-most section of Jamie's graph represents the path of the car (i.e., "it might be going up"), indicating a spatial coordinate system. However, the middle ("plateau") and right-most sections represent the gross change in attributes (i.e., "the distance from the cone goes back up along with the distance traveled"), indicating a quantitative coordinate system.

Discussion/Conclusion

We explored the nature of a student's conceptions of coordinate systems (Lee et al., 2020) and graph reasoning (Johnson et al., 2020) within a digital graphing task involving a dynamic situation. Throughout the course of one interview, Jamie demonstrated evidence of both kinds of conceptions of coordinate systems (spatial and quantitative) as well as different forms of graph reasoning (Motion, Variation, and Covariation). Notably, she drew on these different ways of reasoning in ways that supported her goal of graphically representing the dynamic situation. Jamie's case speaks to the complexity of students' conceptions of coordinate systems and graph reasoning.

Our study supports the notion that students' conceptions of coordinate systems (Lee et al., 2020) and graph reasoning (Johnson et al., 2020) are interconnected (Johnson et al., 2024; Paoletti et al., 2022). On the screen with the Axis Sliders, Jamie demonstrated Variation when representing the change in attribute, and Motion when representing spatial aspects of the dynamic situation. While sketching a graph, Jamie demonstrated Covariation in a quantitative coordinate system and Motion in a spatial coordinate system. In other words, Jamie's conception of a quantitative coordinate system related to her reasoning about changing attributes and their relationship, while her conception of a spatial coordinate system related to her reasoning about the physical motion embedded in the dynamic situation.

Our analysis is ongoing. Jamie is one of three students who the TR has conducted multiple interviews with using multiple different techtivities. We are continuing to employ exploratory teaching (Steffe & Thompson, 2000) and use Wolcott's (1994) framework to learn about how students' conceptions of coordinate systems (Lee et al., 2020) and their graph reasoning (Johnson et al., 2020) are related.

Equity-Based Mathematics Teaching Practices in Pre-Service Teachers' Lesson Plans

Zareen Gul Aga
James Madison University

Youngjun Kim
Montclair State University

Su San Lim
Montclair State University

As K-12 classrooms have become more culturally and linguistically diverse, it is important to prepare pre-service teachers (PSTs) to develop their knowledge of designing and implementing instruction based on equity-based mathematics teaching practices (EMTP). We analyzed 41 PSTs' lesson plans designed in a middle school mathematics methods course from five semesters. A theoretical thematic analysis revealed which EMTP categories appeared in the lesson plans. Findings indicate that PSTs seem comfortable and familiar with some categories, but they need support with other categories. In addition, methods courses should focus on EMTP so that PSTs strike a balance between EMTP categories by engaging students in non-routine, high cognitive demand tasks and by supporting diverse learners in mathematics classrooms.

Keywords: Pre-service teachers, Equity-based mathematics teaching practices, Culturally responsive mathematics teaching, Teaching mathematics for social justice

Objectives

In the U.S., the K-12 classrooms have become increasingly diverse and there is a need to prepare mathematics teachers who can cater to the learning needs of these students while maintaining high standards of teaching and learning (Aguirre & del Rosario Zavala, 2013; Association of Mathematics Teacher Educators [AMTE], 2017; National Council of Teachers of Mathematics [NCTM], 2014). In this regard it is important to prepare pre-service teachers (PSTs) to design and implement instruction based on equity-based mathematics teaching practices (McGraw et al., 2023; Moldavan & Gonzalez, 2023).

Equity-based mathematics teaching practices (EMTP) are pedagogical actions that seek to challenge existing educational norms and allow students to actively participate in learning mathematics (Chao et al., 2014). Such teaching builds on students' strengths, connects mathematics learning to students' knowledge and experience, and engages students in solving problems that are relevant to them (Aguirre, 2009; Aguirre et al., 2012; Civil, 2007; Gutiérrez, 2002; Gutstein, 2006; Turner et al., 2012). EMTP can aid in the development of students' positive mathematics identities so they see themselves as doers of mathematics (Berry, 2008; Boaler, 2002; Martin, 2000, 2009; Stinson, 2008). There is a need for teachers to develop classrooms where students can see themselves as mathematicians (Aguirre et al., 2024).

Our study focuses on instances of EMTP included in the lesson plans. The specific research question is: *What EMTP can be gleaned from PSTs' lesson plans designed to connect mathematics and social justice learning goals?* For our study, we analyzed 41 PSTs' lesson plans designed in a middle school mathematics methods course. We engaged the PSTs in developing mathematics lesson plans that included both mathematics and social justice goals.

Theoretical Framework

Mathematical identity can be defined as beliefs that students develop about their own ability to use mathematics effectively and in various contexts, versus being unable to do mathematics (Aguirre et al., 2024). Identity itself can be defined as the stories people tell about themselves or that others tell about them (De Fina, 2015). Students' identities outside of school can play a

powerful role in how they perceive themselves as students, both in general and specifically as mathematics students (Martin, 2000).

Aguirre and colleagues (2013) defined five EMTP that can help develop students' mathematics identities. These practices are: Going deep with mathematics; Leveraging multiple mathematical competencies; Affirming mathematics learners' identities; Drawing on multiple resources of knowledge; and Challenging spaces of marginality. These practices can overlap and work together to support students in feeling a sense of belonging inside mathematics classrooms (Allexsaht-Snider & Hart, 2001; Espinosa, 2023).

Here we provide a brief description of each of the five EMTP. Going deep with mathematics suggests that mathematics lessons include high cognitive demand tasks that allow students to become mathematically proficient. Leveraging multiple mathematical competencies means valuing students' areas of strength in terms of mathematics, and providing learning opportunities where students with various strengths can serve as resources. Affirming mathematics learners' identities refers to instruction that can support the development of a student's mathematical learning identity. For example, the teacher encourages perseverance in problem solving, removes a focus on speed in computation, allows students to fix their mistakes and frames mistakes as opportunities for learning. Drawing on multiple resources of knowledge encourages a teacher to perceive the student as a source of knowledge and experiences and use the student as a resource for teaching and learning mathematics. Students might have mathematical, cultural, linguistic, interest-based, family or community knowledge. The teacher can use this knowledge to connect mathematics to real life experiences and encourage students to solve problems connected to their lives. Challenging spaces of marginality stresses that teachers let go of the traditional mathematics teaching practices with a focus on lecture and also to question biases about who should be in a mathematics classroom. According to this practice teachers should acknowledge the various ways in which students can be mathematicians and expand their own vision of what it means to do mathematics.

Methods or Modes of Inquiry

We employ Phenomenology to identify instances of equity-based practices in the PSTs' lesson plans. Phenomenology allows us to analyze the lesson plans to unpack PSTs' perceptions about EMTP based on the activities included in their lesson plans (Moran, 2000). In other words, we analyzed our data while PSTs' were not explicitly asked to design their lesson plans based on the EMTP. By doing so, we were able to obtain spontaneous, not intentional, patterns of PSTs' use of EMTP in their lesson plans.

The study took place at a mid-sized university in the Mid-Atlantic region of the United States inside a middle school mathematics methods course. The course was geared towards pedagogy of mathematics and specially focused on culturally responsive mathematics teaching and teaching mathematics for social justice. PSTs were asked to develop lessons that included both mathematics and social justice goals. They were asked to include at least one social justice standard (Learning for Justice, 2022) as a social justice goal. PSTs were also required to include supports for emergent multilingual learners (EMLs) in their lesson plans.

Participants were 41 PSTs enrolled in the methods course during Spring 2021, Fall 2021, Spring 2022, Fall 2022, and Spring 2023 semesters. PSTs' lesson plans from these semesters were analyzed. Since our research question is explicitly related to specific teaching practices, theoretical thematic analysis was employed to report patterns within our data (Braun & Clarke, 2006). Due to our focus on equity-based practices, the lesson plans were analyzed based on

categories of Aguirre et al.'s (2013) five equity-based mathematics practices. We perceived each of the practices as follows:

Table 1. Description of five equity-based mathematics teaching practices.

Category	Description
Going Deep with Mathematics	Student engagement in high cognitive demand tasks, generating questions, using tasks connected to student interests, engaging students in problem solving and applying mathematical concepts.
Leveraging Multiple Mathematics Competencies	Tasks with multiple entry points, engaging students in problem solving, using various mathematical representations, discussions, collaboration and learning from strengths of other students.
Affirming Mathematics Leaners' Identities	Activities that allow student's confidence in their math ability to increase, developing persistence in problem solving, providing various ways for students to demonstrate their math prowess.
Drawing on Multiple Resources of Knowledge	Using students as a resource for learning mathematics, e.g., using data, using students' own knowledge to come up with ideas, themes, conjectures, working in pairs or groups, using peers as a resource.
Challenging Spaces of Marginality	Encouraging marginalized students to become confident math learners, positioning students as math experts, making students feel welcomed in math class, incorporating student interests.

Results

In this section we provide an account of the EMTP that we gleaned from the body of the lesson plans, where we did not specifically ask the PSTs to use these practices. We share what each practice looked like, and provide examples of what was included in the lesson plan. We noticed that Drawing on multiple resources of knowledge was evident in a majority of the lesson plans (29), followed by Leveraging multiple mathematical competences (21), and Affirming mathematics learners' identities (12). We only noticed a few instances of Going deep with mathematics (5) and Challenging spaces of marginality (4).

Drawing on Multiple Resources of Knowledge (29)

PSTs' lessons that included this practice, positioned peers or students themselves as learning resources, followed by an academic resource like a book or handout. Some examples of activities where students employed their peers as a resource included: Think-Pair-Share; students will listen to other students' letters and engage in conversation about free and reduced lunch; teacher will ask if any other group solved the problem differently, if so have them share. These examples take the focus away from the teacher as the only resource of knowledge, guidance or support, and students can learn to depend on their peers to solve problems. Likewise, examples of students seeing themselves as decision makers were: students will be tasked with creating their own mini poster based on at least one of their ideas; students will participate in mathematical modeling and use their own ideas and views to create problems about the picture on the Jamboard; students will create a blueprint of an outdoor space of their choosing … they will use

transformations to make images of the shape around the blueprint; students will research local organizations and choose one that the money in the girl scouts activity will go to; students will get their data for this activity from the United States Interagency Council on Homelessness website, students will decide what data they want to use for their argument. These examples demonstrate the ways in which PSTs perceived classroom activities that allow students to see themselves as experts who are able to take charge when solving a problem.

Leveraging Multiple Mathematical Competencies (21)

PSTs included various forms of activities in their lessons to draw on students' mathematical competencies. For example, allowing students to work independently on activities such as the number line activity, writing ideas on an index card, collecting their own data and then analyzing it. PSTs also planned for students to engage in group work to discuss ideas, represent algebraic expressions, do practice problems, come up with multiple representations or compare their own work with a partner. Planning for both group work and individual work may allow students who prefer a specific working style to have a chance to participate in class. Other activities that could allow the teacher to leverage multiple mathematical competencies were: making and presenting posters, students coming up with various mathematical representations, direct instruction, making comparison between graphs to name a few.

Affirming Mathematics Learners' Identities (12)

PSTs' lessons paid attention to students' interests and we coded instances of student interest as Affirming mathematics learners identities. An example of such an activity is the Minecraft activity where students research and brainstorm if squares and cubes are the best shape for Minecraft, create 3-5 argumentative points that defend their side, then draft a letter of persuasion to Minecraft creators to defend their ideas. Another example includes students choosing a resource from a town map that they wish to move to benefit more people in their area, then students recreate the town map with the resource in its new location (with correctly identified and plotted ordered pair) on a poster or Google Slide, and defend why that resource needs to be placed in that position. These examples point towards PSTs employing students' interests in real life scenarios to help them engage in doing mathematics. In addition, PSTs also supported student participation in the classroom by encouraging students to ask questions and have discussions, assigning roles during group work so that all students get a chance to participate.

Going Deep with Mathematics (5)

While we assumed this would be the most commonly observed equity-based practice, we only coded five instances of Going deep with mathematics. The lesson plans included high cognitive demand tasks, real-world applications, and productive struggle to be in this category. While all the lesson plans included real-world applications we only coded instances where the tasks were designed to maintain a high level of cognitive demand for the students.

Challenging Spaces of Marginality (4)

Although we were expecting to notice little to no instances of this EMTP in the PSTs' lesson plans, we coded four instances of Challenging spaces of marginality. Examples for this practice include: teacher will give some students a differentiated version of the worksheet; teacher will ask guiding questions if students are struggling; students will individually work on their project, however, they will engage in mathematical conversations with their peers and encourage one another through the process; students should be working to get through the math and reflection

with one another as mathematicians do when they are attempting to solve a problem. We noticed that all instances in this category were ways to differentiate instruction.

Discussion and Conclusions

We had sought to learn what PSTs' lesson plans reveal about their use of EMTP. The lessons included mathematics and social justice goals. In addition, PSTs were asked to include supports for EMLs. The EMTP that PSTs included in the body of the lesson plans reveal teaching practices that they were comfortable and/or familiar with. The highest instance of Drawing on multiple resources of knowledge points towards PSTs' knowledge of this practice. Likewise, including activities that would leverage multiple mathematical competencies was another practice with which PSTs seemed to be familiar.

Affirming mathematics learners' identities was an area that PSTs needed support with. This means PSTs need to learn about supporting the development of students' mathematical identities. PSTs' coursework should highlight that developing students' mathematical identity requires teachers to pay attention to students' lived experiences, their feelings towards mathematics and their sense of belonging in mathematics classroom (Darragh, 2013; Kaplan & Garner, 2017). Teachers need to maintain a balance between teaching the content and supporting the development of students' mathematical identities by catering to the learning needs of students and creating inclusive classroom environments (Miller-Cotto & Lewis, 2020).

Our PSTs also needed support with both Going deep with mathematics and Challenging spaces of marginality. According to the Culturally Responsive Mathematic Teaching framework developed by Zavala and Aguirre (2023), teachers need to provide opportunities for students to engage in non-routine, high cognitive demand tasks that foster the development of their analytical and critical thinking skills (Smith & Stein, 1998). Developing deep understanding of mathematics is a major goal of equity-based mathematics teaching practices (Aguirre 2009; Gutstein 2006). Students, in particular EMLs, might need various supports and scaffolded instruction for successful engagement with such tasks (Anhalt, 2014; Turner et al., 2024).

With regards to Challenging spaces of marginality we found that our students' lessons included supports that could best be seen as differentiation. Differentiation can be understood as ways in which teachers make instructional decisions based on students' readiness, their interests and learning needs (Tomlinson, 2017). This includes developing a classroom community where teacher pays attention to excellence in instruction, uses assessment to make instructional decisions regarding students' learning needs and pays attention to tasks that are meaningful to the students, connecting the content to the real world (Hocket & Doubet, 2021). While there is overlap between differentiation and Challenging spaces of marginality, there needs to be a special focus on making mathematics classrooms inclusive spaces for marginalized students (Aguirre et al. 2024). This includes teachers becoming aware of their own biases and engaging in activities that challenge "deficit thinking, segregation and harm" (p. 65).

Our findings indicate that a greater focus on EMTP in PSTs' methods courses is needed to help them intentionally include these practices in their lesson plans. Devoting time in the methods courses to unpack these pedagogical ideas could allow the PSTs to ask questions and learn how to identify these practices during their field experience. We noticed that PSTs included aspects of EMTP that were highlighted in their courses. Guided by the findings, our team will focus on developing method course resources especially focusing on equity-based teaching practices that were missing, or not well attended to in these lessons. We will also focus on supporting field experience personnel to learn about these pedagogical ideas so they can highlight these practices in their classrooms for PSTs during field experience.

Building Hallways to Collaborative Reasoning in Inquiry-Oriented Linear Algebra Activity

Jessica L. Smith
Utah Valley University

Matthew Mauntel
University of New Hampshire

Zachary Bettersworth
Western Kentucky University

This study examines how students engage in collaborative reasoning while working through an inquiry-oriented task on null space in linear algebra. Three students participated in a series of five online group interviews, followed by an individual interview. The task sequence involved exploring subspaces and null spaces using pathways in a school map. We analyzed interactions and identified moments where students built on or connected to one another's ideas, influenced each other's reasoning, or left space for others to contribute. Our findings suggest that students' collaborative reasoning evolved over time, with instances of adopting and leveraging peers' methods. We highlight the role of positioning in group dynamics and how students' contributions to collaborative reasoning influence their understanding of mathematical concepts. The conclusions emphasize the importance of collaborative learning environments in facilitating deeper mathematical engagement and reasoning.

Keywords: collaborative reasoning, positioning, null space, inquiry-oriented instruction

Active and collaborative mathematics classrooms have been found to benefit students' overall mathematical experiences (Freeman et al., 2014; Laursen et al., 2014; Rasmussen et al., 2020), to improve student attitudes toward math (Laursen et al., 2014; Zakaria et al., 2010), and to decrease math anxiety as compared to that related to lecture-based courses (Gholamali Lavassani et al., 2011). Active learning often involves group and whole class discussions and thus comprises students sharing their ideas and engaging with others. Indeed, collaborative math classrooms using group work have been seen as promoting equity in learning (Esmonde, 2009). However, group work can position particular students with authority in their own learning (Langer-Osuna, 2011). Within these positionings, some students can be seen as holders of mathematical knowledge and thus have their ideas explored more often and thoroughly. In contrast, others might not have their ideas explored as often. In this study, we examine the ways three students reason collaboratively in an inquiry-oriented group interview. We investigate the ways students interact with each other's ideas and the inherent positioning in those interactions. We are interested in the ways students position themselves, each other, and each other's ideas while working toward a common goal: understanding null space in the context of an experientially real task.

Conceptual Framework

Inquiry-oriented instruction is one subset of collaborative learning centering students' ways of reasoning and discourse (Kuster et al., 2017). Making students' ideas central to math learning involves navigating differences in reasoning, making these ways of reasoning public, and students interacting with and engaging in each other's ideas in small-group and whole-class discussions. Additionally, it is intended that students work collaboratively to explore, reason about, and connect these different ideas. Students work together to eventually generalize and formalize the math concept of interest.

However, by selecting which ideas to bring forward and how to sequence them, students and the instructor are implicitly assigning value to particular ways of reasoning (Langer-Osuna, 2017). In small groups, the ideas students explore and choose to bring to the class are often

considered the most mathematically correct, which positions students in the group as either having mathematical knowledge or not. The ways that people are positioned can affect which ideas are elevated during problem solving (Langer-Osuna, 2016, 2018). In addition, how a teacher evaluates the merit of a student's work can affect how the group positions and assigns authority to that student. Students' positionings, whether positioned by themselves or others, are informed by factors such as social standing, academic standing, race, gender, SES, and more. For instance, a student who is seen as holding more mathematical knowledge might have their ideas privileged or leveraged more often. However, if the latter student is considered socially popular, then there is potential for their ideas to be taken up more frequently by their peers.

Collaborative learning has been defined as "the form of classroom organization in which students work together, in small groups, on a shared activity and with a common goal" (p. 57, Sam & Tan, 2011). For this study, we focus our attention on collaborative activities such as students' engagement with others' ideas, the connections students make between their ideas, and whether certain ideas were leveraged. This is because we are interested in the ways that students privilege certain ideas over others when engaging in collaborative activity. This inherently involves positioning because if there is collaboration, then students will always be saying something about their own or others' ways of reasoning, whether implicitly or explicitly. These activities have not been explicitly explored as part of collaborative reasoning. Thus, we examine students' positioning within the context of an IOLA task sequence. In our analysis, we seek to answer one research question: *How do students reason collaboratively about null space within an inquiry-oriented task sequence?*

Methods

Three students from across the Eastern United States were interviewed over the course of three weeks by the second author during five collaborative online Zoom interviews. All the students were white males who had recently completed a course in differential equations. Two of the students, Henry and Tyler, had taken linear algebra previously, and Spade had not. Each of the interviews was recorded and transcribed. PDF scans of students' written work were collected via email after each interview.

During the first four interviews, the students participated in a task sequence on subspaces designed for the IOLA curriculum (Andrews-Larson et al., in prep; Plaxco et al., 2021) that supported a conception of vectors as pathways in a school map. The end goal of the sequence was to have students investigate the null space of a linear transformation. In the task sequence, the linear transformation is conceptually represented as a matrix that transforms camera data vectors into room population change vectors. The null space of this linear transformation can be conceived as all the camera data vectors that result in no change in the population of all four rooms, which can be thought of as loops in the school map. The interview on the fifth day was designed to be a playful task where the students were asked to take the original map, rearrange the rooms and hallways, and determine the effect on the null space.

The interviews were transcribed using Zoom. For our preliminary analysis, each author reviewed each video and identified episodes of collaborative activity. These episodes were then reviewed by the group, and collaborative reasoning actions within each episode were identified.

Findings

In this section, we illustrate instances of the three ways that students collaboratively reasoned (and bold those instances) about null space while interacting with each other throughout the interviews. We begin by providing examples from the first day because all three students were

still developing a working relationship with each other and the interviewer. In later interviews, all three students became more familiar with each other and their mathematical ideas. However, we still share findings from the first teaching interview specifically because our students were exhibiting collaborative activities despite the fact they were still getting comfortable with the interview format and each other. Then we provide additional examples from the later days choosing examples that best illustrate the ways our three students reasoned collaboratively.

Day One: Representing All Pathways Between Rooms

In this section, we will discuss the three main collaborative activities in which we saw students engage: one student's reasoning influencing another's, one student connecting their way of reasoning to another's, and students leaving space for another to talk. The students were asked to find a way to represent all possible solutions to movement around the West Wing. The interviewer allowed students time to think on their own and then to talk to each other. For context, Tyler was not present for about 30 minutes of the interview due to a bad connection.

Henry began by saying it reminded him of "a solution set to a matrix or something, so I'm thinking we need to have two linearly dependent vectors and then add two weights to them." Beyond connecting his reasoning to more formal linear algebra concepts, Henry was also able to situate these ideas in the context of the task. He explained that to represent movement from room C to room C, they could do the square loop and the triangular loop and that some combination of these loops would always get them from C to C. However, for A to C, they needed to add on a vector showing movement in cameras 1 and 2 in addition to any amount of loops.

Spade starts his explanation by saying he was "a little lost" but still explained how he was reasoning about the problem. He mentioned doing some sort of n-1 approach but voiced not knowing how to explain it. Henry asked if he meant representing "it as a summation or something." Spade explained that the ways you go from C to C are all the way around, so using the vector <1 1 1 0 1> as many times as you go around that path. Henry started, "Yeah, I think that's actually, I don't want to interrupt you but–actually, just keep going," **making space** for Spade to continue his explanation and contribute to the pair's collaborative reasoning. Spade explained that you just keep adding the vector as you do the path more times, again mentioning n-1 without elaboration. Henry then **made a connection between their ways of reasoning**, explaining that they both used vectors to represent the loop paths and that you can do those as many times as you want. Doing these loops continuously led to needing scalars. This interaction ends with Spade agreeing with Henry. Spade ultimately adopted Henry's way of reasoning about the hallway movement, using vector expressions to represent loops. When Tyler joined the interview again, Spade explained that each vector in the expression representing solutions to movement from C to C represents a loop one could take around the hallways. Spade added that you can do those loops multiple times, introducing the need for scalars. His explanation showed that **Henry's reasoning influenced his own** regarding pathways between rooms.

Day Two: Connecting Camera Data Vectors to Population Change Vectors

During the Day 2 interview, the students began associating specific camera data vectors (e.g., <5 3 5 4 7>) with the corresponding population change vector. For reference, the population change vector associated with the <5 3 5 4 7> camera data vector should be <6 2 -6 -2>, which means 6 students enter classroom A, 2 students enter B, etc. Spade offered his population change vector first, <6 2 -2 -2>, but qualified his response with, "I think I'm a little lost in my work." Tyler said he "almost got that but had different ones for C and D" Tyler then explained his approach to determine why his vector was different from Spade's. Tyler's approach involved a

system of equations that emerged from thinking about the "inputs and outputs" for each classroom, and he explained that this also helped in determining the population change of each classroom, shown in Figure 1. Henry commented that the sum of all the entries of any population change vector should be zero, even though Tyler initially mentioned (before explaining his approach) that he knew his solution could not work because he was "adding students to the system." When moving to the next problem, Henry wanted to represent Tyler's system of equations as a matrix **demonstrating how Tyler's reasoning influenced Henry's**. Spade said he was "trying to just wrap my head around it…I understand what Tyler did, that's what I was trying to do pretty much," demonstrating that **Spade was also influenced** by Tyler's input/output approach. It is worth noting that even though Spade said he was still trying to make sense of the connection between the camera data vectors and population change vectors, he was the first to volunteer a solution to both problems.

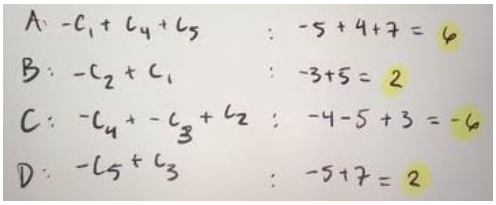

Figure 1: Tyler's system of equations approach to determine the population change vector corresponding to the given camera data vector.

Before moving on to the second camera data vector, **Henry explained a connection between Tyler's system of equations** and the corresponding matrix representation, with which Tyler agreed. It appeared that both Henry and Tyler were interested in using matrices to determine the population change vector for the second camera data vector. For reference, the population change vector associated with the camera data vector <5 5 3 2 3> is <0 0 0 0>. At the end of their working time, Tyler was the first to respond saying that he "did it Henry's way," which implied that **Tyler was influenced by Henry's matrix reasoning**. Again, Tyler did not initially use matrices but used matrix multiplication for the second camera vector (Figure 2a). Spade then explained "I did it your way Tyler…Yup, I got zero for all of them," demonstrating again that Spade was **influenced by Tyler's reasoning** (Figure 2c). When asked who wanted to volunteer to share after Spade finished his explanation, Tyler responded, "Either way, we'll probably say the same thing," **leaving space for Henry** to explain his idea. Henry proceeded to explain his matrix multiplication approach, **making connections** to Tyler's use of systems of equations (see Figure 2(b)). It should be noted that Tyler recognized that he should have placed the coefficient matrix to the left of the camera data vector (Figure 2a) and proceeded to give a thorough explanation of the relationship between the matrix equation and his initial systems of equations approach, demonstrating **a connection to Henry's approach** and his initial approach.

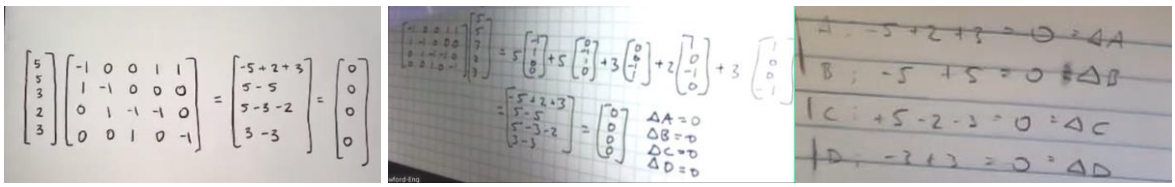

Figure 2: a. Tyler's approach using matrices based on Henry's explanation, b. Henry's matrix multiplication approach that corresponds to Tyler's system, c. Spade's system of equations approach based on Tyler's explanation.

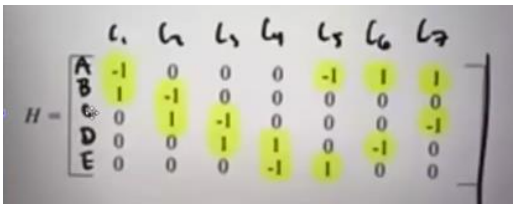
Day Four: Developing Maps from a Matrix

The students were asked to construct maps corresponding to the matrix (Figure 3).



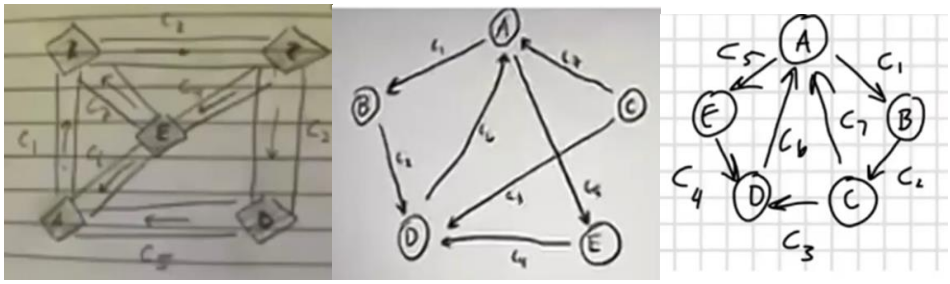


Figure 3: Matrix with Tyler's highlighting.

Each of the students worked independently and then were asked to share their work. Spade began by sharing that there was an additional room and hallway when compared to the previous map. Thus, he took the previous map, added a room in the center, and connected the hallways (Figure 4a), saying that he just "kinda did it." Tyler created a map (Figure 4b) by considering the entries in each column, that "the negative one" was people "leaving somewhere" and "the positive one" was people "arriving somewhere." This idea gave him a way to connect rooms in his map. Henry's map (Figure 4c) was similar, and he **explicitly connected his reasoning** to that of Tyler except Tyler's "went counterclockwise." After listening to Tyler and Henry explain their map, Spade redid his map, **building his own reasoning off of Tyler's reasoning**. When the students were sharing out, Henry went last, making space for the other students to share first.

Figure 4: Student-generated hallway maps for the given matrix.

Conclusion and Discussion

In the first day of the interviews, students began to reason collaboratively by engaging in and connecting each other's ideas, even as far as to adopt another's way of reasoning. Henry was eager to make connections between his and Spade's ways of reasoning but instead made space for Spade to continue his explanation. These key ways of collaboratively reasoning continued throughout the interviews. For instance, Tyler tried Henry's method of developing a matrix equation, while Spade adopted Tyler's method of setting up a system of equations. We see from these examples that all three students reason interdependently, where students were connecting, building off, making space for, and sometimes adopting each other's ways of reasoning. These activities played a pivotal role in how students reasoned collaboratively and developed their understanding of null space. In the next stage of our analysis, we plan to examine our data more thoroughly to find additional episodes of collaborative reasoning. We are interested in further exploring the implications of students making space, or not, for each other, in addition to our other key ways of collaborative reasoning.

Derivative Process-Object Preferences of Post-Secondary Teachers

Michael Gundlach
Utah Valley University

Derivatives are often considered the central part of introductory calculus (Kidron, 2019). While there has been consideration of how non-mathematicians use the derivative differently than their mathematical colleagues (Dray et al., 2019), there has been no survey data to aggregate these differences over many respondents. This study begins to explore how such data can be gathered and analyzed using a survey generated by the researcher to determine the process-object conception of the derivative (Dray et al., 2019; Zandieh, 2000) favored by various post-secondary teachers. In its current form, the survey distributed showed few significant differences between favored process-object levels in the framework of Dray and colleagues (2019). Survey improvements are discussed.

Keywords: calculus, derivatives, STEM education

Calculus is often used as a "gatekeeper" or "filter" for STEM majors (Bressoud et al. 2015). In other words, students must first pass calculus before entering upper-level non-mathematics classes. Ostensibly, this is to ensure that students are prepared to use calculus concepts in non-mathematics classes. However, researchers have found that calculus may not be fulfilling this preparatory purpose, with many students seeing their mathematics classes as disconnected from their future careers. (Black & Hernandez-Martinez, 2016; Brown et al., 2008; Di Martino, 2019; Hernandez-Martinez & Vos, 2018; Rellensmann & Schukajlow, 2017; van der Wal et al., 2017; Vos, 2018). Graduates of various engineering programs have "perceived their mathematics courses as islands, with no relation to the rest of their education" (van der Wal et al., 2017, p. S98). Similarly, others have noted that "For too many students, [calculus] is either an insurmountable obstacle or—more subtly—a great discourager from the pursuit of fields that build upon the insights of mathematics" (Bressoud et al., 2015, p. v).

Many studies have explored how to improve calculus instruction, most notably the 2015 Mathematical Association of America (MAA) national study of college calculus (Bressoud et al., 2015). These studies have often focused on instructional methods, with less emphasis on aligning content with the needs of non-mathematics classes. Some researchers have sought to understand how different professionals understand and use derivatives (e.g. Dray et al., 2019), but there have been few large-scale examinations of the needs of students entering non-mathematics classes. A notable exception to this was a MAA workshop in 1986 to discuss how calculus could better serve students pursuing non-mathematics majors (Douglas, 1986). However, with more recent research showing students struggling with mathematics concepts in their major coursework, more work is needed to refine calculus curriculum to better meet students' mathematical needs.

The goal of this study was to pilot a survey to determine the aspects of the derivative most valued by teachers of non-mathematics courses and to compare those data with those of the mathematicians teaching calculus courses. The survey focused on the derivative since the derivative is the central concept covered in introductory calculus classes (Kidron, 2019). If this survey can be refined, validated, and deployed to a national or international audience, the results could be used to offer recommendations for how calculus curriculum could be improved to better serve all students.

Theoretical Framework

This survey was designed to align with the framework for representations of the derivative developed by Dray et al. (2019). These researchers sought to design a framework to describe the differences that had been observed in how mathematicians and non-mathematicians use the notion of a derivative outside of an introductory classroom context. This framework was itself an expansion of a framework developed by Zandieh (2000) to organize the facets of student understanding of the derivative.

The redevelopment of Zandieh's (2000) framework by Dray and colleagues (2019) stemmed from observation made by the researchers while mathematicians and non-mathematicians were asked to find a derivative on a "partial derivative machine." Using this machine, participants could adjust strings on one part of the machine to change the position of weights on another part of the machine. Participants were asked to find a derivative on the machine. The non-mathematicians suffered no difficulties in doing so and were able to quite easily fulfill the prompt. Mathematicians, however, struggled to develop a limiting process that could be used to replicate the limit definition of the derivative.

This difference led Dray and colleagues (2019) to define the notion of a "thick derivative," where non-mathematicians use "good enough" approximations as stand-ins for the theoretical limit process. This notion of a thick derivative emphasized how scientists use an average rate of change over a small change in an input value to approximate an instantaneous rate of change, something antithetical to the mathematicians who worked on the partial derivative machine in Dray and colleagues' study.

This notion of a thick derivative (Dray et al., 2019) influenced their modification of Zandieh's (2000) framework for understanding of the derivative. In both frameworks, the concept image (Vinner, 1983) of the derivative held by a person is divided into multiple process-object layers as well as different representations. The process-object layers represent how, as initially noted by Sfard (1991), a mathematical process is reified into an object that is later used by a person in other mathematical processes. In the case of the derivative, in the various representations of the derivative, a rate of change is first found using a ratio of changes in an output variable to those in an input variable. This process is then reified into an object of which a limit is taken to find an instantaneous rate of change. The result of this limit process is what mathematicians often term a derivative (Dray et al., 2019). These limits are reified into an object that is then used to generate derivative functions. Thus, this derivative understanding framework breaks the derivative down into ratio, limit, and function layers. These layers and then used within different representations of the derivative to understand and solve various problems. Dray and colleagues included five representations of the derivative in their framework, namely graphical, verbal, symbolic, and numerical, and experimental representations. Zandieh (2000) had only four representations, namely the graphical, verbal, symbolic, and physical representations.

Dray and colleagues argue that scientists use an approximation of the limiting process to generate a thick derivative that can be used as part of their work (2019). Thus, instead of a derivative only being defined at the "limit" layer of their framework, they argued that the *ratio* layer, over a small enough change in the input variable, is sufficient to produce a thick derivative that can be used in applications. As such, they argued for an increased focus on reasoning with differentials in calculus classes. This survey aimed to validate this call as well as use their framework to better understand what aspects of the derivative are most valuable for non-mathematics majors.

Research Question

This study sought to begin answering the question of whether there is a difference between how mathematicians and non-mathematicians value different process-object layers (Dray et al., 2019; Zandieh, 2000) of the derivative.

Significance of this Study

As noted by Dray and colleagues (2019), scientists may place their concept image of a derivative within the ratio layer of their framework, rather than in the limit layer as is done more formally within mathematics textbooks. If respondents in this survey produced placed more emphasis on the ratio and function layers, this would lend credence to the arguments of Dray and colleagues that a greater emphasis should be placed reasoning with differentials rather than with limits when discussing derivatives. Additionally, resulting differences between subject areas could inform institutional decisions on developing siloed or major-specific calculus classes, an initiative that has seen some success in increasing engagement and persistence in calculus classes (Ellis et al., 2021; Klingbeil & Bourne, 2013; Luque et al., 2022; Voigt et al., 2020).

Methods

This study was carried out using a survey designed by the researcher. On the survey, respondents were asked to name their primary subject area (i.e. mathematics, physics, chemistry, etc.) and then to respond to several Likert-scale items rating the importance of various items an instructor may find important for a student to understand at the end of an introductory calculus course. On each item, respondents could rank the item as, "Not at all important," "Slightly important," "Moderately important," "Very important," or "Extremely important." The items were broken up into sections according to the representations of the derivative discussed in the framework of Dray et al. (2019). Within each of these sections, there was one item corresponding to each process-object layer of the derivative. This resulted in five questions corresponding to each of the process-object layers within the framework. For each respondent, the five questions for each subject layer were then averaged to create a score on their value for each of the ratio, limit, and function process-object layers. These scores were considered scale variables, as they came from combined Likert-style questions (Field, 2018).

Data Analysis

I examined the relationship between subject area and the value respondents ascribed to the different process-object layers. I treated subject area as the independent variable, with the three different process-object layer scores as dependent scale variables. These variable types led to data being analyzed using multivariate analysis of variance (MANOVA) (Field, 2018; Huck, 2012). To find significant differences between responses of individual subject areas, Tukey's post-hoc test was used. Additionally, a one-way analysis of variance (ANOVA) was conducted to determine if there were significant differences between the values respondents in general ascribed to the three different process-object layers, as well as within specific subject area groups.

Participants

Wyoming post-secondary faculty were surveyed as part of this study. Specifically, faculty in majors requiring calculus were invited to participate. Although this does not represent a national random sample, Wyoming colleges all conduct nationwide hiring searches that require faculty to have similar educational credentials as those for other colleges throughout the United States

(Higher Learning Commission, 2019). Additionally, Wyoming state law requires that colleges throughout the state have identical course names and course outcomes (Common College Transcripts, 2018), ensuring that instructors from similar disciplines but at different institutions would have similar prerequisite calculus knowledge required for their courses.

Results

After the survey responses were cleaned to remove incomplete responses, there were 75 complete responses that were analyzed as part of this study. Since there were only one or two respondents from some of the original subject areas included on the survey, respondents were grouped as is seen in table 1.

Table 1. Respondents Grouped by Subject Area

Subject Area	Number of Respondents
Mathematics	23
Physics & Chemistry	8
Biology	6
Engineering & Computer Science	12
Other	26
Total	75

Reliability Results

Table 2 shows the reliability scores on each of the sets of items used to assess the ratio, limit, and function layers. As is seen in the table, the values for Cronbach's alpha were relatively high for each layer, suggesting high internal reliability in the results.

Table 2. Reliability Results

Layer	Cronbach's Alpha
Ratio	0.769
Limit	0.848
Function	0.876

Test Results

Based on Roy's Largest Root, the results of the MANOVA were statistically significant, showing that there is a difference in the value of the three different process-object layers by teachers of various subject areas, $V = 0.294, F(4, 70) = 5.146, p = 0.001$. However, when results were broken down using Tukey's post-hoc test, the only significant difference found between subject are groups were between the "other" group and the mathematics group on each layer. When one-way ANOVA tests were run on the overall ratings for each process-object layer, the results were not statistically significant. This lack of significance suggests that overall, teachers value each of these three layers equally.

Discussion

Although the MANOVA yielded a statistically significant result, the small number of significant differences between individual subject groups is disheartening. However, as this was a pilot study for the survey used, the results suggest several ways the survey can be improved. Additionally, the results that were significant offer clues to how this research could be applied.

Survey Improvements

As noted previously, this study piloted the survey used. Since the intergroup significant values were found only between the mathematics group and the "other" group, the options for subject area on the survey need to be expanded. Some respondents to the survey noted in a comment section that subjects such as economics, geology, and chemical engineering were not included in the suggested subject areas. The intent of the survey was to have respondents who marked "other" on the survey state their subject area in a text box, but as no respondents filled in that text box, this feature was not employed properly.

There is also no validity data for this survey at this point. Interviews should be conducted with respondents to the survey to make sure respondents understand the intent of the questions. These cognitive interviews would help improve questions to better assess which of the layers the respondents value more. Additionally, in discussions with some other researchers, there are concerns that the survey questions may not have aligned as closely with the framework of Dray et al. (2019) as was originally intended. Refinements to questions will help better delineate differences in values in these layers.

Most importantly, a larger sample size needs to be collected to better validate these results. While the current sample size of 75 is enough to run some analyses, a larger sample size would allow the use of tools such as factor analysis to determine validity (Field, 2018). With a larger sample size, significant differences between the values ascribed to the three process-object layers may emerge, allowing for more specific feedback on the suggestion of Dray and colleagues (2019) to focus more on differentials in calculus classes.

Possible Applications of Current Results

With the understanding that these results come from a pilot study, some suggestions can be made from these data. Firstly, since significant differences were observed between the mathematics and "other" group, the nature of the known members of the "other" group can inform some instructional choices. Some members of the "other" group, as seen in some comments in the survey, came from subject areas such as accounting and business majors. These students often take some form of "business calculus" where certain aspects of calculus, such as trigonometric derivatives, are removed from the mainstream calculus curriculum. These results, where the mathematicians valued all the process-object layers more than those in the "other" group, seem to confirm that such a reduced calculus curriculum may be desired by teachers in accounting and business majors.

However, as the sample size for this survey was so low, and the known number of accounting and business majors in the survey was so low, such claims are preliminary at best.

Future Applications of this Survey

Once this survey is validated and refined, this survey could be deployed to a larger audience of post-secondary teachers to better make recommendations for how calculus curriculum can be modified to better suit the needs of the non-mathematics students in calculus classes. This larger audience could include college faculty, research scientists, and professional engineers just to name a few. Such results could help calculus better serve students entering STEM fields, rather than serving as a barrier to success.

A Case Study on Undergraduate Students' Interpretation of Misleading Graphs in Public Media

Debasmita Basu

The New School

Hong Nguyen
The New School for Social Research
The New School

Contemporary news media frequently utilizes graphs to simplify the presentation of complex information. However, prevalence of misleading graphs on public platforms often makes readers susceptible to false information. This raises pertinent questions regarding the efficacy of our education system in adequately preparing students to interpret graphs. In this paper we present a case study that aims to explore undergraduate students' interaction with misleading graphs and unpack their mathematical reasoning as they do so to identify patterns that can explain their graph interpretation abilities. The study's findings suggest that students who focused on the data in a graph, rather than its shape, demonstrated better proficiency in graph comprehension and in identifying misleading elements.

Keywords: Graphs, Media, Misinformation, Critical mathematics

Today, most of the news media uses different forms of visualizations to simplify the presentation of complex information. Our brains better process data when they are presented in visual forms, such as graphs and tables, enabling us to discern significant patterns that might otherwise be overlooked (Tufte, 1985). While graphs can significantly improve information processing, the prevalence of misleading graphs in news and public media exposes readers to false information and poses a significant threat to democracy (Cairo, 2014). The risk is heightened during critical events such as pandemics and elections, as misleading graphs can directly influence public perceptions and decision-making regarding health and voting behavior. Under such circumstances, the question remains to what extent are students prepared to interpret graphs and identify misleading graphs published on public platforms?

While prior research has reported students' struggle with identification of misleading visualizations, particularly graphs (Ramly et. al., 2021), there exists a lack of understanding of the reasons behind such struggle. With the aim to fill the gap, in this paper we present a case study that investigates the question, how do undergraduate students interpret misleading graphs in public media, and what patterns in their mathematical reasoning can explain their ability or inability to identify inaccuracies in these visualizations? We hypothesize, once we identify these patterns, we can introduce them in our teaching and learning of graph comprehension and foster within students a habit of critically assessing the accuracies of graphs.

Theoretical Framework

This study is developed on the theories of critical mathematics literacy (Frankenstein, 1994) and graphicacy (Wainer, 1992). While critical mathematics literacy views mathematics as a socio-political tool for identifying and questioning societal injustices (Frankenstein, 2001), graphicacy focuses on understanding and interpreting graphical data (Wainer, 1992). By combining these frameworks, we argue that during this age of prominence in visual data, students' graph comprehension skills would enable them to uncover hidden patterns or biases embedded in visualizations and prompt them to ask relevant questions about data that would develop their fundamental critical analytical skills and enables them to comprehend the complexities of society.

Researchers have proposed various frameworks for evaluating an individual's graphical comprehension; this study utilizes Curcio's (1987) framework, which assesses graph comprehension through three aspects: reading the data, reading between the data, and reading beyond the data. While extracting data from graphs is emphasized in reading the data, identifying relationships between variables presented in graphs is the focus of reading between the data. The advanced level of graph comprehension, reading beyond data, involves making future predictions based on given trends in data. In this study, students interpreted graphs extracted from news media and we used the framework of reading the data, reading between the data, and reading beyond the data to measure their graph comprehension skills.

Method

Worksheet

To investigate students' interaction with misleading graphs, we asked them to complete a worksheet containing graphs with some mathematical inconsistencies. In the first bar graph on federal welfare (Figure 1- Left) presented by the Republican side of the Senate Budget Committee, the y-axis was truncated, and in the second "job loss by quarter" graph (Figure 1- Right) extracted from Fox News, the scales along the x-axis and the y-axis were inconsistent.

Figure 1. Left - Graph on US Federal Welfare; Right- Graph on Job Loss by Quarter

To measure students' ability to comprehend graphs, each graph was accompanied by three questions assessing students' capacity to read the data, read between the data, and read beyond the data (Curcio, 1987). For instance, with the "job loss by quarter" graph, to investigate students' ability to read data we asked them to identify the number of people who lost jobs in September 2008. To measure students' capacity to read between the data, they were provided with a hypothetical situation where a local news agency claimed that joblessness increased at a constant rate between December 2007 and June 2010 and asked them if they agree with the claim. Finally, students were prompted to predict future job losses based on current trends to evaluate their ability to read beyond the data. Students were asked to write justifications for their answers to help the research team gain insights into their mathematical reasoning and identify patterns that can possibly explain why some students are better able to identify misleading graphs, while others are not.

Participants

This research was conducted in an urban private research university in the North-Eastern Region of the United States. Nineteen undergraduate Business Administration students enrolled in a Quantitative Reasoning Course participated in the study. The first author administered an anonymous graph worksheet to the students, which was independently answered by the students.

The research team performed open coding (Strauss & Corbin, 2004) to analyze the students' responses and the written justifications. In this paper, we will present our findings on students' interaction with the misleading graphs and will uncover patterns in their mathematical reasoning that could explain their comprehension of graphs published on public platforms.

Results

Students' responses to the three questions accompanying the two misleading graphs revealed that for both the graphs, students could correctly read the data. However, they experienced struggles while reading between and beyond the data from the graphs, especially for the graph on job loss numbers (Table 1).

Table 1. Table showing students' responses to the three levels of reading data for the two misleading graphs on Federal Welfare and Job loss numbers

Graphs		Graph 1 (Federal welfare)		Graph 2 (Job loss)	
Type of responses →		Right	Wrong	Right	Wrong
Type of Questions	Read the data	19	0	18	1
	Read between the data	17	1	9	10
	Read beyond the data	19	0	2	17

To unpack the reasons behind this challenge with reading between and beyond the data, we analyzed their written justifications. To measure their ability to read between the data for the "job loss by quarter" graph (Figure 1- Right), we asked them, "A local news agency claimed that joblessness increased at a constant rate between December 2007 and June 2010. Do you agree with the claim? Justify." Ten out of 19 students answered incorrectly, asserting that job loss increased at a constant rate in the given time period. Upon examining their rationales, we found that all the students attributed their conclusions to the shape of the graph. They made statements such as "The line is pretty straight which means it is steady and constant" and "I do agree with the claim due to the linear slope of the graph indicating the constant rate", indicating that students relied on the linearity of the graph to infer the constant increase in job loss numbers.

On the contrary, eight students correctly discerned that job loss numbers did not increase at a constant rate. On analyzing their written justifications, we found that the students consulted the numbers presented in the graph and performed mathematical computations. For instance, one student calculated "the slope between Sept 2008 and Mar 2009 is 0.75 (13.5 - 9 mil / 6 months) and the slope between Mar 2009 and Jun 2010 is about 0.1 (15 - 13.5 mil / 15 months)." They said, since "slopes do not equal, then the growth is not constant." Hence, for the "job loss by quarter" graph, students who concentrated on the shape of the graph, missed the discrepancy between the actual data and the graph's shape. In contrast, students who focused on the numerical data recognized that the job loss numbers given on the graph do not support the linear shape of the graph and thus identified the graph to be misleading.

A similar pattern emerged from the "US Federal Welfare" graph (Figure 1- Left). To assess students' ability to read between the data, we asked them, "A local news agency claimed that the number of Americans who received federal welfare doubled from the first Quarter of 2009 to the fourth Quarter of 2009. Do you agree with the claim? Justify." Only two students failed to identify the misleading nature of the graph and asserted that the number of Americans who received federal welfare during the fourth Quarter of 2009 doubled from the first Quarter. Upon analyzing their written justifications, we found that both students focused on the relative height

of the bars to reach the conclusion. One student said, "The size of the bar for 2009 in the fourth quarter could be considered double what it looked like in the first quarter." Conversely, students who answered correctly mainly focused on the numbers given on the graph and engaged in some form of mathematical calculation. For instance, one student who answered correctly to the question, wrote, "Find the bar that says 2009 Q1 and the bar that says 2009 Q4 on the x-axis and identify the number of Americans by reading the y-axis. Find the difference between the two data. In 2009 Q1, the Number of Americans was about 97,000,000 and in 2009 Q4, it was about 101,000,000. There was only a 4 million difference."

To assess students' ability to read beyond the data presented in the "job loss by quarter" graph we asked them "With the current trend following, what would be the total number of job losses in the next quarter?" Given that the graph was misleading, we hypothesized that students' responses to the previous question would influence their approach to this one. If students acknowledged in the prior question that job loss did not increase at a constant rate, it might lead them to infer that it is not feasible to predict the future job loss numbers. To streamline the coding process, we decided, students who would not make any predictions would be considered as having answered the question correctly. All other responses were marked as incorrect.

In the previous question, ten students who failed to recognize the discrepancy between the job loss numbers and the shape of the graph, made some predictions about future job loss numbers. Upon examining students' prediction strategies, we found that most students calculated the job loss numbers in the three given quarters, found the average job loss numbers and used the value to predict the job loss number in the next quarter. During the process although they found that in each quarter job loss numbers did not increase constantly, they did not make any explicit comment on the nature of the graph. Among the nine students who correctly discerned that job loss figures did not exhibit a constant increase, two expressed their inability to forecast future job loss numbers. One of them said, "I can't say because the progression of the numbers is not going at a constant rate." The seven other students who recognized that the graph was misleading, projected some future job loss numbers. They made assumptions about the rate of job loss from the previous three quarters and conducted mathematical computations to reach their conclusion. For instance, one student predicted that the cumulative job loss number by the end of the next quarter would be 16.66 million because, between March 2009 and June 2010, job loss numbers increased by 11.11%, and "considering 11.11% increase rate, the number of job losses in the next quarter (Q3'10) would be approximately 16,666,500".

Upon reviewing students' responses to the "reading beyond the data" question, we realized that, although our intention was for students to recognize that the misleading graph was not a reliable tool for making predictions, the way we phrased the question might have unintentionally limited students' thinking about the inconsistencies present in the graph. Most students focused on a hypothetical situation and made assumptions about the current rate of job loss to make future predictions about the same. Further, upon analyzing each student's predicted job loss numbers, we found that many of them made errors in their mathematical calculations. However, the goal of the study was not to measure the mathematical correctness of the students' calculations; rather focus on their strategies that could explain their graph comprehension.

Discussions

Based on students' responses to the graph worksheet, this study draws the following conclusions. Students showed greater proficiency in reading data from the graphs compared to reading between and beyond the data. Students who failed to identify misleading elements of the graphs relied more on the shape of the graphs rather than the actual data. Conversely, students

who closely examined the data provided on the graphs and conducted mathematical calculations, used their mathematical outcomes as evidence in support their answers. The findings of the study, mainly the gap between students' potential to reading the data and reading between and beyond the data is particularly worrisome. It suggests that as news consumers, while we may excel at extracting data from graphs, we often fail to thoroughly analyze the relationships between variables depicted in visualizations and think beyond what is presented to us. As a result, if confronted with a misleading graph, such as the one on job loss numbers, we would be prone to accepting the information at face value rather than questioning the accuracy of the data. Since the study had no scope to get deeper into students' responses through interviews, we are uncertain of the reasons behind the gap between students' ability to read the data and critically analyze the data.

Consequently, this study proposes the following recommendations to enhance students' graph comprehension. First, educators should encourage students to focus on the data presented in graphs rather than being distracted by their visual shapes or design elements. Second, graph literacy should be introduced through authentic, real-world graphs rather than hypothetical ones, as understanding graphs requires more than just knowing mathematical rules-they must be interpreted within relevant contexts. Lastly, fostering graph comprehension in real-life scenarios involves cultivating students' habit of critical questioning prompting them to ask who the graph represents and excludes, and what biases might be embedded in the graphs.

A Preliminary Scoping Literature Review on Mixed Methods in RUME

Kathleen Melhuish
Texas State University

Jennifer A. Czocher
Texas State University

Through a scoping literature review of 40 RUME studies from 2019 to 2024, we examined how researchers use and describe mixed methods. We categorized these studies by country, subject area, and self-reported implementation process (e.g., sequential, parallel), methodological priority (qualitative or quantitative),and study design (exploratory, explanatory, triangulation). While mixed methods are used in RUME, we found that only half of the studies explicitly define their methodological framework, often missing opportunities to maximize the potential of integrating multiple data sources. Our findings highlight the importance of adopting more nuanced and deliberate mixed methods approaches to fully exploit the strengths of both qualitative and quantitative research in advancing the field.

Keywords: mixed methods, RUME

Much of the research in RUME uses qualitative methods. Artique (2021) critiqued the field's "excessive predominance of small-scale qualitative studies, involving a very limited number of students or teacher" (p. 14). Our recent survey of the field's creation and use of quantitative measures suggests that RUME scholars do a substantial amount of quantitatively oriented work as well (Melhuish et al., 2024). What may be the case is that qualitative and quantitative researchers are operating in separate spheres. This is sensible when thinking about what kinds of research questions are answerable (broadly) by these paradigms. Questions of comparison or prediction cannot be paired with cognitive constructivist teaching experiments, for example. However, sometimes the weaknesses and biases in one approach (e.g., surveying college instructors about their practices) can be mitigated by the strengths of another approach (e.g., observing classrooms). So, the separation does lead to calls for increasing complementary approaches to investigating phenomena of interest to RUME (e.g., Weber, 2013).

Artigue's critique zeroes in on the *size* of the research sample, which is only one aspect of generating trustworthy information about a research topic – one that matters less for qualitative work than for quantitative. What does matter, quite a bit, is using the sample to get the right kinds of information to address a research question or to obtain convergent information about an issue. Quantitative methods are useful for measuring and aggregating patterns across individuals; qualitative methods aid in interpreting patterns of meaning to individuals. Mixed-methods approaches can draw on both paradigms to "provide a more complete understanding of a research problem than either approach alone" (Creswell, 2014, p. 4). They can answer questions like, "Which group performed better, and why?" or "To what extent does the frequency of negative teacher feedback reflect students' perceptions of their own competency?"

Yet, we do not frequently see these complex, multi-perspective questions posed in the RUME research literature. We became interested in detecting the extent to which RUME researchers had responded to calls to integrate quantitative methods in their work. In this preliminary report, we share a scoping literature review aimed at identifying and classifying the types of mixed methods approaches RUME researchers report they use. We share both how researchers describe their own work and the degree to which they are explicit and specific about the methods they use.

Background

An historical definition of mixed-methods research is an inquiry that includes "at least one quantitative method (designed to collect numbers) and one qualitative method (designed to collect words) (Greene et al., 1989, p. 256). Contemporary descriptions recognize that qualitative methods are not merely about words-as-data and that there can be many configurations for how the qualitative and quantitative information are treated, relative to their level of integration and relative to their centrality to the research question. For example, qualitative inquiries in RUME include questions about the meanings teachers hold for equitable participation in a mathematics classroom, gestures that calculus students use to express changing rates, or the mental operations that produce novel quantities. Some methodologists have attempted to classify mixed-methods research approaches based on whether qualitative or quantitative data sources are given more prominence, whether data are sourced concurrently or not, and whether the analysis treats data from different sources in parallel, in sequence (and if so, in what order), in an integrated manner, an embedded manner, or seeks to convert one form to another (Buchholtz, 2019; Creswell, 2014). Each of these descriptive criteria for the methods used in a study is important because they correspond to analytic decisions which govern which research questions can be answered.

Types of Mixed Methods Approaches

Here, we focus on major descriptive features (Creswell et al., 2011); for the implementation process (concurrent, parallel, conversion), purpose of the study (exploratory, explanatory, development, triangulation, conversion, initiation, etc…), and priority of the methods (qualitative or quantitative). Priority is often indicated by how the researchers frame the study. A study meant to test relationships among variables that were created from written responses likely gives priority to quantitative methods. A study that uses a survey to identify individuals who hold certain beliefs about the nature of mathematics, and then conducts oral histories to understand how those beliefs may have formed gives priority to qualitative methods. In each case, one data source is subservient to the other. A related concept in mixed methods is the purpose of the study and how it uses the different data sources. When data sources are used in sequence, the study is usually described as exploratory sequential or explanatory sequential. Exploratory sequential may use qualitative findings to develop an intervention, and then test the intervention's efficacy. This can be a useful approach when variables to include in the intervention are not known a priori. Explanatory sequential first collects and analyzes quantitative data, then digs into particular cases qualitatively to explain why quantitative patterns might exist. One can easily imagine that an ANCOVA comparing an IBL approach to teaching proof to a "business as usual" classroom would seem rather dry without examining paradigmatic cases of student reasoning that lead to one classroom outperforming the other. Data sources might also be analyzed in parallel, where the purpose is to establish multiple threads of evidence in favor of a claim. For example, measurement validity studies often seek multiple sources of information like open and closed form responses and clinical interviews about the items to ensure that items are behaving well. In other writings, this is *convergence* or *triangulation* (Flick, 2014). Evaluation studies might choose to use qualitative methods to analyze processes in parallel with quantitative methods to measure outcomes. In such a case both pieces may be given equal priority and address separate but related research questions about how an intervention is working in a setting. A particular approach to mixed methods research that is common in education and the social sciences is *conversion* of one data type to another data type. When the conversion is from qualitative to quantitative, the process is referred to as *quantizing*, where nominal or ordinal values are assigned to data that was initially conceived as non-numerical (Sandelowski et al., 2009). For

example, a classroom lesson could be analyzed using content analysis or constant comparison according to a conceptual framework, then assigned a count-based or time-based frequency and analyzed quantitatively.

Uses of Mixed-Methods in Mathematics Education Research

Mixed methods are not uncommon in mathematics education research or education research more broadly. Several researchers have examined the prevalence in particular journals including JRME (36% of articles from 1995-2005, Hart et al., 2009; 34% from 2006-2010, Ross & Onquegbuzie, 2012), ESM (17% from 1995-2005, Hart et al., 2009) and JMTE (22% 1995-2005, Hart et al., 2009). These researchers also argued, "Mathematics education researchers appear to utilize lower levels of quantitative analysis complexity, when used alongside qualitative procedures" (Ross & Onquegbuzie, 2014, p. 71) with majority of the mixed methods articles using only descriptive statistics. A cursory look at RUME proceedings from 2023 reflects a smaller number of mixed methods studies. Of the 151 papers, 9 stated they used mixed methods of some sort. However, we caution this small number but may reflect that proceedings may contain portions of studies.

Methods

Although typologies of mixed methods are useful for organizing and contrasting various approaches, especially for researchers new to thinking about mixing methods, they have limited utility for guiding mixed methods research due to the emergent needs for adjusting the procedures as the data sources are collected and analyzed (Poth, 2023). Nonetheless, we use a few dimensions of common typologies to help organize the RUME literature that purports to use mixed methods. For our scoping study, we limited our literature search to a five-year span (2019-2024) and to the twenty mathematics education research journals identified by (Williams & Leatham, 2017). To focus more on RUME, we also included the *International Journal of Research in Undergraduate Mathematics Education*. Our main search term was "mixed methods" anywhere in the text. We used Publish or Perish citation software to pull all 459 matching articles. We then preserved any article that explicitly purported to use mixed methods, included quantitative *and* qualitative data sources, and used a RUME sample. By RUME sample we mean undergraduate mathematics students or instructors. A total of 40 articles met these criteria. For each article, we then used a simplified blend of typologies from Teddlie and Tashakkori (2006) and Creswell & Clark (2011) to classify articles according to the following simplified criteria: (1) whether they cited a mixed methods article or methodological text to justify their approach, (2) which implementation process (sequential, parallel, conversion), (3) gave primacy to qualitative or quantitative methods (4) the research design (explanatory, exploratory, triangulation, complementary, experimental design). We note, we did not infer these designs nor evaluate if their goals were met, but rather report what was shared by the research team.

Preliminary Results

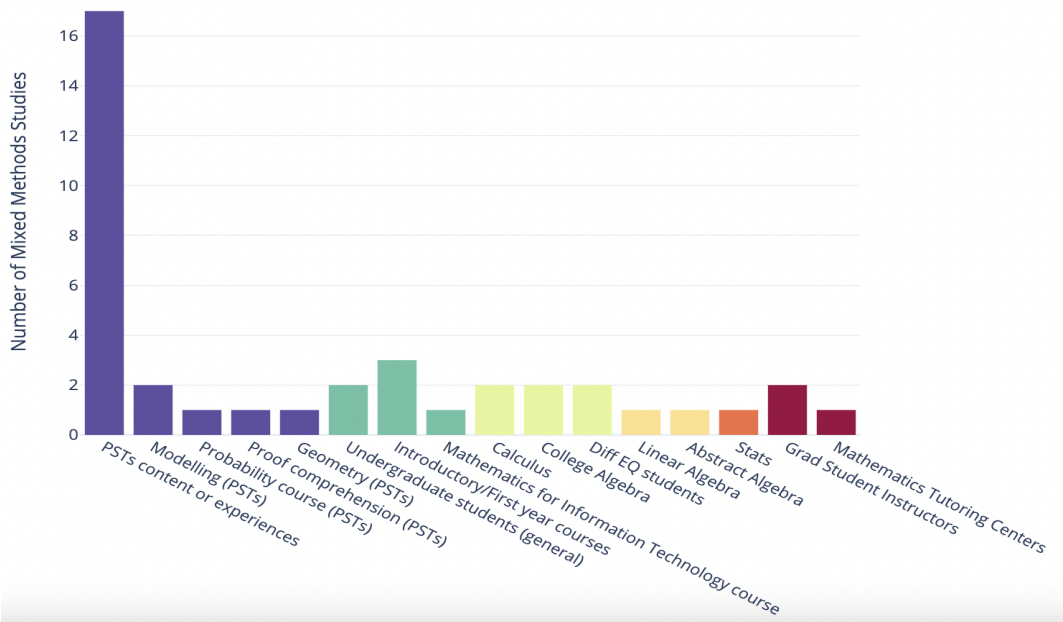

Figure 1. Distribution of $N = 40$ mixed-methods studies in RUME, across content areas and populations

We identified forty articles that met the criteria of being self-described as mixed methods and studying a population of undergraduate mathematics students or instructors. Slightly over half of the studies were conducted in the United States (21) with the remaining 19 spanning 12 countries (Iran, Finland, Australia, New Zealand, Vietnam, Germany, Turkey, Spain, Canada, Israel, South Korea, and Norway). The studies' focal content (which often entails a population/sample) can be found in Figure 1. Note that pre-service teacher content and experiences dominate the mixed methods studies. We conjecture that the mixed methods may be more reflective of teacher education researcher methods than the RUME community. If we removed studies with this focus, we would eliminate over half of the manuscripts.

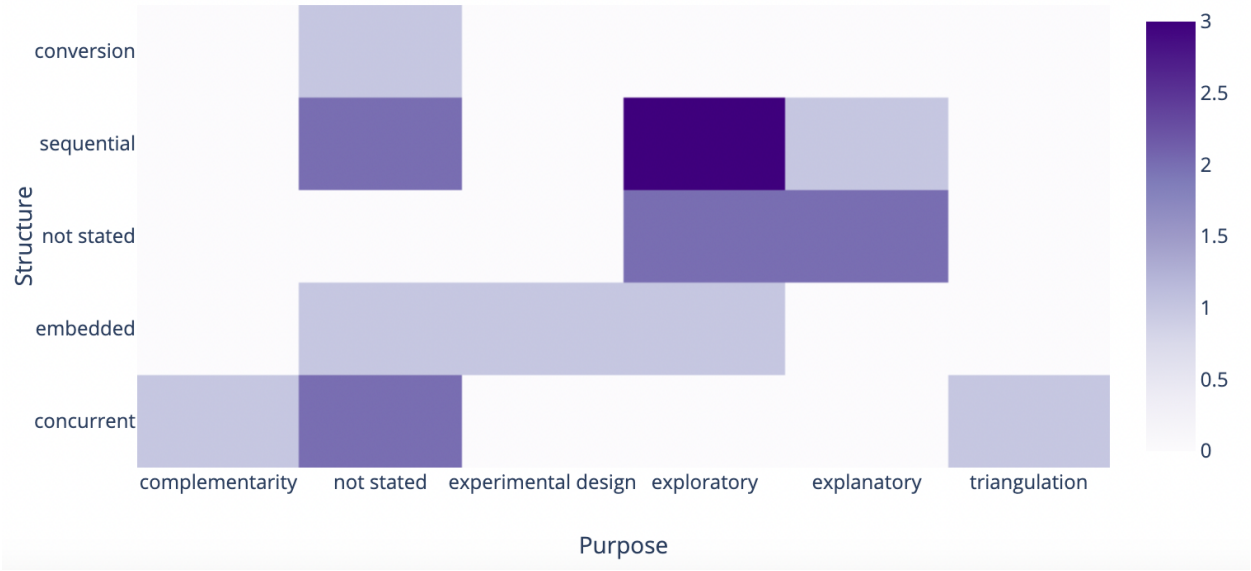

Figure 2. Heatmap of Purpose and Structure for the 20 Studies Explicating That Information

The most cited author was Creswell with 14 citations, followed by Yin with three, and Teddlie and Tashakkori with two. Of the forty articles, only half (20) explicated their mixed methods typology in any way beyond stating it was a mixed methods study. Several studies pointed to the mixed methods being embedded into other methodologies including one instance of instrument validation (Donovan et al., 2024), one "conceptual replication of a quasi-experimental study" (Yudt et al., 2024), and three case studies (Ellis et al., 2021; Galligan et al., 2019; Johns et al., 2023). Two studies indicated their larger approach was "longitudinal" (Woolcott et al., 2021) or "pseudo-longitudinal" (Safrudiannur, et al., 2022).

An overview of the 17 mixed methods studies that addressed their typology can be found in the Figure 2. Not that the most frequent type was exploratory sequential and only occurred three times. Note, an additional three studies mentioned the dominance of qualitative or quantitative data: two equal status and one qualitative dominated. Finally, we note one study (Yee et al., 2024) described their methods as an "integrated generalization design" (Srnka & Koeszegi, 2007), labeled as conversion in the above figure.. This design is two stages and involves qualitatively coding dating, then quantifying these results in order to conduct statistical data analysis. Sometimes this structure is referred to as "quantizing" (Morgan & Hoffman, 2021) where qualitative data is converted to numbers, typically through counting. While it is a common approach in our field, it requires careful attention to sampling and generalization to make inferences from such an approach (Czocher & Melhuish, 2024).

Discussion

This preliminary analysis illustrated that RUME researchers are using mixed-methods, but often with little attention to unpacking key elements of the methodologies. Mixed-methods can be positioned as a way to avoid the limitations of using qualitative or quantitative approaches alone; however, they also introduce tensions and require careful attention to methodological details and theoretical assumptions. Quantitative approaches grew out of positivist and post-positivist paradigms, whereas qualitative approaches typically (though not exclusively) arise from constructionist or interpretivist paradigms. One key distinction is that qualitative approaches, especially naturalistic or interpretive ones, do not share the expectation of objectivity or the supremacy of the researcher's perspective over the research subject's perspective. As Denzin and Lincoln (2005) sharply observed: "The mixed-methods movement takes qualitative methods out of their natural home, which is within the critical, interpretive framework" (p. 9).

Guetterman et al. (2017) looked for Mixed Methods-Grounded Theory studies ("across disciplines") and found that (1) lacking methods detail (2) lack of actual theoretical development (3) most were convergent mixed methods design, as opposed to sequential/exploratory designs. This finding comports with our own perception, as readers of mixed methods studies in mathematics education, that often "mixed methods" implies a coding procedure followed by reporting descriptive statistics for the frequencies of coded segments in the categories. This does not "reach the full potential" (Guetterman et al., 2017, p. 180) of mixing grounded theory, to say the least, let alone reaching the full potential of mixed methods more broadly.

Given the prevalence of grounded theory-based approaches to data analysis in RUME, it seems that exploratory sequential studies (creating a theory and testing it empirically) would be a a natural fit (Smith et al., 2023). Future work can examine the extent to which these kinds of studies are following best practices (Guetterman et al., 2017; Smith et al., 2023) or just following their gut instincts towards the least publishable unit (as discussed in Stewart, 1998).

Explicit Group Norm Framing by MGTAs

Pablo Duran Oliva
Virginia Commonwealth University

Ben Haynes
VCU

Mary Beisiegel
Oregon State University

Considerable attention has been given to the role of Mathematics Graduate Teaching Assistants (MGTAs) in fostering classroom norms. This is especially pertinent in active learning settings where students extensively engage in group work with minimal direct instruction. Social stereotypes can be pervasive within small group dynamics, often hindering participation of students in mathematical discourse. Implementing explicit classroom norms is an effective strategy to promote a more inclusive distribution of learning opportunities. However, more research is needed on how these norms are enacted and supported. Our findings reveal significant differences between MGTAs who consistently frame group norms and those who do not, highlighting the benefits of explicit norm framing for promoting meaningful discussions, structuring group work, and ensuring inclusivity. These results underscore the importance of professional development focused on norm setting to enhance inclusive student engagement in mathematics classrooms.

Keywords: Classroom norms, Inclusion, Teaching Assistants

In recent years, considerable attention has been given to instructors' roles in establishing and fostering classroom norms that promote equitable and inclusive learning environments. The importance of these norms becomes even more pronounced in active learning settings, where traditional lectures give way to collaborative, student-centered activities. In these environments, students engage in problem-solving, discussion, and peer teaching, often working in small groups with minimal direct instruction from the teacher. The shift from passive listening to active participation is meant to enhance student learning processes, but it also brings significant challenges. Without appropriate support, group dynamics can easily mirror broader societal inequities, leading to uneven participation and marginalization of certain students based on gender, race, or other characteristics. Previous studies have demonstrated the pervasive nature of gender and racial stereotypes within small group dynamics, negatively impacting the equitable participation of minoritized groups in mathematical discourse. For instance, studies have shown that women and students from racial or ethnic minoritized groups often have their contributions overlooked, dismissed, or undervalued in group settings, which can lead to decreased confidence, lower participation rates, and reduced learning outcomes (Boaler, 2008; Esmonde, 2009). These patterns of exclusion not only limit the learning opportunities for those students but also reinforce harmful stereotypes about who is "good" at mathematics, reinforcing a cycle of inequity.

To address these issues, educators and researchers have increasingly advocated for the implementation of explicit classroom norms that could promote a more inclusive distribution of learning opportunities (Horn, 2012). Classroom norms can be understood as taken-as-shared beliefs and expectations guiding interactions within the classroom. These norms play a critical role in shaping how students engage with one another and with the content, influencing both the cognitive and social dimensions of learning (Yackel & Cobb, 1996). Rather than being explicitly stated, these norms often emerge through repeated interactions and are implicitly agreed upon by instructors and students. However, when classroom norms are explicitly articulated and consistently reinforced, students are more likely to engage actively and constructively with their

peers, leading to a richer and more inclusive learning experience for everyone involved (Esmonde, 2009).

Despite the growing recognition of the importance of explicit classroom norms, there is still a need for more research on how these norms are enacted by instructors. This is especially true for MGTAs who are often in the early stages of their teaching career. While some studies have explored the use of norms in K-12 settings (Boaler, 2008), less is known about how MGTAs—who may have limited teaching experience and training—understand, implement, and sustain norms in the college-level mathematics classroom. This study seeks to fill these gaps by investigating the use of explicit classroom group norms by 19 MGTAs in a university setting. MGTAs were observed in their classrooms on three separate occasions. Following these observations, three significant interactions between MGTAs and groups of students were analyzed in-depth to characterize the impact of these norms on student engagement. Two main research questions guided our study: 1) To what extent do MGTAs make use of explicit group norms in active learning classrooms? 2) How do MGTAs make use of explicit group norms in active learning classrooms? By examining how MGTAs articulate and reinforce classroom norms, and how these norms shape the dynamics of group work, this research aims to provide insights into effective teaching practices that foster inclusive and equitable learning environments in undergraduate mathematics education. Ultimately, the findings of this study could inform professional development programs for MGTAs and other instructors, contributing to the broader goal of making mathematics more accessible and welcoming to all students.

Methodology

The initial dataset included classroom videos from 19 MGTAs from three different institutions: Beta (5 TAs), Epsilon (5 TAs), and Gamma (9 TAs). During a year of professional development, MGTAs were asked to reflect on the impact of classroom norms on equity and inclusion but were not necessarily asked to give students detailed and explicit instructions on how they should work with peers in groups. Videos from all the MGTAs from a first PD cohort (2022-2023) were included. Due to time constraints, only two MGTAs from a second cohort (2023-2024) were included. TAs' classrooms were video recorded three times over an academic year. The first observation did not necessarily correspond to the initial class meeting. Although this limitation reduced our ability to capture a probable instance when instructors might establish classroom norms, it enabled us to identify moments where MGTAs felt the need to reinforce these initial norms throughout the semester. We hypothesized that MGTAs who explicitly reiterated group norms after the first class would place greater importance on being explicit about these norms than those who only addressed them on the first day.

To analyze such a large amount of data, we focused on three instances in each classroom observation: classroom setup, first interaction, and second interaction. Classroom setup occurred within the first 5-10 minutes of the lesson, during which the instructor set the tone for the class. Instructors outlined general expectations, goals for the session, and any specific guidelines for participation. We identified the end of this setup when MGTAs stopped addressing the whole class and most students were visible working in groups. The two subsequent interactions sampled after the classroom setup were often brief but were considered valuable as we expected that MGTAs might see them as an opportunity to reinforce the expectations given during classroom setup. These interactions were the first two instances 10-20 minutes after the classroom setup where MGTAs approached students to offer assistance. At that point we expected students would have had an opportunity to ponder the concepts or problems of the day.

We conducted three rounds of coding. In the first round, we established our data sample, identifying classroom setup, first and second interaction for each classroom video of each TA. In our second round of coding, we examined the extent to which MGTAs explicitly framed group norms during classroom setup, first or second interactions. Group norm framing was defined here for analysis purposes as instances when TAs not only communicated expectations about how students should work in groups, but also supported and nurtured group work in the classroom by facilitating the formation of groups, interacting with students via their groups, and attempting to answer questions by generating discussion within the group rather than prescriptively between themselves as a single student. In cases where MGTAs' answers were focused on answering individual content-related or logistic questions not intended to promote group work, we did not code the interaction as norm framing. A third round of thematic coding was conducted to characterize instructors' norm framing or instructors' alternative to norm framing when interacting with student groups. First, transcripts labeled as classroom setup or student interactions were coded and grouped into broader categories aligned with the study's research questions. Through iterative review, these categories were refined and collapsed into overarching themes, such as "clear expectations" and "individualized assistance."

Results

The total number of codes associated with explicit group norm framing by MGTAs who had at least four total codes is shown in Table 1.

Table 1. Number of codes by MGTA after second round of coding.

Id	Inst	Cohort	Setup	Interactions	T	Id	Institution	Cohort	Setup	Interactions	T
G1	Gamma	1	16	8	24	G3	Gamma	1	2	4	6
E1	Epsilon	1	11	3	14	G4	Gamma	1	2	2	4
E3	Epsilon	2	9	3	12	E1	Beta	1	0	4	4
G2	Gamma	1	9	1	10	B2	Beta	2	3	1	4
E2	Epsilon	1	6	3	9						

TAs with fewer than four codes total were excluded from the analysis as we considered their norm framing negligible for this study. The distribution of codes per participant in this table shows a low occurrence of explicit framing group norms in our sample with about 20% of MGTAs with higher than ten instances. The main themes identified in the third round of coding of the two MGTAs (G1, E1) with **high explicit framing group norms** were: clear expectations, structured groups, meaningful discussions, and inclusivity. First, at the beginning of the class, MGTAs set **clear expectations** of what group work was going to look like that day. These expectations were focused on communication within groups. For instance, G1 starts their class indicating that group discussions, sharing ideas, and helping each other are all valued during class. This is illustrated in the following quote of the first two minutes of class:

> *G1.* We'll get into groups. We'll take a little private think time and then we will discuss it in groups. So, remember that this is just… time to develop your mathematical thinking, and really share some rough draft thinking [...] It's totally fine if you have questions, if you

don't have an idea, that's OK, your group can help you out, you guys can help each other […] let's take just like, 2 minutes and then… we'll turn our desks and get into groups.

The **structured groups** theme characterizes the MGTAs' efforts to make sure all students were part of a group. MGTAs in this code impose this as a condition to work. The **meaningful discussions** theme is best illustrated in the following quote from G1 who addresses a group of three students (S1, S2, and S3).

S1: We're just not sure we're right.

G1: OK, what was your idea? [while the crouching down to students' eye level]

S1: So our idea was, we have 10 people… [hard to hear].

G1: OK, I like part of that. Let's talk about counting how many handshakes. Now, you're right that everyone [inaudible]. but consider this, put yourself in a room [...] with 20 other people, how many people's hands are you going to shake?

S1 and S2: 19 [while S3 remained silent]

G1: 19, right, 'cause you're not going to shake your own hand, so that's awesome, and you [pointing at S2] are going to share 19 hands, and [says S3's name] is going to shake 19 hands, so what would that lead us to? If every single person is going to shake 19 other people's hands... Discuss for a second, I'll come right back. I think you can get it.

G1 promotes meaningful discussions by building up on students' ideas ("What was your idea?"), validating their thinking ("I like part of that"), and scaffolding their thought with a simplified version of the problem. G1 also gives students time for non-supervised discussion, offering to come back later. The **inclusivity** code characterized instances when MGTAs address students' lack of engagement in a group work. For instance, in the previous interaction, G1 noticed that S3 remained silent and attempts to include them in the discussion while making them part of the example presented to the group. Furthermore, when G1 comes back 3 minutes after the previous interaction, notices that S3 is still not fully included so decides to purposefully stand next addressing them as follows.

G1: [G1 says student's name], how's it going?

S3: I'm good.

G1: Yep, you're good. [The TA stays with S3 and silently reviews the students' work].

G1: So, this is a great idea, I like this. [G1 then validates the S3's ideas and after noticing a mistake asks to explain their thinking, and attempts to guide them to notice it.]

The main themes identified in the third round of coding of two MGTAs (G4, B1) with **low explicit framing group norms** were: brief preamble, unstructured groups, prescriptive feedback, and individuality. The **brief preamble** theme characterized a class start with brief announcements and very little or no time information about the expectations for the day. MGTAs assume everyone will work on the worksheet. Sometimes MGTAs will ask students if they have questions, but in those cases waiting time was brief and students did not volunteer to ask any as shown in the following quote. The **unstructured groups** code represented a freer stance on group work. For instance, G4 in the previous episode made no mention of how groups were to be distributed and later did not force students to be part of a group. Furthermore, individual work is sometimes implicitly or explicitly accepted as shown in the following episode when B1 omit to ask SB1 to join a group.

B1: [Instructor approaches a lone student, asks where their partner is (?)]

SB1: "I was struggling with the integration by parts thing. I was trying to research how to properly do it again. I don't have any questions right now because I'm trying to just wrap my head around the concept."

B1: "Okay. If you've got questions, let me know. [Instructor walks off]

The prescriptive feedback code reflected instances where MGTAs gave detailed instructions or steps to follow, rather than allowing the students to independently explore solutions or discuss different strategies. An example of this can be found in the following episode where B1 approaches a group of four students seated at a table as SC2 asks a question.

SC2: Is that right? {SC2 asks B1 while seated with a group of three students in the same table]

B1: [B1 takes student's paper and quietly reads through problem to himself, and hands it back] Seems fine. I would cancel [something] though.

SC2: [Student clarifies] "I wasn't done with the problem"

B1: [B1 continues monitoring around the room]

B1 directly answered the question of whether SB1's answer was correct, missing an opportunity for instance for the student to explain their thinking. This episode is also an example of the **individuality code.** Although SC2 was in a group of four students, B1 only addressed one of them missing an opportunity to see if peers had a similar concern or make them part of the discussion.

Discussion

This study examined how Mathematics Graduate Teaching Assistants (MGTAs) use explicit group norm framing in small-group settings. Our findings highlight significant differences in the use of this framing. MGTAs who actively engaged in norm framing were able to create more structured and inclusive group dynamics, where students had clearer expectations about participation and communication. For instance, higher norm-framing instructors explicitly outlined the importance of group collaboration and fostered discussions by validating student contributions and addressing misconceptions through scaffolding.

The impact of these practices on student engagement was particularly evident in the inclusivity of students who might otherwise remain on the periphery. One key example from the study was how one MGTA (G1) actively included a previously silent student by personalizing feedback and engaging them in problem-solving, promoting a sense of belonging within the group. This aligns with prior research suggesting that explicit framing of sociomathematical norms can significantly improve student interaction and promote more equitable participation in group work (Esmonde, 2009; Yackel & Cobb, 1996).

Conversely, MGTAs who used lower explicit group norm framing provided minimal direction during group work. These instructors tended to allow students to work individually or without a structured approach to group dynamics. Their feedback often took the form of prescriptive answers rather than fostering collaborative discussions. Such practices, as observed in the study, missed opportunities to promote group cohesion and collective problem-solving. This finding supports previous literature that indicates the absence of structured group norms can perpetuate inequities in participation, particularly for minoritized students (Boaler, 2008; Horn, 2012).

Overall, the study underscores the importance of explicit group norm framing in fostering inclusive learning environments. By providing clear expectations and actively nurturing group work, MGTAs can significantly enhance student engagement and promote equity in classroom interactions. Future research could explore how professional development programs can further support MGTAs in implementing effective group norm-framing practices.

"Everyone wants everyone to do as well as they can": Norwegian First-Generation College Student Experiences in First-Year Mathematics Courses

Margaret Ann Bolick
Clemson University

Matthew Voigt
Michigan State University

First-generation college students' (FGCS) success in higher education is a growing area of research in the United States (US), but is infrequently recognized in the Norwegian education system; there is a need to investigate how FGCS are successfully navigating first-year mathematics courses to best support FGCS' pursuit of a Science, Technology, Engineering, or Mathematics (STEM) degrees in the US and Norway. This study analyzes six interviews from Norwegian FGCS enrolled in first-year mathematics courses for navigational strategies employed to support their success in mathematics. The preliminary results highlight that the structure of the mathematics courses and the accessibility of resources at the university supported a community of collaboration between peers and instructors. The culture of teamwork across students positively influenced FGCS' success in first-year mathematics courses. We highlight the perspectives of each participant and provide directions for future research to gain a further holistic understanding of supporting FGCS thriving in STEM fields.

Keywords: First-generation college students, first-year mathematics courses, navigational capital

Science, Technology, Engineering, and Mathematics (STEM) fields are pillars of the United States (US) economy and key factors in the US' reputation as a world leader (Langdon et al., 2011). However, there is a "demand rapidly rising for skilled STEM professionals" (Science & Technology Action Committee, 2024) and a perpetual shortage of STEM degree holders (Xue & Larson, 2015). The US is not the only country grappling with the disparity between the number of students graduating with STEM degrees, the increased technical skills required for the workforce, and an excess of STEM jobs (OECD, 2024); Norway is currently experiencing a technical and health sector labor shortage with "occupations that require vocational or higher education are among the most difficult to fill" (OECD, 2024). To meet the continuously growing demand for STEM workers, it is imperative that groups of students who frequently attrite STEM majors (e.g., women, students of color) are retained. One group that could fill this growing demand is the vastly underrepresented group known as first-generation college students (FGCS), or students whose parents did not obtain a bachelor's or higher-level degree.

In Norway, there is minimal research conducted on FGCS, there are no FGCS organizations at institutions, and there is a lack of resources catering to the needs of FGCS. Yet, the demographics of Norwegian higher education are changing with an increase in FGCS enrollment, increasing the need for research centering FGCS. In 2015, Norway reported that 18–24-year-olds without tertiary-educated parents comprise 53% of the population (OECD, 2018, p. 243). The population of 25–34-year-olds in Norway who have attained a tertiary degree has increased by 20% over the last 20 years, meaning that as more students attend university, there will be an increase in FGCS enrollment (OECD, 2022). The Organisation of Economic Co-Operation and Development (OECD) addresses this increase in a report calling for governments to fund FGCS-specific programs (OECD, 2019; OECD, 2020). This study is part of a larger dissertation study drawing on a comparative analysis between FGCS in Norway and the US. This preliminary study aims to investigate Norwegian FGCS' experiences navigating first-year

mathematics courses to better understand how systems and structures in place in first-year mathematics courses support FGCS.

Conceptual Framing

We utilized Community Cultural Wealth (CCW), a student-centered, asset-based theory to capture the complexity and unique qualities of FGCS enrolled in first-year mathematics courses (Yosso, 2005). Community Cultural Wealth was originally developed to highlight capital unique to racially marginalized individuals and breaks down forms of non-dominant capital into the following categories: aspirational, linguistic, familial, social, navigational, and resistant (Yosso, 2005). Due to space limitations, this preliminary analysis focuses on navigational capital, which includes students' knowledge of moving through institutions and gaining social capital (Yosso, 2005). Social capital captures students' "networks of people" (Yosso, 2005, p. 79) and resources students can access, including community, academic, financial, or institutional resources. Within the realm of FGCS majoring in STEM fields, this capital can include students successfully maneuvering through mathematics courses and how students find academic, institutional, and financial resources. In this study, we draw on navigational capital to answer the following question: ***How do first-generation college, STEM-intending Norwegian students discuss navigating first-year tertiary mathematics courses?***

Context of Norwegian University

In Norway, first-year calculus courses (much like in the US) are viewed as gatekeepers for STEM disciplines with reports of first-year calculus failure rates ranging from 21.5% to 43% (Gynnild et al., 2005; Zakariya, 2021). Students pursuing STEM degrees commonly take first-year calculus through their specialized department (e.g. engineering department, mathematics department); yet, the structure of mathematics courses is the same across disciplines, requiring students to complete 70-80% of the course assignments to be eligible for the final exam worth the entirety of their grade (Zakariya et al., 2022). However, the Norwegian university in this study is shifting from high-stakes assessment and has developed multiple attempts, multi-exam first-year mathematics courses to reduce stress and improve student outcomes. Additionally, this Norwegian university has a Center for Excellence in Mathematics focused on improving student outcomes through peer-to-peer tutoring.

Participants

This preliminary study features six participants who were recruited from the same Norwegian institution in Spring 2024. Each participant self-identified as a FGCS (neither parent obtained a bachelor's degree), was enrolled in a first-year mathematics course, and anticipated majoring in a STEM field. Additionally, some participants held other identities or backgrounds that impacted their experiences in transitioning to higher education and first-year mathematics courses. However, some participants did not identify salient identities in addition to their major; as a way to

Table 1. Participant pseudonyms and major.

Participants	
Pseudonym	Major
Ellinor	Mathematics Education
Issa	Software Engineering
Jonas	Mechatronics
Maimona	Artificial Intelligence
Minyguy	Mechatronics
Tito	Mechatronics

ensure anonymity of participants in this preliminary study, we are only reporting the majors provided by the participants (see Table 1).

Methods

Author 1 recruited participants through in-person, in-class presentations, Canvas posts, and emails from second-semester STEM courses, including Calculus 2, Core Elements in Mathematics 2 (modeling with calculus, statistics, and probability), Mathematics 2 (linear algebra, differential equations, and multivariable calculus), and Discrete Mathematics 1 (logic theory, graph theory, combinatorics, and formal models). Six participant interviews were collected and analyzed for this qualitative study. Due to the linguistic diversity of the participants, we provided the option to answer questions in the language of their choice with the option of the interviewer later translating their responses. Each participant chose to complete the interview in English and interjected Norwegian, Danish, Arabic, or Kurdish words when applicable. Each interview lasted for about an hour and participants were compensated with a nominal monetary incentive card.

The in-person semi-structured interviews were recorded via Zoom, transcribed using Microsoft Word, and analyzed to determine the clarity, effectiveness, and overall function of the drafted interview protocol (Clark et al., 2021). We reviewed the transcripts to ensure the transcript accurately reflected the audio as well as to start the data familiarization process. Using qualitative analysis software (MAXQDA), we completed two abductive coding passes. The first coding pass captured instances of participants describing their mathematical background and mathematics course structure. The second coding pass focused on predefined capital (Yosso, 2005) and additional forms of capital that emerged from the data. Through thematic analysis (Braun & Clarke, 2012), codes were grouped and condensed into similarly themed clusters. The quotes within each cluster were summarized to develop emerging themes. An iterative comparison between the codes and summaries occurred which produced the preliminary results found in this paper.

Preliminary Results

Participants discussed how the structure of first-year mathematics courses supported their learning and the collaborative community of peers and instructors they built to successfully navigate first-year mathematics courses.

The Structure of First-Year Mathematics Courses

Mathematics courses at this Norwegian university met twice a week for "an hour and 30 minutes usually [with a] 15-minute break in the middle" (Ellinor). The courses were taught in a lecture-based format where students mainly listened to the instructor and followed along with examples. Tito described his mathematics course in the following way: "the teacher explain[s] basics of what we're going to do and then shows [the] theory behind it, and then maybe some practical examples." Maimona recounted her instructor's didactic practices saying "[the instructor] does go through some tasks. And he asks us, what do you think about [the task]? How do you think you should solve [the task]?" Minyguy similarly described the instructional practices featured in class, "[the instructor] go[es] through different topics on the stand and they explain stuff and you can ask questions, but mostly it's the teacher explaining stuff." Overall, the participants' mathematics courses included the potential for student practice but mainly relied on instructor lectures to convey the material.

Some mathematics courses were paired with a group seminar where students engaged in "practice tasks and the teachers [attended] to answer questions" (Minyguy). The practice seminar was used as additional time for students to engage with the material before assessments which regularly took place throughout the semester. Minyguy elaborated on the assessment structure in the following:

> There are five tests throughout the semester and you have four attempts on each one… I like that over having one major exam because it means that there is less of a last ditch effort right before the exam…You have multiple attempts, so there's not really that much pressure.

However, even with the opportunity to practice outside of class and a more forgiving assessment system, some students found the transition to lecture-based classes to be difficult. For example, Maimona shared "I didn't know how the lecture worked because in high school [I] had [a] different class system." Jonas also expressed how the transition to exam-only assessment proved difficult when learning the material, "I spent the first one or two months pretty much just becoming good at the tests instead of actually getting a grasp on what we were working with." Ellinor confirmed that although the transition to the Norwegian university was "as smooth as possible" until she started second-semester calculus where she "came to the first lecture, and everyone's already a week behind." The twice-a-week frequency combined with seminar space for students to practice and the multiple-attempt, multi-exam assessment structure provided FGCS the opportunity to form a mathematics community.

Creating a Collaborative Community with Peers and Instructors

Two students emphasized their relationships with their instructors in addition to their peers as contributing factors to their success in navigating first-year mathematics courses. Jonas realized building relationships with instructors was key to his success, "if I show engagement, [the instructors] show engagement with me. If I show interest, [the instructors] show interest in me. So that's really good." Ellinor and Jonas noted that instructors were keen on having students ask questions in or outside of class.

> It's just like our professors ask us. Say it. If there's something you don't understand, just say it which makes it a little easier to do. Say, I don't understand that, and then they'll just show it again. Explain it in a different way which helps a lot. (Ellinor)

Instructors encouraged students to speak up during class yet made themselves available after class for any lingering questions from students. Jonas recognized that if he just waited, "most of [his] questions [would] be asked and answered throughout the course, and if they [weren't], [he'd] get a one-on-one with the teacher afterward. [The instructors] put in time for it." The instructors of first-year mathematics courses were seen as approachable and supported student growth through encouraging questions.

In addition to collaborating with instructors, students believed that their friends were "quite gifted" (Issa). Multiple students attributed their success in first-year mathematics courses to working with their peers: "those moments when we collectively understand things is… it's probably one of the most fun things I've ever had in math cause it's just so satisfying" (Tito), "everyone wants everyone to do as well as they can, and that is absolutely a support" (Ellinor), and "I learned the topic better. They learn the topic better. I'm having fun. They're hopefully having fun" (Minyguy). Students mainly collaborated on solving problems from lectures and studying for their mathematics assessments. Maimona noted that she specifically utilized her peers for exam review and corrections because every computer-generated exam was different and the multiple attempts provided more opportunities to practice on a mastery scale. "I feel like

that's actually the reason I'm passing that because I do have multiple tries and other people send me their exams that I get to practice" (Maimona). Tito similarly believed that multiple exams influenced how he studied material. "I sit down with my friends and actually solve the problems and learn a lot from having just that type of exam… that's made me learn more stuff which I wouldn't have done if I'd had an exam at the end of the semester."

The culture of collaboration is normalized by the university's Center for Excellence in Mathematics where students have the opportunity to work together in a dedicated mathematics space and seek help from trained peer tutors. Ellinor described the Center for Excellence in Mathematics as "one of the greatest resources [the university has] that is used a lot." Issa also called the Center for Excellence in Mathematics "a system [at the university] that's really helpful" and the tutors as "really great." Minyguy confirmed that "[the Center for Excellence in Mathematics] is very accessible, it's very low bar of entry." The Center for Excellence in Mathematics is a popular option for students to utilize; when "everyone has finals here and there, it's like you have to fight for the spot at [the Center for Excellence in Mathematics], because so many people sit there to work. And it isn't really like that big of a spot. It's just like a corner of the library" (Ellinor). The accessibility of and normalized nature of seeking assistance through tutoring resources influenced how students collectively worked together.

The collaborative essence of first-year mathematics courses at the Norwegian university encapsulated more than sharing old exams or cooperatively solving mathematics problems, students in these courses were genuinely supportive of each other's growth. For example, Ellinor described sharing notes with peers: "you don't have to give up your notes. It's your notes, but it's like, of course because they would do the same. We always exchange everything. And if someone can't be in class, it's okay, then we take extra good notes." Peer-to-peer support extends to meeting the needs of peers and ensuring everyone in the class has the resources to be successful. "Everyone wants everyone to do as well as they can, and that is absolutely a support. I think this helps everyone in our class. I think it's really important" (Ellinor).

Discussion

We found that FGCS at this Norwegian university primarily navigated first-year mathematics courses by adopting a mentality of partnership or interdependent learning (Ives & Castillo-Montoya, 2020) instead of competition, which is noteworthy given the detrimental impacts of competitive cultures in STEM on FGCS (Canning et al., 2020). The structure of mastery-level assessment and practice seminars provided students with the impetus to collaborate and support each other's academic success in mathematics, which is one of the biggest predictors of retention in STEM disciplines for FGCS (Dika & D'Amico, 2016). Building in-class peer relationships and peer tutor relationships proved to be the most successful navigational strategy for FGCS. However, this preliminary study is just one example of ways FGCS can be supported during their first-year mathematics courses. Additional research needs to be done to address other forms of capital FGCS in Norway are leveraging to persist in first-year mathematics courses. In future work, we anticipate expanding to include all forms of capital captured in CCW (Yosso, 2005) and hope to discover additional forms of capital that are unique to FGCS in Norway. We hope that our findings positively impact structures inhibiting FGCS success in Norway and beyond.

The flipped model of instruction has been championed as a method for increasing student engagement and enabling instructors to facilitate more active learning within the classroom. Research on the flipped model also suggests that it may also lead to better course outcomes than the traditional lecture approach. Given this potential for student success and engagement, faculty at California State University, Fullerton have adopted the model in many of their courses. In this preliminary report, we measure the impact of the flipped model on course outcomes of a Pre-Calculus course during the Spring 2024 semester. In addition, we compare student perceptions of the course elements that supported their learning between students enrolled in the flipped sections of the course and those in the non-flipped sections of the course.

Keywords: flipped model, active learning, student experiences

Introduction

The flipped model of classroom instruction is a mode of active learning rooted in the constructivist theory of learning (Bishop & Verleger, 2013). In this model, students consume course content outside of the classroom through video lectures and/or course readings and spend in-person classroom time engaging in collaborative learning and problem solving (Lage et al., 2000; Salifu, 2017). Since gaining popularity during the early 2000's, various scholars have championed the model for its effect on student achievement (e.g., Caviglia-Harris, 2016; Connell et al., 2016; Day, 2018; Le & Ichinose, 2022) as well as attitudes towards learning and classroom engagement (Alebrahim & Ku, 2020; Stone, 2012).

Within the past decade, there has been a great shift towards active learning pedagogies (Stone-Johnstone et al., 2024) within the mathematics department at California State University, Fullerton (CSUF). One of the most popular active learning approaches used at CSUF is the flipped model, with many introductory mathematics courses (e.g., College Algebra, and the Calculus series) being flipped by certain professors. In this preliminary report, we evaluate the effect of the flipped model within the Pre-Calculus course at CSUF during the Spring 2024 semester by answering the following research questions:

1. Is there a statistically significant difference in course outcomes between the students in a flipped vs. non-flipped Pre-Calculus course at CSUF?
2. Are there differences in student perceptions of the course elements that supported their learning between the two groups?

Methods

Context

The flipped model, as employed at CSUF, is a three-part model that consists of online interactive content videos, pre-assessments (Ticket in the Door, TITD), and mathematics labs. Traditional lecture time is reconceptualized within this model as a mathematics lab, where

students work collaboratively on activities in their course workbook during in-person class time. Data for this study was collected during the Spring 2024 semester, where there were eight coordinated sections of Pre-Calculus with an average of 35 students in each section. Out of the eight sections, four were flipped and the other four were non-flipped. In the non-flipped sections, students primarily learned course content within the classroom, with some instructors choosing to post optional resources for students to engage within the learning management system (Canvas). All students were assessed using common midterms and final exams.

Theoretical Framework

Given the emphasis on student classroom engagement within the flipped model at CSUF, we view the data through the lens of the Instructional Triangle (Cohen et al., 2003; Lampert, 2001). The instructional triangle is a framework for articulating the process of teaching and learning. This triangle consists of three primary nodes: student, teacher, and content (see Figure 1). The arrows represent the interactions between the nodes. As Cohen et al. (2003) explained, "instruction consists of interactions among teachers and students around content, in environments" (p. 122).

Student-student interactions may occur through in and out-of-class collaboration. Student-teacher interactions include teacher moves for engaging students and supporting their learning (Ball & Forzani, 2009). Student-content represents how students engage in course content, and this may be through course resources (e.g., homework, videos, textbook). Teacher-content interactions represent the instructional choices for content delivery. The concentric circles within Figure 1 represent the varying levels of the environment in which this learning transpires (in and outside the classroom). Given the differing pedagogical approaches within the flipped vs. non-flipped courses, the instructional triangle enables us to explore the student experience by examining the types of interactions that students identified as contributing to their learning.

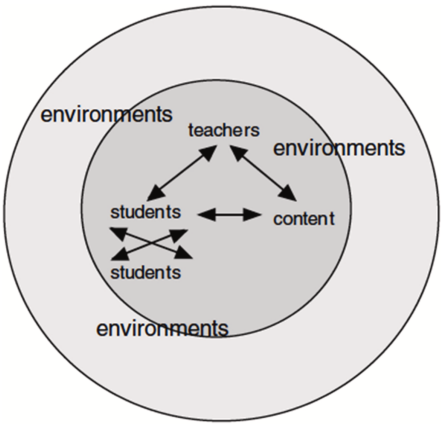

Figure 1. The Instructional Triangle (Cohen et al., 2003).

Data Collection

This study was conducted with approval by CSUF's Institutional Review Board. There were two primary data sources employed to address the research objectives: student course outcome data for all Pre-Calculus students during the Spring 2024 semester and survey data. The authors constructed a Qualtrics survey, consisting of three parts. The first part consisted of Likert-type questions, gauging student perceptions about course structures (e.g., course workbooks, activities, and assessments). The second part consisted of three open-ended questions regarding their perceptions of support and barriers to their learning of course content. The final section

consisted of demographic questions including information about previously attempted mathematics courses, placement scores (for entrance at CSUF), and their projected course grade.

Data Analysis

Employing a mixed-methods approach to data analysis (Creswell, 2012), we answer the first research question by conducting a quantitative analysis. Specifically, we performed a two-sample *t*-test to determine whether there was a statistically significant difference in the course outcomes between flipped and non-flipped courses. Students who withdrew from the course (n = 25) were removed from the analysis since no point value was assigned to a grade of W.

We answer the second research question regarding student perception of the support for their learning of Pre-Calculus, by conducting a qualitative analysis. All Pre-Calculus students were asked to complete the Qualtrics survey during the ninth and tenth week of the semester. Of the 276 enrolled students, 173 completed the survey (approximately 63% response rate): 88 students in the flipped course and 85 in the non-flipped course. For the purpose of this investigation, we focused on students' responses to the open-ended question, "What are two or three components of the course that have supported your learning?"

All student responses were coded using a coding scheme adopted from the Instructional Triangle framework (Cohen et al., 2003). Since students discussed aspects of the course that they found beneficial to their learning, we limited our coding to focus on the Student-Student, Student-Teacher, and Student-Content interactions within the Instructional Triangle. The dataset did not allow for us to explore the Teacher-Content interactions, nor teacher motivations for their instructional choices (i.e., Herbst & Chazan, 2012). Throughout the coding process, a subcode of the Student-Content interaction was created, "External Resources," to describe instances where students relied on learning resources separate from the ones provided by the instructor. A second subcode, "Office Hours," was generated to differentiate between iniclass teacher support and outside-class teacher support, given the additional effort required for the latter.

There were 132 complete student responses to this open-ended question. The first author coded the entire dataset, and 30% of the dataset was double-coded by two other members of the research team. Instances of disagreement were discussed and negotiated, with only two instances of disagreement (95% agreement).

Preliminary Findings

Course Outcomes

The result of the two-tailed independent samples t-test was not significant based on an alpha value of .05, $t(248) = 1.53$, $p = .126$, indicating there was no significant difference in the course performance (course grade point value) between the flipped and non-flipped classrooms. The results are presented in Table 1. While the difference in performance was not statistically significant, the overall mean score in the flipped classrooms was slightly higher. In particular, the mean value of course grades is 0.27 points higher for the flipped modality compared to the non-flipped modality (~ 13.6% difference).

Table 1: Two-Tailed Independent Samples t-Test for Final Grade Point Value by Modality

	Flipped			Non-Flipped				
Variable	M	SD	n	M	SD	n	t	p

Point Value	2.25	1.31	114	1.98	1.36	136	1.53	.126

Perceived Supports for Learning

When comparing the students in the flipped course to those in the non-flipped course, we did not observe meaningful differences in the course components that students identified as supporting their learning. Table 2 illustrates the frequency of the different codes across the two groups of students.

Table 2. Distribution of Code Frequencies between Students in Flipped and Non-Flipped Courses

	Flipped	Non-Flipped
Student-Student	11	5
Student-Teacher	27	22
Office Hours	1	8
Student-Content	57	50
External Resources	2	5

More of the flipped students mentioned Student-Student coded elements as supporting their learning, with one student commenting: "We help out what questions we have to answer as a group while working on the workbook and worksheet." Some students in the non-flipped course also expressed valuing group collaboration, explicitly naming "in class group activities" as supporting their learning.

Students in both groups credited their instructor's in-class explanations and lectures for supporting their learning. However, it is worth noting that eight students from the non-flipped group (compared to just one from the flipped group) specifically mentioned attending their instructor's office hours as a course element that supported their learning.

The majority of the dataset was coded as "Student-Content," with both groups of students identifying the workbook, the online homework, and, for the flipped classroom students, the Ticket in the Doors as valuable to their learning. The primary differences that arose between the two groups were with respect to the types of external resources students credited. Two flipped students mentioned workshops (Supplemental Instruction) as a support, while the five non-flipped students mentioned resources such as YouTube and Khan Academy.

Discussion

The preliminary findings revealed no statistically significant difference in course outcomes between the students in a flipped vs. non-flipped course; however, the data does suggest the flipped model may still have potential benefits for course outcomes. The observed 13.6% higher mean point value of letter grades between the flipped and non-flipped students is promising. Similarly, we did not observe notable differences when comparing the student's perceptions of course supports between the flipped and non-flipped modalities. Students from both modalities primarily credited their learning to course elements such as homework assignments and in-class workbook activities.

Considering the active teaching culture within the mathematics department at CSUF, one could speculate that the non-flipped model might have incorporated more interactive elements compared to a traditional lecture-based course. If so, this could account for the similarities in

student perceptions regarding the course elements that supported their learning between both modalities. The only notable difference in students' perceptions was that non-flipped students reported using Khan Academy and YouTube for video lecture support whereas the flipped students already had instructor-provided videos embedded within the course.

As we continue to explore this data, and the flipped classroom model in general, we invite the audience to consider the following questions:

1. Though we found no significant or noticeable differences between flipped and non-flipped modalities of instruction, how does this finding contend with the current teaching and learning climate?
2. What specific aspects of the flipped and non-flipped course formats might have led to the observed lack of statistically significant difference in student outcomes?

Is it a Simple Mistake?: Tutors' Perceptions of Student Errors

Megan Ryals
University of Virginia

Mary E. Pilgrim
San Diego State University

Linda Burks
Santa Clara University

Undergraduate math tutors frequently interact with students who are currently at a point of impasse or who have experienced failure and are seeking help. This affords tutors the opportunity to impact students' understanding of mathematics as well as redirect their study efforts. Helping students accurately classify their mistakes is a worthwhile effort, but is challenging and requires training and support. However, to provide this training for tutors, we need to know how tutors view student errors. This report details preliminary results from a survey given to current tutors, asking them to classify authentic student mistakes on a test as "simple" or "not simple." We discuss multiple reasons tutors give for their classifications, including some which stand in contrast to those we might use as researchers.

Keywords: error analysis, tutoring, college algebra, simple mistakes

Experiences in first year mathematics courses influence persistence in Science, Engineering, Technology, or Mathematics (STEM) majors (Seymour et al., 2019). The presence of a math tutoring center, outside the classroom, has been shown to be significantly related to a positive student attitude toward mathematics (Bressoud et al., 2019). A key element of tutoring is identifying student mistakes and addressing students' misconceptions. Consider the following student work from a College Algebra exam.

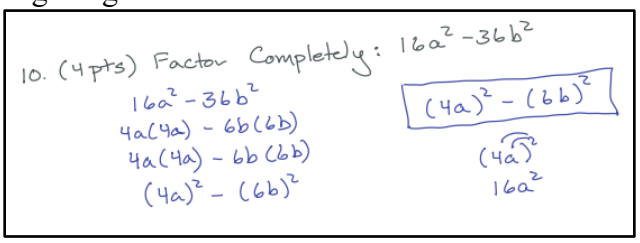

Figure 1. A student's work on a College Algebra exam problem asking students to complete factor $16a^2$-$36b^2$.

When presented with the student work (Figure 1), some undergraduate math tutors classified the mistake as being simple and others did not. A tutor who felt that the mistake was simple stated, "The student recognized that both 16a^2 and 36b^2 are both perfect squares…I think this mistake is just a lack of pattern recognition and can be solved with just more reps and familiarity." In contrast, another tutor felt that the mistake was not simple, stating "I don't think they understood what the question was asking and knowing what to do when asked to factor is important." When people in support roles, such as tutors, provide assistance to students, their perceptions of students' errors can impact the type of assistance they decide to give. However, tutors are often expected to provide guidance and instruction without training in how to analyze student work or respond to it. This preliminary report discusses how tutors classify College Algebra students' errors on an exam, specifically addressing the question, *What justifications do undergraduate math tutors provide when classifying a student's error as simple or not simple?*

Literature and Theoretical Perspective

Errors are typically described as a deviation between "the current state and the desired state" or a lack of adherence to convention (Tulis et al., 2015). Mathematical mistakes may be a result

of misconceptions or "inadequate cognitive schemes" or due to a mental "slip" (Molina et al., 2017). We distinguish between a "simple mistake," which is "one that could be made accidentally, would likely not be repeated, or violates a mathematical convention rather than a rule" and a "not simple mistake" which provides evidence of "lack of conceptual understanding" (Ryals et al., 2020). Prior work has shown that students and teachers view mistakes differently (Lannin et al., 2007), and students are more likely than researchers to categorize their own errors as simple mistakes (Ryals et al., 2020).

Our study is motivated and guided by our valuing the "constructive error climate," which Benecke and Kaiser (2023) describe as "one where both teachers and students acknowledge errors as potentially helpful" and "errors are analyzed and used as learning opportunities" (p. 164). The traditionally negative view of mistakes as something to avoid, is shifting toward a more positive view of mistakes as contributing to learning (Borasi,1987; Dweck, 2006). Reflecting on mistakes helps learners establish correct mental models (Kapur 2010; Kapur 2014; VanLehn et al. 2003). Still, students do not often use errors to learn, as learning from errors is challenging and more demanding than simply looking at a correct solution (Kyaruzi et al, 2020; Heinze et al., 2012). Students need guidance in learning from mistakes. While researchers have shown that beliefs and self-regulation strategies are important, teachers still concentrate primarily on content rather than on problem solving, metacognition, and beliefs (Schoenfeld, 2022). They typically do not direct students' attention to ways to avoid similar errors in the future (Rach et al., 2013). We therefore recognize an important opportunity for tutors to support individual students to analyze, understand, and learn from their errors.

While new concepts are typically introduced during class time, it is during office hours and tutoring sessions that students can discuss their mistakes. Undergraduate peer tutors view mistakes from two perspectives; they recognize their own mistakes as students, and they recognize common mistakes they see in their students' work (Ryals et al., 2022). Peer tutors also work in the environment of a tutoring center where the teacher is not present and the student may be more comfortable discussing their mistakes. While tutors have a unique opportunity to help students understand and learn from their errors, and do so in a positive manner, they would likely need training to do so (Johns, 2022). To provide effective training, we first must determine how tutors view students' mistakes and how those views differ from our own.

Methods

Data Collection

We designed a survey with six student errors from a College Algebra exam, including the one presented above. We selected these examples strategically, wanting to provide a mixture of examples that we, as researchers, considered simple and not simple errors. We also wanted to choose student work that contained one specific error, rather than several, so that attention could be drawn to that one error for analysis. Each problem itself along with the student work was displayed in the survey, and we provided a short description of the error that was made. We asked the tutor to classify the error as Simple or Not Simple and to explain their choice. We did not give the tutors a definition of a simple mistake and did not provide examples of mistakes we would consider simple or not simple. At the end of the survey, tutors were asked to summarize how they distinguish between simple and not simple mistakes and how the type of mistakes students had made on a recent test would influence how they help a student prepare for future tests.

The survey was distributed to all current tutors employed in the campus Math Learning Centers at two institutions in the Spring 2023 term. Eleven tutors at Institution A and 9 at Institution B submitted the survey. Of these 20 submissions, 11 submissions were complete. We omitted responses to the sixth error because we had provided an incorrect description of that error in the survey. Therefore, our analysis focuses on the categorizations of 5 errors by 11 tutors. We have not yet analyzed responses to the final two questions of the survey, where tutors were summarizing their definitions and discussing how they would assist students who had made particular types of mistakes.

Analysis

We began by reading through each tutor's response to each student error. We individually used open coding to begin developing a codebook. We then discussed each response and the codes we had individually developed and came to consensus on which codes to apply for each tutor response. We decided that multiple codes could be applied to a single tutor response. We added these to the first version of our Codebook.

We then individually used this codebook to do a second round of coding and used the constant comparative method to refine and develop new codes (Glaser, 1965). We noted difficulties in applying these codes and met a second time to resolve the codes. In the third round of code development and modification, we began condensing codes and creating subcodes. For example, we had applied the code "Lacking Knowledge" to many tutor responses. We grouped the responses based on similarities and replaced this code with four more specific codes that identified what type of knowledge the student was lacking (e.g., conceptual, specific formulae).

Results

We begin with a discussion of responses tutors gave to support their classification of a student error being simple. Later we will discuss responses given to support not simple classifications, and finally those that could be used for either simple or not simple. The diagram below (Figure 2) shows each code and whether it was applied more often to responses that classified the error as simple or not simple.

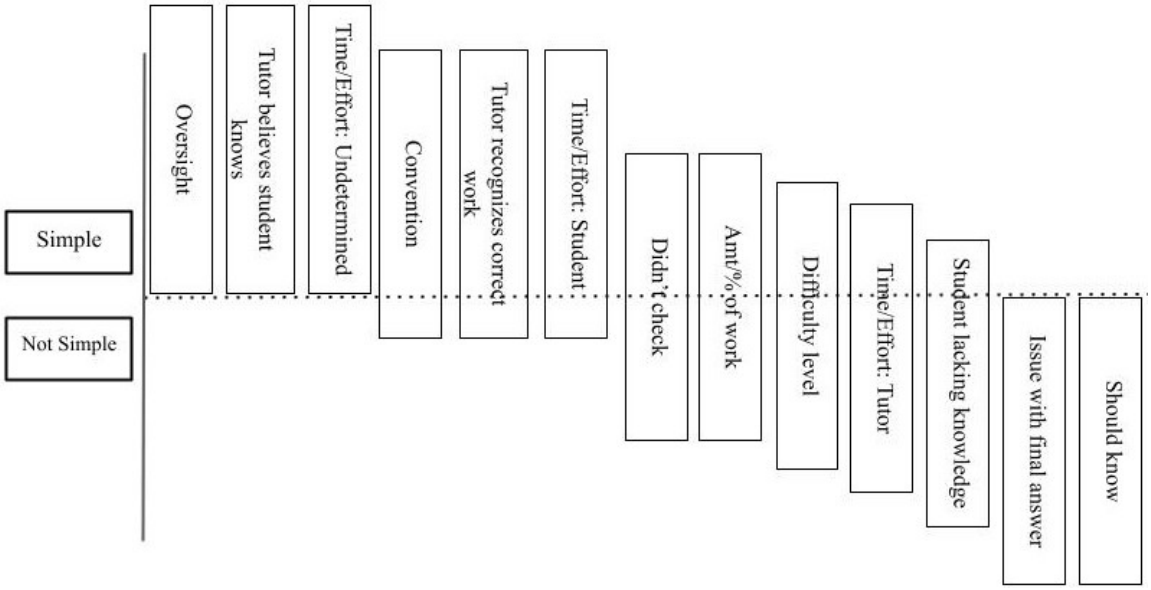

Figure 2. Codes Describing Reasons Tutors Provide for Error Classification

Codes for Simple Mistakes

There were three codes we developed that were applied only to responses where tutors had classified an error as simple. The first was *oversight.* We applied this code when the tutor claimed the mistake was simple because the student had overlooked something or worked too quickly. The second was *tutor believes student knows*. This code was used when tutors stated or implied that despite the error, the student understands the concept or knows the procedure. We also created a code, *time/effort: undetermined* that we used when tutors indicated the mistake was simple because not much time or effort would be required to prevent the error. When this code was applied, it was unclear whether the tutor was referencing time and effort on the part of the tutor, student, or both.

Other codes were used almost exclusively for mistakes tutors classified as simple. Tutors sometimes claimed that the student had not made an error, but rather had failed to adhere to classroom expectations or convention, such as simplifying an expression to a certain point. To these we applied the code *convention*. There were also tutor explanations that focused on the work completed in the problem. We applied the code *tutor recognizes correct work* when tutors explained the student had successfully completed the difficult part of the problem or noted students had demonstrated the knowledge needed to avoid that error somewhere else in the problem. Finally, sometimes tutors focused not on the work done in the problem but what could have been done prior to the exam to prevent the error. Multiple responses indicated an error was simple because the *time/effort* required by the *student* to avoid the error was relatively low.

Codes for Not Simple Mistakes

Several reasons were used by tutors exclusively to justify classifying errors as not simple. The first of these was that the student *should know* how to solve this problem correctly. In cases where we applied this code, tutors discussed their expectation that students in the course should not have made this error or this was not an understandable mistake. A second code, *issue with final answer*, was applied when a tutor claimed an error was not simple because the error caused the student's answer to be significantly different from the correct response.

Many tutor responses attributed errors to the *student lacking knowledge*. We identified four types of knowledge they referenced; two of these were applied only in situations where the tutors were claiming an error was not simple: *lacking conceptual knowledge* and *lacking knowledge of specific content or rules*. When the code lacking conceptual knowledge was applied, tutors described a lack of understanding, reasoning, or fundamental knowledge. The code, lacking knowledge of specific content or rules, was used when tutors had indicated the mistake was not simple because the student was unfamiliar with or had forgotten a rule or formula.

Codes for Both Simple and Not Simple Mistakes

We developed two other codes to use when tutors referenced a lack of knowledge. In the first, *structure and strategy*, tutors attributed errors to an inability to recognize the problem structure or identify an appropriate strategy for solving the problem. Closely related was the code *goal state issues*. This was applied when tutors indicated the student could not identify what the problem was asking or what type of answer they were expected to provide. Both these codes were applied at times to justify classifying a mistake as simple, and others to justify the choice of not simple. Other codes related not to the knowledge tutors believed students had but to student behavior while solving the problem. These include *didn't check* and *amount/percent of work*. Tutor responses with the code didn't check indicated the error would have been avoided if the

student had checked their work. Responses coded as amount/percent of work focused on the amount of work shown or the percent of the problem that was successfully completed. Again, these codes were sometimes used to support classifying a mistake as simple and at other times to support classifying a mistake as not simple.

Two additional types of responses were used to justify both simple and not simple classifications. In the first, tutors would describe the amount or type of assistance they would need to provide the student for them to avoid the error. This was coded *time/effort: tutor*. Not simple errors were ones that would require significant intervention by the tutor. In the second type of response, the tutor focused not on the student's answer but on the *difficulty level* of the problem itself. It was common for tutors to associate problems they perceived as easy with simple mistakes, though this wasn't always the case.

Codes About the Tutors' Reflective Process

The codes discussed above were reasons tutors gave to explain their classification of an error as simple or not simple. However, three additional codes were created that describe the tutors' reflective process as they determined whether students' mistakes were simple or not. While these codes do not directly address the research question, we wanted to capture recurring themes in the tutor approach to analyzing student work that may be useful in future analysis. The first of these codes was *more information*. This was applied to responses where tutors expressed uncertainty about their decision to classify the error as simple or not simple. The second was *tutor notes multiple reasons* and was applied if the tutor gave multiple possible explanations for the student's mistake. Finally, the code *tutor references past experience* was applied if tutors made mention of a mistake being common or seeing this issue with students in the past.

Discussion

In this study we asked undergraduate math tutors to classify student errors on a College Algebra test as simple or not simple and provide justifications for their decisions. We saw that at times tutors provided similar distinctions between simple and not simple errors that we had previously made ourselves (Ryals et al., 2020). For example, tutors typically said that mistakes made in-the-moment due to *oversight* or errors that could be attributed to not conforming to *convention*, such as simplification, were simple. Tutors also tended to classify a mistake as simple if the student had demonstrated the necessary knowledge or skills elsewhere in the problem. In contrast, the tutors were much more likely to consider a mistake not simple if they attributed the mistake to a *lack of knowledge*.

Some of the tutors' distinctions between simple and not simple stood in contrast to our own. For example, tutors sometimes attended to features of the problem itself, rather than the student work. In other cases, they focused on what would need to be done, either by the student or tutor, to prevent the error. If the time and/or effort required was small enough, tutors considered the mistake simple. We also saw cases of the tutor deciding whether a mistake was simple based on how much the error impacted the student's final answer.

We have more data to analyze from the completed survey and would like to distribute the survey more widely. We pose the following questions for discussion:

1. How might we modify the format or administration of the survey in future iterations to collect data we can use to further refine our current codebook?
2. How does the experience level of the tutor impact/influence their categorizations about the simple/not simple distinction? Can we answer this using our current data?
3. How can we use these results to provide training for new and experienced tutors?

Identifying Pedagogical Proof Moves

Valentin A. B. Küchle
Auburn University

Paul C. Dawkins
Texas State University

Drawing on the concept of "moves" from English for Specific Purposes (ESP) genre theory, we identified pedagogical proof moves—moves proof authors make for pedagogical purposes—in a corpus of 40 abstract algebra proofs. We share 12 such pedagogical proof moves, presenting three in greater detail.

Keywords: move analysis, pedagogy, proof

There exists an image of mathematics texts as consisting of "pages of information with virtually no repetition, no varying of pace, few topic and concluding sentences, as few words as possible [… where] clarification is achieved by constructing very precise sentences without any extra words" (Tobias, 1989, p. 49). This observation about the terseness of mathematics texts could be made about proofs in particular—and *is* perhaps the image of prototypical proofs (see Dawkins and Weber, 2017, documenting the norm that "irrelevant statements are not presented in a proof," p. 131). Yet, in our experience, proofs, particularly those written for undergraduate students, are *not* solely presented as a chain of deductions without repetition or clarification. Consider the following example from Abstract Algebra lecture notes:

> **Theorem VI.2.** *Let (G,○) be a group and let a be an element of G. Then a has a unique inverse.*
>
> PROOF. Our proof follows the same pattern as the proof of Theorem VI.1, and you'll see this pattern again and again during your undergraduate career. Almost all uniqueness proofs follow the same pattern: suppose that there are two of the thing that we want to prove unique; show that these two must be equal; therefore it is unique. ((This paragraph has the phrase "*key trick!*" written in the margins next to it.))
>
> For our proof we suppose that *b* and *c* are both inverses of *a*. […] ((proof continues))

As we hope the reader will agree, the entire first paragraph is logically unnecessary. But the author's choice to include such "superfluous" elements indicates that they are not superfluous and do serve a purpose. Specifically, the paragraph's purpose appears to be to facilitate learning by distilling and pointing out the key idea behind most uniqueness proofs so that the learner may recognize the given proof as being an instance of this particular proof type.

To describe this first paragraph (and similar pedagogical elements of proof), we draw on a concept from English for Specific Purposes (ESP) genre theory: moves. Moves are functional units of a genre, that is, units which are focused on what a text is doing, not on what a text is saying or its form (Hyon, 2018). Moves have been studied since Swales's (1981) identification of a four-move structure in journal article introductions, later amended to a three-move structure (Swales, 1990) (e.g., establishing a niche). Relevant to our study is that moves: (a) may vary in size and do not need to align with grammatical units, (b) can be optional (i.e., not all moves need to appear in every text), and (c) can be flexibly used (i.e., moves need not occur in a specific sequence) (Bhatia, 1993; Hyon, 2018). With this in mind, we see the proof's first paragraph as realizing a move which one might call *commenting on proving*. Given our focus on the genre of proof and our interest in those moves that appear to serve distinctly pedagogical purposes (i.e., facilitate learning), we seek to address: *What pedagogical proof moves do authors of undergraduate texts make in their proofs?* To better describe these moves in our Results section,

we will also draw on concepts from close cousins of ESP genre theory: (a) intertextuality from Bakhtinian genre theory, and (b) metafunctions from systemic functional linguistics (SFL) genre theory.

Relevant Literature

Mathematics education researchers have termed mathematical proof a genre (e.g., Lew & Mejía Ramos, 2020; Selden & Selden, 2014), a claim that we recently demonstrated aligns with modern genre theory traditions (Küchle & Dawkins, 2024). Since "[a] genre comprises a class of communicative events, the members of which share some set of communicative purposes" (Swales, 1990, p. 58), (slight) differences in communicative purpose can lead to (slightly) different genres. Therefore, we concur with Lai et al. (2012) and Lai and Weber (2014) that it is appropriate to view "proof[s] […] presented to students for pedagogical purposes" (Lai et al., 2012, p. 147) as a sub-genre of proofs.

This sub-genre itself contains some variation. Both Lai and Weber's (2014) and Pinto and Karsenty's (2020) mathematician participants expressed that features of their proofs for pedagogical purposes would depend on whether the proof was presented in lecture or written for a textbook. Both studies showed that mathematicians believed that textbook proofs should be rigorous and complete, whereas lecture proofs—due to lectures' affordances (e.g., reading the audience, gesturing) and constraints (e.g., time)—are allowed to omit details but should incorporate pictures, highlight main ideas, and communicate intuitions. Thus, pedagogical additions to proof (e.g., incorporating pictures, highlighting main ideas) appeared to be more associated with lecture proofs than textbook proofs for the mathematician participants.

Yet, Lai et al. (2012) demonstrated that in textbook proofs written for pedagogical purposes, mathematicians valued more than just rigor and completeness. By asking participants to improve the clarity of two proofs intended for a sophomore- or junior-level mathematics major, Lai et al. (2012) identified three types of revisions the mathematicians made: additions (e.g., adding a picture), alterations (e.g., altering phrasing), and deletions (e.g., deleting irrelevant statements). Further, Lai et al. (2012) confirmed mathematicians' beliefs that the quality of a proof presented for pedagogical purposes could be improved by: (a) "adding introductory and concluding sentences that highlight the proof's framework" (p. 158), (b) "highlighting the main ideas of a proof with the judicious use of formatting" (p. 158), and (c) avoiding the addition of "unnecessary or irrelevant assumptions or computations" (p. 158).

In sum, there is evidence that proofs for pedagogical purposes is a sub-genre of proof and that mathematicians are aware of it. Moreover, mathematicians appear to distinguish between proofs for pedagogical purposes in lectures and those in textbooks. In particular, mathematicians appear to find that several pedagogical ideas (e.g., incorporating pictures, highlighting main ideas) seem to have less of a place in textbooks than in lectures. At the same time, Lai et al. (2012) identified some additions, alterations, and deletions that mathematicians make to textbook proofs to increase their pedagogical merit.

Methods

Data Collection

To build a corpus of proofs, we selected ten random proofs from four Abstract Algebra texts for a total of 40 proofs. The four Abstract Algebra texts were selected to be similar in content but different in style so that pedagogical moves might stand out more. They were: (a) Abstract Algebra lecture notes that the first author remembered for their pedagogical merit (e.g., see the

example at the start of the paper); (b) Gallian's (2017) *Contemporary abstract algebra*, which "[m]ay be the most widely used undergraduate algebra text" (Isaacs et al., 2015); (c) Dummit and Foote's (2004) *Abstract algebra*, chosen for its terseness; and (d) Carter's (2009) *Visual group theory*, chosen for its inclusion of visuals—common in mathematics, broadly, but, in our experience, less common in abstract algebra.

The 40 proofs were randomly selected as follows. For each text, a random number generator was used to select random pages. If a page contained no proof, we moved to the next randomly generated page number. If a page contained one proof, we selected this proof. If a page contained multiple proofs, a random number generator was used to select a proof from this page.

Data Analysis

As Lai et al. (2012) found, mathematicians add, alter, and delete texts (and pictures) from proofs to make them more pedagogical. Given our data (i.e., fixed proof texts), we decided to focus entirely on additively-realized pedagogical proof moves, that is, pedagogical proof moves that we were able to discern because they are realized through the addition of text. (Thus, the moves we eventually identified are a strict subset of all possible pedagogical proof moves.)

To identify these (additively-realized) pedagogical proof moves, we began by using a heuristic, by which we mean an "economical shortcut procedure[] that may not lead to optimal or correct results, but will generally produce outcomes that are in some sense satisfactory or 'good enough'" (Chow, 2015, pp. 977–978). In particular, we began by reading through the 40 proofs and crossing out as much text as possible to still leave a proof we judged to be logically valid. There were several instances in which we were unsure whether text could be crossed out, in which case we erred on the side of crossing it out. (Since we would later study this crossed out text more carefully, this means we erred on the side of overcoding.)

Studying the crossed-out text and asking questions around which text could be omitted to still leave a valid proof brought to our attention two types of moves, which we had felt unsure about crossing out from proofs:

- delimiting (Konior, 1993) moves (i.e., moves which indicate the beginning or ending of [a part of] the proof) (e.g., "Conversely, […]"); and
- justifying-supporting moves (i.e., moves which do not justify, but which provide justifying support by acknowledging that a warrant is needed) (e.g., "As in the proof of Cayley's Theorem, it is easy to verify that […] ((author omits argument))").

With awareness for these moves gained, we next coded each proof from beginning to end for:

- proving moves (i.e., moves which support the logical structure of the argument) (e.g., deducing, instantiating, defining);
- delimiting moves;
- justifying-supporting moves; and
- other (moves).

Given that moves can occur at various grain sizes (Hyon, 2018), our moves range in size from a word (e.g., "Conversely" realizing a delimiting move) to multiple sentences (e.g., the first paragraph of the Abstract Algebra proof at the start of this paper). Further, since text segments can perform multiple functions simultaneously, we allowed for the possibility of text segments realizing multiple moves at once.

We then focused our attention on the "other (moves)" code (to discern pedagogical proof moves) and coded its instances for their function(s) via process coding (Saldaña, 2009), whereby we described their function(s) using a verb or verb phrase (e.g., *simplifying notation*). We are

currently engaging in pattern coding (Saldaña, 2009), that is, we are in the process of combining and consolidating our process codes into a smaller number of pedagogical proof move codes.

Results

Below, we present the three most common pedagogical proof moves in our corpus. We then briefly list the other identified pedagogical proof moves.

Reminding the Reader

The pedagogical proof move that occurred most often (30 times) and in all sources was *reminding the reader*. To further describe this move, we found the concept of intertextuality useful, which refers to "how texts draw upon, incorporate, recontextualize and dialogue with other texts" (Fairclough, 2003, p. 17). We observed authors reminding the reader by: (a) expanding on intertextual references, and (b) making eliminable intertextual references.

In the case of expanding on intertextual references, authors reminded readers of the details of the reference they were making (e.g., reminding the reader of a definition, process, notation). For example: After "Let's recall what the quotient process does to arrows between cosets," the author proceeded to describe the quotient process. This type of reminder saves the reader the potential work of looking up the details of the reference being made.

In the case of making eliminable intertextual references, authors drew a connection for readers to past work (e.g., "This is similar to the proof of Proposition 25"). Thus far, we have discerned two distinct pedagogical uses. First, authors pointed to past work to explicitly or implicitly leave part of a proof to the reader. For example: "This has almost the same proof as Fermat's Little Theorem. I'll leave the necessary modifications as an easy exercise." This way, the author provides the reader with an idea of how the statement could be proved. Second, authors appeared to make eliminable intertextual references to get readers to see similarities between proofs, possibly so that readers might draw on previous experience and/or objectify a proof approach (e.g., the start of the proof presented at the beginning of this paper).

Indicating the Difficulty of an Argument

In all four sources, authors used language that indicated the difficulty of an argument they were making. Yet, there appeared to be different purposes. First, we observed authors using words such as "clearly," "obviously," and "it is immediate" to serve as placeholder warrants (or warrants of self-evidence) (12 times). Given that they were still part of the warrant structure, we coded these as justifying-supporting moves, not necessarily as pedagogical proof moves.

Given our focus on pedagogical proof moves, it was more interesting to us that we also observed words describing effort (e.g., easy, not very hard, only basic algebra, simple) or apparency (e.g., of course, just, straightforward) *not* being used as placeholder warrants (17 times). Instead, they were used to describe the effort a problem would take (e.g., "I'll leave the necessary modifications as an easy exercise"), sometimes alongside an exercise for the reader, sometimes as a description of the upcoming steps. These examples appeared to serve at least one of the following two functions: (a) reassuring the reader, and (b) putting a (sub)proof into perspective. In particular, drawing on the SFL idea of a text's three metafunctions (i.e., ideational, interpersonal, and textual), we see descriptions of effort and/or apparency as possibly intending to reassure the reader (interpersonal function) as well as putting into perspective a (sub)proof so the reader knows where (not) to focus their attention (ideational function). As Halmos (1970) noted, "the reason for saying that [statements] are obvious is to put them in proper perspective for the uninitiate" (p. 137).

Last, motivated by our data, we share an observation—probably familiar to mathematics educators but novel to (undergraduate) newcomers—about the use of "trivial," a seemingly close cousin to the above words of effort and apparency. Although "trivial" can be used to indicate the difficulty of an argument, it also has its very own mathematical meaning as "the most simple example of something" (cringo, 2012) or "the canonical obvious thing" (Brett Frankel, 2012) (e.g., trivial solutions, trivial representation, trivial subgroup). By differing (slightly) from the colloquial meaning, we posit that "trivial" could be received differently by newcomers than intended (see Pimm's, 1987, writing on semantic contamination).

Adding Clarification

The third move we saw all sources engage in was *adding clarification* (20 times). We documented authors adding clarification for two main purposes:

- to add precision (e.g., "We really mean that ($\mathbf{Z}/m\mathbf{Z},+,\cdot$) is a commutative ring."); and
- to "unpack" (or verbalize) symbols and diagrams (e.g., "(In words, T_g is just multiplication by g on the left.)").

Other Moves

There were three other moves we documented in multiple sources: (a) emphasizing (e.g., "it is the **least positive** integer") (12 times), (b) simplifying notation (e.g., "Write $g = \gcd(a,m)$") (3 times), and (c) providing extra information about mathematical objects, processes, or claims (e.g., "Define […] (This mapping is called the *natural homomorphism* from G to G/N.)") (3 times). Furthermore, we identified six moves that each appeared in only one of the sources: (a) visualizing a mathematical idea (10 times), (b) giving an example (6 times), (c) labeling an (set of) equation(s) for possible later reference (3 times), (d) amusing the reader (2 times), (e) pointing out a common student mistake (1 time), and (f) commenting on proving (1 time).

Discussion

As our current findings suggest, there is more to writing textbook proofs for pedagogical purposes than writing rigorous and complete proofs. In particular, the authors of the proofs we studied added a variety of logically unnecessary (but pedagogical) moves to their proofs—in contrast to the image of prototypical proofs. Although our focus was on pedagogical proof moves, this work also raises awareness of delimiting and justifying-supporting moves, which often intersected with pedagogical proof moves and merit further study.

As touched upon, a limitation of our work is its exclusive focus on pedagogical proof moves realized through the addition of text (as opposed to the alteration or deletion of text). Accordingly, we wonder: How could we empirically identify pedagogical proof moves in non-eliminable text? Further, we acknowledge that there are eight "other (moves)" segments that we have been unable to further describe with our current move codes. It is unclear to us if this is an issue with our identified moves or rather a natural finding about the prevalence of text segments without easily discernible purpose. Third, we recognize that although our corpus is appropriate in size for a move analysis, it has been limited to one domain of mathematics. Heeding the warning of Dawkins and Karunakaran (2016), we are in the process of expanding our corpus to Real Analysis and Linear Algebra texts, giving us an opportunity to evaluate our codes in other domains. Finally, although we have presented our work in the typical fashion of highlighting the most common codes (i.e., popular pedagogical proof moves), we wonder: Should this line of work instead highlight less common (and perhaps idiosyncratic) pedagogical proof moves to provide new ideas and possibly disrupt the status quo of (pedagogical) proof-writing?

Developing Understandings of Accumulation: A Preliminary Research Report

Allison Olshefke-Clark
University of Delaware

This preliminary research report examines how undergraduates develop quantitative meanings of accumulation from rate, a foundation for understanding the definite integral and the Fundamental Theorem of Calculus. This study is a pilot study for a larger project. It consists of a pre-/post-assessment and a teaching experiment. The task sequence provides opportunities for students to develop productive meanings for speed, distance, and their relationship as rate of change/accumulation. Preliminary analysis of the pre-assessment indicates that students struggle to conceptualize average and instantaneous speed, which suggests that the teaching experiment can be productive. In this report, I outline the theoretical framework, task sequence, preliminary findings, and ongoing work. I conclude with areas for audience discussion: Seeking feedback on analysis and ideas for expanding upon this pilot study.

Keywords: calculus, definite integral, accumulation, quantitative reasoning, student learning

The definite integral is a concept used for mathematical modeling in many disciplines including physics (e.g., Griffiths, 2013), economics and business (e.g., May & Bart, 2024), and biology (e.g., Garfinkel et al., 2017). Approaches to teaching the definite integral in high school and college calculus courses often promote a meaning for the integral as the area of a region bounded by a function's graph and the x-axis (Huffman Hayes, 2024). However, this meaning of the definite integral is idiosyncratic to the Cartesian coordinate system (e.g., Moore et al., 2014), and it is not productive for modeling all physical contexts (e.g., Sealey, 2006) or for making sense of all mathematical situations, such as backwards integration (Bajacharya et al., 2023).

Over the past decade, a small but growing body of literature has advanced the idea that students should be supported in developing quantitative meanings for the definite integral, i.e., focusing on the meanings of each component of the definite integral in a situation (Jones & Ely, 2023). In their review of literature, Jones and Ely (2023) outline two distinct approaches that researchers have used to develop students' quantitative meanings for the definite integral: Adding up the pieces (AUP) and accumulation from rate (AR). In brief, the difference between the AUP and AR approaches lies mainly in the relationships and quantities that compose the integrand. With an AUP approach, one conceives of the integrand as a multiplicative relationship that forms the target quantity when these "tiny bits" of the target quantity are summed (e.g., Oehrtman & Simmons, 2023; Stevens & Jones, 2023). In an AR approach, the relationship between the integrand and target quantity is explicitly covariational in that it considers how the changing rate of the target quantity affects the total accumulation of the target quantity (e.g., coordinating how total distance driven varies with instantaneous speed; Thompson et al., 2013).

Most of the recent research on students' meanings for the definite integral advances approaches that are compatible with AUP (Jones & Ely, 2023). This emphasis in the literature base may be because the AUP approach is seen as more intuitive and accessible for many calculus students. Intuitive because an AUP perspective can be more easily visualized for many of the bounded, physical contexts that students encounter in their college coursework. Accessible because students often enter calculus with limited understandings of rate (Frank & Thompson, 2021; Thompson 1994), which may make using the AR approach more challenging.

I argue, however, that the AR approach has benefits that outweigh its challenges. The AR approach is derived directly from the Fundamental Theorem of Calculus (FTC), which is the backbone of the discipline and is a major idea in many calculus curricula (Huffman Hayes, 2024; Lanius, 2024). Thompson (1994) emphasized the FTC as "the realization that the accumulation of a quantity and the rate of change of its accumulation are tightly related—is one of the intellectual hallmarks in the development of the calculus." (p. 8). Despite its importance, students have difficulty conceptualizing and operationalizing the FTC, and proponents of AR believe that this approach can coherently guide students to understanding it (Thompson et al., 2013). Moreover, I posit that the AR approach also prepares students for authentic intellectual work in many STEM fields, like engineering, as accumulation from rate is a crucial idea in approximation and predictive modeling (A. M. Clark, personal communication, April 10, 2024).

Although studies have attempted to use an AR approach with students (e.g., Thompson 1994), more research has focused on the way that students develop understandings of the definite integral across a unit via an AUP framework (e.g., Lehmann, 2024; Stevens & Jones, 2023). Thus, there is a need for further examining the viability of using an AR perspective to develop ideas about the definite integral and FTC. This study, which is a pilot study for my dissertation, focuses on investigating how students' thinking about accumulation of rate (as a precursor to the definite integral and FTC) develops over a series of tasks that advances the AR approach. In this preliminary research report I describe the task sequence and theoretical framework underlying it. I then report the results from the pre-assessment and discuss the ongoing teaching experiment. Finally, I conclude with planned next steps for this study and pose areas for audience discussion I anticipate engaging in during the session.

Methods

This pilot study is comprised of two parts: A whole-class pre-/post-assessment and a teaching experiment with a pair of students (Steffe & Thompson, 2000). At the time of submitting this report, the pre-assessment data has been collected and the teaching experiment is ongoing. The teaching experiment will continue across the Fall 2024 semester, and the post-assessment will be conducted in early December 2024. Preliminary analysis of all data will be completed and addressed in my presentation at the 2025 RUME conference. In this section, I describe the setting and participants involved in this pilot study. I also outline the task sequence and the theoretical framework that underlies them.

Theory and Tasks

Carlson et al. (2003) detailed a framework of the requisite mental actions needed to engage with the FTC (Table 1). The mental actions trace the development of an understanding of accumulation from rate that progresses from discrete to infinitesimal intervals. Guided by this framework, I compiled a task sequence that I hypothesize will provide students structured opportunities to develop each of these mental actions.

Table 1. Carlson et al.'s (2003) mental actions of the FTC

MA1	Coordinating the accumulation of discrete changes in a function's input variable with the accumulation of the average rate-of-change of the function on fixed intervals of the function's domain.
MA2	Coordinating the accumulation of smaller and smaller intervals of a function's input variable with the accumulation of the average rate-of-change on each interval.

MA3	Coordinating the accumulation of a function's input variable with the accumulation of instantaneous rate-of-change of the function from some fixed starting value to some specified value.

The pre- and post-assessment items are the *Round-Trip* task and the *Where's the Car?* task (Figure 1), which have the potential to elicit students' thinking about average rate of change and its accumulation in ways compatible with Carlson et al.'s (2003) framework. The purpose of the Round-Trip task (a version of San Diego to El Centro using relevant cities, which are masked for confidentiality; Hackworth, 1994) is to elicit teachers' meanings for average rate of change. It asks:

> A car went from College Town to The Beach, a distance of 90 miles, at 40 miles per hour. At what speed would it need to return to College Town if it were to have an average speed of 60 miles per hour over the whole trip?

The productive meaning for average speed is "the constant speed that the car would need to travel to go the same distance in the same amount of time as the actual trip," though teachers (and likely their students) often use the arithmetic mean to calculate the average speed (Yoon et al., 2015, p. 341).

The *Where's the Car?* task builds on this idea and is intended to provide students an opportunity to engage in MA1 (Table 1). In this task, students must use information about a car's instantaneous speed, provided in a table, to approximate an average rate of change for each discrete interval and determine the accumulated distance. The prompt and corresponding table for this task is shown in Figure 1 below.

The table below shows information about a car's speed at various time after the engine started. Assume that the car travels in a straight line after the engine starts. Approximately how far does the car travel in these 30 seconds?

Time since the engine started (seconds)	**Speed** (meters/second)
0	0
5	11
14	20
30	25

Figure 1. The Where's the Car? task

The teaching experiment consists of a series of four additional tasks. The first task, *Over and Back* (Thompson & Thompson, 1994), is used to further determine students' understanding of speed and develop productive meanings for average and instantaneous speed. Students are presented with an interactive applet of a 200ft race between a rabbit and a turtle. Students can change the animals' speeds to answer a variety of questions designed to promote an understanding of speed as the rate of change of distance (e.g., "Give Rabbit a speed that will make him go over and back in 7 minutes"). Once students have developed meanings for speed conducive to engaging with its accumulation, students will then have an opportunity to develop MA1 by engaging with the *Which Racetrack?* task. This is an extended version of *Where's the Car*? in which students use given speed data to determine which racetrack a car was driving based on its total distance. In *Designing a GPS,* students build to MA2 by gathering instantaneous speed information from a video of a racecar's dashboard to track the ongoing

distance accumulated. By having access to a relatively continuous stream of instantaneous speed data, I will challenge students to "coordinate the accumulation of smaller and smaller intervals" (Carlson et al., 2003, p. 167) in order to calculate better estimates of the distance and begin to explore the idea of instantaneous speed. The final task, *Drag Race,* builds to MA3. This task asks students to use a model of a racecar's speed in a drag race expressed in function notation, i.e., $v(t) = 71 \times (1 - (1/3)^t)$, to determine the car's distance from the starting line (i.e., distance accumulated) at specific times and eventually at any time. By using an explicit function, students can progress from MA2 to MA3 by considering the "instantaneous rate-of-change of the function from some fixed starting value to some specified value" (Carlson et al., 2003, p. 167).

Participants and Analysis

The participants in this study are a group of 12 undergraduate students enrolled in an undergraduate mathematics course focused on covariational and quantitative reasoning at a large, public university in the Mid-Atlantic United States. All students have previously taken Calculus I and thus have been introduced to the integral and FTC, though it is unknown to what extent they have had opportunities to think about these topics quantitatively. The whole group will take the pre- and post-assessments, and a pair of these students are the focal students of a teaching experiment. As a teacher-researcher, I can engage deeply with the thinking of the focal pair of students. In my instructional role for this course, I will also be aware of the progress of the non-focal students over the semester. This dual position will allow me additional insight as I analyze the changes between the pre- and post-assessments and conduct analysis.

During the first course session, the instructor administered the pre-assessment, which was composed of two items designed to probe students' incoming meanings for average rate of change and its accumulation. Students completed the pre-assessment independently. I coded student responses based on my interpretation of the type of quantitative meaning(s) for speed that the student used to solve the problem. The coding scheme for the *Round Trip* task was influenced by the rubric developed for the *San Diego to El Centro* task (Yoon et al., 2015) but was adapted to more closely characterize the meanings exhibited by this group of students. The coding scheme for *Where's the Car?* was developed inductively (Saldaña, 2021) and is presented in the following section.

Preliminary Results and Data in Progress

In this section, I present preliminary results based on students' responses to the two pre-assessment tasks. I also briefly discuss anticipated results from the ongoing teaching experiment.

Pre-Assessment Results

Most students did not exhibit evidence of quantitative meanings for speed that allowed them to productively calculate and/or accumulate average speed in either pre-assessment item.

In the *Round Trip* task, only four (33%) of the responses indicated a final answer that was a value for speed. Of these, only one response correctly identified the necessary return speed as 120 mph. The remaining three responses used the concept of arithmetic mean to calculate the needed return speed as 80 mph, echoing Yoon et al.'s (2015) findings. The final eight (67%) of the responses did not address the written prompt. These responses either did not clearly indicate a final answer (n = 3) or provided a final answer that was not a speed (n = 5). For instance, three students indicated their final answer was "1.5 hours." Notably, this is an intermediate measurement towards calculating the correct answer: 1.5 hours is the time it takes to travel 90 miles at 60 miles per hour.

Responses to the *Where's the Car?* task followed a similar breakdown. Three (25%) of the responses are potential evidence of MA1. These responses used the instantaneous speeds indicated to calculate a distance the car traveled over intervals based on the information in the table and then summed these distances to find the total distance over 30 seconds. A further four responses (33%) presented intermediate calculations that were consistent with MA1 activity within a single time interval, but did not calculate or accumulate the subsequent distances. For instance, some calculated that in the first five seconds the car traveled 55 meters, but they did not calculate the distance traveled in any other interval. Four students (33%) did not exhibit productive quantitative meanings for speed. The most common responses in this category added up the four provided instantaneous speeds and indicated the resulting sum as the total distance traveled. A final student simply responded, "I'm not sure."

Data in Progress/Anticipated Results

The results from the pre-assessment suggest that the students will benefit from further opportunities to develop quantitative meanings for speed (average and instantaneous) and distance as well as the relationships between them. I intend the ongoing teaching experiment to provide these opportunities, and I anticipate that engagement with the task sequence described above will help students develop productive meanings for these quantities in relation to the definite integral.

I have selected two students who did not get either pre-assessment task correct to serve as my focal pair for the teaching experiment. Through working with these students on the task sequence over two course sessions (about six total hours) I anticipate that I will be able to model how their thinking about accumulation from rate of change develops. In particular, I predict that by the end of the teaching experiment I will have clear evidence of the students operating with each of Carlson et al.'s (2003) mental actions.

Potential Areas of Audience Discussion

By the time of the conference in February 2025, I will have collected, compiled, and begun to analyze all the data from this study holistically. This includes the pre-assessment, exploratory teaching, and post-assessment data. Because this is a pilot study for a larger project, getting feedback from an audience at this stage of the research process will be incredibly helpful in refining the findings for presentation to my committee and in brainstorming how this work can be expanded upon for a larger study. I also hope that other researchers who investigate students' thinking about the definite integral will share their reactions to my findings, especially those who focus on quantitative approaches. Additionally, I am interested in further examining the benefits and drawbacks of the AUP and AR frameworks in different situations. Specific questions I intend to ask the audience include:

1. How does the analysis I present compellingly show students' developing reasoning within the AR conception of the definite integral? In what areas could I provide more nuance or further evidence?
2. In what ways do you think this study could be expanded upon? Are there any lines of thinking that would be particularly interesting to follow? Any new areas that would be useful to explore?
3. For calculus instructors: In what ways do my findings resonate with or challenge your experiences teaching the definite integral to undergraduates? What implications might these findings have for your own practice?

While Latine/Hispanic higher education enrollment rates have increased over time, enrollment in STEM, and mathematics in particular, has been slower to change. As part of a larger study, our team interrogates the experiences of those who have successfully navigated the mathematics pathway. Specifically, we look to understand how our research participants leveraged the support of both social (familial, peer, etc.) and institutional (mentors, faculty, administrators) along their academic pathways. We investigate primarily using in-depth qualitative interviews of five individuals who hold bachelor's degrees in mathematics and STEM PhDs, to ascertain both positive and negative influences on their education, utilizing the community cultural wealth framework. While the Latine PhD population is, of course, not monolithic, our findings suggest that social, familial, and navigational capital were instrumental in their ultimately successful navigation of both graduate and undergraduate education.

Keywords: community cultural wealth, mentorship, social networks, student experiences,

The increasing number of Latine students enrolling in higher education institutions has led to an increase in Hispanic Serving Institutions (HSIs) in the United States (Lane et al., 2024; Pawley, 2017). While certainly an increase in Latine/Hispanic student enrollment is an achievement to be celebrated, research on HSIs (Garcia, 2020, 2023) indicates that these institutions are still grappling with what it means to hold the HSI label and often struggle to serve their Latine student populations adequately. It is no secret that US higher education institutions have significant issues supporting, retaining, and graduating students from marginalized backgrounds in STEM and, specifically, in mathematics. According to the National Center for Education Statistics (2023), even with an increase in Latine/Hispanic student enrollment in colleges and universities, only 14.6% graduate with a STEM bachelor's degree, 11.4% obtain a STEM master's degree, and 9.2% are awarded a doctoral degree in STEM.

All stakeholders in the higher education space must understand the current educational landscape better in the context of Latine education if their goal is to truly serve and support Latine/Hispanic students. As part of this imperative, our research team investigates the experiences of those who have successfully navigated the math PhD pathway, focusing specifically on how they leveraged the support of both social (e.g., familial, peer, etc.) and institutional (e.g., mentors, advisors) actors in their academic endeavors. We aim to address the following research question: *What types of resources did Latine mathematics teaching-focused faculty draw from that helped them navigate and persist in the higher education space?*

Theoretical Background

Drawing from Critical Race Theory (CRT), Yosso (2005) developed the *Community Cultural Wealth* (CCW) framework, which takes an asset-based approach by recognizing the cultural wealth held by students who identify as underrepresented minorities (URMs) as valuable forms of knowledge in the education space. The CCW framework is composed of six forms of non-

dominant capital, which include (1) aspirational, (2) familial, (3) linguistic, (4) navigational, (5) resistant, and (6) social. Aspirational capital refers to maintaining hopes and dreams despite educational barriers. Familial capital relies on kinship and family ties that individuals can draw from as they navigate higher education. Linguistic capital refers to the multiple languages and communication styles that URMs can utilize from context to context. Resistant capital can be characterized by the knowledge, skills, and resources individuals can utilize to challenge systems built with dominant cultures in mind. Social capital encompasses the resources that individuals gain as they develop relationships and social networks. The CCW framework reorients cultural capital to a more dynamic model (Sablan & Tierney, 2014), providing an anti-deficit approach to the resources that URMs possess and leverage in their pursuit of a successful education.

In mathematics education, previous research studies have used the CCW framework as a guide for analysis to explore student and educator experiences at varying stages. This framework has been applied to investigate teaching practices (Holbrook, 2021) as well as the experiences of multilingual learners (Pelaez et al., 2023), teaching assistants (Poulsen Stringer, 2023), and others. For this paper, we center our analysis around what forms of capital were attained and when they were leveraged at the undergraduate and graduate levels by current Latine mathematics faculty who have successfully navigated a pathway through STEM. Herzig's (2004) exploration of the experiences of women of color in doctoral mathematics programs and Ong's (2011) study on the challenges and mitigations involved in the transition from undergraduate to graduate education highlighted the pivotal role that supportive environments play in helping these students achieve success in graduate mathematics education. Furthermore, research emphasizes the detriment of chilly and exclusionary climates in STEM departments (Camacho & Lord, 2013), particularly in mathematics departments (Herzig, 2002).

Methods

Emerging from a more extensive study focused on generating equitable hiring procedures for the hiring of Latine teaching-focused faculty (TFF) in STEM departments (Funded by NSF Award #2113355), our project centers on a subset of five TFFs across multiple institutions who completed at least a bachelor's degree in mathematics. We categorize each faculty member as "teaching-focused" if they devote at least 50% of their time to teaching. Four of our participants attained PhDs in mathematics and/or statistics. Of these, three hold faculty roles in mathematics departments, while one participant is a TFF in a digital and computational studies department. The final participant received a PhD in biology and is in a TFF position in a biology department.

We conducted five semi-structured interviews (Bernard, 1988; Zazkis & Hazzan, 1999) that were approximately one to two hours in length. These interviews were held via Zoom, audio recorded and transcribed using Otter.ai, and analyzed with the ATLAS.ti platform. All of our participants were compensated for their time. The interviews hinged on enabling our participants to reflect on their academic journeys and were divided into two parts: (1) experiences leading up to the faculty role and (2) TFF experiences in their current position. For this paper, we focus on the first section of the interviews.

We analyzed the data using a deductive and inductive approach (Corbin & Strauss, 1990; Miles & Huberman, 1994). Our analysis implemented a deductive approach to test the CCW framework using the six constructs of non-dominant capital as a priori codes. Next, we used an inductive approach to generate overarching themes from the data. Researchers collectively coded multiple transcripts until they reached a suitable level of inter-rater reliability (*Krippendorff's alpha = .68*), then coded the remaining transcripts separately.

Results

The nuances in participant experiences allowed us to have a rich dataset that we use to tell their stories and give them a voice. We found that our participants drew from multiple forms of support to navigate their higher education journeys, including peer support, mentorship, and familial support, comprising all the CCW constructs, particularly aspirational, familial, navigational, and social capital. In the subsequent sections, we will explore participants' motivations to pursue mathematics careers and their various forms of support along the pathway.

Familial Support

Familial capital has the potential to serve as a cornerstone for motivating students to seek a STEM career and supporting them along the mathematics trajectory. Our research participants often described family education and expectations as influencing factors in their decisions to pursue higher education. Consider Maria, an Argentine American TFF at an R1 institution whose guardians had varying levels of education. Maria's mother had an accounting degree, her father did not finish high school, and her grandmother did not experience any formal schooling:

> *I have an older brother [attending college] that was, you know, four years ahead of me or five years. So, it [was] clear [that] I was going to go to college…Also, [my family and friends] value [a] faster way to change [social] classes…So [this was] kind of a way of changing and getting a good life so that's really important… – Maria*

For Maria, her family values were an essential factor in her decision to pursue higher education, demonstrating evidence of familial capital. Specifically, Maria expressed that her love for mathematics at a young age encouraged her to pursue the mathematics field.

During our interview with Brian, a TFF at an R1 institution who was a first-generation (FG) college student, he expressed that his parents provided immense support for him to value education as they had high aspirations for their children. Brian reported that his parents made multiple investments to ensure their children could develop a solid educational foundation through private education. Brian and his siblings were expected to perform well in school and to pursue a higher education degree as their "...inheritance was essentially [a] strong education at the get go." The cultivation of substantial familial capital allowed Brian to strengthen his aspirational capital, aiding his navigation of higher education as an FG college student.

Peer and Institutional Support

Without recognizing the influence of peers and institutional actors, no discussion of support systems for those in higher education would be adequate. Fellow students, faculty, advisors, and mentors (both official and unofficial) were instrumental in providing motivation, guidance, and overall support across all our research participants' educational trajectories.

Sergio is a TFF in Mathematics at a doctoral-granting institution in the Midwest; he describes how, as a FG student entering an Ivy League college for his undergraduate he felt a lack of support from faculty in his department but found support outside of his department based on shared cultural backgrounds (ethnicity, FG student status, and both being community college graduates in this case):

> *One thing that I've benefited from was having mentors, but specifically, mentors that have similar backgrounds to me, because you can see yourself in them and think, oh, they succeeded. And I could do it, too. – Sergio*

The efficacy of mentoring based on shared cultural experiences and identity characteristics was a theme throughout our project, and all our mathematics participants described some form of this

in their educational journey. Our women research participants described connecting and feeling supported by other women in faculty positions, particularly those who shared some other cultural touchpoint with them (e.g., international student status, ethnicity, and FG student status). All five of our participants described how, in their current faculty positions, they seek out and participate in mentoring relationships based on shared identity and cultural experiences, often describing students reaching out to them for these reasons.

All our participants highlighted the vital role that peer support networks played in helping them persist in mathematics and STEM. In addition to seeking mentorship from students who were more advanced in their programs and leveraging identity networks (e.g., Latine/Hispanic organizations), emotional and academic support from peers were reported to serve as tools in navigating the process of achieving essential milestones on the pathway, such as high-stakes situations:

> *So, we had our group, and it was a very supportive group. I [joined] with my best friend…without her, I wouldn't have passed my prelims because she was always pushing me to go to study every day, or, you know, asking me if I was ready for X or Y. – Gina*

Social capital in the form of accountability is evident here. Still, aspirational and resistant capital also play a role. Gina, a Costa Rican American TFF at an R1 institution, describes how her best friend encouraged her to remain hopeful about passing her preliminary exams and helped her persevere despite the challenges and pressures. It is clear that social, aspirational, and resistant capital facilitated overcoming a hurdle that graduate students often face.

Tanya, an associate professor of digital and computational studies at a private liberal arts college, reported that her peer networks helped her find institutional support:

> *One of my fellow graduate students was like, well, my advisor is really great. And she asked about you the other day, and I think she would be willing to help…So I reached out to her like, because I was like, oh, she cares about me… So, I reached out and she really got the ball moving on, on that and made sure that that the defense happened. – Tanya*

This use of social capital to navigate difficult situations in their PhD journey exemplifies the critical nature of peer networks and how those can bridge to positive faculty relations. Without this peer network, Tanya would have been left in a difficult situation, without a faculty member to advocate for her during a critical moment in the dissertation phase of her graduate studies.

It is important to note that peer relations are not unilaterally positive, nor are faculty interactions. Our women participants described having to navigate microaggressions from peers and advisors based on various factors. Gina describes being assumed as less competent than her domestic peers based on her country of origin:

> *One of [the professors] told me that he was not expecting [me to do well on my preliminary exams] because of where I was coming from…I hated that he said it, but at least it was in my face, because I know a lot of them were thinking about that…the stereotypes of growing up in a country that allegedly does not have any academia…or thinking that my curriculum was not strong enough because I come from Latin America… that was something that always affected my self-confidence. – Gina*

While peers and institutional actors certainly can provide negative experiences in academia, overall, our participants described the benefits of positive experiences with both institutional and peer actors as a critical form of support along their educational journeys. However, we want to highlight that these individuals' stories only capture one piece of a larger puzzle: those who successfully navigated the 'leaky pipeline' of STEM higher education.

Discussion and Recommendations

In answer to our central research question, we found that social and familial capital support were central to the success of our participants in their academic journeys. Notably, forms of capital were leveraged simultaneously to overcome significant barriers along the pathway, suggesting the dynamic nature of CCW. For example, social and aspirational capital often served as a conduit for access to navigational capital, indicating that these forms of wealth are transmutable. We agree with previous scholars in the STEM education literature (Camacho & Lord, 2013; Herzig, 2004) who have discussed how the chilly climate of STEM departments is a significant barrier to Latine student success within higher education. Our contribution centers on the role of CCW and non-dominant forms of cultural capital that allow students to survive and thrive in these institutions and hostile cultural climates.

In terms of our recommendations for how institutions can effectively leverage and bolster these forms of support, we have two recommendations. The first is cultural, in that universities at a fundamental level need to recognize and acknowledge the funds of knowledge (Moll et al., 2005) that minoritized students bring with them into both the classroom and campus community. Instead of trying to force students to assimilate into the form of a model student by adopting and imitating hegemonic forms of cultural capital, we can encourage and appreciate their unique perspectives and forms of cultural wealth.

Second, our research has detailed the importance of culturally sustaining mentoring through the experiences of our research participants' journeys. This aligns with research on retention and student success in higher education in STEM (Johnson & Elliot, 2020). It cannot be understated that our participants described feeling isolated and marginalized, which was partly remedied by peer and faculty interactions with some form of cultural touchpoint. Our participants may have lacked the support necessary to succeed on the STEM pathway without these relationships. To enhance culturally responsive peer and institutional actor support, we suggest that colleges and universities (1) hire more Latine/Hispanic TFFs to lessen the already heavy load these faculty have on their shoulders, (2) recognize these faculty in tenure and promotion materials for their efforts to support students as agents of change by providing funding for programs they already run and (3) provide support for culturally oriented mentorship programs at the campus level, to move from only admitting Hispanic students to genuinely serving them (Garcia, 2020).

While the Latine/Hispanic experience in higher education is not monolithic, our research highlights the experiences of those who successfully navigated the STEM PhD pathway. However, this ultimately only tells us part of the larger story of Latine/Hispanic graduate education. Some are, of course, pushed out of higher education by institutional or sociological factors. Whether this disparity comes from a lack of mentorship, social/institutional support, discrimination/racism, or other structural factors is not covered by our study. Our suggestion for future researchers is to home in on the population victimized by the ‘leaky STEM’ pipeline to understand the pitfalls better.

Empowering Course Coordinators: Examining Foundational Math Coordination Orientations

Kimberly Cervello Rogers
Bowling Green State University

Nicholas G. Long
Bowling Green State University

This study explores the evolving approaches of eight foundational math course coordinators, uncovering key insights into their coordination strategies and mechanisms to enhance their efforts. These coordinators oversee critical courses, including College Algebra, Quantitative Reasoning, Introductory Statistics, Math for Architecture and Construction Management, Precalculus, Calculus, and mathematics courses for prospective elementary teachers. Through a dataset derived from surveys, self-reflections, and professional development workshops, we investigated their perspectives and experiences as coordinators. We analyzed data from both the coordinators and the graduate student instructors they oversee. Specifically, we highlight the integration of instructional routines that promote mathematical reasoning and the development of course-specific dynamic calendar systems, both of which have the potential to improve the instructional effectiveness and coordination of foundational math courses. Our findings offer fresh perspectives on how to better support course coordinators in their crucial role, ultimately benefiting both instructors and students.

Keywords: Foundational Mathematics, Course Coordination, Professional Development

Introduction

Course coordinators are a key population within college math education because they teach and supervise instruction of thousands of undergraduate students each semester. A key element for course coordinators is streamlining their goals and expectations and communicating those to the instructors they coordinate. This paper reports on data from the first two years of a 3-year grant project (Rogers, 2022-2025) that ultimately aims to test and refine a community of practice (Wenger et al., 2002) among eight faculty members. These faculty members coordinate and teach foundational math courses (FMCs, e.g., College Algebra, Precalculus, Quantitative Reasoning, Introductory Statistics, Math for Elementary Teachers, & Calculus). A community of practice can provide a means for faculty to share/manage professional knowledge, in this case about professional development (PD) opportunities we facilitated among college math faculty.

Key elements for effective coordination include (1) fostering community and (2) maintaining uniform course components (e.g., syllabus, textbook, homework, and assessments; Martinez et al., 2022). When asked, "How do you effectively coordinate FMCs?" coordinators may focus on people-centered approaches or structural components, reflecting their course coordination orientations. These orientations demonstrate an individual's disposition toward their work. Our aim is to explore FMC coordinators' orientations and identify ways to enhance their coordination efforts through PD. We asked both FMC coordinators and graduate student instructors (GSIs) to identify the coordinators' approaches to course coordination, leading to our research questions:

1. How do GSI and FMC coordinator perceptions of course coordination relate?
2. What kinds of support structures could aid in course coordinators' PD?

Literature Review

We are particularly interested in understanding and supporting course coordinators' reasoning as they manage FMCs in ways that are responsive to the needs of the instructors they oversee. Our literature review focuses on two key areas: understanding the perspectives these

coordinators bring to their roles and exploring potential avenues for PD in this context. Over a decade ago, Speer et al. (2010) conducted a review of collegiate math teaching and found that instructors' practices—specifically their pedagogical actions and the reasoning behind them—remain largely underexplored in research. This gap persists, as research on PD in college math education, especially for instructors and tenure-track faculty, continues to be sparse (Florensa et al., 2017). Our project aims to address this gap by examining course coordinators' perspectives and providing targeted PD to enhance their coordination skills.

To investigate course coordinators' orientations, we use Martinez et al.'s (2022) framework, which distinguishes between two orientations: *Humanistic-Growth (H-G)* and *Resource-Managerial (R-M)*. An H-G orientation focuses on the individuals being coordinated, while the R-M orientation emphasizes expertise in managing others or resources (Table 1).

Table 1. Course Coordination Orientation Themes

Humanistic-Growth (H-G) Themes	Resource-Managerial (R-M) Themes
(a) Attends to Student Experience	(f) Draws on Knowledge of Course, Department, & Institution
(b) Expresses Concern about Others	(g) Demonstrates Experience Teaching & Knowledge of Teaching the Course
(c) Takes Action to Build Community	(h) Provides Materials Related to Content & Curriculum
(d) Is Attentive to Instructor Differences	(i) Communicates Clearly
(e) Provides Support for Instructors	(j) Exhibits Strong Administrative Skills

We report on two aspects of our PD for course coordinators. First, we incorporated **instructional routines for reasoning** (Kelemanik et al., 2016). These are "specific, repeatable designs for learning that support" (Lucenta & Kelemanik, 2024, para. 1) students' mathematical reasoning. Instructional routines highlight the interconnectedness of mathematical concepts and offer coordinators practical tools to guide instructors in fostering students' reasoning skills. Second, we considered the use of **dynamic calendars** (Oliver & Olkin, 2021) to organize course materials in a user-friendly, calendar-like format that coordinators can personalize to include notes and recommendations for instructors. This tool can provide a clear structure, helping coordinators communicate expectations and resources effectively to the instructors they oversee.

Method

Context: University and Course Coordinator Backgrounds

At a public, liberal arts college, participants are eight FMC coordinators whose duties include distributing course materials (syllabi, lecture notes, pacing guides, & assessments) to ensure consistency across course sections. They facilitate orientation meetings with instructors, provide observation feedback to novices (esp. GSIs), and address student concerns. They regularly teach the courses they coordinate, but GSIs teach majority of the course sections (Rogers et al., 2024). Most FMCs are taught in traditional, in-person lectures, while College Algebra is taught using a math emporium model (adaptive learning system to individualize student pathways; Cousins-Cooper et al., 2017). Patrick (Table 2) oversees FMCs at the 2-year branch of main campus.

Workshop & Professional Development Context

During the academic year, Author 1 met with the FMC coordinators twice a month to facilitate PD opportunities while also addressing course coordination, administrative, and policy needs. These meetings have expanded to include an annual summer workshop, chosen for its lighter workload for coordinators. In the latest workshop, coordinators learned about the H-G

and R-M orientations and self-identified their alignment within this framework. They also reflected on the group's alignment. We also shared data from graduate students who described their coordinators using relevant themes. The workshop concluded with a session on instructional routines and dynamic calendars, followed by individual worktime.

Data Collection and Analytical Approach

Before the FMC coordinator workshop began, all graduate students who had served as instructor of record of these coordinators' courses were invited via email to participate in a survey. The survey asked them to assess their coordinators based on the five themes of the H-G and R-M orientations. GSIs rated their coordinators using integers on a scale from 0 (theme does not describe the coordination) to 10 (theme accurately describes the coordination) and could also provide open-ended comments. During the workshop, coordinators were introduced to the two orientations and asked to identify which themes they used or did not use. Table 2 shows the count of themes self-reported by each coordinator and the mean ratings provided by GSIs.

Table 2. Participants' Coordination Details and Coordination Orientations.

Pseudonym	Course(s) coordinating	(H-G Count, R-M Count)		No. of GSI Responses
		Self-reported	GSI Reported	
Alice	College Algebra	(4, 3)	(4.80, 5.00)	1
Alexandra	College Algebra	(4, 2)	(4.77, 4.93)	3
Camille	Calc I, Calc II, Calc III	(4, 5)	(3.48, 4.57)	6
Madaline	Prospective Teacher Math	(4, 4)	No GSIs Coordinated	0
Patrick	College Algebra & Precalculus	(4, 4)	No GSIs Coordinated	0
Pricilla	Precalculus	(4, 5)	(3.66, 4.57)	7
Reema	Quantitative Reasoning & Math for Architecture	(4, 2)	(3.37, 4.10)	3
Stella	Introductory Statistics	(4, 5)	(4.73, 4.73)	3

After identifying their orientations individually and as a group, coordinators reflected on these results. To collect reflections from all, coordinators first silently answered each reflection question on a chalkboard and then added further silent reflections using sticky notes after reviewing others' answers. This activity provided qualitative insights into the coordinators' self-perceptions and perceptions of the group. Additional data came from self-reported surveys completed by each coordinator during project year 1. Given the small sample size, no statistical analyses were performed. We compared frequencies by coding open-ended responses for the H-G and R-M themes and counting the themes identified by coordinators while averaging the GSI-provided theme scores (scaling them from [0, 10] down to [0, 1]).

Findings

RQ1: Relationship Between Coordinator and GSI Perceptions

Early in the grant project, coordinators were asked to list what aspects of course coordination they enjoyed and what aspects they found challenging. Two researchers coded the items coordinators listed using the H-G and R-M orientations and reached 100% coding agreement through discussion. For aspects the coordinators enjoyed, 20% of their responses aligned with H-G and 80% with R-M. The themes most frequently mentioned as enjoyable were three R-M: (f) drawing on knowledge of course/department/institution, (g) demonstrating teaching expertise,

and (h) providing materials. Their responses about what they found most challenging were evenly split between the two orientations, exclusively mentioning challenges identified as (c) building community, (e) providing instructor support, (h) providing materials, and (j) exhibiting strong administrative skills. After later being introduced to these descriptions at the workshop, coordinators identified their orientations by recognizing themes they use or do not use (column 3, Table 2). Across the eight participants, each coordinator identified only one H-G theme they did not use and wanted to incorporate more explicitly, as follows: (b) concern about others (37.5%), (c) seeking to build community (25%), (d) attending to instructor differences (12.5%), and (e) providing instructor support (25%). These results aligned with their earlier survey responses of areas of challenge, while also adding items (b) and (d) to the list.

During the workshop, there was some noticeable agreement among the coordinators when they identified R-M themes they were and were not using. Three coordinators selected all the R-M themes as ones they were currently using. The five coordinators who indicated not using at least one R-M theme all selected (j) exhibiting strong administration skills as an aspect they were not explicitly incorporating. One or two coordinators also selected (i), (f), or (g) as R-M themes they were not currently using as well. The group discussions built upon these findings with coordinators asking how "strong" the word "strong" in item (j) was intending to be? They considered replacing that word with "some" and then they would consider selecting it. Their discussion also noted the group's strength among the R-M orientation themes. Additionally, the coordinators all agreed that there is "room to grow" in their course coordination and that they wanted to more intentionally use H-G themes (or in the case of Alice and Alexandra, who both recently were appointed as coordinators, more R-M themes).

GSIs, who were given the same descriptions of 10 themes for course coordination orientations, responded (column 4, Table 2) in ways comparable to the coordinators. Building community (c) was commonly one of the lower scored themes by GSIs, but not the lowest theme for any single coordinator. An exception is Alice and Alexandra, who see GSIs every day due to the emporium format, for whom (c) building community was the highest-scored GSI-response theme. Alice and Alexandra also self-selected (c) building community as something they currently use. In the open-ended responses, GSIs most commonly discussed the absences of (d) attentiveness to instructor differences and (e) providing instructor support. When asked to comment about the presence or absence of any R-M themes, only 16% of GSIs chose to provide open-ended responses as opposed to 44% of GSIs commenting about H-G themes.

RQ2: Coordinators' Receptivity of Professional Development Tools

On the second day of the workshop, after further debriefing some GSI-responses together, coordinators engaged with examples of dynamic calendars and instructional routines for reasoning and then broke out for an hour of practical work time. Coordinators' reception of the newly introduced dynamic calendar consisted of positive remarks, with half of the group either actively creating a dynamic calendar for an FMC during the work time or commenting on ways they plan to do so soon. For example, Camille began designing a cloud-based document with key topics, activities, and sample assessments for the first week of Calc I. She plans to continue constructing it during the semester to share next semester. Although Camille had these various documents accessible to instructors in a variety of folders, the dynamic calendar provided an

overarching structure and direct links to the most relevant files for each week. Providing such a resource could potentially address some of the H-G and R-M themes (e.g., (e) provides instructor support, (i) communicates clearly, and (j) administrative skills).

We modeled three types of instructional routines, and half of the group spent the entire work time adapting class materials to an instructional routine structure, while a fifth coordinator split their work time between the two tools. Using existing FMC activities, coordinators noted how they could adapt them to the routine structure, thereby providing opportunities for students to think deeply about the mathematics. Alice reflected on the experience saying incorporating instructional routines could help "students build some problem-solving skills and see past just the steps of a single topic." We noticed that four of these five coordinators identified at least one R-M theme they wanted to more explicitly incorporate, and their written workshop reflections suggest they saw routines to provide more effective course materials for FMCs.

Discussion and Questions for the RUME Audience

After being introduced to the course coordination orientation framework, the coordinators self-identified one H-G area that they had not previously identified that was also not apparent in the GSI responses: (b) expressing concern about others. The groups of GSIs and coordinators both noted that (c) building community and (e) providing instructor support were areas that could use more explicit attention. We posit that the integration of instructional routines or dynamic calendar could be a mechanism for addressing some of these areas needing attention. We emphasized that coordinator are not expected to address all ten themes across both orientations. But noted areas where the coordinators desired to (and GSIs requested they) give more attention.

Moreover, in analyzing these findings, we observed a parallel between the roles of instructional routines for reasoning and dynamic calendars, each serving different populations within FMCs. We compare how instructional routines can influence undergraduate students' conceptualization of mathematics and how dynamic calendars can shape FMC instructors' teaching practices. When instructors employ instructional routines for reasoning, they provide students with a framework to approach mathematical problems and engage in reasoning across various contexts. Similarly, when coordinators develop dynamic calendars for FMCs, they are constructing a framework for instructors to guide their course planning and teaching. This organizational structure can help instructors conceptualize the course, choosing which resources or teaching strategies to incorporate. We are eager to gather feedback from RUME on how these parallel structures might further support both students and instructors. We want to hear thoughts on how this relationship might inform future PD initiatives. Additionally, we plan to explore potential challenges or pushback coordinators might face when implementing these strategies, which could lead to valuable insights for refining our approach. To facilitate this discussion, we will also ask the audience the following questions during our presentation:

- What research-based, practitioner-focused resources should we consider to help coordinators to learn from course coordination efforts nationally?
- As we enter the final year of this project, what data should we prioritize gathering about coordinators' instructional and course coordination practices, and why?

Using the Instructional Tetrahedron to Classify College Algebra Instructors' Peer Observations

Keely Ramirez
UT San Antonio

Jessica Gehrtz
UT San Antonio

Priya V. Prasad
UT San Antonio

Professional learning communities (PLCs) can be a way to support college mathematics instructors in shifting their instruction to be more student-centered. This study focuses on what College Algebra instructors noticed when observing their colleagues' teaching in a video club setting within the PLC. We used the instructional tetrahedron to classify what instructors noticed according to the four vertices: Content, Students, Teacher, and Tools and Technology. Results highlight that instructors' discussions shifted away from Tools and Technology after returning to in-person classes and that instructors' discussions about Tools and Technology differed depending on the in person or online class context. We also found that instructors frequently noticed Teacher interactions, which points to their perceptions about the goals of the PLC - to provide feedback about teaching and to generate ideas about how to improve one's own instruction. Finally, what instructors notice about their colleagues' teaching might shed light on that instructors' goals and beliefs about teaching.

Keywords: Instructional triangle, Peer observations, Professional learning community

There has been increased attention on instructional practices that center students' activity and thinking during class time because of the positive student outcomes associated with these practices (Freeman et al., 2014; Laursen et al., 2014). However, instructional change at the college level is often difficult to catalyze (Apkarian et al., 2021). As such, college mathematics instructors may need additional support to shift their instructional practices to center students and their thinking. For this study, we leveraged a professional learning community (PLC) as a means of professional development. PLCs provide a long-term structure for on-going discussions and incremental improvements, which can increase instructors' interest in making changes to their teaching (Wildman et al., 2000). We also incorporated video clubs within the PLC as these have been shown to support teachers' learning and focus on student thinking and can result in shifts in instructional practices (Sherin & Han, 2004; van Es & Sherin, 2010).

Theoretical and Analytic Framework

The Instructional Triangle is a classic model for conceptualizing instruction since it consists of "interactions among teachers and students around content, in environments" (Cohen & Ball, 2001; p. 122). The Instructional Triangle represents these three components (teacher, students, and content) as vertices and includes edges that represent the interactions between each of the vertices. Recent research at the college level has used the Instructional Triangle to characterize instructor discussions during an online working group centered around inquiry-oriented instruction in Abstract Algebra (Kelley & Johnson, 2022). Kelley & Johnson (2022) found that the focus of instructors' comments shifted over the course of the working group to focus less on content and more on the relationship between content and students. In other recent research, Liu & Buchbinder (2024) proposed the Instructional Technology Tetrahedron, which is an extension of the Instructional Triangle to include a vertex for technology. Their conceptualization of the Instructional Technology Tetrahedron places the Technology node in the center of the Instructional Triangle and in the same plane as the other vertices, indicating that technology is more than an element of the learning environment (which is how prior extensions of the

Instructional Triangle have included Technology; Tall, 1986; Olive et al., 2010). Liu & Buchbinder (2024) used the Instructional Technology Tetrahedron to analyze pre-service teachers' noticing of their own online teaching, and how what they noticed changed as they gained experience.

In order to investigate the types of things the instructors in this study noticed, we leveraged the Socio-didactical Tetrahedron (Rezat & Sträßer, 2012), which is an extension of the Instructional Triangle to include a vertex for artifacts such as physical or digital manipulatives, digital technologies, and textbooks. Rezat & Sträßer's (2012) conceptualization of the Socio-didactical Tetrahedron connects a node for artifacts with the Instructional Triangle in a 3-dimensional space, such that the Instructional Triangle is the base of 3-D tetrahedron. Rezat & Sträßer (2012) argued that the mediation of artifacts is inseparably intermingled with the three vertices of the instructional triangle, and as such, perspectives of how artifacts interact with other vertices should be able to be represented by the surfaces of the Socio-didactical Tetrahedron.

Our work seeks to classify what college instructors notice when examining their colleagues' teaching in online and in-person classroom environments. Specifically, we aim to answer the following research question: What do instructors teaching the same class notice when observing a recorded lesson from one of their colleagues? This research is important because it highlights what components of instruction (content, student, teacher, and technology) instructors focus on when observing their colleagues, which could shed light on their personal goals, knowledge, and beliefs (Russ & Luna, 2013). Further, it could indicate a particular instructor's strengths or opportunities for growth with teaching.

Methods

This paper uses data gathered from a project which began in Fall 2021 and concluded in Spring 2024. From this project, we focus on two semesters, Spring 2022 and Fall 2022, in which instructors of College Algebra participated in a PLC to share and review recordings of each other's lessons in a video club setting. In the Spring semester four instructors participated in the PLC, while in the Fall semester two additional instructors joined PLC. In this study, we will focus only on observations of the four instructors for which we have two semesters of data for. Each instructor had three recorded lessons observed every semester, with the exception of Nicholas, who only had two lessons observed in Fall 2022.

Instructors were rotationally paired in such a way that they watched their partner's recorded lesson beforehand, then led a portion of the video club meeting by sharing snippets of the video-recording along with commentary of interesting aspects they noticed; after initial observations, all instructors were invited to discuss any aspects they found interesting of the lesson, too. Video-recordings of these meetings were transcribed verbatim and coded according to an adapted version of the Socio-didactical Tetrahedron, which we refer to as the Instructional Tetrahedron, composed of four vertices -Content (C), Teacher (T), Student (S), and Tools & Technology (E)- and the edges and faces between them. This resulted in fourteen codes. For this coding, we considered Tools and Technology to diversely cover computer-based software like Desmos, Zoom, and PowerPoint, but also non-digital classroom tools such as textbooks and whiteboards, since all items listed are used as support tools for learning.

Participating instructors were interviewed at the end of each semester by a facilitator of the PLC. The interviews included questions where the instructors were asked to reflect on their experiences with technology and peer observations. We use quotes of two instructors from these interviews to highlight possible reasoning for features found in results of our data.

Results

For this report, we focus on overlapping clusters of the four main vertices of the Instructional Tetrahedron -Content, Teacher, Students, and Tools & Technology- because this provides a coarse breakdown of what instructors focused on in their observations of each instructor. These are referred to as Cluster C, Cluster T, Cluster S, and Cluster E. Note that the clusters are composed of overlapping codes. For example, a Content-Teacher interaction will be reflected in both Cluster C and Cluster T. Table 1 includes the percentage of coded segments for each cluster from the instructors' discussion in the video club when observing the lessons taught by the instructor listed in the left column. Since the clusters are composed of overlapping codes the percentages of the rows do not sum to 100%.

Table 1. Frequency of Codes from each Instructor's Observations

Instructor		Cluster C	Cluster T	Cluster S	Cluster E
Alex	%	48.99	74.75	50.51	28.79
Nicholas		39.25	70.09	75.70	28.04
Ivy		44.71	66.47	44.12	32.35
Shay		42.00	71.33	43.33	37.33
Average	%	**43.74**	**70.66**	**53.41**	**31.63**

In addition to looking at what the instructors focused on when observing a given instructor, it is also important to consider the context in which the two semesters' data were collected. The semester of Spring 2022 began online, which then shifted to in-person instruction for most participants. By the Fall 2022 semester, only Nicholas was leading online classes. Table 2 highlights the percentage of segments from the observation discussions for all instructors related to each cluster from Spring 2022 to Fall 2022. In the following sections we discuss insights from Table 1 and Table 2.

Table 2. Average Frequency of Codes from Each Semester

Semester		Cluster C	Cluster T	Cluster S	Cluster E
Spring 2022	%	32.77	71.44	40.48	38.16
Fall 2022	%	62.50	69.11	62.26	21.51

Noticing of Tools and Technology-Focused Interactions (Cluster E)

Overall, the discussions focused on Tools and Technology interactions were consistently lower than other clusters, with an average of only 31.63% of the conversation revolving around this cluster (Table 1). Each instructor implemented tools like Desmos, Zoom, PowerPoint, whiteboards, etc., in a variety of ways during lessons, and many of these implementations are discussed within the video clubs. However, there is a decreased focus on Cluster E from Spring 2022 to Fall 2022. Specifically, Table 2, which breaks down the discussions revolving around each cluster by the semester these discussions occurred, shows instructor noticing of Tools and Technology decreases from 38.16% to 21.51%. We hypothesize this change of about 17% is related to the switch of online to in-person classes for the majority of instructors. Since we also

consider technology to be an environment, we speculate that when instructors are removed from this environment, their noticing of Cluster E interactions instead shift toward viewing technology as a tool. Instead of instructing through a medium of technology by necessity, after shifting to in-person classes instructors may or may not deliberately bring in technology to lessons as learning tools.

In order to shed light on the types of Tools and Technology interactions that were part of the discussions within the video club, we provide a comparison of instructor noticing during observations of Nicholas, an online instructor, and Shay, an in-person instructor. For comparison of these two instructors, we will refer to Table 1. Nicholas, who solely teaches online classes in both semesters and must constantly utilize technology for all of his lessons, only has 28.04% of instructors' noticing discussion points to Tools and Technology interactions. This could be because the technology serves as an environment that operates in the background, almost unnoticed. Interestingly, observations of Shay have the highest percentage of noticing focused on Tools and Technology, with 37.33%. Many of these observations come from Shay's use of Tools and Technology to segment lessons, such as personal whiteboards and review games created in PowerPoint. During the final video club of Fall 2022, when leading discussion of one of Shay's lessons, Alex describes the lesson as "high energy," and goes on to elaborate more during this same lesson:

> But then I kept it going because, showing the whiteboards I thought was such a good idea, bringing in those whiteboards, mixing it up. They're not on the computer. Like, you could feel that the energy in that class is changing just from something new happening.

As a complimentary point of view, in an interview in Spring 2022 with Nicholas, when asked about whether he would have implemented active learning and technology like Desmos without intervention of the project, he responded:

> We were already doing group activities in the classroom and having that active learning happening. And so…I guess the only thing that changed was the implementation method. And so now getting them to do it online, we are using the Desmos [Classroom].

When we consider the environments of Shay's and Nicholas' classrooms, they are both heavily influenced and reliant on Tools and Technology in different manners: one reliant on technology to function and the other bringing in tools as learning supports.

Finally, we notice that observations focused on content-interactions (Cluster C) increase by about 30%, and student-interactions (Cluster S) increase by about 22% from the Spring 2022 to Fall 2022 semester. We hypothesize that the instructors' discussion is shifting away from Tools and Technology (Cluster E) as they are becoming more comfortable with the technology used in the project, Desmos Classroom, which also allows them to be more focused on other aspects of instruction.

Noticing of Teacher-Focused Interactions (Cluster T)

The teacher-interactions (Cluster T) only has about a 2% shift from one semester to the next. This consistency of noticing teacher interactions may suggest that participating instructors view one of the main goals of video clubs as a time to give feedback to colleagues and reflect on their own pedagogy. An excerpt from Shay when interviewed in Spring 2024, gives clarification of her view of the valuableness of the video-club observations:

> Observations are really good for course coordination, but again, not setting it up for people to criticize other people. It's more of 'oh, I did that. And this went really well for me', 'Oh, you know, this is something that I could do in the future.' So I like observation reports because it was spun in such a positive way.

Shay's reflection of video clubs shows that she considers dialogue in these meetings as useful feedback to compare and develop with her own classroom experiences. Shay's response shows how she may be contributing to the collective noticing of teacher-interactions, due to her perception of the video clubs.

Noticing of Student-Focused Interactions (Cluster S)

During viewings of Nicholas' lessons, instructors observed more student-related interactions when compared to other instructors' teaching. While observations of Alex, Ivy, and Shay range from about 43% to 51% in noticed student-interactions (Cluster S), observations of student-interactions during Nicholas' lessons are 75.70% of discussions. We hypothesize the noticing of student interactions, during Nicholas' lessons, to Nicholas actively focusing on a student-centered classroom environment. In an interview in 2023, Nicholas reflected on his view of tools like Desmos during the previous year, mentioning that he considered Desmos to contribute to "more student interaction and independence." In a later interview from Spring 2024 with Nicholas, he is asked to reflect on his role as an instructor, which he responds to by calling himself a "facilitator." He then expands on this by explaining:

> I don't feel the need to take control of the class. And I feel like that gives [the students] back ownership for the class, that I think they take their work and their commitment to the class differently because of it. Because it's not my class.

We consider the autonomy Nicholas has afforded his students in their learning to be noticed by other instructors, as indicated by the percentage of compiled noticing of Cluster S. We also see this from comments during a Fall 2022 video club session, when reviewing a lesson from Nicholas, a comment from Alex coded as a teacher-student-technology interaction (TSE) is:

> [I] guess just for like the wider context, Nicholas spends most of the class like going through the Zoom and or the Desmos and always looking at student work while also shuffling through rooms. But if they're not having a problem in the room, he doesn't, you know, bother them or anything. He's just checking on all the rooms and also looking at all the Desmos stuff.

In an observation of himself from Fall 2022, Nicholas simply notes himself to be "a more effective instructor" in online classrooms like Zoom, which other instructors also tend to notice during video clubs.

Discussion

This work shows what aspects of the instructional tetrahedron instructors participating in a video club within a PLC noticed when observing their colleagues' teaching. It is important to highlight that what happened in class (what the instructors were doing and what the students were doing) during a video-recorded lesson impacted what might have been notable in an observation. For example, if the instructor was primarily lecturing while the students listened, then an observation would likely highlight either Teacher or Content interactions. This raises the question: Could a shift in the focus of discussion in a video club point to a shift in instructional practices? We hypothesized that the shift in discussion about Tools and Technology after the change from online to in person teaching resulted in less discussion about this cluster in the video clubs. It will be important for future work to investigate this connection between what is noticed and discussed during a video club and how that might reflect shifts in teaching practices.

"If you are good enough, that can transcend the gender stuff"

Talia LaTona-Tequida
San Diego State University

Women in advanced mathematics continue to be underrepresented despite representational progress in K-16 mathematics. Existing literature has investigated women's mathematical identities at the undergraduate level and revealed varying ways women organize their mathematical selves in response to the masculine context of mathematics. In this paper, I expand on the existing identity research about women in undergraduate mathematics to better understand the mathematical identities of women in doctoral mathematics. I discuss themes related to women's mathematical identities and the cultural discourse of "Women in Math."

Keywords: Gender, graduate mathematics, identity

Despite improvement in representation at the undergraduate level, women are still underrepresented in doctoral mathematics with only 28% of doctoral degrees awarded to women in 2018 (National Science Foundation, 2021). In addition to inequitable representation, women in doctoral mathematics have experienced overt prejudice, feelings of invisibility, insufficient or negative advising experiences, and a lack of belonging (Herzig, 2004). Furthermore, women's reports of success are often mitigated by expressions of struggle, bringing into question the quality of their experiences (Ataide Pinheiro, 2021).

The limited research investigating women in advanced mathematics is overwhelmingly focused on understanding the individual factors influencing persistence and attrition (Herzig, 2002a, 2002b; Miller, 2015), with few studies (e.g., Ataide Pinheiro, 2021; Lubienski & Ataide Pinheiro, 2020) focused on the school and societal contexts and their effect on women. Identity research is a potential solution in bridging broader contexts to individual experiences and allows one to reveal the taken-for-granted or status quo that privileges some and excludes others (Darragh, 2016; Gutiérrez, 2013). Identity framing affords researchers the ability to highlight how students "fit into a broader discourse about the politics of language, racism, sexism, and teaching and learning" (Gutiérrez, 2013, p. 44).

Gendered discourses and discourses that create hierarchies of mathematical ability are pervasive in mathematics (Leyva et al., 2021; Mendick, 2006). Mendick (2006) details how gendered identities and practices are produced and reinforced in mathematics classrooms and how certain discourses contribute to the association of mathematics with masculinity. The association of mathematics with masculinity, paired with the idea that mathematical ability is innate, creates an impasse for women who are generally underrepresented in mathematics. At the undergraduate level, mathematics education researchers have taken up the investigation of women's mathematical identities and their relationship to broader discourses about mathematics and gender, finding that these discourses make developing strong mathematical identities a challenge (Damarin, 2008; Hottinger, 2016; Mendick, 2006; Rodd & Bartholomew, 2006).

Women in undergraduate mathematics have responded to these seemingly incompatible identities of woman and mathematician in several ways. They may explain their mathematical talent while maintaining the feminine identity, and/or distancing themselves from a masculine identity by explaining their mathematical ability as abnormal or special. Alternatively, women may choose to downplay their ability as a result of hard work rather than natural talent, contradicting how they ascribe innate mathematical ability to men (Rodd & Bartholomew, 2006).

Solomon et al. (2016) describe another option in which women may develop hybridized mathematical and woman identities through recognition of and reflection on the contradiction posed by being a woman and mathematician. While these studies have not focused on graduate mathematics, there is no reason to believe these discourses are not shared across mathematical contexts and that women in advanced mathematics face some of the same cultural obstacles in adopting mathematical identities. However, doctoral mathematics also differs from undergraduate study and more research is needed to understand the experiences of women in advanced mathematics.

Building on and expanding the literature, I focus on women doctoral students. My goal is to understand the discursive processes by which women construct their mathematical identities. I investigate how woman doctoral students respond to the discursive label of "Woman in Math." by answering the research question: *How do women in doctoral mathematics describe being a "Woman in Math?"*

Theoretical Framework

In response to research of women in doctoral mathematics which focuses on individual factors, I adopt the figured worlds framework, in an effort to connect individual experiences to broader societal narratives about what it means to be a woman in mathematics (Holland et al., 1998). Figured worlds are defined as "socially and culturally constructed realms of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (p. 52). As a sociocultural theory, figured worlds assumes a reflexive relationship between social activity and individual development.

In particular, Holland et al. (1998) emphasize that identities are developed through participation in the activities organized by figured worlds, and figured worlds are produced and reproduced through the work of participants. Their definition of identity states:

> People tell others who they are, but even more important, they tell themselves and then try to act as though they are who they say they are. These self-understandings…are what we refer to as identities (p. 3).

This conception of identity includes the stories we tell about ourselves and others as well as our behaviors which are influenced by these stories.

Drawing from Vygotsky, Holland et al. (1998) emphasizes semiotic mediation with respect to human activity and identity building. This means that cultural artifacts such as objects, discourses, and even people are ascribed meaning and taken up as individuals structure their identities. Holland et al. (1998) draw connections that equate discourses and artifacts, with both being used as tools for mediation. Others have described discourses as "symbols, signs, artifacts, and other cultural representations" (Reinholz, 2022, p. 37) and a source of individuals' meaning making and knowledge (Gutiérrez, 2013). Under this perspective discourses do not describe objective truths; they structure our worlds. The parallels between artifacts and discourses help to understand the way broad social narratives occur in daily social interactions and are appropriated by individuals as they develop their identities.

In the context of doctoral mathematics many aspects of the figured world may signify meaning and value and be taken up by women as they refine their mathematical identities. For example, if a student has a prestigious advisor this might elevate their status in the department and lead to more confidence. Other factors such as grades, qualifying exams, social connections, and of course gender may also influence how they view their mathematical selves.

Gender

While the figured worlds framework does not have a particular focus on gender, I take the understanding, based on the literature (i.e., Mendick, 2006), that gender is part of the value-laden context of doctoral mathematics. Furthermore, I take gender to be a social construct that is continually performed and enforced through various cultural and institutional practices (Butler, 1990). This suggests that gender is not innately residing within individuals but is rather something they *do*. Butler (1990) argues that gender is performed through a repetition of norms, gestures, and discourses that present an image of stable identity. This conception of gender destabilizes the idea that masculinity and femininity are essential, fixed categories (as evidenced in Solomon et al. (2016)). However, despite the theoretical understanding of gender as a continuous, fluid performance, there is a societal commitment to a gender binary (Butler, 1990; Wilchins, 2011), which is paralleled in mathematical contexts and evidenced through a gendered hierarchy of mathematical ability (Hottinger, 2016; Mendick, 2006).

Woman in Math

In the process of interviewing and getting to know the participants in this study I realized that the label Woman in Math held more meaning for them beyond their individual experiences. It invoked many responses, some proud, some distancing. It became apparent that there was a larger cultural meaning associated with the label "Women in Math." Furthermore, all the participants were members of their local Association for Women in Mathematics (AWM), creating a local cultural meaning for them in their department. In retrospect this makes sense considering all the many programs and initiatives taken to increase gender diversity in mathematics at all levels. As such, I consider "Woman in Math" a societal discourse and take it up as an object of interest in this study.

Context and Methods

Southwest University (SU) is a large public university in the southwest United States and is classified as a very high research activity institution. The mathematics department at SU has approximately 200 students enrolled in their doctoral program, with about 15% of students identifying as women. There are approximately 60 faculty, a minority of whom are women. The structure of the program is typical of many mathematics PhD programs in that the first and second years of the program are dedicated to coursework in preparation for three written qualifying examinations, followed by original research.

Participants included five women enrolled, or recently enrolled, in the doctoral mathematics program at SU. The women were selected using a stratified purposeful sampling (Patton, 1990) with respect to years' experience in the program. This included one woman enrolled in coursework, two women in early research, one woman in advanced research, and one woman taking a leave of absence after completing coursework. Additional sampling criteria included participation in the local graduate chapter of the AWM. Data sources included one-hour narrative interviews (Mueller, 2019) from each of the five participants and a focus group interview with four of the five participants. The focus group and narrative interviews included a range of questions about the participants' experience in doctoral mathematics. In this report I focus my analysis on two questions – "*What does it mean to be a woman in mathematics?*" and "*How has being a woman shaped your experiences in mathematics?*" The interviews and focus group were transcribed and open coded for distinct, meaningful ideas (Braun & Clarke, 2006). Preliminary results include three themes – *anticipating doubt, proving yourself,* and *transcending gender* – and their potential connections.

Preliminary Results

There were myriad responses in response to the questions analyzed. However, most participants expressed some version of the first two themes, anticipating doubt and proving yourself. I include that last theme, transcending gender, despite only two excerpts coded from the same participant as it is closely related to the theme of prove yourself.

Anticipating Doubt

Four of the five participants expressed the idea that people might make assumptions about them because they are women in mathematical contexts. For example, one participant explained:

> I also think that a lot of people kind of like do not expect women to be good at maths. Like even in grad school that I think that maybe like in study groups like not maybe taking women seriously or like kind of ignoring what they're saying, because there is kind of an implicit assumption that it's not going to be like, useful or correct.

Here the participant describes her expectation for people to doubt her mathematical ability. She notes different contexts, such as study groups and her phrasing of "even in grad school" implies this an experience she has had in the past and present. Another participant states:

> I think that the instant assumption first off, is going to be that I'm not a mathematician at all. And secondly, I have an idea in my head that may not be true, that I'm sort of guilty until proven innocent.

Despite her brief expression of doubt this participant makes a stronger statement, that people will assume she is not a mathematician at all. The latter half of her statement also expresses the idea that people's first instinct will be to doubt her ability. Overall, this was a common experience to most of the participants. Some women also expressed responding to this perceived doubt by proving themselves to be competent mathematicians.

Proving Yourself

Like the previous theme, four of the five participants expressed the need to prove their mathematical ability. One woman said:

> I felt like to get someone's respect, you had to usually show you were smart enough. Maybe you're working on a problem set and you figure something out and then maybe people will then start listening to you and including you.

In this excerpt the participant describes having to prove she was smart enough but also that if she did this could lead to her gaining more access to working with others. In this way there appears to be consequences and benefits to proving her mathematical ability. Another participant presents her perspective as more high stakes:

> I always felt that I had to be unequivocally better than all of the men in order to be taken seriously… So I always had to have perfect scores, have the best grade in the class, have everything super, super correct because I always felt like if I missed five points on the

> exam, if I was a 95 instead of a hundred, then that would be the reason that someone would write me off.

This passage describes a need for perfection in order to be beyond reproach. She expresses that there is no room for mistakes otherwise her credibility will be questioned. Unlike the previous excerpt, this participant explicitly compares her performance to men. This aspect of her response highlights a connection to the previously discussed hierarchy of mathematical ability and the association of mathematics with masculinity. Most of the women who expressed the need to prove themselves did not describe a need for this level of perfection. However, this participant is the only woman who had responses coded as transcending gender.

Transcending Gender

The transcending gender theme captures the idea that if you are recognized as exceptionally good or successful, then you can escape any implications of being a woman in mathematics. Only one participant expressed ideas related to this theme in response to the interview questions. The first time she discusses the mathematical prestige of her advisor as well as her own accomplishments. She explains:

> …I think something that I've talked to with one of my friends a lot is that I have a certain, have a lot of good at math privilege, even though I don't have male privilege…my advisor's very impressive and it seems that the results that I have done in my PhD are very impressive. So it seems that, yeah, my advisor's a woman and I think she probably dealt with lots more things than I dealt with, but the weight of her famousness in the field and her good reputation far outweighs any sort of women in math stuff.

Here she acknowledges that her standing as someone who is successful in mathematics allows her a certain privilege that is valuable but distinct from the privilege men have. She offers evidence of her privilege through the status of her advisor and of her PhD results. She goes on to say that her advisor's reputation distances her from any implications of being a woman in math. Later in the interview she revisits the idea when she says "But I have experienced a sense that if you are good enough, that can transcend the gender stuff." In this excerpt she speaks strictly about her own experience. Taken with her previous sentiments about her PhD results and her "good at math privilege" one can get a sense of what it is required to transcend gender as a woman in mathematics. Furthermore, her statements in the previous section about needing to be perfect to be beyond reproach gain new meaning as she explains what the reward is for perfection; she can outperform her position as woman and "other" in mathematics.

Conclusion

Preliminary analysis shows that women often anticipate that their mathematical abilities will be doubted. Additionally, women may respond to this anticipation by working to prove themselves as competent mathematicians. Some women saw proving themselves as a way to gain access to participation in study groups or mathematical conversations. However, one woman expressed that if she proves herself enough, she can escape being a woman in math completely. These themes reflect an awareness and response by the participants that being a woman is a meaningful aspect of their experiences in advanced mathematics.

Mathematics Instructors' Perspectives on the Affordances of LA Implementations in the Undergraduate Classroom

Paul Regier
University of Science and Arts of Oklahoma

Keith Gallagher
University of Nebraska – Omaha

This study explores undergraduate mathematics instructors' perspectives on the benefits of Learning Assistant (LA) programs. Interviews with seven faculty members highlight LAs' roles in providing student support, enhancing instruction, and promoting student-centered learning. Instructors also noted that LAs gain valuable teaching experience, build relationships with faculty, and grow in confidence. These findings align with the established LA program goals of improving undergraduate education and preparing future teachers. However, the LA program goals of engaging faculty with educational research and institutional change were less evident. Future research will examine how LA use aligns with or diverges from established program objectives.

Keywords: Learning Assistants, Student Support, Faculty Perspectives

Learning Assistants (LAs) are typically undergraduate students who have successfully completed a course and support students currently enrolled in the same class (Talbot et al., 2015). Since its development in 2003, the LA model has become commonplace in higher education. This paper presents a preliminary analysis of interviews with mathematics faculty who have worked with LAs within the past five years (since Fall 2019). This study aims to identify the key benefits that faculty perceive LA programs offer to students, LAs, mathematics programs, and institutions of higher education.

Literature Review

The LA model was developed at the University of Colorado Boulder (CU Boulder) and the University of Colorado Denver with four key goals: (1) transform undergraduate STEM education, (2) recruit and prepare future teachers, (3) engage faculty in discipline-based educational research, and (4) change departmental and institutional culture (Otero, 2015). Talbot, Hartley, Marzetta, and Wee (2015) exhibit similar, directly related goals of improving student learning in undergraduate science courses, supporting reform efforts, and giving high-performing students opportunities to be exposed to science teaching as a career choice.

In addition, Talbot et al. (2015) describe three "foundations" of any LA program – content, pedagogy, and practice. Firstly, content (or preparation) refers to LAs meeting regularly to discuss course content, plan upcoming classes, reflect on past activities, and provide input from students' perspectives to the instructor. Second, LAs participate in a regular pedagogy to discuss learning theory, teaching strategies, formative assessment, and student conceptions in the context of their work. Thirdly, LAs primarily serve to interact with students to guide them in students' own learning process.

Barrasso and Spilios (2021) conducted a scoping review of 39 research papers to assess the effectiveness of Learning Assistant (LA) programs in achieving the four goals outlined by Otero (2015). First, their review highlights evidence that LA programs can lead to increased student satisfaction, reduced DFW rates, greater learning gains, and enhanced student comfort in interacting with peers and faculty—factors that contribute to a stronger STEM identity. Second,

although there is limited evidence regarding improved teacher preparation, the LA program at CU Boulder has seen a rise in student enrollment in its teaching certification program since its implementation (Otero et al., 2006). Third, several studies suggest that the LA model can influence faculty teaching practices (Van Dusen et al., 2015; Caravez et al, 2017). Finally, evidence of departmental and institutional changes can be found in case studies of multi-institutional partnerships utilizing LAs (Cochran et al., 2016; De Leone et al., 2019).

Recent research by Karch, Mashhour, Koss, and Caspari-Gnann (2024) with instructors and LAs demonstrates the ways instructors implement the LA model can vary across institutions and classes and are influenced by their perspectives on learning and curricular goals. Moreover, these differences result in distinct roles for LAs, which impact how LAs learn and interact with students. Thus, the way an LA model is implemented (and its success) depends on how instructors define and implement the role of LAs in the classroom.

This study is a preliminary exploration of how instructors position LAs in their classrooms and why they do so. Specifically, it investigates the extent to which instructors from institutions of varying sizes align their use of LAs with the established goals of the LA model. The research questions guiding this study are:

1. What goals or benefits of utilizing LAs do instructors describe for both classroom environments and departmental culture?
2. In what ways do instructors' descriptions of their work with LAs embody the goals of the LA model?

Methods

Participants

Participants were recruited through a screening survey sent by email from a RUME listserv. A total of 15 participants were chosen based on the following criteria. First, all participants had experience teaching undergraduate courses with one or more LAs within the past five years. Second, participants represented, as best as possible, a range of institution sizes. For this preliminary report, we further reduced our sample to seven participants as outlined in the Analysis section below.

Table 1. Distribution of participants by institution size

Institution Size	Count
1,000 - 4,999 students	1
5,000 - 9,999 students	3
10,000 - 19,999 students	4
20,000 students or more	7
Total Participants	15

Data Collection

Each participant engaged in a one-hour semi-structured interview following the same basic sequence of questions. First, five questions explored the structure and format of course(s) taught with LAs. Second, seven questions explored the ways the student and participant (instructor)

interacted with the LA. A third sequence of questions explored which aspects of learning the LAs provided the most support. Finally, participants were asked for advice for someone training or working with LAs for the first time. Each interview was conducted online by one of the authors using video conferencing software. Interview recordings and computer-generated transcriptions were used for subsequent analysis. Additionally, a post-interview survey was sent to participants to collect additional demographic, educational, and institutional information along with any comments they thought of after the conclusion of the interview.

Analysis

An individual interview was used as the unit of analysis. For this preliminary analysis, one participant's interview was chosen for trial coding based on the clarity of the examples provided during that interview. Both authors individually coded this interview for instructor evidence of work and teaching with LAs in ways that aligned with the goals of the LA model, as described by Otero (2015), along with the subgoals developed in Barrasso and Spilios' (2021) review of the LA literature.

Both authors then met to compare their coding, agreeing on a set of codes that best captured the range of affordances of LAs described in the interviews. These codes are shown in Table 2. The resulting coding scheme closely aligns with the provisional coding method described by Saldaña (2013), as codes were based on existing research frameworks but expanded to better reflect the range of affordances of LAs as described by instructors.

For instance, under the goal of "recruiting and preparing future STEM teachers," the subcodes "giving LAs first-hand leadership experience" and "providing LAs with practice in supporting student questions" were added, as distinct from "engaging LAs in learning about learning" (which we further defined as second-hand study of learning and pedagogy).

At the time of this report, the authors selected six additional participants (for a total of 7 out of 15) to represent the range of institution sizes in the data corpus; the remaining interviews will be analyzed in the completed analysis. One author coded each participant's interview using the coding scheme mentioned earlier. Lastly the codes were aggregated for analysis as described in the next section.

Results

Table 2 displays the coding scheme used in the preliminary analysis of interviews of seven of the 15 participants in our study. Subcodes are listed under primary codes and are indented. A column is provided for each of the seven coded interviews, with the interview heading showing the size of the participant's home institution, as detailed in the key at the bottom of Table 2. Each cell is marked with a "1" if the code was present in that participant's interview, and a "0" if it was not. Additionally, the total number of occurrences of each code across the seven participants is shown on the right, indicating the relative frequency of each code representation across the seven interviews.

Primary code 1 and its associated subcodes relate to the benefits LAs provide to students. In 100% of the interviews analyzed thus far, participants made observations related to subcodes 1a, 1b, and 1c. Code 1a indicates these seven instructors have observed students receiving direct support from LAs in the form of LAs answering their questions about mathematics or institutional knowledge or LAs providing affective support or encouragement. Codes 1b and 1c are closely related; this result indicates that all seven instructors feel that having LAs in their

classroom both improves the overall instruction students receive as well as the amount of student-centered instruction students provide. One participant captured a sentiment shared by several others: "[LAs] can feel the pulse of the room much more than [I can]." Four participants also spoke about code 1d, which relates to improving student retention and filling a need for remediation.

Table 2. Coding scheme and codes present for each participant's interview

Codes and Subcodes **Institution Size***	**A**	**B**	**C**	**C**	**C**	**D**	**D**	**Total**
1. Transforming undergraduate STEM education								
1a. Direct student support	1	1	1	1	1	1	1	**7/7**
1b. Improving instruction in general	1	1	1	1	1	1	1	**7/7**
1c. Developing student-centered instruction	1	1	1	1	1	1	1	**7/7**
1d. Supporting reform efforts	0	0	1	1	1	0	1	**4/7**
2. Recruiting and preparing future STEM teachers								
2a. Building mentorships with faculty	1	1	1	0	0	1	1	**5/7**
2b. Engaging LAs in learning about learning	1	0	1	1	1	1	1	**6/7**
2c. Promoting positive STEM identities in LAs	1	0	0	0	0	1	1	**3/7**
2d. Giving LAs classroom leadership experience	0	1	0	0	0	1	0	**2/7**
3. Engaging faculty in discipline-based educational research literature	0	0	0	0	0	0	0	**0/7**
4. Changing departmental instructional culture to value evidence-based teaching	0	0	0	0	0	1	0	**1/7**

** Institution size: **A** = 1-5k students; **B** = 5-10k; **C** = 10-20k; **D** = above 20k students*

Primary Code 2 and its subcodes describe the benefits LAs receive through their participation in the LA program at their institution. While these benefits concern preparing LAs as future STEM teachers, many of the LAs described by our participants were neither pre-service teachers nor enrolled in teacher education programs. The most frequently mentioned subcode of Primary Code 2, cited by our seven participants, is 2b, which relates to teacher professional development. Most often, participants indicated that LAs met at least once per week either the instructor of the course in which they assisted, the course coordinator, and/or the LA program coordinator at their institution. Some participants also indicated that LAs were required to take a pedagogy course, where they discussed classroom challenges and topics related to metacognition.

Five participants mentioned that LAs built relationships with the instructors they assisted, providing LAs with a faculty mentor they could come to for advice or letters of recommendation. Subcode 2c was referenced by three participants, who observed LAs gaining confidence in their mathematical and teaching abilities. Subcode 2d was mentioned twice, indicating that at two of the participants' institutions, LAs had the opportunity to lead a classroom, either through leading recitations or hosting review sessions.

Lastly, the authors note that it is not surprising that the interviews analyzed contained so few instances of participants mentioning primary codes 3 or 4, as these were not directly referenced in our interview protocol. However, several open-ended questions allowed participants opportunities to mention these topics if they felt them relevant. The one reference to changing

departmental culture to value evidence-based teaching was from a senior faculty that also served as coordinator for the course.

Future Work

Based on this preliminary work, instructors' perspectives of their work with LAs appear focused and aligned on the first two goals of the LA model – transforming undergraduate STEM education and recruiting and preparing future STEM teachers. The degree to which instructors are aware of and motivated by goals three and four (engagement with discipline-based educational research and change in departmental culture to value evidence-based teaching) falls outside the scope of the methods of this current study. Thus, we plan to expand our analysis to better understand: (1) how instructors and departments position LAs in active learning classrooms, (2) the reasons instructors assign LAs to these roles, and (3) how LAs are supported or trained to develop these roles. In this way, we hope to better understand ways the productive use of LAs may align and diverge from the goals outlined in current LA program research.

Acknowledgments

We sincerely thank the 15 faculty members who participated in our interviews. Your insights have contributed much to our understanding and appreciation of LAs and the value they bring to the undergraduate mathematics education community.

Underrepresented Students' Legitimization as Peripheral Participants in the Mathematics Research Community of Practice

Carolyn Johns
The Ohio State University

Dusty Grundmeier
The Ohio State University

John Johnson
The Ohio State University

This paper presents preliminary findings on underrepresented students' experiences as they navigate the mathematics research community. Three undergraduate mathematics majors from underrepresented groups were interviewed regarding their experiences at their home institution, research experiences for undergraduates, and an undergraduate mathematics conference. Using communities of practice as a theoretical framework, we explore these students' status as legitimate peripheral participants in the mathematics research community of practice. Analysis led to bridging the communities of practice framework with Gutierrez's (2009) four dimension of equity. In this paper, we focus on the ways in which students' real or perceived legitimacy were impacted by identity and power. In particular, students experienced de-legitimization via the power of the dominant group and via less peripheral members.

Keywords: mathematics majors, community of practice, identity, equity

Mathematics majors engage with mathematics research in a variety of ways during their time as an undergraduate. These experiences go beyond the classroom and their work with their advisor at their home institution. Increasingly, STEM majors participate in activities such as research experiences for undergraduates (REUs) (National Academies of Sciences, Engineering, and Medicine, 2017) and conferences. These experiences are essential for students seeking entry into graduate school (National Academies of Sciences, Engineering, and Medicine, 2017; Peterson & Rubinstein, 2016; Russell et al., 2007). Activities such as REUs expose students to greater opportunities for research, faculty connections, and peer networking. Work examining the holistic experience of mathematics majors must take into account these critical aspects of their development as researchers.

In addition, little research exists on the experiences of underrepresented students as they navigate mathematics research, REUs, or conferences. Research on STEM undergraduates in REUs has shown increases in persistence and promotion of mathematics identity formation (National Academies of Sciences, Engineering, and Medicine, 2017). However, much of the work on the role of REUs in identity formation has not been specific to underrepresented students (Palmer et al., 2015; Seymore et al., 2004). Given importance of these activities for access to graduate school, equity work within the mathematics community must consider how underrepresented students experience not only their local home institution environment but also their holistic experience including activities such as REUs and conferences.

Using a community of practice lens, this work seeks to answer the research question: How do underrepresented mathematics majors describe their experiences in the mathematics research community?

Theoretical Framework

A community of practice is defined by Wenger (1998) as having three dimensions: a joint enterprise, mutual engagement, and shared practices. For example, the work of tailors is a community of practice (Lave & Wenger, 1991). In a community of practice, experienced members (experienced tailors) mentor newcomers (apprentices) to take-up the practices of the

community. These practices include ways of doing, knowledge, and language. To join the community, newcomers must be granted access through sponsorship by an old-timer. At this time, newcomers become legitimate peripheral participants in the community, having gained legitimacy through their sponsorship. The newcomers are participants in that they engage in the joint enterprise of the community, but their work is peripheral as they are given smaller, easier subcomponents of the work and have a great deal of oversight from a more experienced member. Overtime, newcomers are given more complex tasks and independence as they update the community's practices and become fuller members.

To better understand the experiences of underrepresented minorities as mathematics majors, we seek to bridge community of practice (Lave & Wegner, 1991) with Gutierrez's (2009) four dimensions of equity. Gutierrez outlines four dimensions of equity, lying on two axes. On the dominate axis are access and achievement and on the critical axis are identity and power. We view each of these four dimensions as tied to aspects of legitimate peripheral participation. Newcomers to a community of practice need access as granted by sponsorship by an experienced member, providing their legitimacy as a member of the community. As newcomers gain achievement, their participation becomes less peripheral as they moved towards full participation and membership. Further, as newcomers participate in the community, their identities shift based on how they perceive themselves and their participation in the community (White & Lowenthal, 2011). Finally, the full members in the community who hold power are those who are able to decide what it means to be a legitimate participant (Gutierrez, 2013). White and Lowenthal argue minority students must "adopt a form of discourse that originated in and often perpetuates oppression" (p.289) to participate in the community, as dictated by those in power.

In this work, we focus on the mathematics research community as a community of practice. Newcomers are students who are mathematics majors and experienced member are advisors and tenured faculty. Non-tenured faculty, graduate students, and more advanced peers are relative experienced members to mathematics majors These members of the community of practice have greater legitimacy and fuller participation than the mathematics majors but less legitimacy and participation than tenured faculty. Students choose to enter the mathematics research community by declaring a mathematics major and are granted access, or legitimacy in the community, by their advisors. The ability to gain legitimacy and enter the community is connected to Gutierrez's (2012) dimension of access. Students are peripheral participants in the mathematics research community as they are given smaller tasks with close oversight by advisors. Achievement in these activities and coursework, as well as uptake of community practices are required to become a fuller participant in the community and to move away from the periphery. As students negotiate their place in the community, their identities will shift. Students will possibly experience tensions between their dynamic identities and as their perception of their role within the mathematics research community changes. Each student will experience the power relations within the mathematics research community differently. Some will find the privileged mathematic research community discourse to be similar to their everyday discourse. Others will need to learn a new discourse to "fit in". Among legitimate peripheral participants, power relations may be based on identity, institution, area of research, awards won, or any number of achievements, access, and identity markers.

Methods

Data for this study was collected during a conference for undergraduate mathematicians. At the end of the application process for the conference, students were asked to complete a demographic survey, a subset of questions from the X-PIPS-M survey (Apkarian et al., 2019). Of

the 59 students accepted in the undergraduate mathematics conference, 18 students completed the survey and consented to participate in the research. The results of the demographic survey were used to select students to interview, seeking women and/or underrepresented students. This work reports on three mathematics majors with intersectional identities as underrepresented students across multiple demographics. Pseudonyms are used to protect student identities. Amira self-identified as female, black or African American, middle eastern, and white. She was also a transfer student. Cuc self-identified as non-binary and southeast Asian. They were a first-generation college student and transfer student. Ethan identified as male and Hispanic or Latinx. He was an international student and first-generation college student. Interviews were conducted on the final day of the conference and the week after. Interviews were conducted as semi-structured with students being asked questions about their experience as a mathematics major at their home institution, their experience with research experiences for undergraduates (REUs), and the undergraduate mathematics conference. Questions were aimed to get a sense of factors influencing students' trajectories and how their identities contributed to their experiences. Interviews were then transcribed. Data analysis was conducted via thematic analysis (Braun & Clarke, 2006). Interview transcripts were read multiple times before inductively coding each talking turn to capture the essence of the turn. Codes were then compared to look for themes across the data. Themes continued to evolve as frameworks were applied to make sense of them.

Results and Discussion

Our results focus on the most encompassing theme which emerged from the data: Legitimacy as a Participant in the Mathematics Research Community of Practice. In our data, we found students' perceptions of their legitimacy to be heavily influenced by their interactions with peers. Specifically, students questioned their legitimacy based on their interactions with students in the dominant group and with students perceived as having greater achievement in the mathematics research community.

We connect students' real or perceived legitimacy within the mathematics research community to Gutierrez's (2012) critical axis of identity and power. We see power as held by members in the community who are able to grant or restrict legitimacy within the community. Students belonging to the dominant group within the mathematics research community have greater power over their nondominant peers. In addition, students with greater achievement have moved further into the community, becoming fuller participants, granting them increased legitimacy and power. Students' identities as legitimate members of the mathematics research community are determined in part by the individual and in part by others (Gutierrez, 2013). That is, their peers play a role in students' mathematics research community identity formation.

Delegitimization via the Power of the Dominant Group

Several students detailed negative experiences with peers either at their home institution, an REU, and/or the undergraduate mathematics conference. For some, these included microaggressions such as scoffing, interrupting or "mansplaining". Amira described feeling "on edge" before asking a question, nervous she would justify her peers' behaviors. Through their behaviors, peers indicated Amira didn't belong in the mathematics research community, that is, she was not a legitimate participant. Davies (2005) notes that it is not enough to participate in the community, but one must be accepted as well to become a full member. Amira was concerned that her mathematics questions or contributions in class would prevent her from being accepted into the community and confirm that she was not a legitimate participant.

For similar reasons, Ethan described that as a Hispanic first-generation college student, he had developed a "math personality". Ethan described this personality as "very professional" and that he would talk with others in the community "about math…not so much on my background because there's just not a lot of people from my background." By describing his mathematics research community identity as professional, Ethan implied that his background was not professional and did not belong in the community. Ethan adopted an identity which he felt legitimized him as a participant in the mathematics research community. He focused on connecting with his peers through mathematics and their similar mathematics experiences, avoiding discussing his background. Similarly, Cuc felt the need to hide their use of she/they pronouns after a negative interaction with a few students whom they felt didn't "have good allyship". Ethan and Cuc felt the need to change or hide aspects of their identity in order to belong to and be a legitimate member of the mathematics research community. White and Lowenthal (2011) describe conflicts that occur when students' individual culture differs from the academic discourse community, here, the mathematics research community. Ethan and Cuc both describe code switching to navigate between their individual culture or identity, and what was required to belong in the mathematics research community.

De-legitimization via Perceptions of Less Peripheral Members

Amira and Ethan both described feeling intimidated by their peers. Ethan felt some students were pretentious and tried to impress others which led him to feel the mathematics research community wasn't for him. Peers used the discourse of the mathematics research community to come across as less peripheral members. This display of power resulted in Ethan feeling as though he didn't belong in the community. However, Ethan also stated that over time, he knew more about mathematics and could tell when students were trying to sound impressive. As Ethan himself became a less peripheral member, he could identify these embellishments of power. At the same time, he was still cautious, not wanting to look dumb or confirm stereotypes. Similarly, Amira described feeling nervous around "celebrity" students whom she described as high achievers who are known across institutions, and who are prestigious based on who they work with and know. "I was very nervous because…I knew that there were like, very prestigious programs that like, sent their students [to the undergraduate mathematics conference] and very high-level students and I was sort of worried that like, for example, my presentation might pale in comparison". Amira was concerned others would think her research wasn't good enough, or legitimate. Both Ethan and Amira worried about their legitimacy in the mathematics research community in relation to peers they viewed as more legitimate and less peripheral, experiencing imposter syndrome (Murray et al., 2023). Murray and colleagues found those with imposter syndrome do a large amount of emotional work to "survive and thrive in exclusionary environments" (p.754). The power the less peripheral members held led both Ethan and Amira to question the own legitimacy in the community, leading to additional emotional work as they engaged in the practices of the mathematics research community.

Conclusion

Underrepresented minority mathematics majors described experiences related to power and identity as they navigated the mathematics research community. As they interacted with peers, these students questioned their own identity as a member of community. In particular, peers who belonged to the dominant group or with greater achievement in the mathematics research community had power to grant to rescind these students' legitimacy to the community.

Future work will explore the ways in which these students described their entrance into the mathematics research community. Specifically, why they chose to join the community and how they experienced gaining access to the community. In addition, future work will examine the students' access to *mirrors* (Gutierrez, 2012) with which to see themselves in the mathematics research community.

A Methodology for Mapping Connections Between Persistent Learning Challenges

Joseph Antonides
Virginia Tech

Anderson Norton
Virginia Tech

Rachel Arnold
Virginia Tech

Emma Feinstone
Virginia Tech

Michael Holman
Virginia Tech

Much research within mathematics education is dedicated to understanding the challenges that students often face when encountering new mathematical ideas. Some challenges, called epistemological obstacles (EOs), persist despite research-based instruction designed to target those challenges. The purpose of this report is to describe a methodology for mapping connections between EOs as they emerge during mathematical discussion and problem-solving. We illustrate this methodology through a preliminary analysis of whole-class data collected in an introductory proofs course.

Keywords: Methodology; Epistemological Obstacles; Transition-to-Proof

Understanding the obstacles that students face in mathematics teaching and learning is an essential part of mathematics education research. Much research has focused on identifying and understanding students' cognitive obstacles in mathematics learning (e.g., Smith et al., 1994). Such obstacles are often identified and studied independently, but we have found that many obstacles do not occur independently. Existing research methods, however, do not allow for identifying ways that cognitive obstacles may co-occur. This report provides such a method, allowing researchers to gain greater insight into the ecology of EOs across research areas.

Brousseau (2002) defined three main types of obstacles that students may experience: ontogenetic, didactical, and epistemological. Ontogenetic obstacles occur due to limitations in one's current biological (neuro-physiological) maturation. Didactical obstacles occur when instruction overlooks or potentially exacerbates conceptual challenges in students' mathematical understanding. However, even with instruction designed to target known conceptual challenges, and with sufficient biological maturation (e.g., students who have reached Piaget's formal operational stage), some challenges may persist in students' mathematical reasoning and sense-making. Following Brousseau (2002), we refer to these persistent challenges as *epistemological obstacles* (EOs).

EOs often manifest as a pattern of repeated errors or uncertainties observed by a teacher or researcher. However, EOs are not simply mistakes or the product of ignorance; they are "the effect of a previous piece of knowledge which was interesting and successful, but which now is revealed as false or simply unadapted" (Brousseau, 2002, p. 82). EOs are part of a complex cognitive system and cannot be simply replaced or eradicated (Smith et al., 1994). Our conceptualization of EOs is consistent with what Steffe calls *necessary errors* (Steffe, 1992); they are products of a student's current overall way of operating.

Students may experience an EO when they experience cognitive dissonance, often accompanied by a perturbation, but teachers may experience such dissonance first. Within The Proofs Project, our goal is to identify known EOs in the context of logic and proof, design tasks intended to elicit students' experience of EOs, and leverage inquiry-oriented instruction (Kuster et al., 2018) to provide opportunities for students to address EOs head-on. Consistent with our Piagetian framing, we hypothesize that overcoming an EO requires a structural change in a

student's way of operating (i.e., a metamorphic accommodation; Steffe & Thompson, 2000). Understanding connections between EOs can support instructional design for promoting such structural change.

The purpose of this report is to describe a methodology for mapping co-occurrences between EOs as they emerge through mathematical discussion and problem-solving. We first provide an overview of our methodology. We then illustrate this methodology by drawing on preliminary analysis of whole-class data from an introductory proofs course.

Methodology for Mapping Connections Between Epistemological Obstacles

Our method for mapping connections between EOs is summarized in these six steps:

1. Conduct a literature search to identify known EOs related to a particular mathematical idea, generating a codebook consisting of EOs, their definitions, and potential evidence
2. Collect video recordings of students engaging in mathematical discussion or problem solving (with each other and/or with a teacher or researcher)
3. Analyze video recordings using the EO codebook, creating a spreadsheet containing timestamps, key moments in discussion, low-inference notes justifying codes, and important student quotes, adding emergent codes to the codebook that satisfy the definition of EO as needed
4. Decide upon a "chunk" size (e.g., a discussion topic or classroom task) for determining co-occurrence of EOs, and demarcate chunks in the coding spreadsheet
5. Create an adjacency matrix by counting co-occurrences of EOs within each chunk
6. Represent adjacency using a weighted vertex-edge graph (where vertices represent EOs and weighted edges represent number of co-occurrences).

Step 1 is necessary for understanding the EOs that students may face. Being as specific as possible about potential evidence (behavioral indicators) of each EO (as informed by prior research) is critical. To conduct this search, we recommend beginning with a keyword search using Google Scholar, Scopus, and library databases such as Academic Search Complete. Because researchers use disparate terms to refer to persistent challenges in students' mathematical knowing and learning, a broad range of keywords will likely need to be included using AND/OR Boolean operators and asterisks to include characters that may follow a word, such as "misconce* OR challenge* OR error* OR mistake* OR struggle*," along with keywords pertaining to the specific topic area (e.g., "implication OR conditional"). Conducting a systematic review (e.g., Borrego et al., 2014) will yield the largest set of EOs identified in prior literature and potential evidence for each EO.

In Step 2, students are engaged in contexts where EOs may emerge. Often, EOs emerge in the context of discussing or solving mathematical problems or proofs. Step 3 employs standard qualitative analytic techniques, including making inferences about data, categorizing inferences using codes, and writing low-inference notes to justify one's inferences (Maxwell, 2013). Researchers may also identify emergent codes not identified in prior research and apply these to their analysis (e.g., Corbin & Strauss, 2015). Although not reported here, we identified emergent codes from task-based interviews (Clement, 2000) with individual students and applied these to our analysis (see Norton, Arnold, Antonides, & Kokushkin, 2023).

Step 4 is critical and is context-dependent. For us, given our focus on whole-class discussion and the overall instructional design, generating chunks based on general discussion topics and tasks was most practical. However, an analysis of connections between EOs during a clinical interview setting may permit finer-grained chunks. Step 5 involves the creation of the adjacency matrix itself. To ensure consistency, we recommend only counting each distinct EO once within

each chunk. For instance, we often coded "Reu" on multiple consecutive lines in our codebook, but if they all occurred within a single chunk, then it would only be counted once. Step 6 allows researchers to visualize connections between EOs and the strength of each connection—especially those greater than 1. Notably, our methodology was inspired by prior research that used adjacency matrices to analyze student reasoning (Selinski et al., 2014). However, our approach is relatively novel within the field, given our theoretical framing and focus on EOs.

Illustrating the Methodology

We now turn to illustrating our proposed methodology by drawing on a preliminary analysis of data from whole-class discussions in an undergraduate introductory proofs course.

Step 1: Literature Review of EOs in the Context of Logic and Proof

Prior research indicates that students often assume that if a logical implication (LI) holds, then its converse holds, treating the LI as biconditional (coded LIff; see Epp, 1999, 2003; Rumain et al., 1983; Wagner-Egger, 2007; Wason & Johnson-Laird, 1972). Such meanings are understandable and common in many non-mathematical contexts (e.g., "If you do your homework, then you can play video games," which is likely intended biconditionally). Transforming LIs into a logically related form, such as its contrapositive or negation, poses additional challenges (coded LIt; see Antonini, 2004; Goetting, 1995; Hawthorne & Rasmussen, 2015; Hub & Dawkins, 2018; Knuth, 2002; Stylianides et al., 2004). In particular, students may reason that the negation of an LI should, itself, be an LI (coded NO; see Arnold et al., in press; Epp, 2003), which we call its "opposite" (e.g., the opposite of $p \to q$ is $p \to \sim q$).

Quantifying the negation of a statement poses additional challenges (coded Qneg; see Epp, 2003), particularly uncertainty about whether the negation of an LI should be an existential or universal statement. Many statements in mathematics, including LIs, are not stated with explicit quantification, such as "If a shape is a square, then it is a rectangle." Epp (1999) refers to such statements as containing "hidden" quantifiers (coded Qh), which can pose significant challenges for students. Statements containing multiple quantifiers can pose additional challenges to students (coded Qmult). Students may assume that the order in which two quantifiers are stated does not affect the logical meaning of the statement (coded Qord; for the latter two EOs, see Dawkins & Roh, 2020; Dubinsky & Yiparaki, 2000; Epp, 2003; Piatek-Jimenez, 2010).

Challenges may also emerge when generalizing an argument. To directly prove the validity of a universally-quantified statement, the most common method is to use what Copi (1954) called the Principle of Universal Generalization: a statement holds *for all* $x \in U$ (where U is a universe of discourse) if and only if that statement holds *for any arbitrary* $x \in U$. Students often struggle to make sense of and apply this principle (coded PUG; see Norton, Arnold, Kokushkin, & Tiraphatna, 2023; Selden & Selden, 2013). Additionally, students may attend to the *value* of a variable (e.g., $\delta = .01$), but they may not attend to the *role* played by this variable in a statement or proof, such as the distance between two x-values (coded Qrv; see Dawkins & Roh, 2022).

Lastly, instructors may use visual representations to help students make sense of LIs. Euler diagrams use spatial inclusion and exclusion to illustrate relationships between truth sets of predicate statements. For instance, $p \to q$ can be interpreted as the truth set of p contained within the truth set of q; using an Euler diagram, this would be (conventionally) represented as one circle (representing the truth set of p) contained within another circle (representing the truth set of q). However, students may struggle to make sense of quantification using Euler diagrams, and students may conceptualize $p \to q$ as a circle representing the hypothesis *containing* a circle representing the conclusion (coded Reu; see Antonides et al., 2024; Hub & Dawkins, 2018).

Steps 2-4: Data Collection and Analysis

Data come from an upper-level undergraduate introductory proofs course. The instructor (third author) took an inquiry-oriented approach, with students regularly engaging in small-group and whole-class discussions. All class sessions were recorded (excluding exam days). The analysis reported here focuses on discussions from the 40 class sessions throughout the semester. These data were collected from a video camera installed in the back corner of the classroom ceiling, controlled by a researcher in the neighboring room, as well as four microphones installed in the four quadrants of the classroom.

To analyze whole-class data, we used a codebook of EOs developed by (a) searching research literature related to persistent challenges in logic and proof, and (b) supplementing with emergent codes that were identified in clinical interviews with students (Norton et al., accepted). Because emergent codes did not appear in our analysis of whole-class discussion, we focus only on those codes identified in prior literature.

A pair of researchers (first and second authors) created a spreadsheet to record line-by-line descriptions of classroom activity (e.g., tasks, questions from the instructor, and student quotes) with timestamps for each line. They coded each line that corresponded with evidence for one or more EO. Lines were then "chunked" together by task or discussion topic. Two researchers (fourth and fifth authors) created an initial adjacency matrix of EO co-occurrences between chunks, counting each distinct EO once within a given chunk.

Steps 5-6: Results and Interpretation

Table 1 shows an adjacency matrix of EO co-occurrences (omitting EOs that had zero co-occurrences with other EOs). For instance, the first row, second column, shows that LIff and LIt co-occurred 1 time during whole-class discussions. Overall, of the 10 EOs suggested by prior literature, 9 EOs co-occurred with others in at least one segment of class discussion. The final column of Table 1 shows the total number of connections between each EO and other EOs, found by taking row sums. In particular, the total connections for LIt (10) and Qneg (11) indicate that, in the context of class discussions, students' experiences transforming LIs and quantifying the negation of logical statements are highly connected to their experiences of other EOs.

Table 1. Adjacency matrix of EOs experienced in an introductory proofs course

	LIff	LIt	Qh	Qmult	Qord	Qneg	NO	PUG	Reu	Total
LIff		1	1	0	0	0	0	0	3	5
LIt	1		1	0	0	4	1	0	3	10
Qh	1	1		0	0	1	0	1	1	5
Qmult	0	0	0		3	2	1	0	0	6
Qord	0	0	0	3		0	0	0	0	3
Qneg	0	4	1	2	0		3	1	0	11
NO	0	1	0	1	0	3		1	0	6
PUG	0	0	1	0	0	1	1		0	3
Reu	3	3	1	0	0	0	0	0		7

The weighted graph shown in Figure 1 illustrates connections between EOs. Figure 1 makes salient the relatively large number of paths connecting LIff, Reu, LIt, Qneg, and NO. Additionally, Figure 1 shows that Qord is isolated from other EOs except for Qmult.

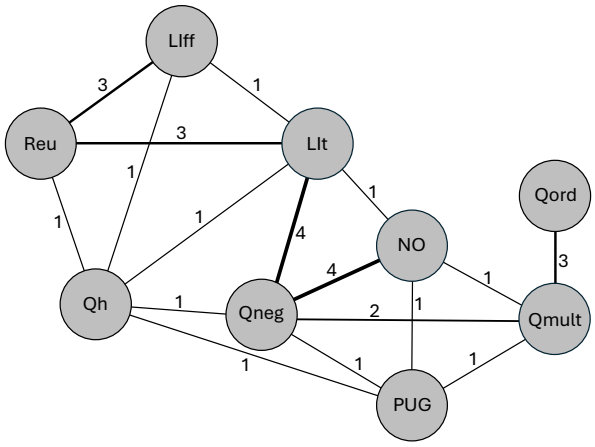

Figure 1. Vertex-edge graph illustrating adjacency among EOs from an introductory proofs course

Classroom Example of a Connection Between EOs

We provide an example of a class discussion intended to elicit students' experience of LIt, NO, and Qneg. The teacher (third author) presented students with the statement p: "For all nonnegative real numbers x, $\sqrt{x} \leq x$" (logically equivalent to the LI: if $x \geq 0$, then $\sqrt{x} \leq x$). The teacher asked students to determine "what statement is equivalent to saying p is false." Following small-group discussion, class discussion began with students mentioning the counterexample $x = ¼$. The teacher then challenged students to generalize this finding into a statement equivalent to saying p is false as follows.

Teacher: ... in general if I say "for all x, something happens," then how would you talk about the other side of the argument?

Student: Um, the false statement would be like, "for all x, something doesn't happen."

Teacher: So, do I need to show that… he said for all x we want to show that open statement doesn't happen.

Student: Oh, for some x in the same set, it doesn't.

In attending to transforming the statement (LIt), the student experienced Qneg and NO; their quantified response "for all x, something doesn't happen" is logically equivalent to the opposite LI, "if x is in the set, then something doesn't happen." The student amended their quantification to "for some x," perhaps in an effort to reconcile their quantification with their understanding that a single counterexample disproves the statement. The adjacency matrix in Table 1 cued us to looking for connections between Qneg and NO, and to proffer explanations for their relatively strong relationship. Indeed, when attempting to transform a universally quantified statement into its negation (LIt), students may initially conceptualize the negation as also needing to be a statement about all values in the universe (Qneg). If this is the case, then it makes sense that students may interpret the negation as its opposite (NO).

Conclusion

This report outlines a methodology for mapping connections between EOs in mathematical discussions and problem solving. Our preliminary analysis of data from an introductory proofs course revealed significant co-occurrences among EOs, such as LIff, Reu, LIt, Qneg, and NO. This methodology can be used broadly to highlight connections between EOs and their potential impact on students' reasoning. Future research should expand this approach across varied mathematical contexts to further refine our understanding of EOs and develop instructional tools and strategies designed to overcome them.

Addressing Equity and Identity in a General Education Mathematics Course

Michelle Homp
University of Nebraska – Lincoln

Lisa Rezac
University of St. Thomas

Theresa Jorgensen
University of Texas at Arlington

Motivated by the goal of reducing equity gaps in achievement at a predominately white, public land grant research university, a team of mathematicians designed and implemented research-based strategies for promoting equitable instruction in a coordinated multi-section general education terminal mathematics course. To assess the impact of the course on students' mathematics identity, we utilized a pre- and post-survey adapted from an instrument developed by Hazari et al. (2020) which included scales to measure the constructs of sense of belonging, interest, recognition, and utility/competence. Preliminary analysis revealed that the means of student responses changed in the desired direction from pre- to post-test, with sense of belonging showing the greatest, statistically significant change. Initial quantitative and qualitative findings suggest the instruction tasks described here, which are relatively simple and inexpensive to implement, can have a significant impact on improving mathematical identity for students in a general education mathematics course.

Keywords: mathematical identity, sense of belonging, general education mathematics

In recent years, STEM education research has focused on student identity and its impact on students in STEM courses (Tytler, 2014). Some researchers have broadly defined science identity as an individual's "understandings of self," the ways in which they "make sense of themselves" and how they perceive they are "made sense of by others" within the context of science (Kane, 2012, p. 458). This definition of identity was applied to students pursuing study in physics (Hazari, Cass, & Beattie, 2015; Hazari, Sadler, & Sonnert, 2013) using a framework developed by Carlone and Johnson (2007) that introduced three constructs of science identity. These three constructs formed the basis of a framework adapted for physics identity by Hazari et al. (2020), who also developed a fourth construct.

Additionally, efforts to promote equitable education and positive STEM identity are widespread, with stakeholders in STEM education offering workshops and programming to guide instructors wishing to implement equitable curriculum and teaching practices. Though examples are plentiful, one such program is The Inclusive STEM Teaching Project, sponsored by the National Science Foundation (NSF), Directorate for Education and Human Resources (EHR), and Division of Undergraduate Education (DUE), and developed by a team of faculty representing Boston University, Northwestern, University of Michigan – Ann Arbor, Des Moines Area Community College, The University of Utah, University of Wisconsin – Madison, and the University of Georgia. (https://www.inclusivestemteaching.org/) Having completed the program, one of the authors conducted focus groups of UNL students to analyze localized needs, and then chose and implemented changes to the curriculum and instructional tasks in the general education mathematics course, Contemporary Mathematics. The strategies involve (1) making visible the contributions of mathematicians from historically underrepresented minority groups in multiple ways (course workbook, Open Educational Resources (OER) course textbook, biography assignments, homework questions, in-class discussions), (2) connecting these contributions to content learned in class, and (3) reflecting on personal learning experiences in mathematics alongside the experiences of contemporary mathematicians via an extended writing assignment.

In this study, we utilize an adaptation of the instrument employed by Hazari et. al. (2020) to assess constructs of identity in the context of mathematics. In particular, we use a pre- and post-survey assessment of mathematical identity in a general education (terminal) undergraduate mathematics course in which concerted efforts to promote equitable instruction and positive STEM identity have been implemented.

Context and Curricular Changes at our Institution

In response to emphasis at University of Nebraska-Lincoln (UNL) on reducing equity gaps in achievement across the institution, UNL's Department of Mathematics made a commitment to implement changes designed to address these gaps. One such change was the widespread use of Open Educational Resources (OER) as textbooks and extended tutoring/support opportunities for equitable access to resources. However, curricular changes were also needed to successfully address achievement gaps. In preparation for determining appropriate changes, the department procured university funding to collect feedback from underrepresented minority (URM) students using focus groups to identify curricular and other barriers to students' success in Math 203. In addition to pedagogical and logistical changes, findings from the focus groups led to curricular revisions specifically designed to address issues of mathematical diversity and identity. Consequently, the curricular changes were intended to help all students (URM students in particular) see themselves as part of the culture of mathematics, as individuals capable of mathematical success, and as being potential contributors to a body of mathematical knowledge fundamental to modern society. This was accomplished by including new or enhanced emphasis on topics for which relevant mathematics is being developed by researchers from URM groups (e.g., mathematical modeling, epidemiology, gerrymandering) and were incorporated into the curriculum in a multi-pronged approach:

1. Relevant content was added to the OER.
2. Each unit of the OER closes with a section featuring the mathematicians from URM groups whose research relates to these topics, featuring images (for quick, visual recognition of diversity), basic biographical data and links for further information.
3. Questions about a subset of the featured mathematicians are included in homework (WeBWorK) assigned for that unit based on these entries.
4. Students are tasked with selecting one of the mathematicians and writing a brief biography following specified prompts.
5. Instructors lead a brief in-class discussion about the mathematicians featured in students' biographies.
6. An extended biography and personal reflection is assigned directing students to the MAA publication "Living Proof" (Heinrich et al., 2019).

Methods

At the beginning of the spring semester of 2024, a pre-survey was administered as part of an assignment to all students enrolled in six different sections of Contemporary Mathematics, UNL's general education mathematics course for non-STEM related majors. Of these, 118 completed the survey expressing a willingness to be part of the study. To accommodate UNL's final week policy, the post-survey was administered as an extra credit assignment and was completed by 84 students at the close of the term. For the purposes of this study, the students are categorized as 78% majority (predominantly white students) and 22% non-majority (students from underrepresented minorities).

The survey instrument is based on one developed by Hazari, et al. (2020) that measures four constructs (interest, recognition, performance/competence, sense of belonging) determined to comprise physics identity in the context of undergraduates studying physics both at the beginning and near the end of their degree programs. We utilized similar questions by replacing references to "physics" with "math" when it made sense to do so and making a few other adjustments to better reflect course content and goals. We also added questions about growth mindset structured in a manner similar to those in the instrument used by Hazari, et al. (2020). A five-point Likert scale was used for responses to the construct items; four free response items were included for justifying a few key Likert ratings and to share comments directly correlated to the new curricular tasks addressing diversity and identity as explained above.

Indicator questions related to students' sense of belonging are shown in Table 1 below, both as an example and to highlight certain significant gains.

Table 1. Belonging Indicators [scale 1=not at all, 3=neutral, 5=very much so]

With respect to other students taking [____], to what extent do you…	[Math 203]	[other math classes]
…feel different from others in the community?	Q1	Q4
…feel alone or isolated?	Q2	Q5
…feel inadequate as a member?	Q3	Q6

Means from the Likert scale responses were analyzed and are summarized in the quantitative findings below. The free response survey questions on the post-test were categorized as positive, negative, or neutral responses by the authors and summarized in the qualitative findings.

Preliminary Quantitative Findings

A two-tailed z-Test in Excel was used to compare pre- to post-means, with α=0.05. Results show means of all individual questions and the combined categories changed in the desired direction from pre- to post-test, with an increased sense of belonging showing the greatest, statistically significant change. (See Table 2.)

Table 2. Pre/post mean comparisons for construct categories

Construct category	Pre-survey Mean (n=118)	Post-survey Mean (n=84)	Difference in Means	*p*-value (*z*-Test)
Interest	2.11	2.20	0.09	0.33
Recognition	3.26	3.36	0.10	0.16
Belonging#	3.77	2.03	-1.74	0
Growth Mindset #	3.28	2.99	-0.29	0.0001
Utility/Competence	3.46	3.62	0.16	0.024
Mathematical Identity	2.88	3.05	0.17	0.057

#The desired change based on the phrasing of questions in the Belonging and Growth Mindset categories is a decrease from pre- to post-means. For all other categories, the desired change is an increase.

A closer look at some individual indicators of construct categories for which combined mean changes were not statistically significant reveals some indicators exhibited greater change than others within their respective categories. Switching to a one-tailed z-Test (based on evidence from Table 2), Table 3 shows the results for two such indicators. Using the same Likert scale explained in Table 1, the desired change is positive.

Table 3. Pre/post mean comparisons for two isolated construct indicators

Construct Category and Indicator Item	Difference in Means	*p*-value
Recognition Q3: To what extent do you believe you have the ability to understand mathematics topics/concepts well?	0.275	0.026
Identity Q3: With respect to one or more of your identities, to what extent do you believe you or people like you can excel in mathematics?	0.22	0.059

Preliminary Qualitative Findings

Here are the three of the optional free response questions with a summary:

Q32: "With respect to one or more of your identities, to what extent do you believe that people like you can excel or are excelling in mathematics?" We categorized 41 of the 58 written responses as positive, nine neutral, and four negative. Additionally, we found responses that we couldn't categorize, due to poor wording or statements like "I don't understand the question." From the 41 positive responses, many students revealed a belief that if someone works hard, they can excel independent of their identity. The positive responses included:

- I think people like me, those who struggle can either do great or not. It all depends on their mindset and work ethic. If they go and continually ask for help and make an effort to understand the material, then they can be really successful.
- I have seen examples of LGBTQ+ people and females excelling in mathematics, especially in this course. I feel that people like me can excel in mathematics if they would like to. I'm glad that there are many different types of people represented in this course and not just old dead white guys.
- I think through my own identity, as a Hispanic female, there is potential for other women like me to excel in mathematics or who are currently excelling in mathematics that influence many others to do the same.

Q33 on the post-survey asked about key takeaways from the assignments related to the biographies of URM mathematicians. 56 of 64 responses were positive, responding that they learned about a wide variety of math careers, or saw a wide variety of identities represented, or they learned that even mathematicians struggle with math. One such response was,

- A big take away from me is that these people are normal people. Some of them did struggle in math in their lives. Not only that but they come from a number of backgrounds, some very similar to mine.

Q34: "If you indicated math will be useful to you in your future career, how do you see yourself using it? If you do not believe math will be useful for your career, can you see yourself using it in daily life? If so, how?" For this question, there were 62 responses. We categorized 59 of the 62 as positive responses, two neutral and one negative. This was an encouraging result, especially since many of those who chose to respond identified themselves as future teachers.

Results from these questions suggest positive outcomes, just as we saw in the quantitative data. The written responses from students identifying themselves as future teachers suggest we

should implement instructional tasks and curriculum changes such as these in courses for future teachers.

Continued Analysis and Conclusions

Our initial statistical analysis compared means from the pooled responses for pre- and post-tests. However, the pre- and post-data can be paired, allowing additional analysis that can potentially address changes in identity at the individual level. Students can be isolated by demographics (gender, race, ethnicity, first-generation) to measure the impact on mathematical identity among these groups (the students we endeavored to reach). Another group of interest are those in the course pursuing a degree in elementary education, as most of these students take this course to fulfill a general education requirement. Improving sense of mathematical identity for future elementary teachers has significant potential to impact future learners of mathematics.

Findings from Hazari et. al. (2020) reveal that while all constructs from their study contribute to a positive physics identity, the impact of each construct is case-dependent. In particular, for undergraduate students at the beginning of their program of study, a strong sense of belonging has the strongest impact on their development of positive physics identity. While Math 203 is a general education course, it is not unreasonable to suggest results similar to those observed in this study (i.e., the strong gains in sense of belonging) have the potential to impact other undergraduate mathematics courses, particularly those at entry-level.

Implications of both quantitative and qualitative results from this study suggest tasks such as those described here, which are relatively simple and inexpensive to implement, can have a significant impact on improving students' mathematical identity for students with or without majors requiring courses in STEM.

Questions for Discussion: (a) How can we tell if we are impacting minority students when our population includes so few of them? (b) What are suggestions for analyzing the data without being affected by our own biases? (c) One goal is to analyze responses from those students going into (elementary) education. Can these curricular strategies and instructional tasks be used as recruiting tools for non-majority students to pursue teacher education? Will the positive changes in math identity among preservice teachers carry over into their practice and to their future students?

This preliminary report explores how students experience playful mathematics tasks in sections of a large Calculus I class. We implemented tasks that have been established to foster playful mathematical engagement and learning in 5 sections, and examined whether students experienced playfulness across multiple dimensions. We found that students enjoyed the class, felt engaged, and considered themselves to have understood the content, which they rated as at least somewhat challenging. These findings are being used to design professional development for future Calculus I teaching assistants, in order to examine potential scalability of playful mathematics and learning to lecture-based classrooms.

Keywords: playful mathematics, calculus, undergraduate

There has been increasing interest in examining how playfulness can be incorporated into undergraduate mathematics as the productivity of play for mathematical learning across age groups is becoming more acknowledged. However, the undergraduate research thus far has focused on smaller seminar-style courses (Holton et al., 2001, Ellis et al., 2022), is often conducted with mathematics education majors who are well equipped to handle the ill-defined nature of many mathematical play tasks (Ellis, Horne, & Bloodworth, 2024; Ellis, Bloodworth, & Horne, 2024), and is usually taught by the researcher who is well conversant with supporting mathematical play. This preliminary research report addresses the first year of a multi-year study, in which the authors implemented playful calculus tasks in five Calculus I sections of a large lecture class, as the first step in understanding how to support such students in playing with and learning about mathematics. The second year will focus on conducting professional development with the section TAs (mathematics graduate students) so that they can implement playful calculus tasks in their own sections. We report on the initial results of the first year of the study, and outline our consequent plans and goals for both conducting the professional development workshops and evaluating the success of student learning from the playful mathematics tasks.

Background

Mathematical play has been well valued in early childhood, as a productive and powerful way for young children to experiment with mathematical patterns in the world (e.g., Wager & Parks, 2014). Scholars have theorized that mathematicians and young children both play with mathematics in similar ways (e.g., Williams-Pierce, 2019), and recently, Horne, Bloodworth and colleagues (2022) have empirically confirmed that mathematicians do in fact play with mathematics. They interviewed mathematicians and found evidence of mathematical play while problem solving, including markers of open exploration, enjoyment, investment, perseverance,

and flow. An open question, therefore, is how mathematical play can be supported after early childhood with learners who are not mathematicians. Researchers have begun investigating how to do so with older children, but still primarily with youth, not college aged students (e.g., Gresalfi, 2015; Williams-Pierce & Thevenow-Harrison, 2021).

A smaller but no less important community of researchers have begun investigating mathematical play in undergraduate and graduate courses. For example, Ellis and others have designed a variety of tasks specifically for undergraduates addressing covariation and function graphs, calculus topics such as derivatives and integrals, and tropical algebra, and found that playful tasks with intrinsic feedback and ample opportunities for problem posing can foster both playful engagement and learning. Instead of using the term 'mathematical play' in their work, they use the phrase 'playful mathematics,' "to describe the activities…and features of an instructional environment that can facilitate mathematical play" (Ellis, Horne, Bloodworth, & Ely, 2025, p. 2). We consider playful mathematics to be a conceptual subset of mathematical play, and one that is particularly well suited to the complex social learning contexts of undergraduate mathematics courses.

Given this considerable evidence that playful mathematics could be a powerful tool for supporting productive mathematical learning, it behooves us to understand how we could support larger-scale implementation at the undergraduate level. We focus here specifically on Calculus I, because it is commonly taught as a large lecture class, and can be a gatekeeper to STEM degrees and careers. While our long-term goal involves designing and implementing professional development for the TAs who run the smaller sections of the large lecture-based classes, and evaluating the influence of the mathematical play on students' calculus learning, the study we report on here is the foundation of that longer-term work. In particular, we wanted to better understand how students experience playful calculus tasks after being used to more traditional mathematical learning environments. Consequently, we asked: How do undergraduate students in a traditional calculus section experience playful calculus tasks? In particular, we investigated how they self-report on differing dimensions of engaging in playful calculus tasks, ranging from how much they believed they learned to how much they enjoyed (or did not enjoy) the tasks.

Methodology

This study collected data from participants in five different sections of two Calculus I courses, taught by the same professor. This 4-credit course at a large public university had a 50-minute lecture three times a week and a 50-minute section twice a week, so students engaged with the course content daily. Each course had 100 to 150 students, and each section was capped at 25 students. Researchers received permission from the professor and TAs to implement playful calculus tasks in seven different sections towards the end of the semester; in two sections, the students all opted out of participating in the study, resulting in data from five sections.

Playful Tasks

The playful tasks used in this study come from previous research (Ellis, Horne, Bloodworth, & Ely, 2025), and address the construction of function graphs as traces of covariation between area and length of swept shapes. For example, an animated growing rectangle would be shown to the students, and they would be asked to 'sketch' a graph on two axes, where y is the area and x is the length, and given no other information. There were no given labels or quantities (i.e., students could not calculate area or length numerically), and students would discuss their reasoning in small groups and then share with the whole class. Each section completed three

growing shapes tasks (rectangle, triangle, triangle-rectangle-triangle), and in only one section did we manage to the fourth task, where students would create their own growing shape.

The primary feedback the students received on their work was through their peer discussions, as the researchers limited themselves to asking questions and encouraging comparison between different student graphs. Refer to the above citation for more details on the task design, and how they foster playful mathematics. The research described in this paper is unique from the previous research in that the tasks were implemented in sections of a large lecture course with undergraduates seeking to fulfill benchmark requirements for their degree programs, whereas other research involved small-group middle school teaching experiments (e.g., Ellis et al., 2025), and undergraduate teaching experiments (Ellis, Bloodworth, & Horne, 2024; Ellis, Horne, & Bloodworth, 2024). The students were ostensibly quite familiar with the concept of covariation and the process of constructing function graphs, prior to data collection, given that they were close to finishing a Calculus I course.

Data Collection

The surveys were adapted from Riling, Dietiker, and Gates (2019), who developed a tool for evaluating students' mathematical experiences in individual lessons. These surveys are brief (one page), with 8 different items, specifically geared towards capturing a variety of student perspectives on a mathematical lesson. In Item 1, students are asked to pick up to three descriptions that 'best describe' their view of the lesson, ranging from positive valenced words such as Fun, Interesting, Surprising, to negative valenced words such as Boring, Stressful, Not Special. Item 2 asks them to rate how they felt they understood the topic - that is, evaluating their learning - with three options: Don't Understand, Somewhat Understand, Understand. Item 3 asks them to choose the best option for how they 'felt,' ranging from "Very bored: I was very bored and wish we would do something different" to "Very interested: I was very interested and the lesson was really fun and/or intriguing." Finally, Items 4-8 were 4-item Likerts ("Strongly Disagree" to "Strongly Agree") with the following prompts: Time flew by; The content of this lesson was relevant to my life; Today's math class was like most days in this class; I wish more lessons were like this one; and The content of today's lesson was challenging for me.

We only included very clean data for this analysis, and plan to incorporate the messier remains in later analyses. In particular, we only included surveys that were administered after the first playful task and at the end of class, discarding surveys administered in the middle (due to inconsistencies in data collection across sections), and surveys found after class with no identifiable temporal provenance. We also removed entire surveys when the respondent indicated more than three descriptors in Item 1. When a single item on a survey was left blank, we replaced it with the average value of other respondents; when someone chose a value between two values on the scale, we used the average value of all the respondents to determine whether to round up or down. We are in the process of incorporating the messier data that we removed for this preliminary analysis, for our next phase of analysis. We used the R base package (R Core Team, 2024) to conduct descriptive statistics on the resulting 85 surveys.

We also collected video, audio, and survey data from consenting students in those five sections (n = 50). We are still working on the transcription and thematic coding of this data due to unexpected data complexities, so the primary data source for this paper is the survey data.

Results

Item 1: Positive and Negative Valenced Words

This item asked respondents to choose three terms that best described their experience with the lesson. We enumerated the positive and negative valenced words, then summed them across students. In the 85 entries, positive valenced words accounted for 201 of 238 choices, and negative valenced words accounted for the remaining 37. On average, each survey had 2.36 positively valenced words, and the medians of 3 (positively valenced) and 0 (negatively valenced). These results indicate that students overwhelmingly enjoyed the playful tasks.

Item 2: Rating their Learning

This item asked students to rate their learning, and whether they considered themselves to have understood the lesson. We assigned values to the three possible responses: 0 (Don't understand); 1 (Somewhat understand); and 2 (Understand). We found that the median response was Somewhat understand, with an average of 1.29, above Somewhat understand. Consequently, we concluded that most students considered themselves to at least mostly understand - in other words, the students generally considered themselves to have learned during the playful task. This result was particularly intriguing when the results of Item 1 are also considered: the students positively described their experience engaging in the tasks, *even though* they only felt like they 'somewhat understood' the mathematics.

Item 3: Rating their Engagement

Item 3 asked students to choose which of four options best described how they felt about the lesson overall: 0 (Very bored); 1 (Uninterested); 2 (Interested); and 3 (Very interested). *Interested* was the most common response by far ($n = 56$), followed by *Uninterested* ($n = 20$), *Very Interested* ($n = 8$), and *Very Bored* ($n = 1$). We considered this to indicate that students tended to be interested in the playful calculus tasks.

Items 4-8: Likert Scales

These five items were developed specifically to triangulate earlier items and test other potential relationships (Riling, Dietiker, & Gates, 2019), and we examined them together. These 4-item Likert scales were forced choice, ranging from Strongly Disagree to Strongly Agree.

Table 1. Response Frequencies of Items 4 through 8. SD = Strongly Disagree; D = Disagree; A = Agree; SA = Strongly Agree.

Prompt	SD	D	A	SA
Item 4: Time flew by	4	19	48	14
Item 5: The content of this lesson was relevant to my life	14	50	21	0
Item 6: Today's math class was like most days in this class	41	38	6	0
Item 7: I wish more lessons were like this one	9	17	51	8
Item 8: The content of today's lesson was challenging for me	15	44	22	4

Students disagreed that the content of the playful calculus tasks were relevant to their lives, disagreed that the content of today's lesson was challenging for them, and tended to disagree/strongly disagree that this was a typical day in the class. On the other hand, students tended to agree that time flew by, and that they wish more classes were like this one. We unpack the complexities of these results in the discussion.

Discussion & Conclusion

In summary, we found that students enjoyed the class (Items 1 and 7) and felt engaged (Items 3 and 4), felt like they somewhat understood the content (Item 2) and agreed that it was at least somewhat challenging (Item 8). They did not consider the content particularly relevant to their lives (Item 5), and they felt that this class session was quite different from other days in section (Item 6). We conclude that our students overall had a positive experience engaging in these tasks, and likely experienced playful mathematics. As a result, we are using these preliminary results to guide the next step in our research.

We are delighted that these playful mathematics tasks appear to have worked as intended outside of their original design context of teaching experiments. In particular, the findings indicate that the students experienced several hallmarks of mathematical play, such as challenge and enjoyment (e.g., Ellis et al., 2022; Williams-Pierce & Thevenow-Harrison, 2021). However, we were unsurprised that students found this class session different from their previous experiences (Item 6). When the first and second authors were originally collecting data, we changed the chairs in each classroom so that students were grouped or facing each other, instead of facing the front of the classroom in neat lines. Several times, students walked in, looked at the chairs, and immediately walked out again to check the room number - in other words, their initial reaction to a non-lecture set up in the classroom was, *this must not be my class*. This anecdotal evidence was supported by the quantitative findings, and if we use Item 6 as a proxy for previous experiences in class, we consider it highly likely that students felt more enjoyment and engagement (as evidenced by Items 4 and 7) with these tasks than in the typical lecture-based section. However, there are numerous potential reasons why they may have experienced these tasks differently, such as the sheer novelty of a different instructor or being part of a research study. Our future research will dig deeper into these potential reasons and other limitations, as well as investigate our professional development efforts with TAs, and the resulting playful mathematics experiences of their students.

Acknowledgments

Many thanks to Dr. Kendall Williams and his TAs for sharing their classrooms, students, and insights! Thanks also to our anonymous reviewers, who were kind even as they critiqued – a wonderfully helpful balance when in the preliminary stages of a research project. Finally, thanks to INFO's HCIM Travel Awards for generous travel funding - much appreciated!

Exploring Undergraduate Student Survey Responses About Engaging and Inclusive Experiences With ELITE PD MGTAs in Their Mathematics Courses

Kelsey Quaisley
Oregon State University

Mary Beisiegel
Oregon State University

Charalambos Charalambous
University of Cyprus

We focus on equitable and inclusive teaching practices in a professional development program (PD) for mathematics graduate teaching assistants (MGTAs). In doing so, we hope that MGTAs will grow to improve the experiences of their students. We analyzed over 1200 undergraduate surveys corresponding to nine MGTAs in our PD program. We completed statistical analyses by comparing means in two ways: (1) the aggregate data for each term and (2) for the individual MGTAs for each term. In the first analysis, we found a statistically significant improvement in scores from the first term to the last term of an academic year. However, for the second analysis, when we analyzed the means of each MGTA's survey responses, we found that two of nine MGTAs had decreased scores over the course of the academic year. Ongoing research is investigating the extent to which experiences improved for different subpopulations of students within MGTAs' classrooms.

Keywords: Graduate Teaching Assistants, Professional Development, Student Experiences, Survey

Introduction

There is a growing body of research documenting undergraduate students' experiences of marginalization and exclusionary systems in mathematics classrooms (Battey et al., 2022; Leyva et al., 2021; Nieminen et al., 2024). Combating such inequities is desirable, but complicated. In recent years, scholars have recognized active learning instructional practices as capable of disrupting inequities in the mathematics classroom (Theobald et al., 2020), but also capable of perpetuating inequities without careful attention to equity and inclusion within those practices (Ernest et al., 2019; Johnson et al., 2020). As such, engaging learners through equitable and inclusive teaching practices is an important skill for instructors to develop.

Given the number of mathematics graduate teaching assistants (MGTAs) teaching undergraduate mathematics and their impact on undergraduate learners (Selinski & Milbourne, 2015), it has become increasingly common for mathematics departments to offer professional development (PD) for teaching to MGTAs (Braley et al., 2023; Ellis et al., 2016), with 'active learning' and 'equity and diversity in the classroom' becoming more frequent topics (Braley et al., 2023). As such, there is much to learn about the extent to which undergraduate students' experiences are shifting in more equitable directions when their instructors are engaged in PD with a focus on engaged learning, equity, and inclusion.

Our research team implemented a PD program for MGTAs that focuses on engaging learners through equitable and inclusive teaching practices. The goal of this preliminary report is to analyze undergraduate student survey responses from the mathematics classes of MGTAs enrolled in the PD program. Our research question is: *Do MGTAs receive improved student survey responses over time in a PD program?*

Literature Review

Many scholars and professional organizations have expressed the need for teaching practices that actively engage students in post-secondary mathematics classrooms (AMS, 2019; Freeman

et al., 2014; MAA, 2019; Saxe & Braddy, 2015). This increased attention to and creation of policies on active and engaged learning are due to years of research that have consistently illustrated that undergraduate learners experience improved outcomes when teachers engage them in mathematical thinking via open-ended questions, problem-solving activities, and opportunities to reflect on their own knowledge (Harper & Quaye, 2009; Laursen, 2013; Laursen et al., 2014; Laursen & Rasmussen, 2019; PCAST, 2012; Wieman, 2017). Active learning has "large and consistent" impacts on undergraduate learning outcomes (Freeman et al., 2014; Wieman, 2014, p. 8319). For example, Rasmussen and Ellis (2013) found that STEM-intending students who experienced more engaging pedagogy in calculus courses were more likely to continue to the next mathematics course than students in lecture based calculus courses. Freeman and colleagues (2014) posited that students in the 50th percentile of a course would improve to the 68th percentile if their instructors implemented active learning.

More recent literature has called for more attention to diversity, equity, inclusion, and access (DEIA) in post-secondary mathematics education (Adiredja & Andrews-Larson, 2017; Gutiérrez, 2018; Voigt et al., 2023). Mathematics classrooms that support DEIA are often those that are active and engage learners in meaningful mathematical activity. However, Brown's (2018) investigation of undergraduates' experiences in mathematics classrooms found that not all active-learning classrooms are equitable. Other studies have confirmed that a focus on active learning alone may be insufficient to address inequities at the classroom level and beyond (Ernest et al., 2019; Johnson et al., 2020).

Mathematics departments often rely heavily on MGTAs for teaching or supporting 100- and 200-level courses. MGTAs often lead multiple recitation or lab sections for large lecture courses or they might teach courses as a lead instructor. At some doctorate-granting institutions, MGTAs teach up to 68% of Calculus I courses (Selinski & Milbourne, 2015). This means that during their graduate programs, MGTAs likely contribute to the learning experiences of hundreds, and possibly thousands, of undergraduate students. Despite their contact with and impact on undergraduate students, there have been few studies that have investigated MGTAs' understanding of teaching practices (Miller et al., 2018; Speer et al., 2010). Thus, it is important to implement and study a PD program for MGTAs that focuses on engaging learners through equitable and inclusive teaching practices. We expect that such a program has the potential for significant impact on undergraduates' mathematics learning environments.

Data Collection and Analysis

In this report, we present initial results from one academic year during which we had four MGTA participants in their second year of the PD program and five MGTA participants in their first year of the PD program.

Context of the Study

Our PD program aims to educate and support MGTAs in enacting instructional practices that center equity and inclusion within active learning strategies. The ELITE PD program has five components that are offered to MGTAs over the course of three years. Each of the components is highly collaborative and fosters regular interactions among cohort members. These are intended to provide a model of effective teaching practices for MGTAs, highlighting facilitation practices, grouping students for active learning, group-worthy tasks, and questioning strategies. The MGTAs begin the PD program with an orientation, which takes place two to three days prior to the start of the term. The orientation includes information about the department and the graduate students' roles and expectations as MGTAs. Leaders of the orientation focus on community

building within the new cohort, and support MGTAs in developing knowledge of teaching practices focused on active group learning and dynamics, classroom logistics, as well as expanding their awareness of the diversity of experiences and access needs of undergraduate mathematics students. Second, in the term subsequent to the orientation, MGTAs take the Graduate Teaching Seminar where they continue to learn about the department, the university's teaching support resources, classroom management, and how to implement small-scale instructional practices with attention to equity and inclusivity through active engagement. The third and fourth components of ELITE PD occur in the second year of their graduate program with the Introduction to Equity and Active Learning seminar during which MGTAs continue to build upon their understanding of and facility with active learning and equitable teaching practices, and the Advanced Active Learning and Equity Seminar, which has MGTAs engaging with specific research-based pedagogical approaches as well as equity research associated with teaching. Throughout the ELITE PD program, MGTAs are observed in their classroom and given feedback about their teaching. Once the first four components of ELITE PD are completed, the fifth component has MGTAs serving as peer mentors to new MGTAs who enter the program.

Survey Items & Responses

We collected survey data from nine MGTAs' classrooms. There were two MGTAs who were assigned to a research assistantship during the year, so we do not have data for those terms for those MGTAs. We administered student surveys toward the end of each of the three academic terms. The surveys had 15 Likert-scale questions (Strongly Disagree (1), Disagree (2), Neutral (3), Agree (4), Strongly Agree (5)) that addressed their experiences with their MGTA primarily focused on students' active engagement (e.g., My TA helped facilitate group discussions that promoted my participation), inclusivity (e.g., I felt welcomed and a sense of belonging in this course), and access (e.g., My TA helped me identify and/or access resources to be successful in the course). We collected 1285 surveys total across all participants as seen in Table 1.

Table 1. Number of surveys collected from ELITE PD participant's classes.

MGTA	Cohort	Fall	Winter	Spring	*Total*
1	1	80	69	26	175
2	1	–	–	37	37
3	1	97	80	32	209
4	1	52	15	39	106
5	2	75	38	–	113
6	2	50	28	52	130
7	2	76	60	46	182
8	2	54	51	73	178

9	2	56	56	43	155
Total		540	397	348	1285

The surveys noted in the table above were collected in the same academic year. During that year, Cohort 1 participants were second year mathematics graduate students in their second year of the ELITE PD program, and Cohort 2 participants were first year graduate students in the first year of the ELITE PD program.

Analytic Methods

In our first approach to the data, we analyzed the entire data set, comparing the mean scores on the surveys Fall to Winter, Winter to Spring, and Fall to Spring. We first applied Levene's Test for Equality of Variances to the data. Then, based on the results of this test, we were able to conduct a t-test for equality of the means. In our second approach to the data, we analyzed each participant's data separately, still exploring whether their student survey responses increased over time. For this analysis, we calculated the average responses for the 15 survey items for each MGTA. Then we found the mean of these values to calculate a composite score for each term for each MGTA. Given the small sample size, we applied the Wilcoxon non-parametric statistic to compare the mean scores between Fall and Winter, Winter and Spring, Fall and Spring.

Results: Improvements in Survey Responses in MGTAs' Classes

Overall, student responses were skewed toward the positive end of the scale for all three terms, with their ratings being higher than 4 (Agree), for 14 out of 15 questions, and slightly below 4 for one question (My TA presented examples that resonated with me or related to my interests).

First Analysis

In our first analysis, where all the data across all participants were analyzed together, there was a slight improvement in means from Fall to Winter, but it was not significant (it could be just random). There was a slight improvement in means from Winter to Spring, which was marginally significant (at α =.05). From Fall to Spring, we found statistically significant improvement in means with a medium effect size (Cohen's d=.70). Table 2 shows the results of the test that compared the means from Fall to Spring. When we look for students' ratings as a whole, they gradually improve over time.

Table 2. Independent Samples Test

					95% Confidence Interval of the Difference	
t	df	Significance One-Sided p	Mean Difference	Std. Error Difference	Lower	Upper
-2.975	924	.002	-.13989	.04702	-.23216	-.04761

Second Analysis

In our second analysis, where we analyzed each participant's data separately, we observed more cases of improvement than of decline from Fall to Spring and from Winter to Spring. The negative Z values in Table 3 indicate improvement of mean responses from one term to the next, but the differences were not statistically significant.

Table 3. Wilcoxon Signed Ranks Test

	Fall to Winter	Winter to Spring	Fall to Spring
Z	-.140	-1.352	-1.521
Asymp. Sig. (2-tailed)	0.889	0.176	0.128

We noticed that seven of the nine MGTAs received improved student responses over time, whereas two of the nine MGTAs received decreases in student responses. These two MGTAs were in Cohort 2, and thus in the first year of their graduate program and the ELITE PD program. The decreases in these cases seem significant and might be skewing the data in such a way that we cannot conclude that the increases across the seven other MGTAs are statistically significant.

Discussion and Directions for Future Work

Based on the results from both analyses, we are optimistic that MGTAs are improving their practices over the course of a year, and curious about MGTAs who experienced a decrease in overall student responses. Our preliminary exploration suggests that MGTAs who participate in ELITE PD with an intentional focus on active, engaging, equitable and inclusive teaching practices have the potential to provide positive classroom experiences for undergraduate students over time. Namely, it appears that the students of such MGTAs can experience an increased sense of participation and engagement, belonging, and clarity of expectations and feedback. These preliminary findings and interpretations are substantiated with another source of data from our larger research project - video recordings of the MGTAs' classes. In our preliminary analyses of these observations (Quaisley & Beisiegel, 2024; Quaisley, Beisiegel, & 2024b), we see, for example, MGTAs learning to set norms for group work discussions and improve in their efforts to facilitate conversations through questioning intended to moderate discussion among all group members.

We will continue to analyze the data from multiple perspectives. Specifically, we aim to answer the questions: Do we see a relationship between the MGTAs' average student survey responses and: (1) the course the MGTAs are assigned to, (2) the identities of the MGTAs, (3) the identities of the students (while it was not reported in this preliminary report, the surveys also collected information about the students, such as their gender, race, age, and more), and (4) the stage of ELITE PD, i.e., before, during, and after completing ELITE PD coursework?

Questions for Further Discussion

We propose these questions to start off the conversation with conference attendees:

- What are ways we can further study students' experiences in MGTAs' classrooms?
- What other analyses should we explore with these (and other) data?
- What purpose do these results serve for the RUME community?
- In what ways do you see this study and its results as beneficial to mathematics?

Investigating STEM Retention Program Participants' Sense of Belonging in Mathematics

Skylyn Irby
The University of Alabama

Research suggests that a sense of belonging in mathematics can influence students' decisions to persist in STEM fields. Programs such as summer bridge programs and Louis Stokes Alliances for Minority Participation (LSAMP) programs are often utilized to promote STEM retention by helping students adapt to college STEM environments. This study explores the mathematics sense of belonging and identity of students in STEM while participating in an LSAMP program after their participation in a summer bridge STEM program. Survey and interview data from the students will be analyzed to identify how participation in STEM retention initiatives may have influenced their mathematics sense of belonging and identity. After taking their first summer mathematics course, students' overall sense of belonging in mathematics appears to decline, according to initial findings. Results of this study also suggest that having interpersonal relationships allowed one student to have an increased sense of belonging in mathematics.

Keywords: sense of belonging, identity, retention, diversity, bridge programs

Students often leave science, technology, engineering, and mathematics (STEM majors) after taking mathematics courses within the first two years of college (e.g., Chen et al., 2013), and historically underrepresented college students are less likely to persist in these areas compared to their peers (e.g., Alkhasawneh & Hobson, 2011). A sense of belonging in mathematics may improve students' desire to persist in STEM (Good et al. 2012), so programs that support the development of a mathematics sense of belonging could be a critical component of STEM retention. LSAMP programs and summer bridge programs contribute to retention efforts of underrepresented STEM students through diverse representation, community, mentorship, and tutoring. However, little is known about how these programs influence mathematics sense of belonging. This project explores the development of participants' sense of belonging, confidence, and identity in mathematics after their involvement in STEM programs. In particular, I ask:

1. How does the mathematics sense of belonging of STEM retention program participants change or differ throughout their participation in these programs?
2. What aspects of bridge programs do participants value and why? How do these valued aspects relate to their sense of belonging in math?

I will answer these questions using student surveys and interviews. These research questions are part of a broader study that also includes program center observations and staff interviews.

Literature Review

Historically underrepresented students (African Americans, Hispanic Americans, Native Americans, and women) are less likely to persist in STEM areas in comparison to their counterparts at the postsecondary level (Alkasawneh & Hobson, 2011; Riegle-Crumb et al., 2019). These students are also less likely to have a sense of belonging in STEM (Rainey et al., 2018). There are many factors, such as climate, lack of representation, and students not having a sense of belonging, that impact the persistence of underrepresented students in mathematics and cause higher attrition rates in STEM (Botella et al., 2019; Chen, 2013; Meador, 2018; Strayhorn, 2012). Postsecondary institutions offer a variety of resources, such as mentoring, tutoring, and supplementary instruction, to help address attrition among underrepresented students pursuing

STEM degrees. STEM retention programs, such as summer bridge programs and academic year support programs, are one way to improve retention in STEM by helping students transition into college STEM environments by offering academic and social experiences, creating a community-oriented environment for underrepresented STEM students to thrive in. Investigating and understanding students' experiences in STEM retention programs can be important for teaching, learning, and retention in STEM.

Research shows that a low sense of belonging (Ahlqvist et al., 2013) and STEM majors leaving these disciplines when taking mathematics courses during the first two years of college (Chen et al., 2013; Seymour & Hunter, 2019) contribute to attrition in STEM. Little is known about how specific environments, such as STEM retention programs, contribute to retention in STEM through mathematics sense of belonging. Towards these ends, this study aims to explore students' mathematics sense of belonging, mathematics confidence, and mathematics identity development while participating in a STEM retention program.

Academic and Social Integration

Research has revealed that the first year of college is a critical period for attrition in STEM (Chen, 2013), particularly as the transition to college involves students negotiating both academic and personal stressors (Ruble & Seidman, 1996). Fostering a stable environment during students' transitions to undergraduate studies can be crucial to their college success.

Sense of Belonging in Mathematics

A sense of belonging can be described as the perception of social support among students on campus and the experience of mattering or feeling valued by and essential to a certain group; this is important for underrepresented students pursuing STEM (Strayhorn, 2012). Meehan et al. (2018) used Good et al.'s (2012) sense of belonging in mathematics (SBM) measure to examine the impact that the transition from secondary school to university mathematics has on students' SBM. Their study also reveals that a growth mindset, meaning that abilities can be developed, instead of mathematics ability being a fixed trait, seemed to help students navigate the mathematical transition (Meehan et al., 2018).

Mathematics Identity

Mathematics identity also impacts students' desire to pursue and persist in STEM areas (Black et al. 2009; Cribbs et al., 2021) and refers to one's perceptions of their own relationship to mathematics (Cribbs et al., 2015). To further elaborate, mathematics identity shapes how students view their abilities, experiences, and potential within the field of mathematics, ultimately influencing their confidence.

STEM Retention Programs

Goff et al. (2019) report how informal education programs can serve as a resource to improve STEM retention through impacting students' interest in mathematics. Their findings show that students who participated in informal science and mathematics environments feel more competent in STEM and report increased interest and greater engagement in STEM areas.

For students from groups historically underrepresented in STEM, two common types of models of STEM retention programs are Bridge programs and LSAMP programs. Bridge programs often focus on underrepresented students, first-generation students, low-income students, or students pursuing specific degrees (Kallison & Stader, 2012). The socially

supportive components of bridge programs include faculty mentoring, peer tutoring, peer mentoring (Bradford et al., 2021). LSAMP programs were developed in reference to Tinto's (1975) model for retention (Clewell et al., 2006) and are specifically tied to STEM retention with an emphasis on supporting historically underrepresented groups in STEM (Clewell et al., 2006).

Theoretical Framework

This work is grounded in the academic and social integration components of Tinto's Conceptual Schema for Dropout from College (1975), which identifies academic and social systems as contributors to one's dropout decision. This theoretical framework has been widely adapted for researching retention in STEM.

Methods

Data were collected using surveys and semi-structured interviews. The survey instrument included the 30-item Good et al. (2012) sense of belonging in mathematics scale, the six-item Lubienski et al. (2021) mathematics confidence scale, and short answer questions about students' identity and sense of belonging in math. A coding scheme for belonging explanations, adapted from Rainey et al. (2018), was used for initial content analysis and coding reasons such as mathematics identity, interpersonal relationships, personal interest, or competence. I used qualitative analysis methods and descriptive statistics to produce results. I describe this in further detail in the analysis section.

Studies have demonstrated that students need social integration, academic support structures, and sense of belonging to persist in STEM (Tomasko et al., 2016; Rainey et al., 2018). This study takes a closer look at sense of belonging among historically underrepresented students in STEM, specifically in relation to their mathematics experiences, as many mathematics courses are one of the first courses that undergraduate STEM majors encounter as a prerequisite for undergraduate STEM coursework. To do so, this study will examine how mathematics sense of belonging, mathematics identity, and mathematics confidence may differ over the course of one semester of participation for students who participated in two preparation programs intended to support historically underrepresented students in STEM fields**.**

Student Surveys

Bridge participants and LSMAP participants were surveyed about a variety of topics, with the goal of understanding students' mathematical sense of belonging, mathematics confidence, and mathematics identity, and the underlying factors that may contribute to these affects. They were surveyed at three points during the school year—once within the first month of semester 1 (Survey 1), once during the last two weeks of the semester (Survey 2), and lastly at the end of semester 2 (Survey 3). E-mail addresses were collected via the surveys to link the surveys and to schedule interviews with those who indicated interest. The surveys contained scales to measure students 'mathematics sense of belonging, mathematics confidence, and mathematics identity. The Good et al. (2012) 30-item Math Sense of Belonging scale was used to measure students' sense of belonging.

Student Interviews

Students were interviewed mid-semester 1, at the end of the semester 1, and at the end of semester 2 about their mathematics sense of belonging and mathematics identity for about 30 minutes each time. Questions focused on asking students to reflect on their trajectory toward pursuing their selected undergraduate degree program and to understand participants' history

with mathematics and mathematical role models. They were also asked to reflect on their bridge program or LSAMP experience to gain insight into their experiences in these STEM retention programs. Finally, participants were asked questions regarding their feelings of belonging, identity, and confidence in mathematics to gain an understanding of the students' beliefs about belonging in math and how they view themselves in mathematics. Student interviews were conducted using semi-structured format that involved me asking interviewees open-ended questions and following them up with probe questions to explore more about their experiences. (Roulston, 2013).

Planned Analysis

The descriptions of my planned analysis are written in the future tense because I have only recently started. All data, however, has been gathered prior to this proposal submission.

Research Question 1

How does the mathematics sense of belonging of STEM retention program participants change or differ throughout their participation in these programs? To analyze the survey responses to the mathematics sense of belonging scale, I will determine Likert scale total scores, frequency of each Likert scale score, and Likert scale mean scores to run dependent t-tests to calculate the mathematics sense of belonging mean scores at time point 1 and time point 2. Descriptive representations will aid in representing the comparisons between the results found at both time points by displaying how mathematics sense of belonging may change over time.

To analyze the interviews and open-ended survey questions, I will use line-by-line content analysis at the sentence or sentence cluster level (Schreier, 2014). The goal of this analysis process is to reveal themes found throughout the participants' responses about their sense of belonging in the open-ended survey questions and interviews. I will be looking for positive and negative connotations of sense of belonging in mathematics using a coding scheme adapted from Rainey et al. (2018).

Table 1. A table showing a summary of the Rainey et al. (2018) coding scheme..

Coding Scheme for Belonging Explanations
(Rainey et al., 2018)

Code	Reason for Belonging	Reason for not Belonging
Interpersonal Relationships	Feels socially connected with peers and/or faculty members.	Lacks a social connection with peers.
Math Identity	Math is a part of their identity as a person.	Lacks a personal connection to the major or material
Personal Interest	Expresses personal interest in course subject or major.	Explicit lack of interest. May find the material boring
Competence	Feels like they understand material or receives good grades	Feels like they do not understand material well

Research Question 2

What aspects of bridge programs do participants value and why? How do these valued aspects relate to their sense of belonging in math? Line-by-line content analysis will be used

to analyze each sentence or sentence cluster of the interview data collected to find what students value most while participating in these programs (Schreier, 2014). The interviews will be analyzed for most mentioned aspects of the LSAMP program that students believe impact their feelings of belonging in mathematics. I will be looking for connections between participants' responses. I will also use some of the initial coding to make sense of broader patterns and find themes of what students value most using open coding (Khandkar, 2009). Moreover, the Rainey et al. (2018) coding scheme, which will identify students' reasons for belonging, will provide insight into how these valued aspects relate to their mathematics sense of belonging.

Preliminary Results and Conclusions

Participants' feelings of membership and acceptance as measured by the Good et al. (2012) sense of belonging in mathematics scale, declined between the start and end of the summer bridge program. However, this decrease may be attributed to the intensive nature of summer courses. Despite these challenges, students valued the mentoring and program components.

Interviews with one participant revealed confidence in their sense of belonging in mathematics with the reasoning being personal interest and competence, often feeling reassured by peers and mentors in the program. Initial findings indicate a decline in students' overall sense of belonging in mathematics after their first college summer mathematics course. Yet, the positive experiences with the bridge program suggest that continued participation may lead to an improvement in their sense of belonging over time. Furthermore, the results of this study so far also suggest that having community and peer interactions allowed the student to have an increased sense of belonging in mathematics. These findings offer insight into the role that STEM retention programs play in fostering diversity within STEM through the lens of an individual students' mathematics experiences.

It will be interesting to see how the findings might evolve following their participation in a STEM retention program throughout the school year.

Next Steps and Questions

Although all data have been collected, analysis has just begun at the time of submitting this proposal. Thus, there only preliminary results to share. Next steps include completing the analysis before the conference in February, at which time I expect to provide further results and conclusions. More specifically, these steps include completing more rounds of coding to draw conclusions from interview data and open-ended survey questions. I plan to also establish connections among students' sense of belonging in mathematics, mathematics identity, and mathematics confidence.

Audience Questions

1. What role do you see institutional factors such as curriculum design, faculty support, or student programs playing in fostering a sense of belonging in mathematics?
2. Can you discuss any specific interventions or strategies you found that were particularly effective in enhancing the sense of belonging of students in your mathematics courses?
3. What are some ways educators and institutions can better assess or measure a student's sense of belonging in mathematics in real-time?
4. Can you think of other frameworks I should consider using to examine this data?

An Analysis of Instructor Feedback on Student Work

Olga Hawranick
Washington State University

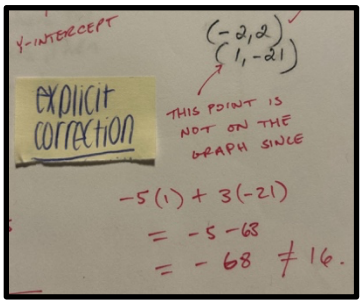
Feedback—the process of leaving remarks, questions, or markings on student work with the aim of enhancing student learning—is one of the more instructionally powerful but least understood features in instructional design (Cohen, 1985). Past studies offer inconsistent results on the features of feedback and little is known about how some of these factors benefit students' interactions with feedback and how deep a student engages in the revision process. This study aimed to learn more about both classroom perspectives of feedback between the instructor and the student. The main population included entry-level college mathematics instructors and students; we examined their feedback practices to gain a better understanding of what elements of feedback are being used and if they match the type of feedback that students report is most valuable. In this paper, we will only focus on the instructor study as that was the primary research question. Instructors graded and left feedback on a collection of student work samples while students completed a questionnaire that asked how they use feedback, how highly they value it, and which feedback type they find most useful. A thematic analysis was conducted on each comment and were classified into specific groupings. Results indicate that the instructor feedback was overall non-actionable but by a small margin. Students preferred actionable feedback, signifying a disconnect between the two populations.

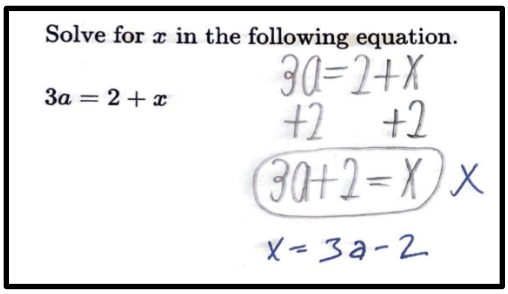
Keywords: Instructor Feedback, Actionable Feedback, Feedback Literacy, Student Success

Introduction

Instructors across every discipline, especially those in common entry-level courses, act as one of the key players in a beginning college student's journey into their course of study, as well as possibly affecting more intrapersonal qualities such as personal identity and acceptance into the respective community they hope to join. Instructors serve as more than just educators; they play a pivotal role in students' personal and academic development. These instructors' actions and choices in the classroom can highly influence a student's path in college, even including their written communication to the student- feedback.

Researchers have defined feedback in various ways such as "information provided by an agent regarding aspects of one's performance or understanding" (Hattie & Timperley, 2007, p. 81) and also as any numerous procedures that are used to inform a student if their response is right or wrong (Kulhavy, 1977). Carless and Boud (2018) capture it with a small twist as "a process through which learners make sense of information from various sources and use it to enhance their work or learning strategies" (p.1). This definition goes beyond feedback solely being the role of teachers. It emphasizes the student component in making sense of the information and using it to revise their previously flawed understanding. We consider feedback to include teachers' comments, questions, and markings (X's, the addition of mathematical content) on students' written work.





Multiple studies have identified teacher feedback as one of the most important instructional practices for promoting and advancing student learning if delivered correctly (Gentrup et.al., 2020; Hattie & Timperley, 2007; Shute, 2008; Griffiths et al., 2023). The last three words in that statement, "if delivered correctly", are the foundation of this study. The effectiveness of teacher

feedback lies not only in its delivery, but also in its specificity, timeliness, and consideration of word choice (Shute, 2008). Some goals of providing feedback to students are to challenge them to adopt new perspectives (Forsythe & Johnson 2017) and to have learners engage with feedback and use these standards as they produce new work (Sadler, 1989).

Our goal was to observe the feedback practices that are occurring within entry-level mathematics courses and answer the question: What are the feedback types commonly used by instructors within a student homework sample?

Feedback Categorizations

Instructors can increase student agency by providing students with actionable feedback- if the message suggests a "course of action that would bring the submission closer to a correct response" (Bergman & Kercher, 2022, p.48). This type of feedback allows the student the opportunity to strategize about how to correct it themselves with some direction from the instructor (Griffiths et.al, 2023; Hattie & Timperley, 2007). Actionable feedback helps promote students' independence (Lee & Hannafin, 2016) and communicates the teacher's belief in the student's ability to improve (Griffiths et.al., 2023). Non-actionable feedback does not provide the student much room to perform the correction themselves; it is either done for them or it is unclear where the student needs to continue. Below is an example of these two types of feedback in the binary system.

Actionable Feedback Example	**Non-Actionable Feedback Example**
	
This comment includes the location of the error and why it is incorrect.	This feedback sample includes the location of the error and the correct answer.

Is there a type of feedback that results in greater potential for learning? Students have different reactions to the same feedback message depending on their motivations, individual expectations, and what they hope to take out of the course so it may be difficult to satisfy each individual's needs. Researchers appear to agree that effective feedback contains both elements of feedback: both actionable and non-actionable (Shute, 2008). A short comment on the location of an error may be better in certain situations, while a more detailed explanation may help in another case. The type of student error and the severity of the total errors in their work can affect whether actionable or non-actionable notes would be better suited.

Below, Table 1 lists each of the 9 feedback classifications we used for the coding scheme extended from Lyster & Ranta (1997) and Wahyuni (2023). A description of each feedback type is included as well as whether it represents actionable or non-actionable feedback.

Table 1. Nine Main Feedback Types Categorized in the Binary System

Feedback Type		Actionable or Non-Actionable?	Description
Explicit Correction		Actionable	Feedback includes the error detection and the reason why it was incorrect.
Recast	Recast 1	Non-Actionable	A correction is only provided (Recast 1) or all of the work is provided to them, with no reason as to why it was an error (Recast 2).
	Recast 2	Non-Actionable	
Metalinguistic Feedback		Actionable	Feedback is offered about specific word choices used; correction may allow students to use better terminology in the future.
Elicitation		Actionable	Feedback is in the form of a question or contains instructions on how to continue.
Indication		Non-Actionable	No words are included in this type of feedback such as underlining or circling.
Summative Feedback	Performance	Non-Actionable	A comment about a specific general performance/ action on the assignment.
	Notice	Actionable	This feedback offers the student a comment about an action to be more aware of in the future.
Reference		Actionable	This directs a student to a certain reference, such as the instructor or a page in the textbook.
Clarification Request		Actionable/Non-Actionable	Comment suggests that the student's work is "ill-informed" and that a revision is encouraged.
Praise		Non-Actionable	Adds no mathematical comments; only offers positive words

Methods

This study involved 8 math instructors representing a mid-sized public university in the Pacific Northwest region of the United States. Data was collected during an in-person meeting involving grading and leaving feedback for 7 student work samples.

Student work samples from a College Algebra course were collected from past students of this institution. These students were not students of any of the instructors in the study; all were hypothetical students that instructors were assigned to grade and leave feedback. All identifiable information was redacted and not included in the study. Only erroneous work was included as a means to answer the call to action in a previous study that stated that "many studies fail to analyze error and correct responses separately" (Kulhavy, 1977, p. 221).

Seven student work samples were taken of the identical problem below on the topic of graphing linear functions. This topic was chosen to accommodate most instructors that teach below the Calculus level. Below is the problem that was selected.

“Given the following equation -5x+3y=16, find the slope and the y-intercept. Explain how you can use the slope and y-intercept to graph the equation. Sketch the graph of the equation.

Results

Instructor comments on student work samples were analyzed and flagged as one of the eleven detailed feedback categories. Figure 1 compares the frequency of each feedback type that was present out of all seven student work samples. In the figure, green represents the actionable feedback types, red non-actionable. 220 instances of feedback were present out of all instructors, more non-actionable comments overall.

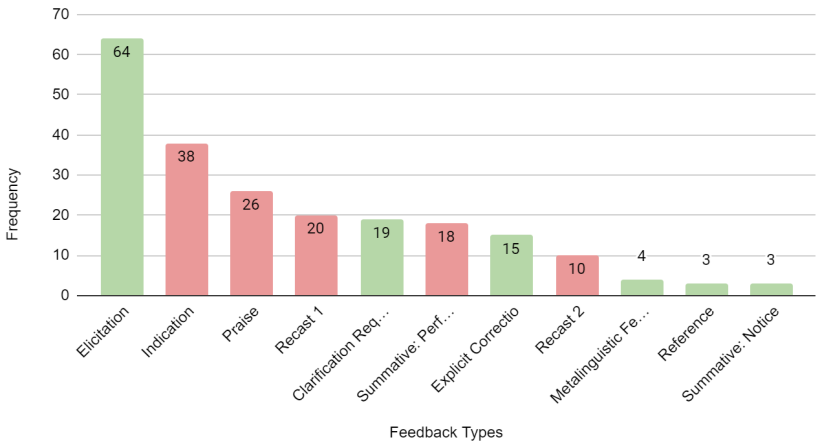


Figure 1. All Instructor Feedback Types Present

Discussion

In this study, instructors provided students with a mixture of actionable and non-actionable feedback and this relates to Shute (2008), where it was noted that effective feedback contains both elements: both actionable and non-actionable. Instructors mainly used Elicitation (actionable) out of all feedback types. Amrhein & Nassaji (2010) found that there exists a dissonance between the feedback that students prefer, actionable feedback, compared to the non-actionable feedback that teachers find more desirable for students. As previous literature found dissonance, this study complemented the Amrhein & Nassaji results and found a disconnect between the student's preferences and feedback received at this institution.

Instructors altogether used slightly more non-actionable feedback types (112 non-actionable/108 actionable comments), but there was quite an even split with non-actionable comments occurring more frequently. These non-actionable feedbacks are found to not contribute to student revision. Students in this study were found to prefer actionable feedback to better understand where their reasoning was incorrect and why.

This study presents a possible way to track and analyze the feedback provided by instructors while attending to students' preferences. The feedback categorization can be used as a professional development topic that can allow instructors to be more intentional with their feedback decisions and provide more effective feedback to students for revision purposes.

Conceptual Chunking and Algebraic Proofs

Vladislav Kokushkin
James Madison University

Research in cognitive psychology identifies chunking as one of the driving information-processing mechanisms in human cognition. Conceptual chunking, a term specific to Halford's relational complexity theory, provides theoretical insights into what constitutes chunking. Specifically, conceptual chunking explains the chunk formation as the result of temporal suppression of relations between the items within the chunk. In this article, I present the analysis of two undergraduate students' proofs from the relational complexity theoretical perspective. Preliminary results suggest that conceptual chunking can help describe students' mathematics and explain some of their difficulties related to proving algebraic conjectures.

Keywords: cognition, theory of relational complexity, chunking, proofs

Beginning in the 1950s, studies in cognitive sciences have revealed substantial evidence for a unifying information-processing mechanism known as *chunking*. In his foundational paper, Miller (1956) described chunking as combining several units of information into a single familiar unit or a chunk. Miller proposed that chunking differs from *grouping* in that the former requires the chunks to correspond to some pre-existing representations. For example, the sequence of 12 seemingly unrelated letters AMIRBRUMEBBC can be chunked into four cognitive units of varying sizes [AM][IRB][RUME][BBC] by identifying familiar words and acronyms. Similarly, Cowan (2001) defined chunks as groups of items with strong, pre-existing associations with each other but weak associations with other items and chunks.

Since Miller's work, researchers have established chunking as one of the key information-processing mechanisms in various aspects of human cognition, including mathematical reasoning (e.g., Harel & Kaput, 2002; Schoenfeld, 2001). Several influential theories in mathematics education are reminiscent of the idea of chunking, such as *encapsulation* (Ayers et al., 1988) or *reification* (Sfard, 1989). With some flexibility of interpretation, chunking can be viewed as an instance of *reflective abstraction* (Beth & Piaget, 1966), in which "a physical or mental action is reconstructed and reorganized on a higher plane of thought and so comes to be understood by the knower" (p. 247).

Despite the recognized importance of various forms of chunking for mathematical reasoning, little is known about the underlying cognitive mechanism. The construct of *conceptual chunking* provides a theoretical explanation for how chunking takes place. Proponents of the relational complexity theory (Andrews & Halford, 2002; Halford et al., 1998) suggest that conceptual chunking involves temporal suppression of the relations between the items within a chunk. Principles embodied in Halford's theory have been validated in several empirical studies (Andrews & Halford, 2002; Birney & Halford, 2002; Halford et al., 2005; Waltz et al., 1999); however, they were never explored in the context of undergraduate mathematics, and, in particular, proof production.

This preliminary study aims to investigate the psychological construct of conceptual chunking in the context of mathematical proofs. The overarching research question is *What are the aspects of conceptual chunking in proving algebraic conjectures?* In this report, I first elaborate on Halford's relational complexity theory and then apply this framework to analyze two undergraduate students' ways of producing an algebraic proof. Preliminary results suggest

that conceptual chunking can be an effective way to model students' mathematical reasoning and explain some of the difficulties related to proving algebraic conjectures.

Framework: Relational Complexity Theory and Conceptual Chunking

Halford and colleagues (e.g., Andrews & Halford, 2002; Halford et al., 1998) proposed that the cognitive complexity of a task should be defined not only in terms of the number of units of information it requires to be coordinated but also in terms of the complexity of relations between them. Consider, for example, the following problem: *Suppose five days after the day before yesterday is Friday. What day of the week is tomorrow?* (Sweller, 1993). This problem may seem to appear frustratingly difficult because of the necessity to establish relations between numerous elements presented in the first sentence, which cannot be considered meaningfully in isolation. As such, the cognitive task becomes more complex when the number of relations that need to be maintained in parallel increases.

The complexity of the task can be reduced via the mechanisms known as segmentation and conceptual chunking. Segmentation entails the decomposition of the task into smaller segments or steps that can be processed serially. Examples of segmentation include breaking the proofs into cases or implementing proof by induction as a three-step procedure (i.e., the base case, inductive hypothesis, and inductive implication).

Conceptual chunking, the construct that is central to Halford's theory and this study, entails combining units of information into a single chunk at the cost of making the relations between the units temporarily inaccessible. Halford illustrates this construct using the concept of velocity (e.g., Halford & McCredden, 1998; Halford et al., 1998). Defined as the ratio of distance over time, V=S/t, this concept involves the interaction of three variables and can be viewed as a three-dimensional representation. It is also possible to think of velocity as the number displayed on the speedometer V=60 km/h – a single-dimensional representation. The transition from the three-dimensional to the single-dimensional representations makes relations between the velocity, distance, and time temporarily inaccessible. Chunked concepts can be further combined with other chunks to construct higher-level concepts. Thus, velocity can be used to define acceleration, which can be used to define the notion of force F=ma. However, if the task requires computing the way velocity varies as the distance doubles and time does not change, the relations between the variables must be restored.

To summarize, conceptual chunking helps students to make progress on the task by temporally suppressing the relations between different cognitive units. Chunking is a matter of expertise (Chase & Simon, 1973) and can be viewed as "a form of learning that takes place over time" (Halford et al., 1998, p. 810). The three general principles of conceptual chunking are

1. A chunk functions as a single entity.
2. No relations can be represented between items within a chunk.
3. Relations between the chunk and other items, or other chunks, can be represented.

Methodology

The study draws on the data collected for a larger project investigating the role of students' gestures in offloading cognitive demands on their working memory during various proving activities, such as reading, presenting, and constructing proofs of mathematical conjectures. The participants were undergraduate students enrolled in an introductory proofs course. The students participated in several individual task-based interviews lasting approximately 45 minutes each. The participants were asked to think aloud as they worked with proofs. Because the goal of the overarching project was to study students' gestures, writing and drawing were not permitted.

In this paper, I report on two students, Ella and Sherry, proving the conjecture known as a Diophantine Equation (Figure 1).

Prove that there are no integers x and y such that
$x^2 = 4y+2$

Figure 1. Interview task.

One way to prove it is to observe that the right side of the equation is even. Therefore, the left side also has to be even. Moreover, because the left side is a perfect square, then it has to be divisible by four. However, the right side is not divisible by four, and thus, no integers x and y satisfy this equation.

At a later date, a stimulated recall interview (SRI) was conducted. During this interview, the students were shown selected video clips of themselves working on the task, and the interviewer asked questions about their mathematical reasoning. All interviews were video and audio-recorded.

Data Analysis

The analysis began with creating the transcripts of the interviews and identifying the episodes where the participants seemed to chunk mathematical objects involved in their proofs. Verbal evidence of chunking included labeling pieces of the equation as "it," "a fraction," "number," etc. Students' responses during the SRI were used to triangulate the initial findings. One of the goals of this preliminary report is to identify more rigorous data analysis procedures for future study design.

Results

In this section, I present the analysis of students' proofs from Halford's relational complexity theory perspective. Specifically, I showcase two episodes of conceptual chunking and illustrate its underlying cognitive mechanisms in constructing algebraic proofs.

Sherry's Proof

Sherry made two attempts to prove the given conjecture. In the first attempt, the student relied on the fact that the existence of rational solutions would entail the non-existence of integer solutions. After some discussion with the interviewer, she realized that her initial approach was invalid. On her second attempt, Sherry started her proof by solving for y and rearranging the equation as $y = \frac{x^2}{4} - \frac{1}{2}$. However, later on, the denominator of the fraction $\frac{x^2}{4}$ was lost, and the equation was transformed into $y = x^2 - \frac{1}{2}$:

> So, to prove that there are no integers x and y such that x squared equals to 4y plus two... Um... I think... I'll think of cases, where x and y are integers. And see if x squared equals to 4y plus two exist. And thus, I rearrange the equation... in y... so x squared minus two equals to 4y, and y equals to x squared over four minus two over four. And since the very simplified rational number of two over four, that's one over two, **we have *y* equals to *x* squared minus one over two**. And since we have assumed that x and y are both integers, ***x* squared is also going to be integers. But then integer minus one over two is just the... em... very simplified version of rational numbers** [i.e., not an integer]. And it will also give a rational

number... *x* squared equals to four... There are no integers *x* and *y*, such that *x* squared equals to 4*y* plus two.

Initially, the participant correctly solved for *y* and derived the equation $y = \frac{x^2}{4} - \frac{2}{4}$. Then, she shifted the focus of her attention to simplifying the second fraction from the right side from $\frac{2}{4}$ to $\frac{1}{2}$. In doing so, the student chunked the components of the first fraction, $\frac{x^2}{4}$, into a single cognitive unit by suppressing the relations between the numerator and the denominator of the fraction. However, the reconstruction of these relations turned out to be problematic and significantly affected Sherry's proof.

Ella's Proof

Ella's approach was based on the valid idea of factoring out 2 from the right side of the equation and observing that 2*y*+1 is odd, and therefore, 2(2*y*+1) is not divisible by 4. However, the interviewer asked her to summarize her proof, Ella lost the coefficient 2 in front of *y*, which implied that nothing can be specified regarding the parity of the quantity enclosed in parentheses:

> We're gonna try to prove that there are no integers *x* and *y* such that *x* squared equals 4*y* plus two. So first, we're going to assume that *x* and *y* are integers, in which case, *x* squared becomes a perfect square number. However, 4*y* plus two, when you pull it two out, **you can factor the greatest common factor of 4*y* plus two is two, which gives you two parentheses *y* plus one because we know that *y*... Wait... shoot... We don't know anything about *y* being even or odd... Em... Here we have cases then...** If *y* is even, then whatever's in the parentheses is an odd number, which means that there is no way that it can be a perfect square or equal to the perfect square of *x* squared. Because there's a two factor that's not matched... within the other factors... to be able to... to take the square root of... in the case that *y* is even, the whatever's in the parentheses... sorry, in the case that *y* is odd, then whatever's in the parentheses will be an even number if it's plus one.... **Oh my gosh. I forgot about the 2*y*.** Can I jump back into my previous [laughing]? Okay, that's what makes it even. That's what I was missing.

Making progress on the task, the participant chunked 2*y* and +1 into a single unit signifying an odd number. Cognitively, this could be done by suppressing the relations between 2, *y*, and 1. However, the details about why this number is odd were temporarily lost. This can be explained by Ella's difficulty in reconstructing the relations between 2 and *y.* As a result, 2*y* was replaced by *y*, transforming the expression 2*y*+1 into *y*+1, which changed Ella's proof. The observed effect of conceptual chunking was confirmed later during her SRI:

> *Researcher*: I find it interesting that, in the middle of your presentation, you decided that the parity of *y* might affect the proof. You had to consider two cases separately: *y* is even and *y* is odd.
>
> *Ella*: Right, because I was saying *y* plus one. Because in my head, it was 2*y* plus two. For some reason, I was looking at the four. Um... Because I think... when I think about, like, the structure of an odd number, right? They give us a... there's, like, 2*k* plus one, right? Where *k* is some sort of the whole number. Um... Because you know that that 2*k* is going to be even and then the other part plus one makes it odd, right? I think of the 2*k*...

together. Like I don't think of it as two times *k*, it's just 2*k*. So, I think that's where I was like **instead of 2*k* I just put *y* there, and why I forgot about that 2*y***. And so I was, like, well, then I could save the inside of that two times whatever's in the inside, *y* plus one. Cause that, they're gonna be even or odd. So, I started going into cases, randomly.

Discussion

Theories of working memory capacity (Baddeley & Hitch, 1974; Pascual-Leone, 1970) suggest that humans can operate on a limited number of chunks at the same time. According to the principle of cognitive economy (Rescher, 1989), we tend to choose the least complex representation available to make progress on a cognitively demanding task. Thus, it is the nature of human cognition to package information into chunks by reducing the complexity of relations between the units.

The study design enabled my participants to coordinate the enormous amount of information and mental representations when constructing the proof of the given algebraic conjecture. The data presented in this study indicate that Sherry and Ella implemented mental strategies that can be described as conceptual chunking. Sherry temporarily suppressed the relations between the numerator and the denominator in the fraction $\frac{x^2}{4}$. Ella temporarily suppressed the relations between 2, *y,* and 1 in the expression 2*y*+1. Although conceptual chunking did help the students to make progress on the cognitively demanding task, the reconstruction of the suppressed relations turned out to be problematic in both cases. Sherry overlooked the denominator of the fraction, and Ella lost the coefficient of 2. The described negative effect of conceptual chunking, as applied to mathematical reasoning, is a finding not previously reported in the literature. More research is needed to investigate this preliminary observation.

Questions for the Audience

I conclude my report with the following three questions for the interested audience:

1. Is conceptual chunking and the overall relational complexity theory appropriate theoretical perspective for explaining the observed phenomenon?
2. What would be an appropriate study design for future research on conceptual chunking?
3. What are the pedagogical implications of these preliminary results?

An Analysis of one Calculus Student's Understanding of Derivative Through Gestures

Nicholas Witt
The University of Arizona

Aditya P. Adiredja
The University of Arizona

Michelle Zandieh
Arizona State University

This preliminary report focuses on investigating the range of gestures students use to explain the concept of derivative in different contexts. Students were asked to explain their meaning of derivative and how they make sense of the formal limit definition of derivative. In addition to taking an embodied cognition perspective in our analysis, we also draw from Zandieh's Derivative Framework to make meaning of the range of gestures we observed. For this preliminary report, we analyzed a video recording of one student during a 30-minute assessment interview for a first semester calculus course wherein he displayed over 40 different gestures. Our findings focus on five representational gestures that were salient in the student's explanation of derivative. We discuss methodological implications about analyzing gesture alongside a cognitive framework of a mathematical concept, as well as how our findings connect with existing themes in research on mathematical gestures.

Keywords: calculus, derivative, gesture, embodied cognition

Embodiment in mathematics education research has contributed much to a more robust conceptualization of students' sensemaking of mathematics (Abrahamson et al., 2020). Introductory Calculus is often seen as a barrier to gaining access to STEM-related college majors and hence, STEM-related careers (Bressoud, Mesa, Rasmussen, 2015). This report attends to the variety of gestures used by a student, Andy, while explaining his conceptual understanding of derivative. This work may support extending current frameworks for analyzing students' understanding of derivatives (e.g., Zandieh, 2000) and promoting the value of attending to gestures by instructors when assessing and advancing student thinking.

Literature Review and Research Questions

Two common phenomena observed in studies of gesture in mathematics education are representational gestures (Alibali & Nathan, 2012) and gesture-speech "mismatches" (Alibali and Goldin-Meadow, 1993). While Alibali and Goldin-Meadow (1993) suggest mismatches indicate students' knowledge in transition or on the cusp of verbalizing it, Abrahamson et al., (2020) argue that "non-redundant gestures" may be an expression of action-based experiences.

In undergraduate mathematics education research, gesture has been studied in content areas such as complex analysis (e.g., Oehrtman et al., 2019), abstract algebra (Soto et al., 2024), and mathematical proof (Kokushkin, 2021). Prior studies of derivative have focused on experts' reasoning through gesture (Oehrtman et al., 2019) and within classroom settings (Arzarello et al., 2009). Individual analyses of Calculus students' understanding of derivatives have frequently drawn from Zandieh's (2000) Derivative Framework, which provides a deconstruction of the concept as layers of process-object pairs woven through various contexts or representations.

Yu and Uttal's (2022) analysis of pairs of Calculus students' as they solve real life rate of change problems about changes in volume of a water bottle found that some of their participants may have developed a Calculus-based way of reasoning about the problem through their gestures. For example, some used a "disk" shaped hand gesture representing a cross section of the water bottle. Alibali and Nathan (2012) refer to these as representational gestures--or those that "depict aspects of their meaning" (Alibali & Nathan, 2012, p. 252). Thus, gestures may

serve as a tool for abstracting complex ideas (such as the formal definition of derivative). The current preliminary research report examines the research question, *what are the range of gestures students use to convey their understanding of the concept of derivative in calculus?*

Theoretical Framework

Theoretically, we situate this study within embodied cognition research, which examines aspects of mathematical thinking and understanding that are "bodily-grounded, *embodied* within a shared biological and physical context" (Núnez, Edwards, and Matos, 1999, p. 46). Contributing to the larger research program of embodiment in mathematics education (Abrahamson et al., 2020), this report further broadly investigates how gestures can "ground formalisms and abstractions to the physical environment, support simulated action of mathematical ideas, and invoke conceptual blends and metaphors" (p. 3). Also supported by findings from current research on gestures, we do not assume that students' speech would always be consistent with the gestures they produce (see also "mismatching gestures" in Hostetter & Alibali, 2019). Indeed, gestures reveal information that students do not or have yet verbalized.

Drawing on Zandieh's Derivative Framework (2000) we connect our analysis of gestures to the landscape of conceptual understanding of the specific mathematical content. This framework helps us to consider gestures in multiple contexts for student understanding of derivatives (primarily graphical, verbal, physical, and symbolic), related to its different aspects (ratio, limit, and function), as well as ways that students produce the gestures as dynamic processes and/or as static objects. Zandieh (2000) argued that the concept can be represented *graphically* as the slope of the tangent line, *verbally* as the instantaneous rate of change, *physically* as speed or velocity, and *symbolically* as the limit of the difference quotient.

Methods

Data Source

The case we consider comes from an introductory Calculus course taught at a large public university in the midwestern U.S. The instructor for the course (first author) heavily embedded Desmos Activity Builder (DAB) to the design of the course to leverage students' voice in classroom discussions, and to facilitate intuition building activities focused on conceptually understanding topics in a first-year calculus course. The data collected for this report comes from a 30-minute interview assessment about derivative for students in the course. It took place approximately two months into the semester. From these meetings, video recordings and written inscriptions created by the participants were gathered as data. Three students in the course consented to the analysis of their interview data and we selected Andy, a white male student, as a case where a wide variety of gestures were used. We focused our current analysis on less than eight minutes of video data where Andy is answering the two assessment questions: (1) what is a derivative to you, and (2) how do you make sense of the formal definition of a derivative?

Analytical Methods

All three authors reviewed the video data together and stopped to discuss moments of interest. Upon observing an abundance of gestures occurring simultaneously with Andy's speech, we rewatched the video with specific attention on his gestures. We then rewatched the video with the sound muted to focus attention on potentially mathematical gestures and selected possible gestures. We watched these selected moments once again with the sound on to guide our discussions on what counts as a mathematical gesture. We considered momentary pauses as

natural separation points between dynamic gestures. When it appeared that multiple gestures occurred in a short amount of time, we watched, paused, and discussed each gesture, frame-by-frame, until we came to an agreement of the timestamps where the gestures started and ended.

We focused our analysis on gestures that demonstrate a mathematical concept (see also "representational gestures" in Alibali & Nathan (2012)), those that simultaneously occurred with speech about mathematics, or those previously identified as mathematical but occurred with different words (e.g., Gesture 3 in Findings). We noted but did not analyze gestures that are more conversational in nature (e.g., Andy's gesturing with his hand to himself while saying "that's the easiest way to explain it…at least for me."). Once agreement was reached, we placed selected gestures within Zandieh's (2000) Derivative Framework. The three authors selected the cell in the table that they feel best fit the mathematical nature of the gesture. We discussed and resolved disagreements and arrived at the placement for the five gestures we are highlighting from Andy.

Findings

During the interview, we found that Andy made over 40 gestures as he described what a derivative is and how his understanding connected with the formal definition. We highlight five gestures that we interpret as particularly salient in Andy's explanation of derivative. We organize the presentation of gestures chronologically corresponding to Andy's responses to the two questions in the Data Source section above. We present the gestures as consecutive images in each figure. We then connect them to Zandieh's (2000) Derivative Framework.

Gesture 1: "Instantaneous rate of change"

On multiple occasions, Andy makes variations of a gesture in which his hands move closer together and sometimes meet each other. The first instance of this occurs immediately after being asked to explain what a derivative is. Over the interval :52-:59, Andy states, "umm, the derivative is like the instantaneous rate of change, at any given, like on[e]--single point," and makes the following sequence of gestures (see Figure 1).

Figure 1. Andy's "instantaneous rate of change" gestures

Gesture 2: "A graph" as a context for instantaneous rate of change

After his initial response to the first question (see Gesture 1 section above), he continues "the instantaneous rate of change…of like [*gesture*]…I know it's more specific than a graph, but a graph [*gesture*]." Note that the gesture is basically the same each time, a positioning of his hand and forearm at an angle in front of himself.

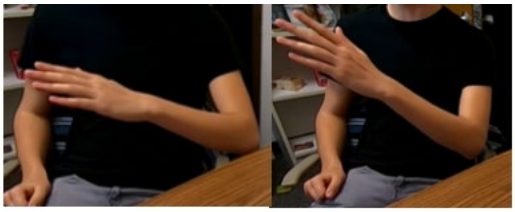

Figure 2. Andy's gesture as he says "of like" and "a graph," respectively

Gesture 3: "velocity graph" and "distance, time"

We refer the following as Andy's "velocity graph" gestures (see Figure 3 below). At 1:20, he states, "a graph that would be measuring velocity, so velocity graph." He elaborates what he means by "velocity graph," and makes two gestures that appear to trace out coordinate axes in the air in front of him (see Figure 3, second and third images) as he says, "so you got distance [*traces horizontally*], speed [*traces up*]. Or distance [*traces horizontally*] time [*traces up*]…"

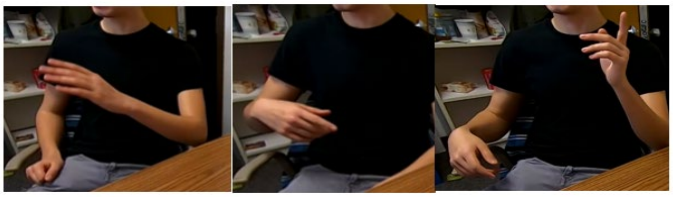

Figure 3. Andy's "velocity graph" gestures

Gesture 4: "h gets closer and closer to zero"

The next two gestures occurred after Andy's response to the second interview question about the formal definition. Prior to being asked explicitly what the h in the formula means, Andy made a similar gesture to that when initially asked what a derivative is (see Figure 1). The gesture here differs in that the emphasis is on the hands becoming closer as opposed to his hands coming to one point as is the case in Gesture 1. Over the interval 4:19-4:31, Andy states, "And then the limit as h approaches zero means the—the two points get closer and closer together, the distance between the two of them becomes less and so h gets closer and closer to zero…" while making the gestures shown in Figure 4.

Figure 4. Andy's "h gets closer and closer to zero" gesture

Gesture 5: "the h"

After being asked to explain what the h in the denominator of the formal definition means, Andy states, "uhh, the h is the distance between the first x and the second. The first input and the second." As he states this, he makes the gestures below (see Figure 5), tapping the table with each hand as he says, "first x" and "second," defining a space between his hands.

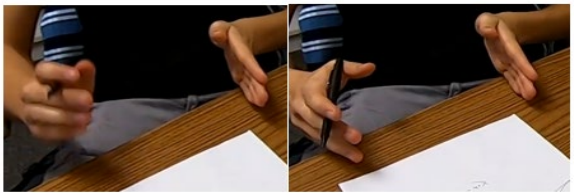

Figure 5. Andy's gesture for "the h"

Andy's gestures and the Derivative Framework

We first placed Andy's five gestures in different cells of the Derivative Framework based on the context as described by his speech when he displayed the gesture: "instantaneous rate of change" (verbal), "velocity" (physical), and limit definition (symbolic). For the process-object layer, Gesture 2 focused on the whole velocity graph so we associated it with the function layer,

whereas Gesture 3 focused on velocity as a ratio of the two "axes" of distance and time. Gesture 5 focuses on the static interval *h*, as the denominator of the difference quotient, whereas Gesture 4 was dynamically illustrating the limiting process as well as the limit. Gesture 1 emphasizes the "single point," without additional explanation. In this way, we also characterize Gesture 1 as a closed circle as the student's gesture displayed a "pseudo-object understanding" of that cell and Gesture 4 as an open circle as the gesture also displayed the limiting "process" involved (Zandieh, 2000, p. 114). There was no graphical gesture because Andy never spoke of "slope" in this explanation of derivative despite sharing gestures of graphical representations.

Table 1. Andy's Gestures within the Zandieh Derivative Framework

	Contexts				
	Graphical	Verbal	Physical	Symbolic	Other
Process-object layer	Slope	Rate	Velocity	Difference Quotient	
Ratio			Gesture 3 (_|)	Gesture 5 (| |)	
Limit		Gesture 1 (^)		Gesture 4 (|→←|)	
Function			Gesture 2 (\)		

Discussion

The Derivative Framework proved productive in interpreting the contexts represented by Andy's gestures. Moreover, it helps us interpret the gesture in terms of the process-object layers that add meaning to Andy's gestures beyond what they represent. This exercise suggests that incorporating a cognitive framework in thinking about gestures can be fruitful. In the other direction, examination of gestures students used to explain the concept has the potential to bolster the framework. The Derivative Framework has largely been used to analyze students' understanding of derivatives via students' verbal and written explanations.

We found Andy's gestures varied widely, may serve different communicative purposes, and became more precise as he attended to nuances of understanding derivative (e.g., the h in the formula). We observed non-redundancy between Andy's gestures and his verbal explanation. Given the value of non-redundant gestures to reasoning (Abrahamson et al., 2020; Alibali & Goldin-Meadow, 1993), instructors' attention to these moments can be important to gaining a deeper understanding of student thinking and might suggest the student is on the cusp of verbalizing something that relates to action-based gestures they make.

This study investigates mathematics graduate teaching assistants' (MGTAs) conceptions of equity based on activities from professional development (PD) focused on active learning, inclusivity, and equity. Using Gutierrez's (2008; 2009) four dimensions of equity (access, achievement, identity, and power), we analyzed survey data collected from MGTAs. These findings led us to create three MGTA profiles: Resource Advocacy, Asset-Based Collaboration, and Resilient Problem-Solving. These findings inform future PD design to enhance engagement with equity issues in mathematics education.

Keywords: Equity, Teaching Assistants, Professional Development

Background

Undergraduate mathematics courses are fundamental in shaping careers in Science, Technology, Engineering, and Mathematics (STEM), with completion of these courses often being a prerequisite for STEM professions and teaching roles (Deshler et al., 2015). However, many students initially interested in STEM do not persist, with this phenomenon disproportionately affecting minoritized students (Ellis et al., 2016; Seymour & Hunter, 2019). Research indicates that active learning strategies, such as problem-solving and interactive teaching practices (Conference Board of the Mathematical Sciences, 2016), significantly improve student outcomes (Braun et al., 2017; Freeman et al., 2014; Handelsman & Brown, 2016), they can also inadvertently exacerbate classroom inequities, particularly affecting female students who may benefit less from such methods (Reinholz et al., 2022). Hence, in addition to active learning, equitable instructional practices, such as addressing student identity and biases, are essential components of teaching mathematics (Yu et. al., 2024). Mathematics graduate teaching assistants (MGTAs) frequently teach introductory mathematics classes (Selinski & Milbourne, 2015), the courses that are commonly viewed as barriers to STEM persistence (Theobald et al., 2020), and many will go on to teach these classes later in their careers. Given their pivotal position, it is essential to ensure that MGTAs receive robust training in active and equitable teaching practices and to understand how this training influences their understanding of equity and their teaching practice.

Due to this, we endeavored to investigate the following question: *How do equity-focused activities in an MGTA professional development (PD) program prompt MGTAs to consider equity in their teaching?*

Theoretical and Analytical Framework

Gutiérrez (2008, 2009) introduced a comprehensive framework for equity in mathematics education, centered on two fundamental ideas: teaching students to "play the game" (dominant axis) and "change the game" (critical axis). The dominant axis consists of *Access* and

Achievement. *Access* involves providing students with the necessary resources, like quality teachers and curriculum, to succeed in mathematics, while *Achievement* is about meeting societal expectations through grades and test scores. The critical axis includes *Identity* and *Power*. *Identity* emphasizes the importance of students bringing their authentic selves and lived experiences into the classroom. *Power* entails student agency to challenge societal inequalities through math. Gutiérrez's equity framework is a valuable lens for analyzing facets of equity. For example, Jackson and Roberts (2017) used this framework to study preservice teachers' conceptions, demonstrating how teachers can foster access by setting high expectations and connecting mathematics to students' lives. They also highlighted the interplay between access and achievement, showing that teachers' low expectations limit students' opportunities to succeed. Similarly, we leverage this framework to analyze MGTAs' conceptions of equity related to their teaching practice.

Methodology

For the present study, we collected data from nine MGTAs participating in the ELITE PD program, which is focused on active learning, equity, and inclusivity, during the 2023-2024 academic year at a Southwestern four-year public university. The ELITE PD program is part of a multi-institutional grant-funded project aimed at developing and researching the impacts of MGTA PD that focuses on active learning, equity, and inclusion.

During the first PD session in the fall of 2023, the MGTAs participated in two activities: building hanging mobiles and the advantages checklist. For the mobile building activity (Schniedewind & Davidson, 1983), MGTAs were divided into groups of three to five and provided with bags of crafting materials (e.g., scissors, glue, colored paper, stickers, makers). They were then tasked to make a hanging mobile (a decorative structure that often hangs above baby cribs). Each bag had varying amounts and types of materials. Groups displayed their mobiles and discussed the materials used, highlighting disparities in the resources available to each group. Following this activity, the MGTAs completed an advantages checklist[1], which included questions about personal advantages such as socioeconomic status and able-bodiedness. Together, these activities help MGTAs reflect on the resources and advantages their students may or may not have access to while also considering how this compares to their own advantages and disadvantages.

After these activities, the MGTAs completed a brief survey to reflect on 1) how these activities supported equity and inclusion, 2) their main takeaways from each activity, and 3) their relevance to their roles as MGTAs. The data set for our analysis consisted of the nine survey responses to the mobile activity and advantages checklist. One MGTA was removed from the data set due to ostensibly misunderstanding the survey questions, resulting in responses that could not be analyzed. Thus, our analysis is of eight MGTA survey responses.

Data Analysis

The first two authors independently coded the eight MGTAs' survey responses using the four equity dimensions (Gutiérrez, 2008) as an a priori coding scheme while allowing patterns within that coding scheme to emerge (Miles et al., 2014). Both coders then met to reconcile coding discrepancies and discuss added codes. The data set was then coded again with the final codebook. Next, the coders looked for themes across and within individual MGTA responses,

[1] Advantage Checklist towards Educational Equity © 2024 by Jamiella Brooks is licensed under CC BY-NC 4.0)

which resulted in three prevalent profiles representing how the activities prompted MGTAs to think about equity. These themes emerged from prevalent clusters of codes (Table 1).

Results

In the coding process, three open codes emerged: *Empathy*, *Self-reflection*, and *Perseverance*. The *Empathy* code represents when an MGTA demonstrated an understanding of their students' experiences and disadvantages or advantages. The *Self-reflection* code represents instances when an MGTA reflected on their own privileges. The *Perseverance* code represents when an MGTA referred to students overcoming challenges in the classroom. Themes for MGTA profiles emerged from prevalent clusters of these open codes along with the four dimensions of equity (Table 1). Below, we detail the three profiles for MGTA responses.

Table 1. The three profiles that emerged were based on the dimensions of equity.

MGTA Profiles		
Profile	Dimensions of Equity	Open Codes
Resource Advocacy	Access	Empathy, Self-reflection
Asset-Based Collaboration	Access, Identity, Power	Perseverance
Resilient Problem-solving	Access	Perseverance

MGTA Profiles

All of our MGTAs' responses fit into one of the three profiles. These profiles reflect how the MGTAs considered the activities related to equity and how they were seen as relevant to their role as MGTAs. In this section, we describe the three profiles: Resource Advocacy, Asset-Based Collaboration, and Resilient Problem-Solving.

Resource Advocacy. Five of the eight MGTAs (MGTA3, MGTA4, MGTA6, MGTA7, MGTA8) were categorized under Resource Advocacy, with access and empathy/self-reflection being the most prevalent codes in their responses. As exemplified by the quotes in Figure 1, these MGTAs saw the PD activities as representing the importance of ensuring access to resources and cultivating empathy for students' diverse situations. Three MGTAs (MGTA3, MGTA7, MGTA8) also connected these activities to their role as MGTAs by reflecting on their own privileges and how the insights gained shaped their approach to teaching. In discussing equity, these five MGTAs primarily focused on access, viewing resources as advantages or disadvantages. Most of these MGTAs also highlighted how they could address students' varying access to resources by offering extra support.

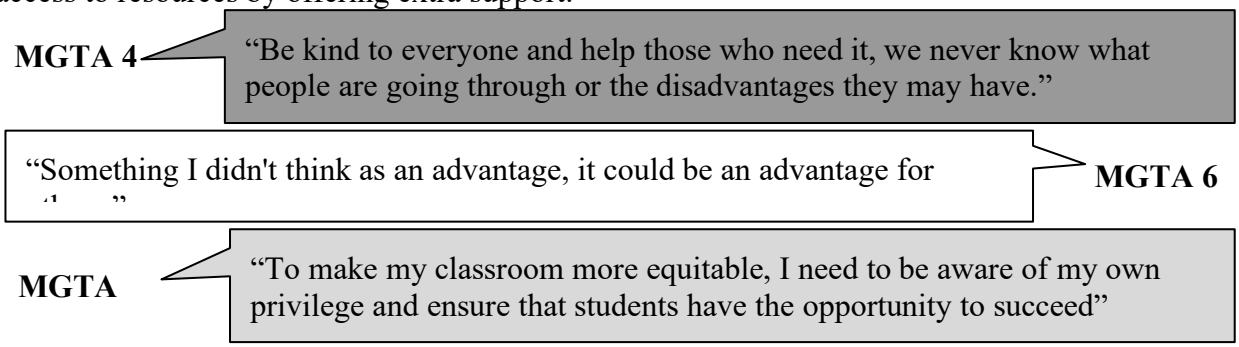

Figure 1. Example responses from the Resource Advocacy Profile.

Asset-Based Collaboration. Two of the eight MGTAs (MGTA2, MGTA5) were categorized under Asset-Based Collaboration, with their responses coded with access, identity, and power. As depicted by the quotes in Figure 2, these MGTAs saw the PD activities as representing the importance of recognizing students' diverse backgrounds and strengths as valuable assets in the classroom. They connected the activities to their role in creating an inclusive environment that leverages these differences and fosters collaboration. This differs from the Resource Advocacy profile in the sense that these MGTAs saw students' different resources as potential assets for them to help one another, rather than solely in terms of advantages or disadvantages, with one of the MGTAs (MGTA5) discussing how collaboration can help students support one another and persevere through challenges. Overall, these MGTAs' discussion of equity centered on access, identity, and power, acknowledging that while students have varying levels of access to necessary resources, their unique backgrounds could be leveraged to support each other and address classroom inequities.

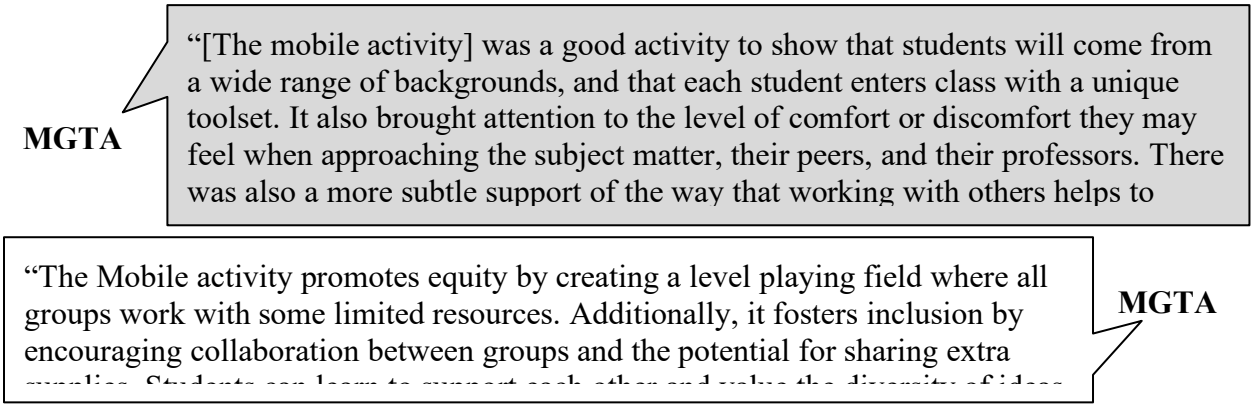

Figure 2. Example responses from the Asset-Based Collaboration Profile.

Resilient Problem-Solving. One of the MGTAs' (MGTA1) responses differed from that of the other MGTAs. As evidenced by the quote in Figure 3, this MGTA perceived equity in the activities as fostering resilience and problem-solving among their students. They linked this to their role by emphasizing the importance of creating an environment that supports students in overcoming challenges and setbacks. Their discussion of equity was focused mainly on access, emphasizing overcoming disadvantages by creating an environment where students could ask questions. This contrasts with how MGTA5 discussed identity as a tool to be leveraged to overcome challenges and support one another. Indeed, MGTA1 was focused on creating an environment where students could learn to help themselves by accessing resources rather than supporting one another by leveraging their identity in the classroom.

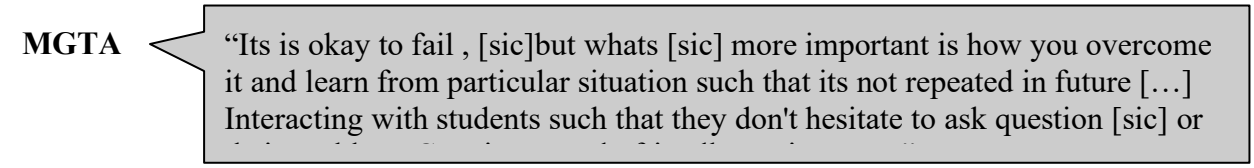

Figure 3. Example response from the Resilient Problem-Solving Profile.

Discussion

Notably, the MGTA profiles in this study reflect conceptions of equity similar to those found by Yu et al. (2024). The majority of MGTAs fit into the Resource Advocacy profile, which reflects the most prevalent conceptions of equity MGTAs have been found to hold. Yu et al. found that the most prevalent conceptions of equity included an individualized approach, awareness of diversity, and making things equal. The mobile activity and advantages checklist in this study prompted most MGTAs to think of equity regarding the resources students bring to the classroom and how these influence their ability to succeed (awareness of diversity). MGTAs related this understanding to their role in providing individualized support. They emphasized the importance of offering disadvantaged students equal opportunities, reflecting the "making things equal" conception of equity. The Asset-Based Collaboration profile seems to reflect less prevalent conceptions, such as valuing different types of thinking, in addition to the more prevalent conceptions.

These findings suggest that the mobile activity and advantages checklist are likely interpreted through the lens of an MGTAs current conception of equity. This prompted a preliminary analysis of how these MGTAs' conceptions shifted by looking at semi-structured interviews with these MGTAs after two semesters of ELITE PD. This preliminary analysis has suggested that these MGTA profiles evolve and shift, reflecting changes in their conceptions of equity. An additional finding of this preliminary analysis is that MGTAs' conceptions of equity align more with critical perspectives when discussing concrete topics like "equitable teaching" rather than the abstract idea of equity, even after a year of weekly equity-focused PD. For instance, several MGTAs mentioned practices like avoiding groups with only one female student to help them feel more comfortable and build community. This has led us to question the value of focusing on abstract equity concepts and consider whether addressing concrete issues of identity and power in the classroom, along with specific strategies, might be more effective.

Future work will expand this study to the other two institutions, allowing us to examine how different contexts influence the impact and implementation of the ELITE PD program. We plan to conduct a longitudinal analysis of exit tickets and other artifacts collected throughout the academic year to track the evolution of MGTA profiles. This analysis will help identify which activities tend to prompt shifts in thinking and in what ways, investigating the nascent shifts we see in MGTA profiles from our preliminary analysis. Additionally, we aim to explore the relationship between changes in conceptions of equity and concrete teaching practices to bridge theoretical understandings with practical application. By broadening our research scope, we hope to understand better how ELITE PD influences MGTAs' conceptions and teaching practices regarding equity.

Lastly, we pose the following questions: Based on each profile, which activities best support a shift in MGTAs' conceptions of equity, emphasizing the critical axis shift toward equity? How have other PD programs or initiatives that train MGTAs balanced equity's theoretical, abstract elements with the concrete implementation of equitable teaching practices? What are the most effective ways to ensure that theory-based activities, discussions, and readings translate into equitable teaching practices in the classroom?

Constructing Instructors' Classroom Practices From Students' Survey Responses

Aditya P. Adiredja
The University of Arizona

Bhargav Kale
The University of Arizona

Becca Jarnutowski
The University of Arizona

This preliminary report shares an outcome from a summer professional development (PD) activity with university instructors. Instructors participated in four PD meetings, then immediately taught a five-day summer workshop using inquiry, working primarily with first-generation minoritized students. While instructor participants' exit interviews of the project identified their experience in the summer PD as pivotal to their development, we know little of how students experienced the instructors' teaching during the workshop. Our analysis focuses on two items from student post-workshop survey wherein students shared their feedback of their instructor and their experiences more broadly. This analysis allowed us to get a good sense of the instructors' individual practices and revealed convergence in their practices. Pedagogically, instructors utilized groupwork and deemphasized direct instructions, while prioritizing students' engagement in discussions and struggling through conceptual ideas. Relationally, instructors were responsive to students' mathematical needs and created a respectful, safe, and welcoming classroom environment.

Keywords: professional development, equity, inquiry

Project Adelante was a three-year professional development (PD) project, aimed to support university instructors to develop skills in teaching with inquiry methods while simultaneously disrupting deficit narratives about minoritized students in mathematics (Adiredja et al., 2024). Broadly, the PD's goal was to develop culturally responsive mathematics teachers (Ladson-Billings, 1995; Zavala & Aguirre, 2023). The project was motivated by the ongoing educational inequities in undergraduate mathematics for minoritized students, and the need to develop skilled university instructors who are responsive to such inequities. In this way, we joined other scholars and national studies with similar foci (e.g., Leyva, 2022; Smith et al., 2021). However, the project engaged instructors and students in several activities where they explicitly discussed the role of race and gender in STEM to build empathy and solidarity. Each year's cohort of students and faculty participated in critical conversations at the university's cultural centers. Instructors conducted Funds of Knowledge-inspired (Moll et al., 1992) interview of a minoritized student from their class. This report focuses on a PD activity as part of a summer bridge program.

The year-long PD started in the summer. Our participants, instructional faculty and graduate students, participated in four meetings in July in preparation to teach a five-day inquiry-based learning (IBL) summer math workshop. The workshop served primarily first-year first-generation minoritized students who were enrolled in the courses: Pre-Calculus, Calculus I, II, Vector Calculus, and Linear Algebra in the following Fall semester. Topics of the meetings included deficit discourse in mathematics education, teaching with IBL, Funds of Knowledge, anti-deficit teaching, and IBL worksheet development. The PD used immediate implementation, and live coaching to give instructors hands-on experience with inquiry. Exit interviews with the instructors pointed to this summer activity as pivotal to their development as instructors. Here, we focus on analysis of students' feedback of their instructor and examine: *What can we learn about the instructors' teaching practices in their classroom based on the students' feedback? And to what extent did the teaching practices meet the goal of the PD?*

Conceptual Framework

We draw on Zavala and Aguirre's (2023) conception of Culturally Responsive Mathematics Teaching (CRMT) to set the landscape of desired practices with our instructors. The authors built their framework by leveraging the well-developed research in K-12 mathematics education around professional development. It is theoretically rooted in three research traditions: Math Pedagogical Content Knowledge (Grossman et al., 2005), Culturally Responsive Pedagogy (Gay, 2002), and Rehumanizing Mathematics (Gutiérrez, 2018). The authors have articulated components of CRMT and organized them into three strands and nine dimensions.

Table 1. Culturally Responsive Mathematics Teaching (CRMT) Tool.

Knowledge & Identities	Rigor & Support	Power & Participation
• Centering Cultural and Community Funds of Knowledge • (Re)Humanizing Mathematics • Honoring Student Thinking and Ideas	• Sustaining High Cognitive Demand • Scaffolding Up • Affirming Multilingualism	• Distributing Intellectual Authority • Disrupting Status and Power • Analyzing and Taking Actions

This framework articulates concrete aspects of "equity" in teaching. Fostering equity in the classroom has been articulated as one of the pillars of Inquiry Based Mathematics Education (IBME; Laursen & Rasmussen, 2019). More critically, the framework embeds active learning goals as part of culturally responsive math teaching. For example, the CRMT framework adds to "inquiring into student thinking"—a different pillar of IBME—the notion of honoring such thinking to emphasize the importance of shifting deficit narratives about URM students in mathematics (Adiredja, 2019). Power and participation issues are the focus in implementing collaboration among students and teachers. In other words, CRMT ensures that active learning strategies serve the goal of inclusive teaching.

Methods

We analyzed student feedback from the student exit survey to investigate the instructors' teaching practices in the classroom. The survey was administered to students at the end of the summer math workshop during each year of the project from 2021-2023. The workshop and the project were conducted at a research university in the Southwest of the US, which is also a Hispanic Serving Institution. In this report, we only focused on the 2023 cohort. The workshop session was led by six instructors, each teaching one course as shown in Table 2. There was a total of 71 students who attended all five days of the workshop. Sixty one of the 71 students (85.9%) responded to the exit survey. Students self-identified their race and ethnicity and might have included more than one descriptor: 38 students identified as Hispanic/Latinx/Mexican American, 26 as White, 18 as Asian/Japanese/Korean/Indian/South Asian/Pacific Islander, seven as Black/African American, three as Native American, and one as Middle Eastern.

We focused on the two questions from the survey which pertained to the instructors' teaching in the workshop. The first question asked students to give feedback to their respective workshop leader/instructor by providing at least one thing which their workshop leader/instructor did well

and one thing they could improve upon. The second question asked students to provide any additional comments they might have about this program, that were not elicited previously in the survey. Each of the students' responses were first analyzed for each instructor individually, to find common themes, and then aggregated to find similar classroom practices across instructors.

Table 2. Instructor course and demographics

Instructor	Course Taught	Title	Race	Gender
Barbara	Pre-Calculus	Career-track faculty	White	Cis-woman
Jinwoo	Calculus I	Career-track faculty	Asian	Cis-woman
Aarav	Calculus I	Graduate student	South Asian	Cis-man
Julian	Calculus II	Graduate student	Hispanic/Multi-race	Cis-man
Caspian	Vector Calculus	Graduate student	White	Non-binary
Daniel	Linear Algebra	Postdoctoral scholar	White	Cis-man

Since each student's response can contain multiple ideas, we deconstructed every response into different sentences, each consisting of a single idea. We kept track of each sentence by identifying the corresponding instructor and student. We filtered the sentence that described the pedagogical practices the instructors engaged in from the general student experiences. Starting with one instructor, we created categories by comparing and grouping the sentences with similar themes. We used these categories to group a second instructor's sentences from their students and created new categories based on the remaining unsorted sentences. We iterated this process for the remaining instructors. We then collected the data in each category for all the instructors and examined the categories shared across most or all instructors.

For example, one student responded that their instructor "[was] very good at pacing and drip-feeding concepts while we work on problems." This response was then split into two sentences: CAS_3_a: A student was comfortable with the pacing in the course, and CAS_3_b: Students were engaged with concepts while working on problems. CAS was the first three letters of the instructor's pseudonym, in this case, Caspian with 3 being the third student who responded from this instructor's class. We note that students' negative sentiment, such as they wished the instructor would lecture more was still informative. We placed that sentence into the category that says that the instructor de-emphasized the use of direct instruction.

The three authors started the analysis with survey responses for the first instructor. The second author continued the analysis of the rest of the responses for the remaining instructors with the third author. Since the second author was a past participant of the workshop, the third author led the analysis of their students' responses. Disagreements were resolved first by the second and third authors, and in some cases with the first author.

Findings

We identified ten categories, which describe classroom practices that the instructors engaged in from the student surveys. We focus on the following six categories which were commonly shared within four or more instructors' feedback: (a) Fostering a classroom environment that is safe, comfortable, and respectful; (b) Offering students opportunities to experience productive struggle; (c) Organizing the classroom around students' engagement with discussions and group work; (d) Focusing on students learning with conceptual understanding; (e) Responding to students' mathematical needs; and (f) De-emphasizing the use of direct instruction. Table 3

shows the distribution of distinct student responses within each category by instructor. Due to space constraints, we will share details about four categories in part due their richness.

Table 3. Distribution of distinct student responses within each category by instructor

Category	Barbara	Jinwoo	Aarav	Julian	Caspian	Daniel	Total
(a) Classroom environment that is safe, comfortable and respectful	2	2	4	2	1	1	12
(b) Opportunities to experience productive struggle	1	0	3	2	2	1	9
(c) Students' engagement with discussions and group work	2	1	4	4	2	1	14
(d) Students learning with conceptual understanding	0	0	1	2	3	2	8
(e) Responding to students' mathematical needs	3	2	3	3	2	7	20
(f) De-emphasizing the use of direct instruction	1	3	3	3	1	1	12

Within the category of *Fostering a classroom environment that is safe, comfortable, and respectful*, 12 total students across all six instructors' classroom identified how their respective instructor contributed to creating an environment that fostered student respect and feelings of safety for students to engage with math. Many responses spoke to how the instructor was kind and respectful, but we also found that instructors created space for exploration, mistakes, and questions. One of Daniel's students expressed that he provided less formal and open explanations that allowed the student to feel like they could learn without fear of being treated like they were dumb. Similarly, responses from Aarav's class expressed that he created an environment where he was approachable for questions and where there were "no wrong answers" or "dumb questions." The instructors fostered a classroom where students were supported and encouraged to make mistakes and ask questions.

Among nine student responses categorized as *Offering students opportunities to experience productive struggle*, we found evidence that five instructors engaged in such practices. These responses identified that students were responsible for most of the cognitive load in the classroom and were given opportunities to make sense of material on their own. In Julian's class, a student identified that he gave them freedom to learn theorems on their own. Moreover, a response from Aarav's class indicated that he did not give students explicit directions while solving problems and encouraged them to explore ideas. Instructors created classrooms where students were given space to explore, struggle, and make sense of material on their own. Some instructors also incorporated a balance between struggling on problems and the big picture ideas of the course. For example, a student expressed that Caspian gave students opportunities to struggle with solving problems on worksheets while also striking a balance with getting students back to the big picture ideas.

The category of *Organizing the classroom around students' engagement with discussions and group work* appeared in 14 students' responses across all six instructors' classrooms. This category provided evidence that these instructors engaged their students in collaborative group

work, but also gave us insight into the nature of class discussions that occurred in the classroom. A student in Barbara's class indicated that Barbara told her students to work [in groups] on vertical whiteboards. In Jinwoo's class, a student expressed they did not like the inquiry-based learning. They said they prefer being taught explicitly where they could take notes, solve practice problems and being corrected. Both these responses, despite reflecting a negative sentiment in Jinwoo's case, were placed in this current category.

Focusing on students learning with conceptual understanding was our smallest shared category with only eight students across four instructors, but it exemplified an important facet of the instructor's teaching practices. We found evidence that the instructors emphasized process and big ideas over procedures and memorization within their classrooms. In Caspian's class, a student expressed that their learning focused on conceptual ideas and problem-solving methodologies over finding computational answers. Similarly, a student in Julian's class expressed that they proved mathematical rules through problem solving and generalized these rules to solve other problems. The focus shifted from knowing a rule to getting a hands-on experience of understanding the derivation of that mathematical rule.

Discussion

Our analysis methods proved fruitful. We were able to construct our instructors' individual classrooms and the practices they engaged in during the workshop by analyzing their students' responses to the two survey items. Moreover, comparing the categories across all the instructors revealed some degree of convergence in the kinds of practices they were engaged in after the summer PD, which was an encouraging result as they are consistent with the practices we advocated during the preparation meetings. We now reflect on these findings relative to the Culturally Responsive Mathematics Teaching framework (CRMT; Zavala and Aguirre, 2023).

Considering the nine dimensions of CRMT, we found consistencies between our categories and several of the dimensions. These dimensions include, (Re)humanizing Mathematics, Honoring Students' Thinking and Ideas, Sustaining High Cognitive Demand, Scaffolding Up, Distributing Intellectual Authority, and Disrupting Status and Power. We did not find evidence for Centering Cultural and Community Funds of Knowledge, Affirming Multilingualism, and Analyzing and Taking Actions. In some ways, this result allows us to think about how much culture was centralized in the summer preparation meetings. On the other hand, we actually did not expect all nine dimensions to be reflected at this early point of the PD. It will be interesting to complement this analysis with other data point from the project where the instructors have participated in critical conversations about racial and gender stereotypes and conducted the Funds of Knowledge-inspired interview with one of their workshop students.

Preservice Teachers and the Triangular Area Puzzle: A Look at Common Errors

Ayse Ozturk
Old Dominion University

Keywords: geometry, area, conceptual understanding, teacher education

Research has demonstrated that enhancing teacher candidates' comprehension of area concepts largely emphasizes the deepening of content knowledge in geometry through the application of geometric principles to real-world problems (Litoldo & Amaral-Schio, 2021). Building on prior studies (McNeal et al., 2018; McNeal et al., 2023), this study examines the common errors identified in elementary preservice teachers' (PSTs) written responses to triangular area questions, linking these errors to PSTs' conceptual and procedural understanding.

The conceptual framework for this study is based on Hiebert and Carpenter's (1992) model, which distinguishes between two types of knowledge: procedural and conceptual understanding. Procedural knowledge encompasses the application of rules, algorithms, and symbols, whereas conceptual knowledge involves grasping the relationships among concepts and the principles underlying the procedures. This framework guided the analysis in the present study, enabling an examination of the relationship between the common errors made by preservice teachers (PSTs) in their written submissions and their conceptual and procedural understanding of the triangular area.

We collected 85 elementary preservice teachers' written work, including homework, midterm, and final assessment questions related to the calculation of triangular area. A total of 200 written submissions were gathered from four cohorts of a Geometry and Measurement content course for elementary preservice teachers over three consecutive academic years. Employing content analysis methodology (Elo et al., 2014), we first analyzed the content of the students' written submissions to identify common errors. We then examined the relationship between these errors and the preservice teachers' conceptual and procedural knowledge, in accordance with our conceptual framework. After 5 individual coding sessions and 6 group checking-in meetings, we finalized developing 6 codes of common errors in preservice teachers' written work including *using of area units, identifying height or/and base of a triangle, using of area formula, connecting the area formula with the adding and moving principle, connecting triangular area with different shapes' areas, and calculation mistake*.

Analysis revealed that among 6 identified error codes, the highest percentage of errors pertained to the use of area units. For instance, preservice teachers (PSTs) frequently confused the terms "square unit" and "unit square," and struggled to differentiate between them using examples. The second-highest percentage of errors involved difficulties in drawing or identifying the height of triangles, particularly in the case of obtuse triangles. These errors often occurred when PSTs attempted to draw the height for calculating the triangular area, struggled to extend the base and determine the appropriate point to start drawing the height, or create a non-perpendicular segment and treating it as the height. The use of incorrect units and the misidentification or incorrect drawing of the height are linked to a conceptual misunderstanding of the properties of triangles. These errors significantly contributed to the frequency of mistakes in area calculations. Although most PSTs correctly stated and applied the area formula in their written submissions, the incorrect use of units and/or height often led to incorrect answers.

Student Mathematical Identity as a Framework for Reflective Practice

Steve Balady
CSU San Bernardino

Dalton Marsh
CSU San Bernardino

Lamies Nazzal
CSU San Bernardino

Keywords: Student Attitudes, Reflective Practice

The 21st century has seen the rise of math education research which seeks to understand and contextualize students' affective beliefs as well as large-scale professional development and policy interventions targeting student identity (Aguirre et al., 2013). The authors of this study are teacher researchers at a large public Hispanic-Serving Institution in Southern California whose prior work investigates student attitudes. Our dual roles led us to the following research question: **How do we use knowledge of students' prior and developed mathematical attitudes in our classes to inform our future teaching?** The goal of our poster presentation is to share a methodology for how scholarship can return to teacher practice.

We use action research, specifically the dialectical action research spiral described in Mills (2018), to frame our analysis. The steps of this process – identifying an area of focus, collecting data, analyzing and interpreting the data, and developing an action plan – are linked in a loop with no fixed starting or endpoint. Based on our prior work and internal evaluation, we use the Mathematics Attitudes and Perceptions Survey (MAPS) (Code et al., 2016) to measure students' *expert-like attitudes* in the dimensions of Growth Mindset, connections to the Real World, Confidence, Interest, Persistence, Sense Making, and the nature of Answers in math; we augment this instrument with an Identity dimension taken from the High School Longitudinal Survey (HSLS:09) (Ingels et al., 2011).

Student data is drawn from the populations of the researchers' courses in Fall 2022 and Spring 2023. The MAPS+Identity survey was used as a metacognitive classroom activity in each of these courses at the beginning and end of the semester; our analysis includes only students who gave informed consent for their data to be used in research. Author 1 identifies as white and non-binary; they teach content courses for pre-service elementary and secondary teachers. Author 2 identifies as white, male, and a former low-income first generation college student; he teaches content courses for pre-service secondary teachers as well as general education courses. Author 3 identifies as white, female, a former first-generation college student, and a non-native English speaker; she teaches general education courses. All three authors are coordinators for courses in the mathematics department at our institution.

Our poster will refine and present the following preliminary results and implications for our practice, based on initial teacher researcher conversations:

- Instruments used in RUME have historically been validated primarily in the contexts of research institutions with predominantly white student populations. Our work extends the validity evidence of the MAPS to our context, which increases our confidence as teachers that these dimensions are salient for understanding our students.
- Recent prior work (Balady & Taylor, 2022) found that students' pre-course Growth Mindset scores were higher than those in earlier uses of the instrument, which the authors suggested might reflect the increasing popularity of K-12 mindset interventions. Students in our population are consistent with this trend, which suggests that such interventions may be reaching a ceiling of effectiveness.

Improving Students' Confidence in Mathematics and Problem-Solving Skills

Rebecca Sorsen
College of Saint Mary

Keywords: Confidence, Motivation, Attitude

Many students have negative attitudes toward mathematics. In the courses that I have taught, I frequently hear "I'm just not a math person" or "I'm bad at math." It has been proven in many different studies that attitude and achievement are highly correlated. Not only does attitude affect achievement, but achievement affects attitude. In fact, this correlation is bidirectional (Goodykoontz 5).

According to research, there are five factors that influence students' attitudes toward mathematics. Specifically, these five factors are teacher characteristics, teaching characteristics, classroom characteristics, assessments and achievement, and individual perceptions and characteristics (Goodykoontz 76). There are multiple types of student confidence: overall confidence in mathematics, topic confidence, and applications confidence (Parsons 55). My project investigated the first four external factors to determine if a single semester in a positive math classroom could increase students' attitudes and confidence in mathematics.

In Spring 2023, I was the instructor of record for MATH1005: College Algebra at the University of Iowa. The students in this course were mostly non-math majors who needed this class for their degree. On the first day of class, I handed out Survey 1. This survey asked students about their attitude, confidence, and motivation toward mathematics. Throughout the semester, I implemented the four external factors discussed above to attempt to increase student's confidence and attitude toward mathematics. For example, to implement teaching characteristics, I always wrote out every step carefully, tried to show multiple ways to approach each problem, and gave real-life examples to emphasize important concepts.

At the end of the semester, I gave the students Survey 2. This survey was nearly identical to the first survey. Survey 1 had 5 responses, which was a 21% response rate, and Survey 2 had 6 responses, which was a 25% response rate. I analyzed the data and created multiple bar graphs comparing the results from Survey 1 and Survey 2. First, I asked the students to rate their confidence for specific mathematical concepts taught in College Algebra. The data showed that students felt a higher confidence level in their abilities after learning the new concepts.

Next, I asked students to rate their level of agreement/disagreement on various statements relating to confidence and motivation. The statements with the largest amount of positive change from Survey 1 to Survey 2 were "I am good at math," "I have a mathematical mind," and "I enjoy solving challenging math problems. The statement with the largest amount of negative change was "Even if I work hard, I still struggle with math." The results show that the students had higher confidence in their mathematical abilities and a more positive attitude toward mathematics in general.

Lastly, I asked the students to identify which specific aspect of the course had the greatest impact on their feelings about math in the course. The top two answers were the instructor's personality/enthusiasm for the course and seeing each step written out carefully for problem solving. Some students also selected feedback on quizzes and exams, seeing multiple ways to approach a problem, and opportunity for one-on-one help. This shows that the teaching characteristics and teacher characteristics were the most influential factors for students' confidence.

Mathematics for Undergraduate Nursing Students: Expansive Framing to Foster Transfer

Kimberly Evagelatos Beck
Weber State University

Keywords: expansive framing, mathematics, nursing, transfer

Mathematics plays an important role for nurses on the job yet practicing nurses do not view their work as being math-dependent, and nursing students find little value for learning mathematics beyond simple calculations (Hoyles et al., 2001). This may indicate that nursing students are struggling to successfully transfer what they learn in mathematics class into the nursing field. *Transfer* occurs when a student takes content or skills learned in one context and applies it to another. Transfer has been studied extensively but is known to be a construct that is difficult to research (Barnett & Ceci, 2002). Expansive Framing theory (Engle et al., 2006, 2011, 2012) acknowledges the transfer debate but refocuses the lens on context, positing that transfer is fostered by linking contextual elements and creating *intercontextuality*, or connections between contexts.

This research employed a teaching intervention in an online College Algebra course at a nursing school. The students in the course received instruction through a weekly synchronous webinar. Participants were placed in two groups: the first group received typical instruction using primarily bounded framing, and the second group received instruction using expansive framing across time, place, people, and topics (Lam et al., 2014). Participants were interviewed about their perceptions of value and transferability and transcripts were analyzed using reflexive thematic analysis (Braun & Clarke, 2022).

Results showed that forming intercontextuality positively influenced perceptions of value and transferability. While the webinars themselves showed mixed effectiveness, other expansively framed course activities emerged as being highly beneficial for influencing perceptions. Overall, this research indicated that broad framing of context was effective in improving perceptions of mathematics value and transferability for nursing students. Based on these results, I recommend that mathematics instructors in undergraduate programs actively seek opportunities to create intercontextuality through broad framing during instruction, but also by applying EF to classroom activities through curricular integration of content.

The accompanying poster provides examples of expansive and bounded instructional framing, quotes from student interviews, and more detailed results. This research provides a unique contribution to the field of undergraduate mathematics education, and while this research focuses on mathematics in nursing, the findings have important implications about mathematics in a variety of applied fields. Expansive Framing is a theory previously applied in the Learning Sciences field and has not yet been widely accepted in mathematics education, yet this research shows that it has the power to facilitate deeper mathematical connections across contexts through the creation of intercontextuality.

Keywords: attributional beliefs, deficit discourses, equity

Deficit discourses are socially constructed narratives that circulate and reinforce negative perceptions about marginalized students (Adiredia, 2019; Adiredja & Louie, 2020). Deficit discourses make claims about "students' academic and intellectual shortcomings" (Adiredia & Louis, 2020, p. 42) and attribute those shortcomings to defects of the student or their community. They claim, for example, that Black and Latinx students are responsible for their own underachievement (Nasir & Shah, 2011), that "women and Latinos are not good at mathematics" (Leyva, 2016 , p. 109), or that Mexican and Black families and cultures do not value school work (Solórzano & Yosso, 2002; Adiredia & Louie, 2020). Classroom environments that reinforce deficit discourses overlook the existing knowledge of students, denying them meaningful opportunities to engage in mathematics (Adiredja & Louis, 2020). This approach also perpetuates false hierarchies that portray "Black, Latinx and indigenous people as mathematically inferior to white and some Asians and consequently as less deserving of meaningful, prestigious and lucrative learning opportunities and careers" (Adiredja & Louis, 2020, p. 43). In a recent study, Leyva et al. (2021) found that even "seemingly neutral behaviors and comments ... reinforced whiteness and patriarchy" (p.28). They call for the future research to scrutinize "precalculus and calculus instructors' consciousness of whiteness and patriarchy embedded in undergraduate mathematics education" (p. 28). Inspired by this call, we propose investigating precalculus and calculus instructors' beliefs about the source of racial and gender differences in mathematics achievement outcomes and investigate links with "seemingly neutral behaviors and comments" (Leyva et al., 2021). We approach this work using a perspective that draws on the attributions of mathematical excellence (AME) framework (Jacobson et al., 2022) which uses theory from social psychology to characterize deficit (and anti-deficit) discourses in mathematics education as genetic, personal, social, or educational. The goal the AME framework is to examine how teachers' understanding of the origins of unequal mathematics education outcomes might be significant for instruction. Some beliefs may reinforce racist and sexist disparities, while others may help to challenge and change them. Importantly, the theory highlights how apparently identity-neutral attributional beliefs about mathematical excellence align with negative racial and gender stereotypes that correspond to deficit discourses in mathematics education. For example, the explanation that succeeding in mathematics requires sufficient effort (personal) is aligned with the discourse that Black and Latino students are underachievers. Building on the Leyva et al. (2021) work on examining racialized and gendered mechanisms in undergraduate mathematics courses, we plan to apply AME in a university context, testing its generalizability in a new environment. Specifically, we see the theory as promising to illuminate the causal factors that mathematicians use to explain students' mathematical success (and struggle), including explanations that seem to be neutral but nevertheless align with negative stereotypes. In this poster, we describe the theoretical framework and outline a study design to address the research question: How does the AME framework capture university mathematicians' attributional beliefs of mathematical excellence?

Neurodiversity Access, Agency, and Accommodation in Mathematics Education for Undergraduate Students

Hayley Milbourne
University of San Diego

Jessyca June Olvera
Western Michigan University

Katie Bjorkman
Richard Bland College

Keywords: DEIA, Neurodiversity, UDL

In recent years, there has been greater emphasis on creating diverse, equitable, inclusive, and accessible spaces for underrepresented students in mathematics. However, neurodiverse students have largely been left out of this conversation. There is evidence that students who are privileged to have access to diagnosis may not disclose their diagnosis or seek accommodations in college due to stigma or lack of information about resources (Borsotti et al., 2024; Edwards et al., 2022) and that even equity-oriented undergraduate faculty often feel under-prepared to teach neurodiverse or disabled students, or treat them only as separate groups rather than creating pedagogies that are accessible to all students (Cotán et al., 2021; Hitch et al., 2015; Moriña, 2022). There is also little research specifically on disabled student accommodations in online and hybrid formats (Edwards et al., 2022). The NAME US (Neurodiversity Access, Agency, and Accommodation in Mathematics Education for Undergraduate Students) project aims to begin this conversation and provide more research into the ways all students can be supported in a mathematics classroom.

This poster will present on the initial results from a pilot study focused on a teaching experiment that applies principles of Universal Design for Learning (UDL) (Fornauf & Erickson, 2020) to an undergraduate mathematics course at an institution that serves high number of students in demographically at-risk groups for underdiagnosis of neurodivergence and learning differences such as women, first-generation college students, and non-white students (Cunningham, 2021; Lockwood Estrin et al., 2021; Martin, 2024; Moody, 2016; Shi et al., 2021). Our specific research questions are:

1. In what ways does applying the principles of UDL to increase flexibility in learning and assessment modalities in introductory mathematics courses improve student outcomes as measured by grades and course evaluations?
2. What evidence is there of under-diagnosis of learning differences or under-disclosure of diagnosed learning differences in students in introductory mathematic course?

The teaching experiment was conducted within two in-person sections of Precalculus I and two online sections of Contemporary Mathematics. All sections of both courses were taught by the same instructor. The control sections were taught using the same materials and course structure the instructor had used previously for these courses. The experimental sections utilized the same textbook, homework assignments, and exams, but UDL inspired changes in content delivery and assessment such as greater flexibility of exam conditions (headphones with white noise or music and fidget toys explicitly allowed) and more accessible presentation of material (more accessible and larger font for textbook and other resources, explicit orientation to accessibility aids within the learning systems).

Our poster will present the initial findings from both the courses and the survey conducted to measure the potential amount of underdiagnosis of neurodiverse conditions and underutilization of campus resources for those with a formal diagnosis. We look forward to discussing the project with the RUME community as a whole and are excited to share our plans for moving forward.

The Impact of Using the IBL Approach and the 5E Framework in Mathematics Classrooms on Students' Motivation and Engagement

Rayan Al Tulyani
Lebanese American University

Rayya Younes
Lebanese American University

Samer Habre
Lebanese American University

Keywords: Inquiry based learning (IBL), 5E Framework, Motivation, Engagement

Many academic fields such as engineering and economics, rely on mathematics as a fundamental discipline (D'Ambrosio, 1995; Diego-Mantecon et al., 2021). One essential goal for mathematics educators should therefore be graduating students who can address real life challenges. This requires an education system that emphasizes practical problem-solving skills. In traditional educational systems memorization is prioritized over real-world applications. As a result, students perceive mathematics as a challenging subject with no practical applications (Diego-Mantecon et al., 2021; Gravemeijer et al., 2017), causing a decline in students' motivation and engagement to learn mathematics (Grootenboer, 2013). For this reason, more and more academics are adopting a mathematics curriculum that emphasizes the relevance of the subject to society. While engagement is active participation, motivation is the willingness to engage in an activity (Fredricks et al., 2004; Singh et al., 2002). In mathematics, engagement is fostered by challenging problems and group learning, whereas motivation is the result of factors such as curiosity, perceived relevance, or outside incentives (Skinner et al., 2008).

In this study, the Inquiry-Based Learning (IBL) approach and the 5E framework were employed to teach a mathematics lesson on logarithms. The subjects of the study were grade 12 students (equivalent to the college Freshman year) in a school situated in a remote area of Lebanon. In this intervention, we aimed at investigating the impact of IBL on students' motivation and engagement. The research was guided by two questions: (1) *How does the IBL approach impact students' motivation to learn mathematics?* (2) *How does the IBL approach impact students' engagement in learning mathematics?* A variety of tools were used to examine the research questions. Those included two questionnaires and an interview. The freely available surveys were the *Mathematics Motivation questionnaire* (Fiorella et al., 2021), and the *Mathematics Learner Engagement Scale* (Rimm-Kaufman, 2010). Interviews were conducted with 6 students after the intervention. Interviews were semi-structured and included 10 questions divided into five domains: Background information, perception of Mathematics in real life, application of mathematical skills, individual needs, suggestions, and feedback. A semi-structured interview was also conducted with the class teacher, and it was employed to elicit information on the educator's perspective and experience with the application of the IBL approach.

The class teacher and the researcher collaborated to design the intervention on the topic of logarithms. To increase students' intrinsic motivation and actively engage them in the classroom, the design incorporated an activity on earthquake intensity, a timely and relevant topic since Lebanon had experienced prior to the intervention a series of rather intense earthquakes. The study findings showed that the implementation of the earthquake activity heightened students' intrinsic motivation. Results also showed that using student-centered pedagogical techniques and building a cooperative learning environment significantly impacted student engagement. Results of the teacher's interview highlighted the shortcomings of traditional teaching approaches and the importance of creative pedagogical approaches such as IBL alongside the 5E framework to pique students' interest in learning.

Exploring Student Experiences in Calculus I: The Impact of Inquiry-Based Versus Lecture-Based Instruction on Math Anxiety

Harman P. Aryal
Stockton University

Keywords: math anxiety, inquiry-based learning, collaboration

Math anxiety affects student learning and academic performance, causing physical, mental, and emotional symptoms (Ashcraft, 2002; Mattarella-Micke et al., 2011; Ruffins, 2007). Math-anxious individuals may dislike math and take fewer math courses, ultimately avoiding math and math-related courses (Hembree, 1990). Due to this significant impact, it is essential to diagnose the causes of math anxiety and determine potential interventions to reduce math anxiety. As such, this study investigated the effects of inquiry-based learning (IBL) vs. lecture-based instruction on Calculus I students' math anxiety through the following research questions.

1. What have been students' experiences and perceptions of taking Calculus I in an online setting via IBL or lecture-based instruction?
2. How and to what extent do these experiences and perceptions influence math anxiety?

Methodology

Sequential Explanatory Mixed Methods Design was employed to investigate quantitative and qualitative research questions. Since the data were predominantly collected through one-on-one online interviews, this study fits more into a qualitative research study.

Participants, Data Collection, and Data Analysis

The sample of this study comprised of students who were enrolled in the Calculus I course and were taught using either IBL or lecture-based instruction during Spring 2021 at a university located in the Midwestern United States. Students who received IBL instruction were in the IBL group, and those who received lectures were in a lecture-based group.

A short version of the Mathematics Anxiety Rating Scale (MARS-S) developed by Suinn and Winston (2003) was used to collect the quantitative data from 15 IBL and 20 lecture-based students. Based on the change in their anxiety scores from pre- to post-MARS-S survey, 9 students from the IBL group and 3 from the lecture-based group were selected and interviewed via Zoom. Quantitative data were analyzed using the SPSS, and qualitative data were analyzed using the NVivo software.

Findings and Implications

Results show that the activities, such as collaborative work, optional and ungraded homework, and the instructor's anytime readiness to meet with his students, decreased IBL students' anxiety, whereas the instructor's readiness to reexplain the material in class and recitation classes by the teaching assistant decreased lecture-based students' anxiety. However, the tests and exams, anticipating the instructor's call for a response, and responding to instructor's questions in front of their peers increased anxiety among both groups of students. Moreover, students with IBL experience felt more confident and empowered compared to the lecture-based learning experience

Reflecting on students' increased anxiety taking tests, it might be worth considering more group-based assignments and fewer in-class tests. Also, since IBL developed confidence and critical thinking among students, implementing an IBL in math teaching might be worth it.

Factors Influencing Persistence for Undergraduate Women in Mathematics or Statistics

Faustina Baah
University of Missouri

Samuel Otten
University of Missouri

Keywords: undergraduate women, mathematics, statistics, college experience

Few women enroll in collegiate mathematics-intensive Science, Technology, Engineering, and Mathematics (STEM) programs compared to non-STEM programs (Rivers, 2017). Meanwhile, the few women pursuing these STEM degrees in colleges are about 1.5 times more likely than men to leave their STEM programs (Ellis et al., 2016). Some studies have explored the factors that account for women's dropout from STEM programs (e.g., O'Connell & McKinnon, 2021). But for the women who continue to enroll in STEM programs, particularly those in math-intensive programs, what college factors explain their continued enrollment in their majors?

In an attempt to better understand this situation, we explored the experiences of undergraduate women in mathematics and statistics programs with a focus on their perception of academic development opportunities and social support in relation to persistence. We define persistence as students' continuous enrollment through the third year, placing them on a presumed path to STEM degree attainment from the university. Academic development refers to the formal and experiential learning opportunities provided officially within the program (e.g., courses, office hours). Likewise, social support describes the help and guidance students receive beyond the official capacity of the program/department (e.g., study groups, major-related clubs).

The participants in the study included 24 self-identified women who completed the student survey sent to all students enrolled in the mathematics and statistics programs at Pink University (pseudonym) located in the Midwestern region of the United States. The survey was intended for only women in the programs. We used an online survey to collect data on key variables such as demographics and persistence factors. The survey consisted of 31 items on a 5-point Likert scale and 5 open-ended questions. The larger study involves group interviews with select respondents but the current analysis focuses on the survey responses to address the following research question: What college factors do women in mathematics or statistics undergraduate degree programs indicate as influencing their persistence in those programs?

We found that women rated academic factors as more influential on their persistence than social factors. Specifically, 91% of the women indicated that the relevance of courses to their career goals and their performance in the courses contributes strongly to their persistence. Likewise, 69% of the women declared that the quality of instruction and internship opportunities influences their persistence in mathematics or statistics programs. However, 75% of the women revealed social support factors have a low to moderate influence on their persistence.

Our results echo similar studies (e.g., Espinosa, 2011; Brainard & Carlin, 1998), and we extend this work by looking beyond introductory calculus to hear from women in their third and fourth years about how these academic and social factors have influenced persistence. Centering undergraduate women's experiences can point to areas where interventions and support can be targeted to improve women's experiences in STEM education.

Learning to Learn Calculus: Equipping Students with Nonacademic and Behavioral Skills

Kathleen Guy
Florida International University

Keywords: Calculus, Educational Interventions, College Readiness, Mathematics Anxiety

Every year, millions of students begin post-secondary education in the hopes of furthering their education. However, research shows that being college eligible is not the same as being college ready, and students struggle with the rigors of higher education. While it is typical to associate success in college with various acquired academic skills, there are numerous nonacademic factors that can determine whether a student will graduate (Capuno et al., 2019; Conley, 2008; Robbins et al., 2006; Tinto, 2017). To help students acclimate to college life and academics, universities and colleges have created student life skills (SLS) courses which focus on nonacademic skills and learning strategies. While research has shown that SLS courses provide some benefits to students, these courses often attend to general concepts and skills without considering their application. Therefore, researchers recommend combining SLS course content with discipline specific content for it to be more beneficial for students (Boaler et al., 2022; Cho & Karp, 2013; Reilly, 2014; Wingate, 2007).

One discipline that could highly benefit from incorporating SLS content into the curriculum is mathematics, as certain mathematics courses in higher education are considered gateway courses to advanced coursework. Learning to learn mathematics is multifaceted, and combining SLS content with mathematics specific content can help students succeed in their mathematics courses and complete their degree in a timely manner. In this poster session I will discuss how I created a special Learning to Learn Business Calculus workshop focused on nonacademic and mathematics strategy skills, the different components of the workshop, and the findings of the research study which measured its effectiveness and usefulness (from the student perspective) as an educational intervention. I will explain how I facilitated the intervention at a large R1 university and discuss how the different activities are connected to non-academic and mathematics strategy skills topics such as metacognition, growth mindset, calculus test-taking strategies, procrastination, mathematics anxiety, and more (I will also provide a QR code where activities can be found). The findings showed the workshop had a positive impact on student outcomes (mathematics anxiety, self-efficacy, and academic achievements) and students found the workshop useful for both personal and academic reasons. The poster will present the findings and discuss their implications for future research and educational practices.

As the integration of nonacademic and strategy skills directly into discipline-specific courses is infrequent and receives limited attention in the field of education, this presentation serves as an opportunity for the audience to become acquainted with a method that enables instructors to incorporate these skills into their curriculum. By harnessing this tool, educators could potentially enhance short- and long-term student retention rates, thereby contributing to a more successful academic experience. This, in turn, would likely lead to improved satisfaction and overall positive experiences for both teachers and students within these critical courses. By attending this session, participants can be exposed to a unique and innovative teaching strategy and get tools and advice to apply it to their own courses. Furthermore, the audience can be exposed to a mixed methods education research study which can be replicated if they wish to measure the effectiveness or usefulness of facilitating this type of intervention at their own institution.

Exploring Students' Understanding of a Limit of a Sequence: Using ϵ-Strip Activity With Realistic Mathematics Education Framework

Ruo Ning (Nancy) Qiu
San Diego State University

Keywords: ϵ-strip activity, realistic mathematics education, defining as a mathematical activity

The concept of limit is crucial in undergraduate mathematics, serving as a foundation for rigorous mathematical reasoning and applications in calculus, real analysis, and advanced courses (Roh, 2008; Roh & Lee, 2017; Swinyard & Larsen, 2012). However, students often struggle to develop a robust understanding of limits (Oehrtman et al., 2014; Williams, 1991).

I interviewed two students to examine if the ϵ-strip activity developed by Roh (2008) could scaffold and help students leverage their intuitive understanding of the limit in a sequence to the mathematically rigorous ϵ-N definition of convergence of a sequence. In particular, I investigated how students reason about the convergence or divergence of a sequence during the ϵ-strip activity. As a theory-building effort, I analyzed the interview data by mapping it into a table figure that integrates the constructs from the Defining as a Mathematical Activity (DMA) framework and Realistic Mathematics Education (RME).

Freudenthal (1991) proposed the RME as an instructional design that aims to foster the invention of mathematical knowledge called "emergent models." It highlights the shift between how students develop *models-of* their informal mathematical activity using tools, graphs, and analytic expressions to *models-for* increasingly sophisticated and formal ways of mathematical reasoning in four phases of Situational, Referential, General, and Formal activities (Gravemeijer, 1999). Zandieh and Rasmussen (2010) further described these four phases with the DMA by integrating the notion of concept definition and concept image (Tall & Vinner, 1981). This integration adds five constructs to the four phases of RME's transition process, which are creating a concept definition, using a concept definition, creating a concept image, using a concept image, and creating a new mathematical reality.

By mapping out the interview data and identifying critical events as explicit evidence for the transition process in a figure, I observed that the ϵ-strip activity aligns well with RME's emergent model and DMA. At the beginning of the ϵ-strip activity, students created a concept image and concept definition of ϵ-strip recalling their past understanding of limit as a model-of, which is what the Situational and Referential activities in an experiential real setting attribute. As they completed more activities, students used the physical ϵ-strip as a model-for to create a concept image and concept definition of the rigorous ϵ-N definition of convergent sequences. In particular, Henry (pseudonym) almost reinvented the ϵ-N definition with De Morgan's Laws by formalizing their concept image, an occurrence of the Formal activity in the wild.

As a result, this study examined the practicability and robustness ϵ-strip learning activity grounded with DMA and RME using a figure to present how the interview data merged into the four levels of activity and five constructs of DMA. Furthermore, I envision that mathematics education researchers and practitioners not only can use the DMA framework to guide the design process of instructional sequences that scaffold complicated mathematical topics related to defining, but they can also use DMA to improve the design of existing instructional sequences like the ϵ-strip activity that has the potential to leverage students' emergent model to formalize their understanding towards rigorous mathematical statements.

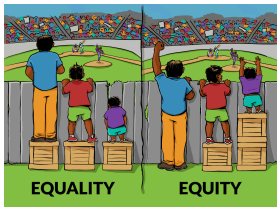
Moving Beyond the Fence: Interrogating Problematic Images of Equity and Envisioning Inspiring Metaphors

Kelsey Quaisley
Oregon State University

Wendy Smith
University of Nebraska-Lincoln

Leilani Pai
Denison University



Matthew Voigt
Michigan State University

Keywords: equity, arts-based methodology, education metaphors, departmental change

Visual imagery and metaphors are powerful. A single image can represent multitudinous and complex conceptualizations of an idea, and evoke emotions tied to a viewer's deep-rooted values, beliefs, and experiences (e.g., Adiredja & Zandieh, 2020). Unpacking this complexity is especially valuable in critical equity work (Levinson et al., 2022). Drawing on our research team's engagement with research-practice partnerships in three networked improvement communities (NICs) in mathematics departments, we are motivated by the following research questions: 1) How do NIC members respond when asked to draw or share an image representing equity work? 2) What emotions are evoked when reacting to these representations for researchers engaged in research-practice partnerships?

We compiled images from NIC members' journals (see Figure 1 for the prompt, left) and subsequently asked each research team member to describe the emotion or word that was evoked upon viewing the image. We first categorized the types of images by how each was created, content (e.g., reflecting the status quo or an aspirational future), and composition. We further categorized the researchers' emotional responses as positive (e.g., curiosity, appreciation, hopefulness) or negative (e.g., disgust, confusion, helplessness), noting how the composition and content of the images evoked our emotions. In many spaces in mathematics education, there is a common scene (or variant of it) used to distinguish equity from equality, which we refer to as *the fence* (see Figure 1, center image; Froehle, 2016). Members from all three NICs submitted images of the fence or a similar variant, e.g., picking apples, comprising 9 of the 20 images submitted. While the fence can be a useful tool for discussion, it is problematic in that it portrays the people as the problem (Equity in Education Coalition, 2018), rather than systemic structures.

"Please draw or share an image (e.g., a picture you took or an image from the internet) that represents what it means to you personally to engage in equity work. Then, write a description explaining why you chose or drew that image."

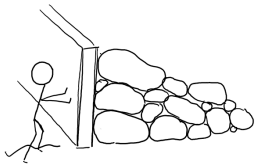


Figure 1. The journal prompt that elicited images (left), the Fence (center), and an Immovable Wall (right)

As a result, repeated images of the fence brought about emotions of irritation and frustration among the research team. We are ready to move beyond the fence. More positive emotions were evoked by other images that NIC members included, such as an immovable wall (see Figure 1, right image), a collage of kites cycling through soaring and crashing, and searching a cave with a flashlight. We found these images to more sincerely convey the tensions, joys, and challenges of doing critical equity work. For our poster, we present a collection of types of images and researcher responses in more detail, and suggest other visual representations of equity as inspiring and creative alternatives to the fence.

Acknowledgments

This material is based upon work supported by the National Science Foundation under Grant Number 2201486. All findings and opinions are those of the authors and not necessarily of the funding agency.

We express heartfelt appreciation for the engagement of our research participants, and their willingness to be vulnerable through their equity-focused learning journeys.

Emulating Social Aspects for Argumentation in Non-STEM Classrooms

Mario Abel Gonzalez
Texas State University

Brandi Rygaard Gaspard
Texas State University

Keywords: argumentation, non-stem students, social constraints

Studies have described accountable argumentation (Horn, 2008), collective argumentation (Brown, 2017), or dialogic argumentation (Hähkiöniemi et al., 2022) for how students can engage with each other to develop rigorous mathematical reasoning. Argumentation, justifying, and proving often come together for students when mathematical proof is not the focal point of instruction (Knuth et al., 2022). A common theme for developing proof is the idea of convincing oneself and another (Yopp et al., 2022). This often entails another person asking for further details or justification about how a mathematical claim is true. For a non-proof-oriented classroom, the idea of a convincing argument is tenable for the development of proof (Czocher & Weber, 2020). Therefore, our research purpose was to investigate how students interact with increasingly socially constrained tasks.

Methods

We developed four tasks to explore emulating the social aspect for convincing another classmate. Each task provided varying social constraints. These tasks were implemented throughout one semester on the exams of three instructors in an introductory mathematics course for non-STEM majors. The first task was "show that the sum of two even numbers is even." The second task was "convince a very stubborn classmate that when you add two even numbers, your result will be an even number. This classmate is not convinced that this is true for every number, especially very large numbers." The third task was like the second but added "This classmate has **challenged** you to show that this is true without using specific examples" at the end. The fourth task was "show that when you multiply two even numbers, the result is even."

We coded the students' responses using deductive argument (DA; akin to a mathematical proof, justifies inferences, or a teacher would accept this), example use with attention to generality (EG; example use with connections to conclusion or references shared characteristics across mathematical objects), example use only (EO; only calculations), other argument (OA; doesn't fit the other types), and non-argument (NA; unclear intentions or irrelevant).

Results and Discussion

In general, among the 46 students who participated in at least one task, EO and OA were the most common response types. For the constrained second and third tasks, the frequency of EO codes decreased, indicating it is possible these constraints interacted with argument constructions. While only one student was coded DA, many OA or EG responses contained ideas of such an argument, so the task variations may motivate deductive reasoning. Of the 42 students who completed at least two tasks, 25 students varied in responses across tasks. Students responded differently to the constraints; for example, several students who started with EO responses later constructed arguments such as OA or EG and vice versa (i.e., OA or EG to EO). Given that over half of the students changed their response type, we argue that studying what students attend to when choosing their argumentation strategies is worthwhile. In future work, we intend to conduct student interviews to focus on how they interpret these constraints.

Acknowledgements

We would like to thank the instructors who assisted in data collection for this study.

"Am I Missing Something?": Learning From Pre-Service Teachers' Routes Through a Mathematical Modeling Cycle

Elise Lahiere
Eastern Kentucky University

Amanda Provost
Montclair State University

Youngjun Kim
Montclair State University

Andre Perkoski
Montclair State University

Geena Taite
Diana Lobosco STEM Academy

Keywords: mathematical modeling, pre-service math teachers, modeling activity diagram

Mathematical modeling has been receiving increased focus with researchers identifying its benefits for students, such as using mathematics in real-world applications and affecting change in attitudes towards mathematics (Maaß, 2006; Stender & Kaiser, 2016). Mathematical modeling also provides the opportunity to support equitable learning by promoting cooperation among students from various mathematical backgrounds with the use of low-floor and high-ceiling tasks (Cirillo et al., 2016). With so many potential benefits, it is important to examine how groups of pre-service math teachers (PSMTs) negotiate the modeling process in order to better prepare them to include modeling activities in their future classrooms.

Modeling is a complex process, with participants needing to connect mathematical concepts with real-world contexts that are not well defined. There have been several modeling cycles published (e.g., Bliss et al., 2014; Blum & Ferri, 2009) that attempt to illustrate how individuals move through the various modeling phases. However, the modeling cycles tend to provide a simplified view of the "messy" and complex nature of these tasks (Albarracín et al., 2019). To gain insight into the modeling process, we planned and taught two mathematical modeling sessions for 24 PSMTs in a combined bachelor's and master's level mathematics teacher education course. This work enabled us to explore how small groups of PSMTs moved between phases of the Bliss et al. (2014) modeling cycle: *building the model, getting a solution, analysis and model assessment*, and *reporting results*. The research questions guiding this study are: How does PSMTs' engagement in a modeling task align with and differ from the Bliss et al. (2014) modeling cycle? What is the context that is taking place as PSMTs deviate from this cycle?

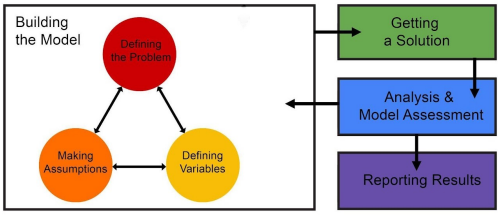

Figure 1. A Modeling Cycle Adapted From Bliss et al. (2014)

In our analysis, we used a modified version of the Modeling Activity Diagram (MAD) framework (Ärlebäck, 2009) to create a visual representation of each group's movements through the modeling cycle phases. Several different types of deviations from the Bliss et al. (2014) modeling cycle were observed. For example, students moved from *getting a solution* back to the *building the model* phase due to a need to make additional assumptions based on their model choices. We explore the causes for such deviations and discuss how this process is more complex than the cycles suggest when PSMTs engage in these tasks within the classroom. These insights can be used to help prepare PSMTs to teach mathematical modeling.

Students' Limit Conceptions and Representational Approaches

Kingsley Y. Adamoah
Middle Tennessee State University

Jeremy F. Strayer
Middle Tennessee State University

Keywords: Concept, limit conceptions, representational approaches

Investigating students' thinking about the limit concept in calculus through representational approaches supports the need for students to learn mathematical concepts with deep understanding and actively build new knowledge (NCTM, 2000/2014). This study takes an asset-based perspective and focuses on students' reasoning, views, and understandings of the limit concept rather than focusing on students' misconceptions and lack of understanding, as some past research has done (Bezuidenhout, 2001; Denbel, 2014; Fernández, 2004; Liang, 2016; Nagle et al., 2017). Additionally, some studies have investigated students' abilities to reinvent the conventional $\varepsilon - \delta$ limit definition (Swinyard, 2011; Swinyard & Larsen, 2012) but have not explicitly addressed how students' reasoning with representational approaches plays a role in advancing to the more formal limit definition. This poster presentation shares a portion of the results from a larger study on students' limit conceptions (Intuitive, Informal, and Formal) and their representational approaches (Graphical, Numerical, and Algebraic) to understanding the limit concept. The two research questions are:

1. *What limit conceptions do students possess?*
2. *What connections exist between students' limit conceptions and representational approaches?*

To address these research questions, pre-assessment surveys were collected from 63 students enrolled in Calculus II from a public university in the southeastern United States. The surveys have six limit-view statements (adapted from Williams, 1991/2001) that constitute the three main classifications of limit conceptions (Intuitive, Informal, Formal) and five multiple/short answer limit problems that constitute the three main representational approaches (Graphical, Numerical, Algebraic). To address research question 1, we analyzed the frequency counts for students' preferred choice of the limit-view statements that best expressed their understanding. To answer research question 2, we compared students' responses to the six limit-view statements to their choice of representational approaches to the five multiple/short answer problems.

We found that the intuitive limit-view had the most significant frequency, which could suggest that students begin to conceptualize limits from an intuitive perspective. Additionally, we found that students' *intuitive limit conceptions* are tied to graphical reasoning, and students' *informal limit conceptions* are tied to numerical reasoning. The results of this study are consistent with Adiredja et al.'s (2020) suggestion that the teaching and learning of abstract concepts in more tangible ways should be done based on students' intuitive reasoning.

Implications of this study offer both calculus instructors and curriculum reformers ways to integrate students' ways of reasoning into calculus teaching and learning. Specifically, results suggest that calculus instructors may leverage different representational approaches to provide opportunities for students to deepen their conceptual understanding of limits.

Liberal Arts Math Through Theater

Emma LaPlace
Teachers College, Columbia University

Keywords: liberal arts, theater, interdisciplinary approach

Liberal arts mathematics courses, a crucial topic in mathematics education research, are typically designed to fulfill an academic requirement for non-STEM majors. They often focus on "real-world" mathematical applications (Penn LPS, 2024), and unlike traditional undergraduate mathematics courses that deeply explore one subject, liberal arts mathematics classes tend to highlight a variety of mathematical topics (George, 2010). Existing literature about liberal arts mathematics courses claim that these classes should highlight the "usefulness" of mathematics for those not pursuing a career in a STEM-related field (Strasser, 2011; Teixeira, 2023), and focus on the fact that "typically, students in these classes are not math enthusiasts" (Teixeira, 2023, p. 106). However, perhaps with a more intentional approach, focusing instead on the beauty of mathematics rather than the utility, these students could engage with rich mathematics in a more meaningful way.

I propose a liberal arts mathematics course that focuses on mathematics in theatrical works (liberal arts mathematics through theater, or LAMTT). Theater has the "capacity to adjoin and to assimilate every other art [the written word, music, dance, costumes, sets, etc.]" (Gertsberger, 2009, p. 70), so it is the most comprehensive medium with which to engage liberal arts students. This would be particularly appropriate for students majoring in a humanities discipline, because "meeting students at the intersection of where their interests lie along with significant mathematics allows educators to better communicate with their pupils" (Meadows & Caniglia, 2021, p. 183). The Database of Mathematical Fiction, curated and maintained by Dr. Alex Kasman is "widely recognized" as a reliable research tool in mathematical fiction, and contains a list of 71 theatrical works highlighting mathematics (Kasman, n.d.; Swallow, 2006).

I have analyzed these 71 theatrical works according to the intersection of "significant mathematics" and "student interest," as indicated by Meadows and Caniglia (2021). A variety of rich mathematical topics can be found in these theatrical works, such as: sequences, partitions, and The Functional Equation of the Riemann Zeta Function in Simon McBurney's *A Disappearing Number*; and Euclidean and fractal geometry, chaos theory, and Fermat's Last Theorem in Tom Stoppard's *Arcadia*. On the Database of Mathematical Fiction, the plays are labeled by their mathematical content (i.e. Probability/Statistics, Mathematical Physics, etc.). The 71 theatrical works also touch on interest areas that may engage liberal arts students, such as mental health in David Auburn's *Proof* and history and Lord Byron's poetry in *Arcadia*, and India and its diasporas in *A Disappearing Number.* I created a table that shows the intersection between mathematical content areas and common liberal arts content areas (i.e. *Arcadia* may fall under *(Chaos/Fractals, History)*). This analysis will be displayed in further detail on my poster, and can be used as a tool for undergraduate mathematics educators to create a LAMTT syllabus.

Ruth, a character in *A Disappearing Number,* says it best with her line: "It may be very hard to define mathematical beauty but that is true of beauty of any kind. We may not know quite what we mean by a beautiful poem, but that does not prevent us from recognising one when we read it" (McBurney, 2007, p. 42). In examining an artistic medium such as theater that both connects with student interests and focuses on the beauty rather than the utility of mathematics, liberal arts students may feel a deeper appreciation for the mathematics that they study and learn.

Teachers' Perceptions of Artificial Intelligence in the Classroom

Shannon Goodwin
James Madison University

Amanda G. Sawyer
James Madison University

We conducted an online survey to analyze how teachers view and use Artificial Intelligence (AI) tools to answer the following research questions: 1. What are teachers' perceptions of AI? 2. What are the characteristics of the teachers using AI in the classroom? 3. How often are teachers using AI in the classroom? 4. How are teachers using AI in the classroom?

Keywords: Artificial Intelligence, Teacher Perception, Curriculum Development

Artificial Intelligence (AI) is "a machine-based system that can, for a given set of human-defined objectives, make predictions, recommendations or decisions influencing real or virtual environments" (US Department of State, 2023, p. 21). According to the US Department of Education, AI is a problem because it can show discrimination and bias in its answers. It is often not helpful when giving answers because it is not human (2023). However, individuals still use it for teaching and suggest its use in the field, with some preservice teachers even considering "It's (AI) like a calculator for math resources" (Sawyer, 2024, p. 20). Yet, the field does not know how teachers perceive AI and how often they use it in their classrooms. Thus, we conducted an online survey to analyze how teachers view and use AI.

We distributed the online survey through a link on Instagram and X, using hashtags such as #eledteachers, #teachersandai, #teachersofX, #teachers, #AI, and #lessonplanning. From the survey, we gained 40 participants from 10 different US states. We analyzed the data using a grounded theory approach (Tie et al., 2019) using thematic analysis (Gibbs, 2007).

Findings

Teachers viewed AI as being able to create some activities. Still, the data stated that 84 % of participants said it needed editing, with only 16% stating it could use editing to create meaningful materials. Of the teachers who use AI, younger teachers are more likely to use AI than older teachers. The teachers identified using AI of any kind, on average, monthly. The participants identified that there are many ways that they are using AI in the classroom. For example, one teacher said they use it when creating multiple-choice tests and answer keys. In another instance in our survey, a teacher also said they use AI to give them ideas for what to write for discussion posts and/or assignments.

The data indicates that younger teachers use AI in the classroom. Thus, they must be trained in their preservice years to be critical of this new technology tool. Another important finding is that everyone believed that AI needed to be edited for the classroom; thus, individuals are already skeptical about using the tools. Mathematics Teacher Educators (MTEs) should use the young teacher's skepticism by providing examples of inaccurate mathematics and inappropriate responses by AI tools like Sawyer and Aga's (2024) paper, "Counterexample to Demonstrate Artificial Intelligence Chatbot's Lack of Knowledge in the Mathematics Classroom". If younger teachers are not educated on AI's abilities, they may end up using it in a way that could harm students. The data demonstrates that MTEs must take responsibility for supporting this vulnerable population.

How Undergraduate STEM Students With Math Anxiety Persist Through Their Academic Careers

Margarette Grace Bajar
California State Polytechnic University, Pomona

Keywords: math anxiety, achievement, calculus, strategies

Background and Motivation

Math anxiety is one of the main reasons that students avoid majors that would require them to take math classes in the process (Ashcraft & Moore, 2009; Dowker et al, 2016). Lee (2009) has found that there are high achievers in math who are also highly math anxious. The antecedents of math anxiety were investigated by Luttenberger et al (2018) in which they have found that significant people in students' lives, such as teachers, can affect students' development of math anxiety. A qualitative study by Quan-Lorey (2017) found that teachers, self-imposed pressures, and bad grades are some of the roots of math anxiety. A motivation of this study is due to the observation that, despite there being numerous studies surrounding math anxiety, most of the studies are with non-STEM college students. Some participants of this study have expressed the need to address math anxiety experienced by STEM majors due to the necessity of math in their respective majors. This study highlights that math anxiety also impacts STEM majors, and what they do to navigate their college careers while persisting through their math anxiety. In this study, I seek to answer the following research questions: (1) What factors affect undergraduate STEM students' math anxiety in college? (2) What strategies are utilized by high achieving students to help them succeed despite their math anxiety? (3) What motivations do students possess to continuing in pursuing their STEM majors despite having math anxiety?

Methods

This qualitative study included 10 STEM students experiencing math anxiety that volunteered to participate. The participants are currently taking Calculus II, given most students in Calculus II are STEM majors and the target demographic. The study was conducted through semi-structured interviews where participants were asked about their earliest experience of math anxiety. From there, participants were asked how they have been navigating their academic career within their respective STEM major given their math anxiety. Furthermore, participants were asked about study and learning strategies they have implemented to help cope with their math anxiety. Aside from how they combat their math anxiety, a key factor that was investigated further was the students' motivations and why they remained in the STEM academia despite their math anxiety. The goal is in knowing how they tackle it and what motivates them to do so will allow future educators and students to be aware of and minimize their math anxiety.

Results

In this poster report, I present evidence that all of the participants have unique experiences with math and the development of their math anxiety. Most of the roots of their math anxiety are aligned with the previously mentioned findings of Quan-Lorey (2017) and Luttenberger et al (2018). As they traverse through college, they find that the levels of their math anxiety vary depending on their teachers and the difficulty of the class. When participants were asked about their motivation in pursuing/persisting through their math anxiety, a couple of themes arose. One of which is the job security that comes with the STEM major that they chose. The other is their innate passion and determination to change the future for the better. I will also discuss in this poster different strategies students implement to manage their math anxiety.

A Cross-Disciplinary Approach to Supporting Mathematically Underprepared First-Year STEM Students

Evelyn Lopez-Parciak
Montclair State University

Amy Daniel
Montclair State University

Keywords: college student mental health, STEM, introductory mathematics courses

Many first-year students intending to earn a degree in a science, technology, engineering, and mathematics (STEM) field begin their studies with inadequate mathematical preparation (ACTA, 2019). These STEM majors are also at a high risk of developing mental health issues due to the stress-inducing nature of their coursework and are less likely than their non-STEM counterparts to seek counseling services (Kalkbrenner et al., 2022). In fact, a third of STEM majors who abandon their degree plans report having struggled "with depression, high levels of stress, chronic anxiety, overwhelm, feelings of guilt, regret, shame, and self-blame" (Holland et al., 2019, p. 330). In response to these issues, the Mathematics and Counseling departments at Montclair State University (MSU) collaborated to integrate counseling services into a unique new introductory mathematics course, Approaches to College Mathematics (ACM).

The MSU Mathematics department developed the ACM course as a prerequisite for students whose placement exam scores indicate they are not ready to take Precalculus. In the past, nearly all first-year MSU STEM majors were placed into Precalculus, which had DFW rates that were sometimes as high as 48%. The content of ACM was therefore chosen to focus on mathematical skills necessary for success in Precalculus (e.g., solving linear and quadratic equations). The ACM developers were cognizant that traditional remedial mathematics courses often have negative impacts on students (Cohen & Kelly, 2020; Larnell, 2016), so they were committed to designing a course that would engage students with course content in a new way, and would help them develop other academic skills required for success in tertiary STEM coursework. The ACM developers created an extensive repository of in-class activities designed to leverage research-based pedagogies, such as engaging students in collaborative learning (Liljedahl, 2020) and situating course concepts in meaningful real-world contexts (Bernacki & Walkington, 2018). They also developed a list of "growth objectives" for the course that were interwoven into class assignments and activities, such as *budgeting time and prioritizing*, *studying effectively*, *learning from mistakes*, and *navigating resources*. Our poster will include examples of the ACM learning activities and how the growth objectives are integrated into coursework.

The MSU Counseling Department provided the ACM program with an experienced counselor to offer counseling services to struggling ACM students, usually identified by their instructors. Students choosing to utilize the counseling resource meet with the counselor through virtual or in-person therapeutic interactions, where the counselor provides support in a safe space where students can discuss the challenges they are facing. Additionally, the counselor visits classrooms at the request of ACM instructors to give presentations and lead classroom discussions about various mental health issues students may be facing. The ACM team is in the early stages of collecting data on students' pre- and post-semester attitudes towards mathematics, their feedback on the course, and the percentage of students utilizing the counseling services. We will also be collecting longitudinal data on their successes and challenges in Precalculus. Some of this data will be available by the time of the conference and will be shared in the poster. This work aims to generate and contribute to conversations about how educators can support mathematically underprepared STEM majors experiencing anxiety and stress in math.

Choices You Make Should Matter: Asynchronous Discovery Activities

Darryl Chamberlain Jr.
Embry-Riddle Aeronautical University – Worldwide

Keywords: Activity Theory, Asynchronous Activities, Digital Applet

In a live undergraduate classroom, the instructor and other students can provide dynamic responses to anticipated and unanticipated student actions. This study investigates the need for theoretically-sound development of math activities where a computer might also provide dynamic responses to anticipated student actions. This poster addresses the following research question: How can sociocultural and cognitive points of conflict be used to develop asynchronous discovery-based activities?

Theoretical Framework – Activity Theory

Activity Theory is a sociocultural theory that attempts to describe the coupling of consciousness and activity, where consciousness is the product of an individual's interactions with people and artifacts in the context of everyday practical activity (Kaptelinin & Nardi, 2009). In Activity Theory, points of conflicts (referred to as *contradictions*) act as opportunities for development. They mark key actions a student would need to make similar to how introducing cognitive dissonance provides an opportunity for concept development (Cooper, 2019) in constructivist theories. By blending Activity Theory with a constructivist lens for a particular mathematical concept, a discovery-based activity can be theoretically-sound by constructing a series of anticipated actions and reactions. This is similar to how a "Choose Your Own Adventure" story has points where the reader chooses an action (go in the left door) and the book provides a reaction (turn to page 105). An overview of key actions for the developed and studied dynamic activity included in a College Algebra course is presented in Figure 1.

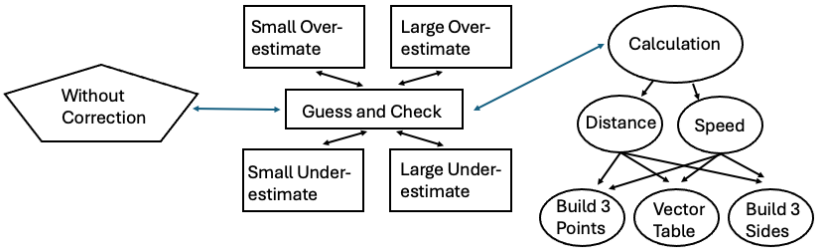

Figure 1: *Graph flow of dynamic activity, with each shape representing a series of prompts and arrows between shapes represent reactions to students' key actions.*

Methodology and Results

Undergraduate student responses to a static and dynamic version of this activity were coded for key actions they presented using either Activity Theory (sociocultural actions) or thematic analysis (cognitive actions). Three new sociocultural actions and one new series of cognitive actions were identified in student responses with the dynamic version of the activity.

Conclusions and Next Steps

Overall, the dynamic activity reflected common methods students used to solve the task. A future study will track every interaction students make with the task.

The "Wicked" Challenge of Improving Education Outcomes

Natasha M. Speer
The University of Maine

Keywords: Wicked problems, change theory

There are certain types of challenges that are so complex, so heavily influenced by social forces and so enduring that scholars have labeled them "wicked" (Head, 2019; Ritchey, 2013). Examples of wicked challenges include addressing homelessness, reducing poverty, or mitigating climate change. It is difficult to make progress on these challenges because of the ever-changing influences they are subject to along with the differing views humans may have about their causes and about the nature of both the challenge and what a solution might look like. Such problems stand in contrast to "tame" problems where the conditions are known (and stable), where solutions to similar problems can serve as models, and where most (if not all) people would agree on criteria for knowing when a solution has been found. Most mathematics problems are "tame;" most mathematics education ones are "wicked."

Improvement of education outcomes often makes its way onto lists of wicked problems, owing to the complex, intertwined influences on teaching and learning, as well as the diverse views and priorities possessed by the large set of stakeholders involved. Members of the RUME community have generated findings that give powerful insights into how students think about and learn many ideas in the undergraduate curriculum. Findings have also revealed what instructors do when creating rich, equitable learning opportunities for students, as well as what instructors need to know and be able to do to create those opportunities. Despite these many contributions to theory and to practice, a challenge we continue to face is achieving wide-spread utilization of findings from RUME in how learning opportunities are designed and implemented. If our challenges were "tame," the history of RUME's role in mathematics education might look quite different, with clear recipes for how research directly shapes practice.

Our challenge fits the definition of a "wicked problem." Often roots or histories of wicked problems are complex and tangled (Camillus, 2008). Such problems are described differently by various stakeholders (Ritchey, 2013). As progress is made, what remains to be worked on shifts, and the wicked problem "changes with every attempt to address it" (Camillus, 2008). "Solutions are temporary, as issues keep morphing into new problems." (Manville, 2016, p. 4). And of immense importance: wicked problems are never completely solved. The very best one can hope for is continual improvement in addressing the issue (Schmida, 2020).

In the 50 years since the term "wicked" was first used to characterize problems and challenges (Rittel & Webber, 1973) a great deal of theory-focused and practice-focused work has occurred. These developments in areas such as public policy and business have helped others learn to make progress. I contend that viewing some challenges in RUME as "wicked" could enhance our capacity to both understand and to make progress on those challenges.

This poster presentation offers a tour of characteristics of wicked problems as seen in scholarship from variety of fields. These characteristics are mapped to features of challenges from the RUME community to provide insights into the nature of those challenges and to leverage what others have learned. This analysis is used to support the claim that there may be significant benefits to our community if we learn how to see some of our challenges as wicked and design our approaches to them with that view in mind.

What Might We Learn About Leadership From Those Outside of RUME?

Natasha M. Speer
The University of Maine

Keywords: Leadership practices, wicked problems, change theory

Improving the teaching and learning of undergraduate mathematics shares many features with other substantial challenges society faces. Those other challenges include addressing climate change, reducing poverty, and others things that have been described as "wicked problems" (Head, 2019; Ritchey, 2013). These kinds of challenges are complex, subject to the ever-changing influences of society, and often viewed or defined differently by the (often numerous) groups of stakeholders. As a result, wicked problems can never be definitively "solved" and instead the goal is making progress in addressing the issues (Schmida, 2020).

Some scholars from non-education sectors have found that progress on wicked problems can be enhanced with use of particular types of leadership (Manville, 2016). These leadership practices reflect what is known about the nature of wicked problems and the approaches that supported groups to make progress on such problems. Given that one objective of the RUME community is to positively influence the teaching and learning of undergraduate mathematics, and given the wickedness of that challenge, we might want to consider what we could learn from those who have provided some insights into leadership for wicked challenges.

Recommendations include ensuring representation and authentic engagement from all stakeholder groups. It can be tempting to involve only a small group in your efforts but we are cautioned that "Those left out won't contribute their valuable knowledge, and may even sabotage the solution" (Manville, 2016, p. 5). Work in RUME includes examples of projects where collaboration between those with research expertise and those with practice-based expertise has generated powerful outcomes. For such collaborations to be of value, there must be trust among those working on the challenge. Thus building (and sustaining) trust needs to be a priority, followed by facilitating the group to some (perhaps short-term) successes to enhance trust and build capacity to take on more difficult aspects of the challenge. Those who work on challenges with long histories (e.g., enhancing equitable access to learning opportunities, designing effective professional learning for instructors) are well-aware of the ever-shifting nature of these wicked problems. Progress takes time and therefore building "on-going, adaptive learning into the process" (Manville, 2016, p. 8) is key. Data-informed processes of the sort found in design experiments and other forms of research can help build "sustainable capacity for inquiry and adaptation in light of new information and issues that inevitably arise" (Manville, 2016, p. 8).

Some of these leadership practices are evident in our change efforts. Others may not yet be part of how RUME leaders have approached our various challenges. This poster illustrates what implementation of leadership practices for wicked problems can entail in undergraduate teaching and learning change efforts. To understand the utility of these practices, the community could undertake several types of research. A meta-analysis of studies of change efforts could reveal which of the leadership practices have been utilized and to what effect. Those findings could then inform studies of new efforts to build leadership capacity and skill in key practices so those could be examined explicitly in various change efforts taken up by our community.

Participants in the poster session will be invited to share their experiences with these leadership practices and contribute to draft ideas for research studies designed to investigate the ways such practices shape change efforts in undergraduate mathematics education.

Considering Emotions in Undergraduate Mathematics Education

Lauren Janda
Arizona State University

Naneh Apkarian
Arizona State University

Keywords: emotional intelligence, mathematical affect, social emotional learning, mathematical intimacy

This poster aims to motivate the consideration of emotions in undergraduate mathematics education. An underexplored area of undergraduate mathematics education is the role of emotional intelligence and the related concept of social emotional learning. Emotional intelligence is a subcategory of social intelligence consisting of three competencies: recognizing and expressing emotions accurately, regulating emotions in oneself and others, and utilizing emotions to problem solve (Salovey & Mayer, 1990). This poster will review constructs such as affect, emotional intelligence, social emotional learning, and mathematical intimacy and connect these constructs to undergraduate mathematics education. In particular, these constructs can be leveraged to improve communication and reduce the impact of frustration in collaborative classrooms.

Emotions are part of mathematical affect but are understudied in undergraduate contexts as compared to other components of the affective domain, such as attitudes and beliefs (McLeod, 1992). One reason for this is that emotions are fleeting, making their study challenging (Leder & Grootenboer, 2005), although the role of emotion has been studied in other educational contexts. For example, secondary school students with emotionally intelligent skills perform better academically (Sánchez-Álvarez et al., 2020); in a high school mathematics classroom where active learning practices were implemented, Ilyas and colleagues concluded that emotional intelligence was productive for the students' learning, indicated by increased responsibility, increased focus, and skillful communication (Ilyas et al., 2018). In light of the calls for undergraduate mathematics classes to become more collaborative, I hypothesize that research focused on emotions could be beneficial to students' academic success at the undergraduate level. For example, in courses which employ inquiry oriented instruction (IOI). One of the four pillars for inquiry based mathematics education is "student collaboration for sensemaking" (Laursen & Rasmussen, 2019). The expectation of inquiry oriented classrooms is that students are sharing their thoughts to make more sense of the material (Kuster et al., 2017).

Emotional responses are also an important aspect of an individual's mathematical problem-solving process (Carlson & Bloom, 2005). Studies have documented that confronting a challenging mathematics problem can make one feel vulnerable, sometimes leading to avoidance of the subject altogether (e.g. Haase et al., 2019; DeBellis, 1998; DeBellis & Goldin, 1999). Researchers have coined terms like "math anxiety" to denote the unique, negative responses mathematics causes for some students (Ashcraft, 2002). *Mathematical intimacy* describes a relationship between internally represented mathematics and its potential connection to that student's value or sense of self. Mathematical intimacy has the potential to bring positive outcomes, but the effects of intimate betrayal can be drastic, such as if a student decides to engage and struggle through a problem but consistently gets it incorrect. There is a vulnerability associated with mathematical intimacy, so experiencing a betrayal can lead someone to develop a negative sense of self (DeBellis & Goldin, 1999). This poster will show how research exploring ways of encouraging and preserving mathematical intimacy and preventing betrayals can support increased student success and persistence in STEM.

A Feminist Approach to Mathematical Modeling: Using Data Feminism for Task Design

Lily Roth
Utah State University

Sindura Kularajan
Utah State University

Keywords: mathematical modeling, feminism, task design

Feminist pedagogy allows for connecting "to our roots, our past, and to envision the future" (Shrewsbury, 1987, p. 6). By recognizing individuals as unique contributors within the social, cultural, and intellectual contexts, feminist pedagogy helps motivate students to learn about themselves and the diverse experiences of others (Torres, 2014). Feminism in education may involve exploration of social-justice issues (e.g. Louie et al., 2022, Gutstein, 2003) or integration of feminist theories into classroom norms (e.g. Abrahamson et al., 2020, Raven, 2014). One relevant feminist perspective is Data Feminism (D'Ignazio & Klein, 2020). The framework provides a way of thinking about data science and data ethics through considering seven core principles: examine power, challenge power, elevate emotion and embodiment, rethink binaries and hierarchies, embrace pluralism, consider context, and make labor visible (p. 17-18). Despite the invaluable nature of feminist pedagogy, the intersection of feminism and mathematics has rarely been crossed (Damarin, 2008), prompting the question: *How can feminism be incorporated into mathematics education?*

Mathematical modeling (MM) offers a viable avenue for including feminism. First, as modeling "uses mathematics to represent, analyze, make predictions" about real world phenomena (GAIMME, p. 8), students can draw on their funds of knowledge and experiences (Moll et al., 1992). This approach aligns with feminist ideal of positioning the scientist within the study (Rubel et al. 2022), enabling students to integrate new learning while modifying past understandings (Shrewsbury, 1987). Second, scholars have found that students have high interest and enjoyment with little boredom when solving real-world problems (e.g., Hartman & Schukajlow, 2021). Thus, modeling has the capacity to engage students emotionally, echoing D' I'ganzio and Klein's (2020) assertion that data is neither neutral nor objective but should instead embrace "the knowledge that comes from people as living, feeling bodies in the world" (pg. 73). Prior research has incorporated students' lived experiences (e.g., Toor & Mgombelo, 2016), emotion (e.g., Azevedo et al., 2017), and embodiment (e.g., Sinha & Malhotra, 2022) in STEM education; but more work can be done in including feminism to mathematics. Specifically, there remains a gap in understanding how Data Feminism can be integrated into MM curricula. This study will employ Data Feminism principles as a heuristic to (a) design two MM tasks and (b) discuss why the tasks are characterized as "feminist modeling." The question guiding this research is *How can feminism be incorporated into the design of mathematical modeling task?*

Our task design intentionally integrates compatible theoretical frameworks, such as the MM process diagram (e.g., Anhalt et al., 2018), Data Feminism (D' Ignazio & Klein, 2020), and Rubel et al.'s (2022) re-envisioning problem contexts. These frameworks will guide the selection of appropriate context for the tasks (e.g., personal, occupational, societal, and scientific). Tasks will be outlined and compared with "non-feminist" modeling tasks and assessed for their potential in engaging students beyond just the mathematics (e.g. personal experiences, social justice). Through highlighting Data Feminism as a design framework, we stand to help educators create an environment where students are not only equipped to "read the world with mathematics" (Gutstein, 2003, p. 44) but also to develop "mathematical power" (Gutstein, 2003, p. 45). Additionally, this study could influence how modeling tasks are designed and executed.

How One Graduate Teaching Assistant Restructured a Course on Teaching Undergraduate Research

Joseph Starr
University of Iowa

Lori Adams
University of Iowa

Keywords: GTA development, Ungrading, Gradual release, backward design

Expectations that undergraduate students have engaged in research activities before applying to graduate school are becoming more common. Notably lacking from these expectations is the training of those undergraduate students' instructional and communication skills. The development of these skills is critical for producing a well-rounded undergraduate student who will be a successful graduate student. The Iowa Sciences Academy is part of The University of Iowa, our mission is to support the success of undergraduate students interested in research and scientific communication. In furtherance of that mission the course t*eaching your undergraduate research* has been on offer for around five years and is based on the prior work of Hoffmann and Lenoch (Hoffmann & Lenoch, 2013). The course's established goal is to provide experience in instructional design and implementation to undergraduates whose intention is to continue to graduate school. This poster describes a course redesign which focused on implementing a gradual release of responsibility model (Fisher & Frey, 2013) with ungrading assessments (Stommel, 2023) and was carried out by a Graduate Teaching Assistant (GTA).

For the redesign, the following goals were established:

1. Students can engage in teaching as a structured activity.
2. Students are confident to go rogue in their own learning.
3. Students acknowledge that failure breeds success.

Using qualitative methods, we gathered evidence for how the undergraduate students in one course section (n=7) met these three goals. Course discussions and presentations, student created artifacts, regular instructor touchpoints, and peer feedback from multiple teaching sessions all provided rich examples of students working toward these goals. Our preliminary analysis provides an overview of the ways undergraduate students met these three goals. Goal one was met in the creation of a teaching portfolio documenting student, most students selecting the instructor modeled backward design paradigm (Wiggins & McTighe, 2008). Student feedback during touchpoints indicates an increase apperception for the intricacies of instruction as well as increased confidence in students' self-identification as an instructor. Goal two seemed to be more challenging for all the students possibly because their previous success in school was contingent upon their following the rules, where going rogue was likely to have negative effects to their grades. Goal three is seen in the students own retrospective analysis. Students acknowledge failures in their teaching and improvement strategies for their materials. Ungrading, moving assessment from a rubric evaluating teaching to the conversations on the act of preparation seems to have allowed for students to decouple the failure of an aspect of their preparation from the students' failure in the course.

Overall, the gradual release and ungrading models were successful for this small group of undergraduates. Extending these ideas to other course sections would provide additional broader data that would help us disaggregate data across several subgroups of students. We will continue using these instructional strategies and look for others that will help support our three goals.

Using Provided Guided Notes in Coordinated First-Year College Mathematics Courses

Jennifer Huber
The University of Texas at Arlington

Theresa Jorgensen
The University of Texas at Arlington

Keywords: coordinated courses; guided notes; post-secondary mathematics

Lecture-based instruction prevails as the primary pedagogical approach used to teach undergraduate proof-based courses; thus, mathematics education researchers should investigate ways to improve the lecture rather than replace lectures (Melhuish et al., 2022). Course coordination has been successfully implemented in mathematics programs to standardize student experience (Regier et al., 2024), to meet legislative needs (Jensen-Vallin, 2013), and to shift the pedagogical approach across multiple sections of the same course (Golnabi et al., 2020; Rahman et al., 2021). Alternatively, at the individual level, instructors and students have observed positive impacts of the use of guided notes during classroom lecture (Cardetti et al., 2010; Krapf and Pfefforkorn, 2022). As the pedagogy of mathematics education evolves, universities are encountering the overlap of course coordination with the use of guided notes.

The goal of our study is to examine the use of guided notes in coordinated courses. Specifically, for the coordinated courses considered in this study, the guided notes were created by a current/former coordinator of the course and not by the instructor. This study will investigate the research question, "What is the impact of coordinated guided notes (not co-created) in a post-secondary mathematics course from both the perspective of instructor pedagogical choices and student behaviors and expectations?"

Methodology

The study will focus on first-year undergraduate mathematics courses at a public R1 university in the U.S. We will pilot the study with multiple sections of a coordinated course in Spring 2025 and plan to expand the study to gather data on additional coordinated courses in Fall 2025. The goal of the poster will be to outline the methodology and seek feedback.

To understand the coordination expected of the instructors in our study, we first will interview the course coordinators to determine what curricular materials are provided and how instructors are expected to use the provided materials. Then, we will ask the instructors about their plans to use provided guided notes while teaching their course and survey their Mathematics Teacher Self-Efficacy (Zuya et al. 2016). During the semester in which they are teaching the coordinated course, we will host group interviews of the instructors to discuss their classroom approach, focusing on their use of guided notes and their math teacher self-efficacy. Each of these components will provide insight on how and why the post-secondary math instructors use guided notes in lectures. We will investigate the degree to which instructors incorporate their mathematical insight in their lectures.

Additionally, we will observe class meetings that cover common mathematical content to assess student engagement in coordinated courses with guided notes. After the observed class meetings, the researchers will gather student note-taking artifacts to document how students record formal and informal mathematics. A questionnaire will be shared with students to obtain their perception and expectation of utilizing guided notes in the class lectures. These components will focus on the students' behaviors and expectations. Compiling the various resources will delineate the instructor-student interaction to determine how the student and instructor expectations align.

Development and Preliminary Validation of Enrolment in Engineering and Robotic Sensing Scale (EERSS)

Christopher A. Ocheni
University of Alabama

Nigar Altindis
University of Alabama

Sevgi Zubeyde Gurbuz
University of Alabama

Chris S. Crawford
University of Alabama

This study addressed the persistent gender disparity in STEM fields, particularly in engineering and robotics, by developing a survey instrument, "Enrolment in Engineering and Robotics Sensing Scale (EERSS)." The results of the study demonstrated good psychometric properties for the EERS scale, supporting the interpretation and use of the scale for understanding and measuring factors that influence the participation of female students in STEM fields.

Keywords: Engineering, Robotics, STEM, Gender Enrolment, Psychometrics, Scale development

STEM education makes learning real by allowing students to see the connections between the content they are studying and the application of that content in relevant ways (NSTA, 2024). At the K-12 levels, the involvement of boys and girls is integral in promoting STEM education (Merayo & Ayso, 2023). Despite ongoing efforts to ensure gender inclusivity in STEM education, the enrollment of girls in engineering and robotics remains disproportionately low compared to their male counterparts (Merayo & Ayuso, 2023). Studies have highlighted various factors and barriers, including lack of exposure, students' interest, motivation, self-efficacy (Msambwa et al., 2024), perception of STEM, and role model influence (Dasgupta & Stout, 2014). Other barriers include gender stereotypes (Cheryan et al., 2017), inadequate support systems, confidence in STEM, engagement, educational policies, attitudes, and pedagogy (Ibanez, 2022; Van der Hurk et al., 2019).

Research suggests that fostering interest and confidence, ensuring a compelling and inclusive school vision, etc., in STEM subjects like engineering through early interventions can significantly increase the likelihood of pursuing engineering-related careers, especially for girls (Ibanze, 2022; Wang et al., 2023). These factors, which influence the decision of students to enroll in STEM careers, especially engineering and robotics, need to be precisely measured and understood through evidence-based strategies. Thus, the study developed and validated a survey instrument (Enrolment in Engineering and Robotic Sensing Scale-EERSS), to identify these factors that could influence females' enrolment in engineering and robotics careers. The study addressed the research question: What are the psychometric properties of EERSS?

This paper reported on several stages of survey development, such as item generation, expert validation, and pilot testing. The scale has a demographic section addressing students' grade level, gender, race, and language and engineering. The generated items were reviewed by subject experts to ensure the content and face validity of the scale. A pilot study was then conducted on a sample of 96 secondary school students to refine the instrument through exploratory factor analysis (EFA) and reliability testing. The study used the Partial Credit Model (PCM) to evaluate the psychometric properties of the EERS scale. The results all showed acceptable fit indices for the EERS scale. These findings presented empirical evidence that supports the interpretation and use of EERS scale in the measurement of students' enrolment in engineering and robotic sensing discipline.

Exploring Impact of Task on Mathematical Sensemaking in Undergraduate Biology

Anita Schuchardt
University of Minnesota – Twin Cities

Desi
Sriwijaya University

Keywords: mathematical sensemaking, biology, task

Mathematical equations are a key part of undergraduate biology instruction (Cohen, 2004). While biology is often perceived as the refuge of the math averse (Steen, 2010), students in biology classes have mathematical resources they can use to make sense of mathematical equations (Schuchardt & Schunn, 2016). Sensemaking has been defined as using pre-existing knowledge or skills to figure out a problem (Martin & Kasmer, 2009; Odden & Russ, 2019). Five types of sensemaking in mathematics have been identified (Zhao & Schuchardt, 2021). Theoretically, the tasks students engage in could affect the types of sensemaking they use (Li & Schoenfeld, 2019). The effect of different tasks on students' use of mathematical sensemaking is underexplored. **RQs:** How do different tasks on mathematical equations in biology affect the types of mathematical sensemaking, and connections between types, discussed by students?

Incoming biology majors at a large R1 university participated in a session on mathematical modeling of population growth as part of a summer orientation program. Pairs of students were recorded as they engaged in a sequence of two mathematical tasks. The first task varied in different sessions, but the second task was always the same, modifying an equation from the first task. The first task was one of the following: DM) developing a mathematical equation, CM) comparing two mathematical equations, MR) describing relationships between variables in an equation, and PS) solving problems after being shown how to do so. Four to six recorded discussions for each task were coded by two independent coders for types of mathematical sensemaking and for connections between mathematical sensemaking types (Krippendorf's alpha= .78, .76). Counts were standardized for number of groups and time on task.

Students who engaged in PS in the first task tended to focus on how to perform the steps in the problem-solving process (Math-procedure sensemaking, 67% of instances) compared to students in the other tasks (DM=29%, CM=18%, MR=44%). Students in DM and CM tasks tended to focus on equation structure (Math-structure sensemaking, DM=57%, CM=62% vs. MR=17% and PS=6%). For all groups, the second Modify tasks were more similar in their sensemaking with frequency of Math-procedure sensemaking for all tasks ranging from 23% for CM to 40% for PS, and Math-structure frequency ranging from 37% for PS to 57% for CM.

Connections between mathematical sensemaking types may enhance student problem solving and understanding (Li & Schoenfeld, 2019). Across the first tasks, connections were low, ranging from 4 to 7 average instances per group. For the second task, Modify after CM averaged only 3 instances of connections per group while the other Modify tasks averaged from 12 (after PS) to 19 instances (after MR). Across the Modify DM and CM tasks, group discussion focused on connections between Math-procedure and Math-structure sensemaking and Math-structure and Math-relation sensemaking (relationships between variables). However, for Modify MR and PS tasks, these connections occurred less often and connections between Math-procedure and Math-relation occurred frequently (49%, 66% of connections respectively).

Results suggest an impact of task on type of sensemaking that students discuss and the connections they make, suggesting that for research and instruction, it is important to align task with intended objective. Qualitative analysis is underway to provide an explanation for observed differences in patterns by determining how students are using sensemaking in the tasks.

Connecting Mathematics and Social Justice Goals in Preservice Mathematics Teachers' Lesson Plans

Youngjun Kim
Montclair State University

Zareen Gul Aga
James Madison University

Su San Lim
Montclair State University

Keywords: Preservice mathematics teachers, Lesson plans, Teaching mathematics for social justice, Culturally responsive mathematics teaching

As students in K-12 classrooms in the U.S. become increasingly diverse, it is necessary to prepare preservice mathematics teachers (PSMTs) to consider their students' learning needs, understand the nature of achievement gaps, and foster the development of their mathematics identity (De Freitas, 2008; Dunn, 2005; Koestler, 2012; Register et al., 2022; White, 2002). Designing and implementing mathematics lessons based on equity-based mathematics teaching practices can help PSMTs support their culturally and linguistically diverse students (Moldavan & Gonzalez, 2023). In particular, researchers (Aguirre & Zavala, 2013; Gay, 2000; Ladson-Billings, 1995) underscore the importance of attending to students' funds of knowledge and teaching mathematics for social justice in order to promote academic prowess and equity for marginalized students. Thus, it is important to understand how PSMTs connect mathematics to social justice (SJ) goals when designing lessons. The research question that guides this study is: *How do preservice mathematics teachers connect mathematics and social justice goals when designing lesson plans?*

Aguirre and Zavala's (2013) theoretical and analytic framework – culturally responsive mathematics teaching (CRMT) – forms the basis of this study to investigate how PSMTs make connections between mathematics and SJ goals in their lesson plans. CRMT informs PSMTs by helping them understand equity-based teaching practices and how to effectively teach culturally, ethnically, linguistically, and socio-economically diverse students. Thus, CRMT is useful to analyze teacher practices in their lesson plans to see if these plans meet diverse students' learning needs.

In this study, we collected and analyzed a total of 41 lesson plans designed by PSMTs in a middle school methods course throughout five semesters (Fall 2021–Spring 2023). In the lesson plans, PSMTs were asked to include both mathematics and SJ goals. PSMTs were particularly asked to choose SJ standards in a framework for anti-bias education (Learning for Justice, 2022). By using open coding, we analyzed which mathematical topics and SJ standards are frequently used as well as the relationship between them.

As a result, we found that the three most frequent mathematical topics are graphs, rational numbers, and linear equations; and the most frequent SJ standard is Justice 12 (Students will recognize unfairness on the individual level and injustice at the systemic level). Our findings imply that graphs, rational numbers, and linear equations are useful to express and recognize social issues (e.g., unfairness and injustice). Supporting PSMTs in connecting mathematics to SJ goals can help them learn about social issues themselves and equip PSMTs to support their future students' learning of critical issues.

Acknowledgments

Assessment Design Promotes Peer Learning in a Calculus Course for Engineering Students

Thomas Gjesteland
University of Agder, Norway

Keywords: Peer learning; Assessment; Community of Practice; Student engagement

This study reports on how students experience peer learning in a first-year engineering mathematics course with portfolio assessment. The course has recently changed the assessment form from a high stake, closed book exam at the end of the semester, to a portfolio exam. An analysis of the traditional approach to teaching mathematics, with large lectures, problem solving sessions, and a high stake, closed book exam at the end of the semester, shows that students participate passively in their own learning (Zakariya et al., 2022). Students reports that they receive little feedback, and the course suffers a high failure rate (up to 40%). Several studies, such as Freeman et al. (2014) claims that students in STEM subjects perform better in classes with active learning methods compared to traditional lectures. Biggs et al. (2007) argue that all types of students will benefit from active learning methods. It is what activities the students do that is important for their learning. The term "active learning" can describe many learning activities. Here we will define peer learning as active learning. Peer learning is when students form study groups and work together with mutual engagement and shared responsibility for learning. We describe these groups using Community of Practice (CoP) framework from Wenger (1998).

This study analyzes data collected from the course's midterm evaluation, a standardized survey administered and anonymized by the university. The survey comprises 17 Likert-scale questions (5-point scale) and 4 open-ended questions. Of the 447 students enrolled in the course, 194 (43.4%) completed the survey. The analysis incorporates mixed approaches.

The course assessment consists of 4 digital tests and a written assignment. The digital tests were closed-book exams, utilized the STACK assessment tool (*STACK*, 2024) to generate randomized questions. Students could attempt each test up to four times, with their highest score contributing to their final grade. During these tests, students solved problems manually on paper and submitted answers digitally, receiving immediate feedback on correctness.

After the test we observe that students gathered in groups to discuss their solutions, suggesting that peer learning played a significant role in their preparation for subsequent attempts. On the 5-point Likert question "Academic collaboration among students (in groups or study circles) contributes to a good learning environment" 117 (60%) of the students answered, "Strongly agree" (5) and 59 (30%) students answered "agree" (4). While the course retains traditional instructional components, such as large lectures and problem-solving sessions, we suggest that the new assessment format foster peer learning. Students report frequently using the university's mathematics support center, further indicating a strong reliance on peer and institutional support networks. Peer learning is particularly valued for its contributions to understanding complex concepts, maintaining motivation, and building a collaborative learning culture. Observations suggest that students naturally form Communities of Practice because of the digital tests, using these interactions to enhance their learning outcomes.

"Trust me, I am an Expert!": Combinatorial Problem Solving and Thinking Processes in Researchers With High Mathematical Preparation

Luca Lamanna
University of Milan (Italy)

Laura Branchetti
University of Milan (Italy)

Keywords: Combinatorics, Problem Solving, Experts, Combinatorial Thinking

Combinatorics plays a key role in mathematics and its teaching: on the one hand, it represents a core in discrete mathematics while, on the other hand, in the school curriculum, it plays a role in the development of topics both in mathematics and in other disciplines (Batanero et al., 1994), offering students the opportunity to develop and train problem solving skills in an environment that does not rely on specific mathematical prerequisites (Kapur, 1970). In this sense, the research literature presents several studies that focus on the problem solving processes developed by students from elementary school (e.g., English, 1991) to university (e.g., Lockwood & Gibson, 2016). We note, however, that most of the research has focused on solvers without high combinatorial expertise. With our work, we propose a further step in the development of this line of research by focusing on combinatorial problem solving processes as developed by what we call experts, who in this work are to be considered as academics whose field of research and/or expertise is or includes combinatorics (e.g., statistics, probability, etc.).

Framing our research within Schoenfeld's model of problem solving (1985), the focus of our work is on analyzing the different phases that occur during the resolution of some combinatorial tasks, paying particular attention to the heuristics involved (based on the comprehensive description presented in Lamanna et al., 2022) and the dynamics that develop across the dimensions of combinatorial reasoning (formulas/expressions, set of outcomes, counting processes - Lockwood, 2013). We proposed an elementary task (i.e., solvable with a single application of a combinatorial formula) and a compound non-standard task (i.e., a task for which a closed direct solution formula does not exist) to observe how experts approach the two tasks and if/how they change and adapt their approaches between the two tasks. In summary, our research question is: Which heuristics and dimensions of combinatorial reasoning are involved by a group of experts when solving an elementary and a non-standard combinatorial task?

To answer our research question, we involved five experts in individual interviews in which they were proposed two combinatorial tasks to solve in a think-aloud process explaining each step of their reasoning. The results showed that in the case of the elementary task, experts tend to provide a solution that includes heuristics for direct counting of all configurations, thus involving only two of the three dimensions of combinatorial thinking and often skipping the problem solving phases of exploration of validation. On the other hand, when dealing with a non-standard task, experts rely on a broader set of heuristics (in particular involving enumerative processes), thus shifting the dynamics of their thinking towards the inclusion of all dimensions of Lockwood's model – which are often involved in the problem solving phases that were skipped in the solution of the elementary task. Comparing the two solving processes, we observe that while there are cases in which the experts seem to use efficient counting techniques, there are also situations in which they demonstrate an expertise that is built on a base that includes a variety of different heuristics – including enumerative processes that are often discouraged, especially in the case of high school combinatorics (Lamanna & Branchetti, 2024). We observe that the results of this work provide some key insights on the learning objectives that one should pursue to enhance a structured development of students' combinatorial thinking.

Qualitative Themes for Mathematics Capital: Investigations of Graduates with Dual Majors in Mathematics and Mathematics Education

Frances Anderson
University of Nebraska at Omaha

Karina Uhing
University of Nebraska at Omaha

Keywords: Mathematics Capital, Science Capital, Bourdieu, Undergraduate Mathematics

We previously defined mathematics capital as "mathematical assets that actively influence a student's capability or power in the field of mathematics education and how the student utilizes these assets to exert power in the field of mathematics education" (Anderson et al., 2024, p. 494) through quantitative work. Here, we aim to operationalize mathematics capital through qualitative work via thematic descriptions, as Bourdieu did in many of his works in capital (Bourdieu, 1977; Bourdieu & Wacquant, 1992). We answer the research question: *How can mathematics capital be qualitatively described?*

Using a Bourdieusian lens (Bourdieu, 1977; Bourdieu & Wacquant, 1992), we view the components of mathematics education as intertwined. Mathematics capital acts as a bridge between other constructs like social factors, cultural capital, emotions, personal experiences to mathematics education (Anderson, 2024, cf., Bourdieu, 1984). In past work, Archer and colleagues (2014, 2015) used a Bourdieusian lens (1977, 1984) to develop a three-part model for science capital. We aim to continue to extend Bourdieu's notion of capital into the field of mathematics education (Anderson et al., 2024, cf. Archer et al., 2014, 2015, Dewitt et al., 2016).

We conducted semi-structured interviews with six recent graduates receiving dual degrees in mathematics and mathematics education. Then, we performed qualitative analyses using a combination of deductive and inductive coding (Miles et al., 2014) where we developed three overarching themes for mathematics capital (through mutual coding consensus).

We take this thematic approach to redefine mathematics capital to deepen our understanding and to clearly communicate its impact on mathematics education. Theme names and summarized definitions for each are: (a) compounded mathematical achievements *(i.e., valued achievements in mathematics (formal and informal settings) altering responses to mathematics)* (b) productive disposition towards mathematics, *(i.e., a growth mindset, a positive, intrinsic relationship with mathematics, and belief that mathematics is meaningful)* and (c) expected mathematical achievements, *(i.e., expected mathematical success and a nonchalant disposition towards mathematics success*.

We developed three primary themes that characterize and describe mathematics capital. In these, we find appropriate amendments to redefine mathematics capital as "mathematical assets and expectations that influence a student's capacity and power in the field of mathematics education, and the disposition that a student assumes to utilize these mathematical assets and expectations and exert power in the field of mathematics education." In short, these themes help capture the essence of mathematics capital, which extends throughout a person's lifetime and influences how a person *interacts* with, *reacts* to, and *responds* to mathematics and their potential mathematical outcomes. These *interactions*, *reactions,* and *responses* can be intrinsic or extrinsic (i.e., what a person believes or how a person close to another may impose their beliefs on another) and have far reaching implications for mathematics learning.

Designing Games For Approaches To College Mathematics

Toni York
Montclair State University

Eileen Fernández
Montclair State University

Keywords: Card games, Incoming math students, Order of operations, Functions

With mathematics being a singular obstacle to college retention and degree attainment (Douglas & Salzman, 2019), it becomes especially important that students who struggle to place into first-year mathematics courses are provided a strong foundation. We are developing a new class entitled Approaches to College Mathematics (ACM) for students who failed to place into Precalculus. The course developers recognized that the complex system that contributed to these students' struggles wasn't working. We thus spent the summer developing a student-centered ACM and deliberately hired instructors with philosophies supporting the interwoven nature of conceptual and procedural understanding (NRC, 2001). We hoped that this contrast with widespread, teacher-centered, and strictly procedural approaches (Cohen & Mehta, 2017) would provide the missing connections needed to bolster these students' foundations for Precalculus.

Of the 820 students taking ACM and Precalculus, 333 placed into ACM. This poster focuses on 57 of those students. All these students experienced a pandemic in their freshman year of high school. Preliminary surveys indicate that 42 students are interested in Biology; 16 characterize mathematics in strictly negative terms ("stressful," "hard"), while 10 invoked both positive *and* negative attributes ("difficult, complicated, useful"). In their conceptions of a "math person," 21 students relayed attributes focused on intelligence ("someone who is smart"), while 15 recognized a math person's joy in doing mathematics ("enjoys the problem-solving process"). Survey responses indicate the challenge of connecting hard work (not innate intelligence) with mathematics learning, and the promise of playful experiences in enhancing that learning.

Mathematical play is a crucial part of learning and doing mathematics. Encouraging students to play with mathematical ideas can help them to extend their horizons, make their own conjectures and connections, and build their confidence in an environment where mistakes do not feel so threatening (Holton et al., 2001). As a structured form of play, games can be designed or modified to reflect mathematical structures and then used in undergraduate mathematics classrooms to support students in playing with those ideas (Naik, 2017). For example, Herman (2014) adapted Trivial Pursuit for use in mathematics classes for business majors. Students who played the modified game participated more in class discussions, seemed less afraid of asking questions, reported enjoyment, and showed improvement on test scores. Similarly, Galarza (2017) designed a new card game called Groups as a learning tool for undergraduates studying group theory. After playing Groups, students commented on its accessible and enjoyable format, its ability to offer insight into rich mathematics, its use as a learning tool for novices, and its use as both a learning and a review tool for experts. These examples highlight the potential of two different game design strategies: (1) modifying existing games to map mathematical ideas onto their existing rules and (2) designing entirely new games that reflect mathematical ideas.

In our poster we present two games we designed for ACM, one using each of these two strategies. Functionominoes is a modified dominoes game based on categories and features of functions, while the Order of Operations (OOPS) Game is a new card game about building and evaluating expressions. The poster will feature a synopsis of the value of games to math learning, a description of two ACM classes and students, an overview of our two game designs, examples of our students' work with our games, and links to our game printables and activity guides.

From Theory to Practice: Examining Pedagogical Development in Graduate Mathematics TA Seminars

Laurie Short
North Carolina State University

Logan Gray
University of North Carolina at Chapel Hill

Keywords: Graduate Mathematics Teaching Assistants, Teaching Assistant Training

Graduate mathematics teaching assistants (GMTAs) typically have a great deal of the responsibility for the instruction of undergraduates but often have little opportunity to explore teaching methods beyond those they have personally experienced or seen demonstrated by their faculty mentors (Speer, Gutmann, & Murphy, 2005). Most students arrive to their graduate programs with little to no teaching experience (Speer et al., 2005). With little formal training and limited guidance, GMTAs are expected to help undergraduates bridge the gap between high school and college-level mathematics while managing the heavy demands of their own graduate coursework (Belnap, 2005). This unique challenge highlights a need for structured and supportive TA preparation that will help GMTAs be successful teachers and graduate students.

Through this study, we aim to add to the knowledge of GMTA preparation by examining how one training seminar prepares GMTAs for their teaching responsibilities. We conducted a case study on a teaching seminar course for beginning GMTAs at a large, public, research university in the Southern United States. Our data collection methods included observations of the seminar, semi-structured interviews with the instructor and GMTAs, and document analysis of instructor observations of GMTAs and course materials, which were triangulated to ensure reliability (Stake, 1995). This study aimed to answer the overarching research question: *How does a graduate mathematics teaching seminar shape GMTAs' development as educators, and how does it compare to established TA training frameworks?*

This study was framed using an adapted version of Justice's (2020) framework for preparing GTAs to teach statistics. This framework emphasizes community-building, challenging teaching beliefs, and developing teaching knowledge. Selected for its STEM focus and alignment with the literature, the framework was modified to fit mathematics better and emphasize the importance of cultural understanding and inclusivity in teacher training (Felton-Koestler, 2020).

Analyzing our data through this lens, we found that the GMTA seminar provided opportunities for pedagogical growth through collaboration, approximations of practice, and technology training. The most valuable aspect, according to both GMTAs and the instructor, was the gradual shift toward legitimate peripheral participation. However, a significant challenge was the persistence of pre-existing beliefs, which limited the seminar's overall impact. GMTAs also expressed a desire for more informal spaces to discuss teaching, where they could share experiences, ask questions, and exchange advice. Additionally, some felt that the seminar's structure did not fully reflect the instructional strategies it aimed to promote, leading to frustration with the disconnect between its design and its goals. Addressing these concerns could strengthen the seminar's overall effectiveness.

The goal of our poster presentation is to engage RUME conference participants in discussing how we can support GMTAs in their dual roles as educators and students. The findings from this study have the potential to inform the (re)development of professional learning opportunities for incoming GMTAs and shape future research on how these professional learning opportunities impact GMTAs' development as educators.

Homework Resubmissions: What is the Impact on College Students' Exam Scores?

Emma Hakes
Brigham Young University

Dawn Teuscher
Brigham Young University

Keywords: College Algebra, Exam, Undergraduate Students

Homework is a debated issue in educational research. Many researchers have explored aspects of homework including: effort, amount, justification, and value (Núñez et al., 2014; Cooper et al., 2006; Xu, 2023; Fan et al., 2017; Epstein, 2023). This research aims to assess the different qualities of this common practice for both students and teachers. One area of homework research that currently contains few studies is homework resubmissions. Homework resubmissions have been researched in different disciplines, countries, and age groups (e. g. Zhu & Leung, 2012); this study addresses the gap in research on homework resubmissions and exam scores in undergraduate mathematics in the United States. In this study we address the research question: how are undergraduate College Algebra students' homework resubmission patterns influencing their exam scores?

Data Collection and Analysis

We collected 141 undergraduate College Algebra students' homework scores and exam scores during one semester. Each exam had a number of associated homeworks (HWs): four HWs for Exam 1, three HWs for Exam 2, three HWs for Exam 3, and all 12 HWs for the Final. For each exam, students' HW resubmission patterns were ranked into five groups. Two examples of rankings are as follows: (1) students who resubmitted their HWs and improved their scores were ranked above students who resubmitted and did not improve their score, (2) students who submitted their homework and received perfect scores were ranked above students who resubmitted and improved their HW scores. An ANOVA was conducted to compare students' HW resubmission patterns with their exam scores.

Results and Conclusions

We report here specific results from Exam 2. Two significant results were found from our analysis of students' HW resubmission patterns. First, there was a significant difference in exam scores among the HW resubmission patterns ($F(4, 136) = 12.394$, $p<0.001$). Tukey's HSD post hoc test results revealed that the students who resubmitted HWs earned exam scores that were not significantly lower (M=95.24, SD=4.07) compared to students who received perfect HW scores (M=96.35, SD=4.6). Second, Tukey's HSD post hoc test results revealed that students who did not submit or not resubmit their HW earned exam scores significantly lower (M=61.6, SD=15.59; M=76.94, SD=17.16) compared to students who resubmitted or received perfect scores (M=95.24, SD=4.07).

These results suggest that homework resubmissions are beneficial for student learning. The positive relationship between homework resubmissions patterns and exam scores supports the inclusion of homework resubmission in more undergraduate math classes. We hope our results inspire more research into homework resubmissions at the undergraduate level and more opportunities for students to learn content through the resubmission process.

Community College Mathematics Instructors' Conceptions of Equity

Nicholas Jacome
San Diego State University

Keywords: equity, community college instructors, professional development

Active learning has been shown to improve student success in STEM courses (e.g., Freeman et al., 2014; Theobold et al., 2020). However, research also shows how such instruction can have inequitable impacts on the student experience and subsequent success (Reinholz et al., 2022). Thus the implementation of active teaching practices needs to be grounded in equity. A goal of this project is to implement a professional development (PD) program for community college introductory mathematics instructors. As part of that work, three rounds of interviews were conducted with instructor participants at a Hispanic-Serving two-year college (11 in fall; 8 in spring). Instructors were asked about their conceptions of equity as related to teaching during these interviews. In this poster, I will share some common themes from four instructors' conceptions of equity and how those conceptions evolved over the course of a year while engaging in PD centered on active, equitable, and inclusive teaching.

Results

Table 1. Four teachers' initial views of equity, final views of equity, and equity goals.

Instructor	Initial Views	Final Views	Goals
Paul	Equity is providing the right amount of support to each person.	Inquiry can be leveraged to improve equity within a class.	Wants to transfer lessons about gender equity into racial or ethnic equity.
Stella	Considering and attending to individual needs	New Perception of student needs	None
Sandra	Providing many forms of support to increase meaningful engagement and a sense of belonging	Considers race and ethnicity as factors is participation and sees a need to be flexible	To close the achievement gap within her class and increase the passing rate
Sun	Provide students with the means to succeed based on their individual needs	Give females a stronger voice and make effort to gain insight into students	Create class environment for students to fully engage and feel welcomed

Instructors discussed various teacher moves to support these views and goals that included purposefully creating mixed demographic groups, increasing wait time, allowing for multiple forms of participation, and increasing access to resources.

Conclusion

With a better understanding of how instructors think about equity, the project team is better positioned to meet the instructors where they are in terms of equity-focused PD. We can strengthen the connection between equity and teaching practices, for example, like making the connection for Stella that wait time can be a useful tool for attending to equity. Lastly, we can celebrate small steps toward equity. Equity does not have to mean big changes at the start. Rather, progress towards achieving classroom equity can be an ongoing process.

Mathematics and Science Sensemaking While Developing Equations Representing the North Atlantic Current

Amber Armstrong
University of Minnesota

Keywords: Mathematical Models, Integrated STEM, Environmental Science

Global warming is often believed to be synonymous with climate change, a misconception which leads individuals to think that climate change entails that every region on Earth warms in a similar fashion (Renert, 2011). However, the North Atlantic Current, for instance, can slow due to rising temperatures and freshwater influxes from melting ice, limiting the flow of warmer water traveling to the polar regions (Stommel, 1961). With less warmer water traveling to polar regions, Earth's polar regions become even colder as the equatorial regions remain warm. Such dynamics of the North Atlantic Current can be represented with mathematical equations that carry scientific meaning. Thus, working with such mathematical equations provides opportunities to deepen students' understanding of mathematics and science.

I studied how college algebra students made sense of the mathematics and science behind a two-box system of the North Atlantic Current. This model accounts for how density differences, determined by the salinity level and temperature of the ocean water, affect the rate of flow of water between the polar and equatorial boxes of the two-box model. Typically, mathematical models representing these dynamics consist of a system of ordinary differential equations, which is typically learned after taking the college calculus series (Kaper & Engler, 2011). Instead, I made these concepts accessible to students who have not taken calculus by requiring students to use recursive equations, which primarily relied on their algebra knowledge.

I analyzed students' *sensemaking*—i.e., making meaning of new situations based on prior experiences and knowledge (Odden & Russ, 2019)—as they developed these equations over the course of three 75-minute class periods. More specifically, I coded instances of students' sensemaking from transcripts of student discourse as they worked on the mathematical model, according to the *Sci-Math Sensemaking Framework* (Zhao & Schuchardt, 2021). Preliminarily, I have found that students used a variety of mathematics and science sensemaking types to justify the choices they made in the mathematical structure of their equations. Students used science mechanisms such as heat transfer to justify the structure of equations, as well as making qualitative predictions to describe what they think will occur in the system over time and how this is reflected in their equations. Students also discussed mathematical concepts related to limits and changing rates of change. Overall, students made sense of mathematical relationships and concepts, alongside justifications from science, to translate the complexities of the North Atlantic Current into mathematical equations.

Students also reflected on the broader implications of their mathematical model in the real world. When considering the impacts of a slowed North Atlantic Current, students reflected on the multitude of significant impacts this would have on humans and other living organisms. Some students also recognized that models of the real world are imperfect and require assumptions and simplifications. Thus, not only did students make sense of the mathematics and science behind the mathematical model, but they also gained insight into the limitations of mathematical models, as well as a deeper understanding of the role of ocean circulation on Earth's climate, ecosystems, and society.

Mathematics Credit Loss Upon Transfer: The Need for Specific Research

Cory Wilson
Oklahoma State University

Katie Bjorkman
Richard Bland College

Ahsan Chowdhury
George Mason University

Keywords: community colleges, credit transfer, vertical transfer, gateway math

Introduction

Mathematics courses are often regarded as gatekeeper courses for not only STEM fields, but degree attainment in general (Kopparla, 2019). Entry-level or developmental mathematics courses in particular have high rates of repetition or failure across institutions (Fink et al., 2018; Schudde & Keisler, 2019; Zientek et al., 2020; Snead et al., 2022); in the case of students who begin at two-year institutions, this effect is more pronounced, as their mathematics courses must be transferred from the two-year institution to a four-year institution in order to earn their baccalaureate degree (Hodara et al., 2017). This type of transfer, called *vertical transfer*, has been the subject of limited study (Doyle, 2006; Bicak, 2023). We hypothesize that it is likely that losing credit for first- and second-year mathematics courses during vertical transfer is likely to have a similar effect on student outcomes as repeating a course for other reasons, and echo the call of Bicak and colleagues (2023) to urge that specific research on the vertical transfer of mathematics credit is needed.

Review

Vertical transfer of credit is the process by which a student completes work at a two-year institution and transfers to a four-year institution to complete their baccalaureate degree (Chase 2010). Among community college students, there are major inefficiencies in the credit transfer process; this is associated with delays in degree attainment (Doyle, 2006; Monaghan & Attewell, 2015), decrease in persistence to degree (Monaghan & Attewell, 2015; Hodara et al. 2017), and an increase in financial commitment to the degree (Fink et al., 2018; Sandoval-Lucero et al., 2024). Vertical transfer rate has been associated with successful completion of mathematics courses (Zhang 2019), and repetition of entry-level mathematics courses has been shown to be a contributor to attrition from STEM degrees or from higher education altogether (Kopparla, 2019; Bicak et al. 2023).

Academic study of vertical transfer tends to focus on snapshots of particular transfer programs at particular times and tend to measure success as the percentage of credits transferred for any kind of credit at the receiving institution (Doyle, 2006; Giani, 2019), due in part to limited data set availability (Giani, 2019). Credit loss is attributable to many things, including grade requirements, coursework content, program applicability, or state-by-state differences (GAO, 2017). A study done within the CUNY system found that approximately 47% of transfer students lost credits to vertical transfer, with an average of between 10 and 13 credits for each student (CUNY Office of Policy Research, 2022), while a similar study in Texas approximated that students lost approximately 12 credits upon transfer (Bicak et al., 2023). Monaghan and Attewell (2015) used national data to estimate that approximately a third of transferring students lost between 10% and 89% of credits upon transfer. Mathematics coursework, especially in entry-level courses, functions as a predictor of degree attainment and time to completion and excess credit accumulation (Fink et al., 2018; Schudde & Keisler, 2019; Bicak et al., 2023). Specific studies of the vertical transfer process for mathematics credits are necessary as a better understanding of the process will likely result in improvements of transfer student outcomes.

Department Culture and Math Graduate Teaching Assistant Professional Development: A Tale of Two Institutions

Mariah Gabriella Moschetti
San Diego State University

Blue Taylor
San Diego State University

Mary E. Pilgrim
San Diego State University

ELITE PD Research Group
EHR #2013590, 2013563, and 2013422

Keywords: graduate teaching assistants, professional development, departmental change

Mathematics Graduate Teaching Assistants (MGTAs) play a crucial role in undergraduate mathematics education, often providing instruction in smaller settings (e.g., recitation sections) where they can directly impact student learning and experiences (Selinski & Milbourne, 2015; Smith et al., 2021). While professional development (PD) is necessary to enhance MGTA teaching effectiveness, PD varies widely across institutions (Deshler et al., 2015).

As part of the larger ELITE PD program focused on MGTA PD in active learning, equity, and inclusion, we analyzed 11 interviews with department leaders (e.g., chairs, course coordinators, PD providers, etc.) from two participating institutions (Institutions Epsilon and Gamma) during the 2021-2022 academic year. Our goal was to investigate what supports or inhibits change when implementing the ELITE PD program. Using Reinholz and Apkarian's (2018) adaptation of Bolman and Deal's (2017) four frames (power, people, structures, and symbols) as a lens through which to examine each institution's culture, we identified five distinct areas (agenda setting and authority, autonomy and constraints, expertise and resources, collaboration and alliances, and institutional and departmental initiatives) that highlight the relationships between the frames within each department. For this poster, we focus on the relationships between the structural and symbolic frames, as symbols fundamentally influence how structures are implemented (Reinholz & Apkarian, 2018).

Our results revealed distinct approaches to MGTA development and involvement at the two institutions. Institution Epsilon emphasized symbols of teaching excellence and structured community, implementing hierarchical agenda setting through mandatory coordination meetings and PD focused on active learning, reflecting autonomy constraints. MGTAs participated in orientation, PD, and received support from experienced peer leaders, reflecting structured expertise and resource sharing. In contrast, Institution Gamma symbolic value of individual autonomy was reflected in informal coordination and optional coordination meeting attendance for MGTAs. While both symbolically valued active learning and equity, Institution Gamma's structures allowed more flexibility in their interpretation, positioning MGTAs as developing professionals through a required teaching and career readiness seminar. These contrasting approaches suggest different pathways for implementing the ELITE PD program. Understanding these institutional differences is crucial for effective PD implementation and fostering sustainable change. Future work will investigate how the ELITE PD program was taken up at each and its impact on MGTAs' teaching practices and institutional beliefs. A third institution in the ELITE PD program will also be included for further analysis and comparison.

Unnecessarily Hard: How Student Emotions, Course Components and Rigor Collide in Calculus

Kairi Black
Duke University

Victoria Akin
Duke University

Shira Viel
Duke University

Hannah Scanlon
Duke University

Rachel Tremaine
Loyola Marymount University

Nancy Kress
University of Colorado Boulder

Keywords: mathematical rigor, student emotions, calculus, case study, focus groups

Rigor is considered an important component of successful Calculus courses (Rasmussen et al., 2014). The authors provide a definition of rigor adapted from the Dana Center at UT Austin (2019): In a rigorous math classroom, students (a) use mathematical language to communicate their work with clarity and precision; (b) demonstrate that what they have done works within the appropriate context; (c) answer the question, "How do we know?"; and (d) apply their understanding to new contexts and situations. In addition, student emotions are connected to mathematical achievement (Pekrun et al., 2017). Confidence and anxiety play important roles in student success and persistence (Ellis et al. 2016; Barroso et al., 2021).

In this poster, we present a case study of Kappa University (KU), a private institution in the Southeastern United States. Our case study focuses on students' experiences of their introductory calculus courses, which they often describe as "unnecessarily hard." There may be a disparity at KU between what instructors and students perceive as necessary for student learning. An investigation of the interactions between student emotions, course components, and instructor conceptions of rigor could help instructors better support students in rigorous courses. We thus chose to investigate the question: How do classroom practices associated with the instructor ideal of rigor align with students' emotional experiences in introductory math at KU?

To perform this investigation, a team of faculty, undergraduates, and graduate students at KU formed a Networked Improvement Community (NIC) as part of a broader multi-institutional DEI initiative. NIC members conducted 4 hour-long focus groups of 5-8 students each (for a total of 26 student perspectives). All but one participant had taken a single-variable calculus course at KU. The questions asked included, "How did you experience the rigor or challenge of your course? Do you feel like you were challenged appropriately?"

We leveraged Braun et al.'s (2023) reflexive thematic analysis process, which began with open coding. Codes were collected into three categories: course components, student emotions, and rigor. While the method of data collection makes frequency analysis limited in scope, we studied the relative frequency of coincident codes. Preliminary analysis shows that, with access to sufficient resources, students can feel supported in working on challenging novel problems. For example, one student described, "*[KU] does give you harder problems, like harder versions of the same concept… and they don't necessarily give you exactly what you need to figure it out… I think that's intentional, so that you like, learn to figure it out, learn to be able to do a problem at that level, so that you could eventually do every and any problem… But I think, yeah, the fact that they have the help room there… made it definitely not as bad as I was expecting.*"

Digital Gestures in a Math Game

Marcus Wolfe
James Madison University

Keywords: Fractions, Video Games, Gestures, Gestures as Simulated Actions

Objective

Autumn Hostetter and Martha Alibali (2019) framework called *Gestures as Simulated Action* (GSA) suggests that people's cognitive processes trigger gestures. It does not yet account for digital interactions and environments. In 2011, Alibali et al. conducted research examining the role of limiting physical gestures on reasoning. When playing a game to develop math knowledge, players have a digital world and a controller that all play a role in the gesturing process. The primary research question of this poster is: How does inhibition in the digital space work when a player is reasoning in a game designed to improve fraction knowledge?

The brain is the intersection of reason, perception, and movement. Nemirovsky et al. (2012) asserted that the "understanding of mathematics is expressed in and constituted by perceptuo-motor activity, and learning of mathematical ideas is shaped in non-deterministic ways" (p. 288). Math is often understood as grounded metaphor (Lakoff & Nunez, 2000) Videogame levels can be grounded metaphors for participants to experience virtually to support their fraction knowledge development.

Methodology

This study took place at a large university located on the East Coast. The participants were four soon-to-be first-year students at the university who were enrolled in a remedial summer program. Students played Mario Maker 2 levels designed to evoke the actions in fraction number schemes. Students were asked replay the levels and to make connections between game levels and mathematical content of a fraction worksheet given that day. These replay interviews were transcribed using gesture-enhanced transcription methods. This study used a thematic analysis.

Results

There were three different categories of gestures that occurred. The most common types of gestures were with one hand on the controller using the other free hand to gesture and as a pointing device, and with no hands on the controller and gesturing with both hands. There was also one player who kept two hands on the controller and used the avatar to gesture within the game, including slowing down the avatar to focus on parts of the screen (displaying the game) and making the character jump/move as a pointing device. The controller affected student play and gestures.

The act of play and the digital gestures associated with making connections can be in conflict with one another. It appears that players who see the act of play as incompatible with the digital gestures of connection-making physically gesture outside of the game, whereas players who see the act of play as compatible with such gestures digitally gesture with the avatar. We need studies to highlight what exactly is the difference in connection strategies between digital avatar gestures and physical gestures. Designers of educational games need to actively consider the player avatar movement in their design.

Undergraduate Students' Conceptions of the Function of Mathematical Definitions in Proving

Rosina Andrews
Middle Tennessee State University

Amanda Lake Heath
University of Houston Downtown

Keywords: Proof, mathematical definitions, definition-function, meta-mathematical aspects

In mathematics education, researchers have attempted to elaborate on many meta-mathematical aspects of mathematical definitions by exploring novice and expert conceptions of the function of definitions in proving (Edwards & Ward, 2004, 2008; Gilboa et al., 2023; Parameswaran, 2010; Torkildsen et al., 2023; Zaslavsky & Shir, 2005). We define *students' conceptions of the function of mathematical definitions* in proving as the work a mathematical definition does for a student during proving (i.e. what a student uses or believes they can use a definition for during the proving process). While studies have suggested that novice provers (undergraduates) may have differing conceptions from expert provers (graduates or mathematicians) about the function of mathematical definitions in proving (Edwards & Ward, 2004; Zaslavsky & Shir, 2005), these studies are almost entirely observational, interpreted through the lens of the proof educator/researcher (Gilboa et al., 2023; Haj-Yahya et al., 2023; Tabach & Nachlieli, 2015). To date, there exists a paucity of research characterizing students' conceptions of the function of mathematical definitions in their own words: the language of the novice prover. In this project, we sought to answer the question: What conceptions do novice provers have about the function of definitions in mathematical proving?

Methods

This study was conducted in two introduction-to-proof (ITP) courses at two primarily undergraduate universities in the Eastern United States. Written reflection data were collected from a total of 26 undergraduate students enrolled in the ITP courses at two different points in the semester. Following in-class collaborative proving activities relating to logical equivalence and rational numbers, participants were prompted to write a response to, "What function did the mathematical definition for [topic] serve in your proof construction attempts?" Responses to this question were first open coded (Saldaña, 2016) and then open codes were sorted into thematic categories. Finally we deductively coded the data with these categories. All data were coded by both authors, and we discussed any disagreements until 100% consensus was met.

Findings

Through our deductive analysis we identified ten different conceptions that students held regarding the function of mathematical definitions in proving. The conception most frequently cited by participants (n=19, 73.1% of reflections) involved how definitions provided something operable within their proving. For example, Shawn wrote, "the definition was our cornerstone[...] it was about manipulating and applying them to form a coherent and sound proof." We will include a complete summary of the findings in our poster presentation, including examples of students' conceptions from each theme. Through improving the RUME community's knowledge of students' conceptions about the function of definitions in their proofs, this project can help proof instructors and researchers leverage students' conceptions into their development as authentic provers. During the poster session, we will solicit feedback for how to continue this investigation and questions about students' conceptions of the function of mathematical definitions that the RUME community would like to see answered in the future.

Factors Affecting Students' Mathematical Affect: Layered Analysis

Naneh Apkarian
Arizona State University

Andrew Ritchey
Arizona State University

Keywords: quantitative methods, mathematics affect, student experience, precalculus, calculus

Introductory mathematics courses are a critical juncture in undergraduate students' STEM trajectories. Unfortunately, these courses often erode students' *mathematical affect* – their attitudes and beliefs about their relationship to mathematics – reducing success and persistence (Ellis et al., 2016; McLeod, 1992; Rainey et al., 2018). We set out to better understand, at scale, what aspects of students' experiences influence changes in students' mathematical affect while enrolled in introductory courses by answering the following research questions: (1) What factors influence students' reported change in mathematics affect across a term? (2) What influences students' *reports of those factors*, when in the same classroom?

Data for this poster comes from a large set of precalculus and calculus student responses from 21 universities. The survey covered students' experience in their course, academic and personal identity, beliefs about themselves and mathematics, and more (Apkarian et al., 2019). Of particular relevance to this study, these included both retrospective and introspective questions about students' mathematics affect, which were compared to create the composite variable *change in math affect* (ΔMA); items about instructional practices were transformed using principle component analysis and oblimin rotation into composite factors (Jolliffe & Cadima, 2016). We leveraged *least absolute shrinkage and selection operator* (LASSO) regression analysis methods to answer both research questions. We used 10-fold cross-validation to train the model on 80% of the, reserving 20% for testing. LASSO creates a parsimonious, interpretable model by penalizing the absolute size of regression coefficients, dropping less important models out of the model by forcing their coefficients to zero. We select the model with the fewest variables following the "one-standard-error rule," a conservative approach which further reduces overfitting (Hastie et al., 2009).

To answer RQ1, we employ LASSO with the outcome variable ΔMA and 15 input variables, including demographic characteristics and reports of classroom practices (N=22,923). In this model (MAE=0.74; HL=0.45; R^2=0.21), the only variable whose coefficient does not shrink to zero was *MathENG*, a composite variable measuring students' reported engagement in meaningful mathematics. MathENG exhibits wide variance, even among students enrolled in the same course, leading us to specify the second research question as: *What influences variation in students' reports of MathENG within the same course?*

To answer RQ2, we employ LASSO regression with the outcome variable *MathENG_cen*, a recalibration of students' responses centered around the mean response of their classmates, modeling how 12 variables relate to students reporting higher/lower MathENG than their peers (N=23,201). Factors which did not disappear from this model (MAE=0.58; HL=0.22; R^2=0.03) are gender (negative impact on women vs. men); major (positive impact on STEM majors vs. non-STEM majors); and reports of how class time was spent (positive association with class discussion; negative association with listening to the instructor lecture and solve problems).

The poster will further detail the model and fit characteristics and explore conjectures, implications for research and practice, and next steps needed to further understand these phenomena.

Student Trajectories in a College Algebra With Support Course Using Standards-Based Grading

Karina Uhing
University of Nebraska-Omaha

Xiaoyue Cheng
University of Nebraska-Omaha

Nicole Infante
University of Nebraska-Omaha

Keywords: College Algebra, Standards-Based Grading, Assessment

We share how the implementation of a College Algebra with Support (CAWS) course affected student success in mathematics and subsequent course taking behavior. The CAWS course added one additional credit hour to the existing College Algebra course and includes student supports such as just-in-time reviews and study skills. The course uses student-centered pedagogies (Abell et al., 2018; Bressoud et al, 2015; Deslauriers et al., 2019; Freeman et al, 2014; Theobald et al., 2020) and standards-based grading (Nilson & Stanny, 2015; Zimmerman, 2020). CAWS was first implemented in Fall 2023, with an enrollment of 610 students. In Spring 2024, 507 students enrolled in CAWS. As part of the standards-based grading structure, a significant portion of a student's grade was earned by completing learning checks (quizzes) on individual learning objectives (LOs). Students were expected to demonstrate skill twice on each LO. We sought to examine the question: *What are common student trajectories in a CAWS course that uses standards-based grading?*

Institutional data were collected from the university Systems Intelligence and Data Analytics Office. Course level data on when LOs were met during the semester were gathered from course coordinators. Although five years of data were collected, the analysis presented here focuses on Fall 2023 and Spring 2024. Data included: demographics, mathematics course enrollments, final course grades, and learning objective data from CAWS in Fall 2023 and Spring 2024.

To analyze the data, we first looked broadly at how final course grades were distributed based on student demographic data. We then conducted hierarchical clustering analysis on the Fall 2023 data based on the week when students successfully completed each LO for the first and second time. Students were grouped into six clusters by the similarity of their performance on LOs. Group 1 has 272 students (44.6%) who demonstrated consistent strong learning performance and mostly received A's. Group 2 contains 61 students (10%) who started late in LO#1 but caught up since LO#2 and consistently met most of the LOs twice. Most of them received A or B's. Group 3 has 66 students (10.8%) who had a slow start and most LOs were met after week 9. Most students in this group received B or C's. Group 4 has 34 students (5.6%) who started strong in the first three LOs but then struggled to complete later LOs. Group 5 with 99 students (16.2%) mostly started after week 7 and were inconsistent with completing LOs. Group 6 has 78 students (12.8%) who did not complete almost all the LOs. Groups 4 and 5 have high DFW rates at around 80%, while students in Group 6 have 100% DFW rate.

In addition to studying CAWS, we started examining student success in future courses. There has been a significant increase in the number of students taking Trigonometry as a result of the implementation of CAWS, particularly by students of color. This suggests that these students are persisting on STEM degree paths that require them to take calculus. Our goal is to use our analyses to improve CAWS and better support students as they continue to take mathematics courses. Future work will continue to analyze student trajectories in courses such as Trigonometry and Calculus I.

Interactive Digital Activities in Real Analysis for In-Service Teachers

Zachary Bettersworth, Western Kentucky University
Sarah Hartman, Middle Tennessee State University
Nicholas Fortune, Western Kentucky University

In this poster presentation, we present pilot data describing how secondary mathematics teachers enrolled in a fully online, Real Analysis course in the Southeastern United States engaged with interactive digital activities. Further, we describe what mathematical meanings were elicited in this context during semi-structured interviews where students engaged with mathematical tasks via the activities. These pilot data will inform two future goals. First, it will inform the design of interactive digital activities in our Advanced Geometry course. Second, it will inform our future work on a larger study about overall engagement with various touchpoints (i.e., ways to participate) in fully asynchronous classes.

Keywords: Secondary Teachers, Real Analysis, Interactive Digital Activities

Mathematics teachers who seek promotion or to teach dual-credit classes at their jobs often pursue graduate education as a way to achieve the requirements for that promotion. As these teachers are full-time employed teachers, asynchronous online programs in graduate mathematics provide ways to achieve these professional goals. Our work exists in spaces like these that are very common across the United States. An important goal for us as mathematics educators is that even in asynchronous online environments, students engage in inquiry-based mathematics education (Laursen & Rasmussen, 2019). One way to achieve this is to include *interactive digital activities (IDA)* as ways to engage with our students remotely. Because there are many different kinds of IDAs we define each word within the term. An **activity** is a mathematical task where students actively build understandings related to a set of mathematical ideas. **Digital activities** can include applets (Moore, 2009), animations (Moore & Thompson, 2015), digital learning games (Mauntel et al., 2021), or activities that incorporate augmented or virtual reality (Kang et al., 2020). This list is not exhaustive; any activity that utilizes digital resources and engages students in mathematical activity could be considered a digital activity. Finally, there are **interactive digital activities**. These are activities where students are required to engage, in the moment, with some aspect (such as a slider, button, etc.) of the digital activity and get in-the-moment feedback (Zandieh et al., 2018). Therefore, the students' interaction depends on the nature of IDA and not all students will engage with the IDA in the same way.

Our research team collected pilot data to understand how in-service teachers engage with IDAs focusing on real analysis content and what mathematical meanings are elicited during this engagement. Our research questions are: *1) When students who are enrolled in an asynchronous online graduate mathematics class engage with interactive digital activities, what mathematical meanings are elicited? 2) How do students engage with interactive digital activities?* In this poster, we present preliminary results from semi-structured mathematical task interviews on polynomial asymptotes with six in-service teachers. The various ways in which the teachers interacted with the IDAs informed the possible meanings that could have been elicited. For instance, a teacher may have overlooked an aspect of the design of the IDA which then meant that the mathematics question they were answering was limited in scope. This work represents an initial attempt to understand how IDAs can be improved and used in asynchronous classes. The goal is to consider how these IDAs fit into larger engagement with mathematics, learning, other students, the instructor, etc. in online asynchronous classes for in-service teachers.

Who Feels Like They're (Not) Getting Attention in Class?

Olivia Bruner
Arizona State University

Naneh Apkarian
Arizona State University

Keywords: Inclusion, Student Experience, Identity, Introductory Mathematics

Students' experiences in their introductory courses impact their likelihood of pursuing and completing undergraduate degrees in STEM (Holland, 2019; Seymour et al., 2019). A sense of belonging or inclusion supports their pursuit of these degrees, while feeling excluded hinders that pursuit. This is particularly pronounced for students from marginalized and/or underrepresented groups, who may enter such courses already feeling like "outsiders" (Ellis et al., 2016; Riegle-Crumb et al., 2019). We explore links between students' demographic characteristics and their reports of receiving similar (or more, or less) attention than their classmates.

The data corpus for this study consists of 32,137 survey responses (complete with respect to our variables of interest) from undergraduate students enrolled in precalculus and calculus courses at 21 universities (Apkarian et al., 2019; Street et al., 2021). Students reported demographic characteristics as well as their perceptions of class activities and their experiences with the course. Students were categorized into three groups: those who reported receiving more, the same, or less attention during class. This categorization was based on students' responses to five Likert items asking them to report whether (compared to their classmates) they had more/less/the same (a) opportunity to ask questions; (b) attention given to their questions; (c) encouragement from the instructor; (d) opportunity to participate in class discussions; and (e) praise from the instructor. The majority (26973; 83.9% of sample) reported receiving the same attention as their classmates, but we focus on those who reported that they were *not* receiving the same attention as their classmates. Testing was conducted to determine if students from different sub-populations were equally likely to report receiving more vs. less attention.

Overall, the 5,164 who were not in the "same" group were 3.29 times as likely to report receiving *less* as opposed to *more* attention than their classmates. We found little variation between men's and women's perceptions of their in-class treatment. However, transgender and gender non-conforming students were 5.4 times as likely to report that they receive less attention. This pattern within men and women held for most racial groups, apart from Alaskan Native and/or Native American students, among whom women were more likely to report more attention than men. We found additional discrepancies based on race. For example, 87.8% of white students (n=16,185) characterize their experience as average, a larger percentage than any other racial group. Within racial groups analyzed, Hispanic/Latinx (n=865) students were 5.13 times as likely to report receiving less attention than more, the highest proportion among groups analyzed. With regards to other special populations, we also found that first-generation students (n=1476) were 4.125 times as likely to report they received less attention than more, and parents (n=48) were 5.857 times as likely. Conversely, international students (n=248) were 1.88 times as likely and disabled students (n=197) were 2.71 times as likely. The poster will include full results for all special populations analyzed in this project, with additional statistical details.

GTA Views on Their Own Roles and Student Roles in the Classroom

Jessica Tolchinsky
University of Rhode Island

Keywords: GTA, instructor obligations, student role, GTA role

Graduate Teaching Assistants teach undergraduate students for 50% or more of their time in a classroom. These GTAs may receive little to no training in teaching and for many of them it is their first teaching experience (Sohoni et al. 2013). GTAs are an important part of undergraduate student learning but unfortunately many universities do not have teaching training programs available for them (Luft et al. 2004). GTAs and professors not only vary in teaching experience but also in the power they have. In some cases, both GTAs and professors teach coordinated courses where some resources, such as exams, homework assignments, and lesson plans, may be available to them and possibly required to be used (Rasmussen and Ellis, 2015).There are professional obligations that instructors can use as resources to justify their teaching decisions being different than what is customary (Ko et al., 2023). These obligations are

(a) "An obligation to interpersonal dynamics and relationships expressed in social groups.
(b) An obligation to individual students.
(c) An obligation to schooling institutions.
(d) An obligation to the discipline of mathematics." (Chazan et al., 2016).

I will refer to them as Interpersonal, Individual, Institutional, and Disciplinary, respectively from this point on. The PRofessional Obligation Scenario Evaluation (PROSE) instrument looks at teachers' recognition of the above obligations (Ko et al., 2023). I designed discussion posts for 11 GTAs at a mid-size public northeastern university enrolled in a teaching course in order to expose them to pedagogy using the PROSE instrument as a guide. There are two scenarios for each obligation. This ensured that every GTA was seeing one prompt related to a class they are teaching and one prompt related to a class they are not teaching. The discussion asked GTAs to state whether or not they agree with the prompt and justify their level of agreement or disagreement, state any context they are imagining as they are reading the prompt and then choose 2 of their peers to respond to for each prompt. In their response to their peers the GTA was asked to state why they agree or disagree with the final decision, whether or not they agree with the justification for the decision, and the level to which they had the same considerations as their peers. In analyzing the discussion posts, using open coding (Corbin & Strauss, 1990), I observed differences in some responses being whether the GTA is responding to the specific question topic in the prompt versus for general topics. Some GTAs related their responses to the courses they are teaching. GTA also discussed how they view the student's role or their own role in a classroom which had related to how they justified their response to each scenario.This will inform what aspects of the Graduate Teaching experience have an effect on how they choose to structure their classroom and how this recognize the four obligations: "Interpersonal", "Individual", "Disciplinary", and "Institutional."

Diversity, Equity, and Inclusion: Gathering Community College Students' Perspectives

Laura Watkins
Glendale Community College

Mary Beisiegel
Oregon State University

Bismark Akoto
University of Minnesota

AI@CC 2.0 VMQI Research Team[1]
EHR #2000602, 2000644, 2000527, 2000566

Keywords: college algebra, community colleges, equity, diversity, inclusion

In this poster, we share our design process and protocols for gathering longitudinal data of students' perspectives on equity, diversity, and inclusion in the college algebra classrooms at community colleges with the goal of documenting their understanding of these terms in the context of college algebra. While some studies explored student experiences in college algebra (Gardner, 2020) and other studies document undergraduate students' experiences of inclusion and belonging in mathematics classes at predominantly white institutions (Leyva et al., 2021), we do not have studies that investigated community college students' understanding of equity, diversity, and inclusion nor how students come to understand these ideas.

We are engaging in an initial cycle of a grounded theory approach (Charmaz, 2006) with the goal of providing an initial understanding of these constructs from students' perspectives. Since community colleges draw students from their local communities, the details of students' experiences vary, and their understanding of equity is influenced by contextual aspects of the institution and of the community. As such, we plan to collect data from 80 students (10 from each college) enrolled in eight carefully selected community colleges, two from each of the following regions: Northwest, Southwest, Central, and Midwest. These colleges were selected for the diversity of students enrolled on their campuses. We seek to recruit students with particular identities including race, gender, ethnicity, physical diversity, and neurodiversity. As student recruitment is critical, our recruitment process will use a multipronged approach that includes reaching out to college units that support a diversity of students.

To capture students' views they will participate in a series of four interviews within a year. During the interviews, students will (1) discuss their personal and mathematical histories related to their current understanding of equity, diversity, and inclusion; (2) provide commentary on short videos of classroom instruction tagging specific characteristics that can be associated with equity, diversity, and inclusion; (3) engage in a Q-sort exercise (Rieber, 2020) of student statements from previous interviews geared to elicit their understandings of equity, diversity, and inclusion; and (4) reflect on this process over time. The time interval between interviews will allow for analysis of student data and fine-tuning of interview protocols. Data collected within an institution and across institutions will complete one cycle of the grounded theory approach which will generate initial theoretical propositions about students' understanding of equity, diversity, and inclusion.

Hawai'i Pacific University

Keywords: mentoring, graduate teaching assistants, post-secondary education

Graduate students in the mathematical sciences are responsible for the teaching of many undergraduate math courses in doctoral institutions (Eller, 2017). To that end, it is highly beneficial to make sure that these graduate teaching assistants (GTAs) are adequately prepared to take on the task of instructing a course. Peer mentors are a key resource in helping these less experienced GTAs to grow in both their teaching and research responsibilities associated with being in a graduate program (Flores-Scott & Nerad, 2012).

Literature Review

Research has shown that participants in graduate student peer-mentoring programs obtain benefits in many different domains including academic, social, psychological, and career development, and mentoring can attend to many of the diverse needs of graduate students (Lorenzetti et al., 2019; Liu et al., 2022). These mentoring relationships work in both directions with knowledge sharing, exploring different perspectives, and giving and receiving feedback (Lorenzetti et al., 2020). In our poster, we discuss mentees' and mentors' perceptions of the benefits mentoring can provide in a teaching-oriented peer mentorship program.

Data, Methods, and Results

As part of our multifaceted and multi-institution GTA training program, *Promoting Success in Undergraduate Mathematics through Graduate Teacher Training (PSUM-GTT)* (Harrell-Williams, et al., 2020; Manzanares, et al., 2024), GTAs participated in peer mentoring. Each mentor was at least a third-year doctoral student in a Mathematical Sciences program at one of the three institutions and was assigned one mentee (sometimes two). Each semester GTAs completed online surveys about their experiences with teaching and mentoring. This poster presents results from survey data from Fall 2019-Spring 2023 and is a follow-up to a conference proceedings paper (Funkhouser, et al., 2021) reporting preliminary first year results. Specifically, mentors were asked how significant they thought their mentoring was to their mentee's success as an educator, and mentees were asked how significant they thought their mentor was to their success as a GTA, both on a scale of 1-5. Across all three institutions and every year, mentees rated the assistance they got from their mentor higher (*mean=3.68, SD=0.34*) than the mentors rated themselves as being successful in mentoring their mentees (*mean=2.84, SD=0.30*). We will situate these results within a discussion of mentoring self-efficacy and how peer mentoring models can provide specific support for their mentors.

Keywords: Departmental change, teaching culture, STEM education, barriers, drivers

Despite an abundance of research applauding the use of evidence-based instructional methods in STEM courses, the majority of math undergraduates are still taught using traditional lecture-based methods (Sonnert et al., 2015; Stains et al., 2018). As such, a deeper cultural shift may be required for these novel instructional methods to be embraced outside the educational research community. As academic departments play a pivotal role in influencing teaching quality, one natural entry point for enacting instructional change is to focus on departmental teaching culture (Henderson et al., 2011; Corbo et al., 2016; Couch et al., 2024). While the implementation of change efforts is an individualized process for each department, value can still be found in identifying key factors that have the potential to impact the change process. Through this exploratory literature review, we seek to answer the following question: what are potential barriers and drivers to departmental teaching culture change and what strategies could be used to encourage embracement of departmental change?

To answer our question, we conducted an exploratory analysis of literature via a keyword search of *(departmental) cultural change*. In particular, identified *barriers to change* include: lack of professional knowledge (Corbo et al., 2016), lack of time and resources (Reinholz & Apkarian, 2018), fear of the unknown (Gaubatz & Ensminger, 2017), satisfaction with the status quo (Gaubatz & Ensminger, 2017), lack of autonomy (Gaubatz & Ensminger, 2017), and resistance to external leaders (Gagliardi et al., 1986). Possible *drivers for change* are: lack of conflict between current values and the values associated with change (Gagliardi et al., 1986), celebration of positive outcomes throughout the change process (Couch et al., 2024), reinforcement of change as an ongoing iterative process (Gagliardi et al., 1986), a commitment to diversity and inclusion (Quan et al., 2019), and the leveraging of departmental leaders as agents of change (Kunst & Mesoudi, 2023). Finally, *change should be framed* as follows: change is at the departmental level (Gagliardi et al., 1986), change is student centered (Quan et al., 2019), everyone is a collaborator in change efforts (Quan et al., 2019), change will have positive outcomes (Kunst & Mesoudi, 2023), and change efforts are data driven (Quan et al., 2019).

Our poster will present a literature-informed action plan for RUME researchers and mathematics faculty who seek to promote cultural change with respect to teaching. For example, current departmental values must be identified to ensure they are not in conflict with the proposed change; any conflicts must be reconciled. Current departmental needs must also be identified in order to be leveraged as positive outcomes of change. In addition, departmental leaders should be identified to be leveraged as agents of change; this includes both department administrators such as chairs as well as peer leaders deemed as influential by their peers.

Comparing the Strategies of Two Precalculus Students Responding to a Novel Mathematics Task

Kiley Pooler
Arizona State University

Keywords: covariational reasoning, quantitative reasoning, continuity, concavity

This study examined the problem-solving abilities of two male Pre-Calculus students at a Southwestern University as they completed three novel mathematics tasks. The tasks prompted students to explain and represent how two quantities in a problem context vary together. My analysis revealed that students' success in constructing meaningful formulas and graphs depended on the students' first conceptualizing the quantities in the problem context and visualizing how they are related and vary together.

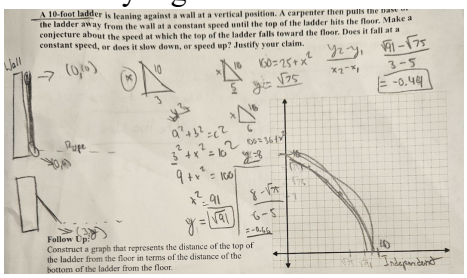

Figure 1. A picture of the task and Student A's work

Student A's mental image (Carlson, O'Bryan, 2022) of the quantitative structure of the ladder problem is illustrated (Figure 1) in the student's drawing. To address the prompt (Figure 1), he sketched the ladder's initial position (top left) and modeled its motion as the bottom of the ladder was pulled away from the wall. He constructed a sequence of triangles to represent snapshots of the ladder falling, ultimately allowing him to conceptualize and compute how much the top of the ladder dropped with each fixed change in the base's movement. His use of covariational reasoning led to him correctly recognizing that the top of the ladder would speed up as the base was moved further from the wall.

Student B immediately made a drawing of the context and concluded that he could use the triangle he constructed and the Pythagorean theorem to write the equation of a circle.

> *Student B:* … the rates of change aren't constant because [omitted] it's a circle… so the ladder is going to start slow, speed up, and then slow down again.

Student B demonstrated fluency in using geometric relationships when he represented the Pythagorean theorem as an equation of a circle and then solved for one variable. When asked to restate how the ladder would fall, he referenced the curvature of the circle on different intervals and claimed the rate of the top of the circle is the inverse rate of the bottom right-hand part. He appeared to be recalling facts he had learned rather than conceptualizing how the quantities in the problem context were related. While his approach of comparing rates of change across intervals was notable, his reliance on abstract geometric reasoning prevented him from verifying whether his answer aligned with the real-world scenario.

While there's no single correct approach to solving a novel problem, constructing a mental image of how quantities are related before modeling them mathematically helps students understand how the quantities vary together in relation to a graph's concavity. The poster will focus on this task so viewers can engage with the task and consider excerpts from each student.

Lowering the DFW Rate in Calculus 1

John Gruver
Michigan Technological University

Patrick McFall
Michigan Technological University

Keywords: Calculus, DFW Rate, Coordination

Educators and researchers have been working to help a wider variety of students be successful in calculus for decades (e.g., Steen, 1987). Researchers have made progress on outlining ways this can be accomplished (e.g., Johnson et al., 2022). We add to this literature by sharing our experience of implementing several small changes that considerably lowered the DFW rate in calculus 1. Specifically, the semester we implemented these changes the DFW rate was 18.8% rate compared to an average rate of 43.2% over the previous six years.

Context and Nature of the Changes

Both before and after the changes we report on were made, Calculus 1 was taught in several medium-sized coordinated sections (about 50 students each), mostly taught by graduate students. The sections met 4 days a week, with new content being introduced on three of those days and the other day being reserved for students to work on problems in class. In addition to typical homework, students also completed Mathematica assignments each week.

Increased Instructional Alignment and Strengthened Coordination

When considering how to change the course to better support students, the course coordinator began by clearly articulating learning objectives for each day of class. He then ensured that in-class activities, homework, and exam questions were aligned with these objectives. He also developed common handouts. These handouts listed the learning objectives relevant to the lesson at the top, with notes on key terms, ideas, theorems and problems below. While the handouts were intended to guide students' notetaking and problem solving in class, they also communicated a potential outline for a lesson plan to the instructors.

Additional Support and Feedback for Students

The course was also changed to include extra support for students and offer several additional opportunities for feedback. The course coordinator created short (3-6 min) videos for each class that students were supposed to watch and take a quiz on before class. The videos introduced the topics in a way that was aligned with the learning objectives. The coordinator also offered weekly reviews that covered just-in-time topics. Students who did poorly on an algebra quiz given during the first week of class were required to get additional support. One option was to attend these reviews. The course coordinator also created short daily "exit quizzes" to provide students with an opportunity to receive feedback on a per class basis. Finally, the course was modified to include three exams rather than two so students could get feedback earlier.

Discussion

The changes we reported here were relatively small in that they were not a major restructuring of the course or an overhaul of the content. Instead, these changes focused on creating strong instructional alignment and providing additional supports for students. However, they seemed to have a significant impact on the number of students who were able to be successful.

Creating Counterspaces Through Critical Conversations About Race and Gender in STEM

Karaline Petty
The University of Arizona

Aditya Adiredja
The University of Arizona

Becca Jarnutowski
The University of Arizona

Keywords: race, gender, equity, community development

Undergraduate STEM educational spaces, and particularly, mathematics educational spaces, are uniquely racialized and cisheteronormative. (e.g., Leyva et al., 2022; Ong et al., 2011). STEM *counterspaces* are academic and social spaces that allow minoritized students to validate one another's critical knowledge from their experiences, share stories of isolation, discrimination, etc., broadly challenge deficit notions of minoritized groups, and establish positive racial climates (Ong et al., 2018, p. 209). Research has begun to uncover the benefits of counterspaces on students, such as improving students' sense of belonging, mitigating feelings of isolation, and affirming students' academic identities (McGee & Martin, 2011; Oppland-Cordel & Martin, 2015). In this poster, we explore the question: *To what extent can critical conversations about race and gender function as a counterspace for minoritized students?*

Critical Conversations (CC) about Race and Gender in STEM was an activity that we designed with the objective of supporting minoritized students and instructors to build empathy, solidarity, and community with one another through affirmations and shared stories. It was part of a larger three-year professional development project at a Hispanic Serving Institution focused on anti-deficit teaching (Adiredja et al., 2024). Three cohorts of students and instructors participated in five conversations, two during a summer math workshop and three during the following Fall semester. We used the same curriculum for each year, and each conversation was facilitated by undergraduate STEM peer mentors from minoritized backgrounds.

We focused our analysis on exit tickets after each of the CCs in the fall because they were held at the university cultural resource centers, thus involving more members of the university community. The fall CCs also discussed topics that were explicitly about race and gender in STEM: stereotype and stereotype threat (Steele, 1997), stereotype management (McGee & Martin, 2011), and community cultural wealth (Yosso, 2005) respectively, all discussed in the context of STEM education. The exit tickets were anonymous and asked for one take-away and one feedback about the conversation. Over all nine CCs, we had 90 participants (75 students and 15 instructors). From these participants, we received 89 responses.

Eleven themes emerged through a constant comparative method (Glaser, 1965), with three being especially relevant: connecting through shared experiences (26 responses), experiencing affirmation and support (20 responses), and learning how to respond to stereotypes (22 responses). These themes connect to Ong's definition of counterspaces, as they provide evidence participants are sharing stories, validating each other's knowledge and experiences, and challenging deficit narratives. Notably, we found that participants reported connecting with each other through shared experiences instead of shared identities, which may make CCs a valuable counterspace for people who feel left out of more homogeneous groups. For example, one participant reported "a good sense of shared humanity with other men," though they were initially worried their sexuality would render them invisible to straight men. They were able to connect over shared experiences "that had different sources but the same impact," and found that "really affirming." Our findings suggest that leveraging shared experiences can support the creation of counterspaces, especially in a department without critical masses of underrepresented groups. Even so, we found the collaboration with the university cultural centers to be fruitful.

Mathematics Capital as a Latent Factor

Frances Anderson
University of Nebraska-Omaha

Karina Uhing
University of Nebraska-Omaha

Jonathan Santo
University of Nebraska-Omaha

Keywords: Mathematics Capital, Structural Equation Modeling, Bourdieu, Mathematics Identity

Students bring their individual characteristics and identities into the classroom, which ultimately impacts their learning experiences and success in mathematics (Cribbs et al., 2015, 2021, 2022; Gutiérrez, 2009; NCTM, 2014). We seek to identify student backgrounds and characteristics that impact their success in mathematics education by analyzing data from students in undergraduate mathematics courses via structural equation modeling (SEM). Our goal is to study a novel theoretical construct, defined as *mathematics capital* (Anderson, 2023, 2024, Anderson et al., 2024, Williams & Choudry, 2016; cf, Bourdieu, 1977, Archer et al., 2014, 2015). Undergraduate students have a plethora of prior mathematical experiences. These past experiences can inform their choice of a college major and set them on a semi-fixed trajectory. Thus, we study undergraduate mathematics students because we view their course enrollment as a marker of their mathematical outcomes.

We use a Bourdieusian lens (Bourdieu, 1977; Bourdieu & Wacquant, 1992) to frame the construct of mathematics capital. Following the work of Bourdieu, we argue that mathematics capital is a unique variable that relates to and acts as a bridge between other constructs in mathematics education such as social factors, cultural capital, emotions, and personal experiences (Anderson, 2024). Like Archer and colleagues (2014, 2015) who have applied Bourdieu's ideas to study science capital, we extend this work into the field of mathematics education (Anderson et al., 2024, c.f. Dewitt et al., 2016).

We collected quantitative data in Fall 2023. A previously validated Qualtrics survey containing items related to mathematics capital (MC), mathematics mindset (MIND), self-efficacy (SE), cultural capital (CC), and mathematics teaching and learning experiences (TEAC) was distributed via email to all students enrolled in any mathematics course at an urban university. We received a total of 685 responses out of 2594 students for a response rate of 26.4%. Only participants who completed the entire survey were included in the analysis for a total of 674 participants. Variables of MIND, SE, CC, and TEAC were used with alpha values ranging from .75 to .94. To create a latent factor of the MC measure, six items were used. A single-factor confirmatory factor analysis was tested using structural equation modeling (M-Plus Ver. 7, Muthén & Muthén, 2012), resulting in a poor fit to the data. Thus, a correlation was added between item 6 and item 7) (as suggested by modification indices). The resulting model was then an acceptable fit to the data ($\chi2(8) = 32.06$, $p < .05$, CFI = .99; RMSEA = .07, SRMR = .01). The internal reliability of the latent factor of mathematics capital was acceptable ($\omega = .90$). We also tested alternative models in which either item was removed, and none were acceptable.

A full model with all other scale scores was tested to elucidate how each were related to the other, but more importantly to the latent factor of mathematics capital. The final model (visual figure on poster) remained a good fit to the data ($\chi2(31) = 103.35$, $p < .05$, CFI = .98; RMSEA = .03, SRMR = .01). This model details the positive relationships between self-efficacy, mathematics mindset, teaching and learning experiences, cultural capital to mathematics capital and reinforces mathematics capital as a separate construct as it is measurably distinct from all other variables (with existing scales) used in this study. This model supports findings from a previous pilot study and provides avenues for future research.

Supporting Mathematical Instruction Around Definitions Through Values-Centered Collaboration

Seth Ricarte
Michigan State University

Mik Mieczkowski
Northern Illinois University

Kristen Vroom
Michigan State University

Rachel Rupnow
Northern Illinois University

Keywords: Norms and values of definitions, undergraduate instruction, collaboration

Extensive research shows students do not learn as much from undergraduate mathematics courses as we would like (e.g., Asiala et al., 1997; Borji & Martínez-Planell, 2020; Siyepu, 2013). Despite research demonstrating the efficacy of non-lecture-based approaches (e.g., Inquiry Oriented Abstract Algebra, Larsen, 2013; Larsen & Lockwood, 2013; Learning Abstract Algebra with ISETL; Leron & Dubinsky, 1995), most mathematics instructors lecture in lower-division courses like Calculus (Kirin et al., 2017) and upper-division courses like Abstract Algebra (Johnson et al., 2018). Dawkins and Weber (2023) suggest mathematicians choose to lecture because it meets their goals, including content coverage, preparing future mathematicians, precision and language, and efficiency; thus, they call for improving instruction by enhancing lectures in ways that feel comfortable to instructors. Our project supports this novel approach to improving undergraduate instruction by centering collaboration between mathematics education researchers and mathematics instructors. We focus on teaching the norms and values of definitions, as definitions are fundamental across different undergraduate courses and have been identified as an area where students and instructors can struggle to communicate (e.g., Martín-Molina et al., 2020).

This project integrates focus groups, class observations, surveys, and interviews with instructors and students to develop a toolkit of instructional innovations for effectively communicating mathematical norms and values around definitions in both upper-division (Abstract Algebra and Real Analysis) and lower-division (Calculus I and II) lectures. This poster presents preliminary observations in the first round of focus groups and surveys with 10 mathematics faculty from two universities. The aim is for the instructors to develop their own minimally invasive activity centered on a definition that communicates a mathematical norm or value (Rupnow & Randazzo, 2023).

Instructors reported challenges with limited time for activities in lecture, highly coordinated courses limiting freedom of instruction, as well as more content-specific challenges. For instance, some instructors explained how it was difficult to plan an activity that shared norms and values of mathematical definitions in such a way that complemented their learning goals. For example, instructors reported difficulty in communicating precision without becoming over-encumbered in fine details (e.g., tensor products). Other instructors expressed difficulty in growing students' intuition about certain definitions (e.g., Laplace Transform) or translating between students' informal and technical understandings (e.g., the informal notion of closeness with the technical nature of ϵ and δ in convergence proofs). As the project continues, the project team is continuing to collaborate with the mathematics faculty to address these challenges (e.g., by understanding which norms and values might afford which learning goals) while supporting their instruction to communicate norms and values in ways that are comfortable and non-intrusive for both the instructors and their students.

"I'VE ALREADY DONE THIS": How Prior Exposure Affects Calculus Students' Mindsets During a Semester of Regular Reflections

Devin Hensley
Auburn University

Haile Gilroy
McNeese State University/Auburn University

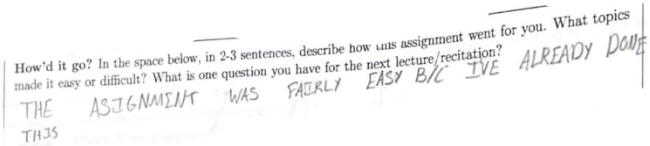
Keywords: growth mindset, mastery-oriented mindset, strategic mindset, calculus

Historically, Calculus I has been a notorious barrier to many students' completion of STEM degrees (Weston et. al, 2019). In Fall 2023, we taught a large lecture section of Calculus I (~250 students) at a large R1 public university in the Southeastern U.S., intending to increase the success rate for students by implementing a minor metacognitive intervention called "How'd it go?" prompts after problem sets. In this poster presentation, we investigate the organic manifestation of calculus student mindsets as they occurred in real-time throughout the semester by analyzing short reflective prompts that the students completed voluntarily. Specifically, we answer the research question: *How do university calculus students' mindsets manifest differently depending on the setting of their first exposure to a calculus class (high school or college)?*

In Psychological Meaning System Theory, *mindsets* are attitudes that people hold about themselves (Dweck, 2000). This study focuses on four established mindset pairings: growth/fixed (Dweck, 2016), mastery-oriented/helpless (Dweck, 2000), strategic/non-strategic (Chen et. al, 2020), and entrepreneurial/non-entrepreneurial (Bosman & Fernhaber, 2018).

The course was conducted in a 2-2 lecture-recitation format. Throughout the semester, students were provided printed packets that contained lecture notes outlines, pre-recitation prep problems, recitation problems, and (in some cases) extra practice problems. The whole semester included 21 packets (called lessons) divided into four units. In this study, we analyzed a random sampling of three packets from each unit. To analyze the data, we used a priori coding (Saldaña, 2013) with codes defined by the described mindsets: (a) growth, (b) fixed, (c) mastery-oriented, (d) helpless, (e) strategic, (f) nonstrategic, (g) curious, and (h) not curious. Note that instead of entrepreneurial and non-entrepreneurial, we only coded for curiosity or explicit non-curiosity because some qualities in entrepreneurial mindset are also qualities of a strategic mindset.

When the data was disaggregated according to students' high school calculus exposure (or not), results revealed that these groups had antithetical manifestations of mindsets. In particular, students with no high school calculus were as much as seven times more likely to display a growth mindset in Unit 2 than students with high school calculus. Results further suggest that engaging students in regular metacognitive reflection coupled with a strategic framing of calculus may significantly increase course success rates within an exam-heavy, highly coordinated grading structure.



How'd it go? In the space below, in 2-3 sentences, describe how this assignment went for you. What topics made it easy or difficult? What is one question you have for the next lecture/recitation?
THE ASIGNMENT WAS FAIRLY EASY B/C IVE ALREADY DONE THIS

Figure 1. An example of a "How'd it go?" prompt.

Exploring Student Strategies for Matrix-Vector Multiplication in a Linear Algebra Video Game

Bitna Choi
University of New Hampshire

Matthew Mauntel
University of New Hampshire

Michelle Zandieh
Arizona State University

Keywords: Design-Based Research, Inquiry-Oriented Linear Algebra, Game-Based Learning

In this work, we investigate the second level of the video game *Vector Unknown: Echelon Seas* (*VUES*, Zandieh, et al., 2018; Mauntel et al., 2019; Mauntel et al., 2020; Mauntel et al., 2021), which was designed to integrate elements of Game-Based Learning (GBL; Gee, 2003; Williams-Pierce & Thevenow-Harrison, 2021), Inquiry-Oriented Learning (IOI; Rasmussen & Kwon, 2007; Zandieh, Wawro, & Rasmussen, 2017), and Realistic Mathematics Education (RME; Gravemeijer, 1994; Freudenthal, 1991). The game, *VUES*, is set within a 3-dimensional environment, providing a unique platform for players to engage with concepts of vectors in a dynamic way. In this level, players use matrix-vector multiplication to aim and fire cannonballs at targeted ships.

Players are given a target vector that is represented by a ship. Players pick one of four matrices, represented by different cannonballs, and one of four cannon vectors, represented by different cannons. After choosing a cannonball, there is a geometric support that shows the player visualize a lattice generated by the column vectors of the matrix. The goal of the game is to choose the matrix and cannon vector that multiply together to form the ship vector. Through this process, players can explore the calculation of different matrix-vector multiplications from a transformation point of view. The game also provides a geometric visualization related to the column vectors of the matrix. By exploring these different interpretations of matrix multiplication, students can deepen their understanding of how matrix transformations influence vector directions in a practical and engaging context. Our research question is: What strategies do students use to complete the second level of *VUES*?

To investigate students' strategies in playing this level, we conducted three paired-teaching experiments (Steffe & Thompson, 2000), each lasting approximately one hour and 15 minutes. These students are currently enrolled in a linear algebra course and have prior experience with 3D games. During the interviews, students were asked to explain their strategies for choosing matrices and vectors and describe how they anticipated the cannonball's trajectory. This approach allowed us to explore their strategies for solving and completing the video game related to matrix-vector multiplication. The interviewers scaffolded information about how to use the grid lines at various levels of gameplay.

In the poster, we will present our preliminary analysis of student strategies. In each interview, the student fired at least 10 cannonballs. When firing the first few cannonballs, most students used guess and check. Some students used a numeric form of guessing and checking by choosing one cannonball (matrix) and multiplying the first row of the matrix by a vector to check whether the result matched the first element of the target vector or not. Others used a geometric form of guessing and checking that involved the geometric support from the game, which included a provided trajectory line based on their choice of cannonball and cannon, to check the multiplication results.

Computational Thinking and Problem Solving

Valentina Postelnicu
Governors State University

Keywords: computational thinking, problem solving, mathematics curriculum

Computational thinking (CT) is a way of thinking about problems that allows their formulation and solution to be expressed using computational steps or algorithms that can be carried out by humans and/or computers (Aho, 2012; Li et al., 2020; Wing, 2006, 2008). Often complemented by mathematical thinking, CT incorporates algorithmic thinking and focuses on problem solving using computer science concepts (e.g., data structures, algorithms, various programming styles, logic, and computation).

The purpose of this paper is to illustrate problem solving using a CT approach and discuss the role of CT within the K-20 mathematics curriculum.

Two studies conducted by the author (Postelnicu, 2025; Postelnicu & Postelnicu, 2020) point out the core components of CT:

- *decomposition* - breaking the problems into manageable components or steps;
- *pattern recognition* - identifying patterns;
- *abstraction* - simplifying the problem by reducing it to a mathematical model or a visual representation;
- *algorithm design* - write a logical sequence of computational steps or an algorithm.

Participants in the studies were middle school and high school students (first study), and mathematics and computer science educators with various backgrounds, including university professors (second study, ongoing). From a mathematical perspective, the problem from the first study can be considered an optimization problem, while the problem from the second study uses recurrence relations and modular arithmetic. The solutions for the two problems highlight the interplay between CT and mathematical thinking approaches. Both approaches to problem solving may share features like *decomposition*, *pattern recognition, abstraction*, and *algorithm design*, but those features shape up differently for each approach. For example, in the CT approach, the *abstraction* may come about through a visual representation (physical model, simulation), while in in the mathematical thinking approach *abstraction* comes about through a mathematical model. The type of a*bstraction* affects the way *pattern recognition* and *algorithm design* take shape. In the CT approach, the concern for *algorithm* efficiency and computational constraints often lead to "good enough" solutions or *algorithms* that are based on heuristics and may lack formal theoretical justifications. In the mathematical thinking approach, solutions or *algorithms* are based on theory, and the aim is to construct exact solutions or *algorithms*, rigorously justified, whenever possible.

The role of CT within the K-20 mathematics curriculum will be discussed. Weintrop et al. (2016) point to the challenges faced by integrating CT and subject-matter curricula, including defining CT and its role in the context of our mathematics curriculum. The discussion is pertinent, given that CT is necessary for understanding data, algorithms, and digital technologies that permeate multiple aspects of our life (Kafai and Proctor (2022).

Sustaining Instructional Practices in Challenging Times

Nancy E. Kress
University of Colorado Boulder

Timothy J. Weston
University of Colorado Boulder

Tim Archie
University of Colorado Boulder

Jenny Valadez Fraire
University of Colorado Boulder

Sandra Laursen
University of Colorado Boulder

Keywords: professional development, technology, online teaching, sustainable change

Motivation and Overview

Durable change of instructional practices depends heavily on instructors' ability to sustain the use of new practices in challenging times, whether the challenges arise at the scale of society (e.g., Covid-19), institution (e.g., leadership turnover), or individual (e.g., life circumstances). The Covid-19 pandemic created unprecedented disruptions to people's routines, work, and lives. For example, in higher education, instructors had to move all teaching online on short notice, drawing on their personal teaching systems (knowledge, beliefs and practices) to shape their teaching in the online setting (Brunetto et al., 2022). Understanding how instructors adapted to pandemic teaching conditions over time provides insight into the durability of their use of evidence-based instructional practices during a challenging era.

Our mixed methods study uses larger contextual systems (Hora & Hunter, 2014) as framing to help us understand the work of undergraduate mathematics instructors' who are committed to improving their teaching and how they adapted to remote instruction. We sought to answer the following questions about how undergraduate mathematics instructors responded during the online instruction phase of the pandemic: 1) What instructional practices did instructors maintain, revert to, or attempt during this phase? 2) What technology and institutional supports did instructors find helpful for teaching online? and 3) When instructors attempted new instructional practices out of necessity, what, if any, of those practices did they hope to retain for in-person, post-pandemic teaching?

Methods, Results and Discussion

Data for this study were collected in spring, summer and early fall 2020 during the online teaching phase of the pandemic, from a sample of instructors who were already participating in professional development. We analyzed instructors' responses to multiple-choice questions about how much time they spent using a variety of instructional practices prior to the pandemic compared to during online instruction, and text responses to open-ended questions about professional learning, technological support and new instructional strategies used online.

This poster will share how instructional practices were different online compared to before the pandemic. For example, instructors reported being less likely to ask students to present problems in class, and more likely to answer student questions via email. Instructors reported posting recorded lectures more often online and they expected to continue this practice after returning to in-person classrooms. We interpret these findings in light of instructors' work within larger systems and consider how what worked for people during the pandemic may shed light on how they sustain—or not—the use of new teaching practices through challenging times.

Math 11A/B is the Calculus for Life Sciences sequence at UC Santa Cruz which focuses on applications of Calculus most relevant to students who are proposing to major in Biology, Chemistry, Ecology & Evolutionary Biology, Psychology, Earth Science, Global & Community Health. In the Fall of 2019, there were approximately 4,500 Latinx students enrolled at UCSC with 28% of these students declaring or proposing a major requiring Math 11A or 11B. From Fall 2015 to Fall 2019, the DFW rate overall in Math 11A/B was 24%, with a DFW rate of 32% for Latinx students and 20% for White students. This data led to the acquisition of a Graduating and Advancing New American Scholars (GANAS) grant to fund the redesign of Math 11A/B.

Methods

Starting in the Summer of 2021, a team of faculty and graduate students worked together to redesign Math 11A/B at UCSC. The team was interested in decreasing the DFW rates and equity gaps and focused on: (a) Which content from the current curriculum for Math 11A/B was being used in the proposed majors of the students and in which contexts was the material being used? (b) How can we support students to succeed in alternative forms of assessment?

We completed interviews with faculty across STEM departments to determine which mathematical concepts were most relevant to their upper division courses, how these concepts are used in their STEM fields, and which mathematical concepts were the largest barriers to student success in their major-specific courses. Following the advice of (Hutchings et al., 2014, p. 10) that assignments should "be connected to one another and aligned and integrated with a broader curricular and co-curricular set of experiences", we designed projects which closely align with the authentic use cases of mathematical concepts and could replace traditional exam(s). This involved reading current scientific papers to distill their necessary background and use of calculus in order to highlight the relevance of mathematics in science and build aspirational capital (Yosso, 2005). We also designed weekly worksheets to supplement students' understanding and to offer low-stakes assignments to practice the broader scientific analysis which they are being asked to perform on the projects.

Results and Discussion

We have data showing a decline in the DFW rates for all students in both Math 11A and 11B since implementing the redesigned materials. We are in the process of reviewing the data to determine what is causing the decline in the DFW rate. We still see significant equity gaps and hope to gather more data to begin investigating the causes.

Acknowledgments

This work was funded by the Graduating Advancing New American Scholars (GANAS) grant, a Career Pathways HSI Title V project, grant number P031S200154.

Navigating Obstacles to Foster Success in Learning Optimization Problems in First Semester Calculus

Rasha Abadir
Rutgers University

Keywords: Calculus; Optimization; Problem Solving; Teaching Experiment

Calculus I serves as either a "gateway" into STEM majors or a "filter" that limits students' career intentions (Ayebo et al., 2017; Baisley & Adams, 2019; Biza, 2022; Bressoud et al., 2015; Rasmussen & Ellis, 2013; Sonnert et al., 2015). Baisley and Adams (2019) asserted that poor performance in calculus I can lead to students dropping out of STEM majors, with significant retention concerns in engineering programs. It is historically documented that many calculus students struggle with solving optimization problems due to its complexity which necessitates quantitative reasoning, modeling, and problem-solving skills (Borgen & Manu, 2002; Brijlall & Ndlovu, 2013; Dominguez, 2013; LaRue, 2016; Mkhatshwa, 2016; Swanagan, 2012; White & Mitchelmore, 1996). Speer and Kung (2016) suggested that further investigation into optimization problems is needed. This poster will highlight aspects of this investigation.

The Pilot Study

Drawing on the social constructivist perspective (Cobb et al., 1997; Confrey, 1990; Noddings, 1990), a qualitative pilot study was conducted to understand how engagement in a collaborative problem-solving activity could reveal evidence of understanding or misconceptions of optimization problems from prior calculus learning. Four students who had recently completed Calculus I in a traditional setting worked together to solve an optimization problem. Student interactions revealed a heavy reliance on procedures and formula recall, with participants exchanging ideas and exploring alternative pathways. Although they referred to calculus strategies like using derivatives and identifying extreme values, these were often applied unsuccessfully or abandoned without thorough consideration. Despite their enthusiasm, gaps in conceptual understanding led to frustration and hindered progress. In exit interviews, students voiced dissatisfaction with traditional calculus instruction and suggested ways to create a more supportive learning environment for future students. The findings of this study highlighted the need to further explore how to support calculus students in developing a deeper understanding of optimization.

Results from the pilot study informed the design of a qualitative teaching experiment aiming to improve the learning of calculus optimization by facilitating the building of knowledge representations among a diverse sample of current calculus students. Guided by Davis's "cognitive science approach to mathematics education," this study investigates: (1) what knowledge representation structures related to optimization do students develop, and (2) how the teaching intervention influences the construction of such a knowledge representation? To deepen students' understanding of calculus optimization, participants worked in pairs on five tasks designed to promote conceptual understanding while connecting optimization to prior knowledge.

Results and Significance

The poster will share brief data from the Fall 2023 pilot study that led to a more extensive teaching intervention in Fall 2024, along with some preliminary findings from the ongoing study.

Exploratory PCA and AI for Assessment Analysis

Jonathan Troup
California State University, Bakersfield

Keywords: AI, PCA, R, validation

Assessment plays a critical role in improving student learning outcomes (Brown, 2022; Karaman, 2021). Exploratory Principal Component Analysis (PCA) can identify latent skill structures in exams, offering educators insight into how well assessments align with their goals (Jolliffe, 2002). Simultaneously, emerging AI tools like ChatGPT-4 Turbo present opportunities for enhancing data analysis accessibility in educational research. However, as AI can hallucinate facts, it requires careful validation (Lee, 2023). Using the author's College Algebra Exam 1 as a test case, this study sought to 1) investigate the latent skill dimensions in a College Algebra exam using PCA, and 2) Evaluate ChatGPT-4 Turbo's reliability and utility in conducting PCA.

Pre-existing data were collected from a 19-question College Algebra exam administered to 60 students across two sections of 30 students each, both taught by the author. ChatGPT-4 Turbo was tasked with performing a PCA, and the author conducted a PCA in R and compared results. Interpretation of the PCA results in both ChatGPT-4 Turbo and R focused on identifying the underlying skills being tested by each component. Key ChatGPT prompts and outputs were saved and are included in the poster (via QR code) for reproducibility.

The outputs from R and ChatGPT differed slightly, though the results were similar enough that the interpretation of the underlying skills was not different. Inspection of the chat history shows that ChatGPT wrote its own code to execute the PCA, and it seems its algorithm differs from R's, given the mildly different numerical outputs. This outcome highlights the potential of ChatGPT but underscores the need for human oversight (Lee, 2023). Preliminary findings identified components reflecting distinct skill areas, such as graphical reasoning and multi-step algebraic problem-solving. The component that explained the most variance suggested a counterindication between procedural and conceptual fluency. As literature overwhelmingly suggests that conceptual fluency naturally increases procedural fluency, this result warrants further exploration (Hurrell, 2021; Rittle-Johnson, Schneider, & Star, 2015). Tools such as PCAs and factor analysis offer a potential framework for uncovering skill structures in exams, which can help educators refine and align test design with learning goals (Jolliffe, 2002). While ChatGPT offers accessible entry points for conducting data analysis, human validation remains critical to ensure reliability (Lee, 2023). The intent of this poster is to highlight the potential of this methodology, rather than focusing exclusively on the structure of a single professor's non-standardized college algebra exam.

Since this study, a new AI version, ChatGPT-4o, was released. In the future, the author will investigate this new version's capabilities in this context. If sufficiently reliable, the methodology could be extended to other datasets to enhance generalizability. Further, AI is a developing field, and best practices are still being determined, such as making prompts transparent for reproducibility. Finally, the counterindication between procedural and conceptual fluency in the author's College Algebra class merits further investigation, as these are typically expected to be positively correlated (Rittle-Johnson, Schneider, & Star, 2015). This study demonstrates the utility of PCA in assessing alignment and explores the potential of AI tools in conducting analyses. While AI offers promising avenues of analysis in educational research, human oversight remains crucial to ensure accuracy and validity.

Preliminary Analysis of Undergraduate Student Problem Posing in a Scaffolded Calculus Intervention

Robert A. Mixell
Dickinson College

Keywords: problem posing, Calculus, mathematical representations, mathematical thinking list

Problem posing, that is, the reformatting of existing problems and the generation of new ones, has been promoted for many years by the National Council of Teachers of Mathematics (NCTM, 2000, 1991) as a valuable practice for deepening students' *mathematical thinking* and habits of mind. Problem posing has been associated with problem-solving ability (English, 1998; Silver & Cai, 1996, 1993) and mathematical creativity (Van Harpen & Sriraman, 2013; Yuan & Sriraman, 2011; Leung & Silver 1997). As a practice, problem posing has also been shown to develop student conceptual understanding (Kapur, 2015; Cai et al., 2013). Problem-posing tasks are not only more cognitively demanding than problem-solving tasks. Due to their low-floor nature, they are also more accessible to students of different mathematical backgrounds (Cai & Hwang, 2021), including undergraduate students (Silber & Cai, 2021).

Single-Variable Calculus serves as a gateway course for undergraduates of various majors and mathematical backgrounds. Yet, such 100-level courses may not provide many opportunities for deep mathematical thinking. NCTM (2000) policy has called for student use of multiple *mathematical representations* for promoting mathematical thinking. Such representations are important for developing and reflecting understandings of mathematical ideas (Huntley et al., 2000; Lloyd & Wilson, 1998). In this study, I explored what kinds of problem scenarios (i.e., analogous, somewhat original, or original) undergraduate Calculus students created during a scaffolded, representation-based intervention to analyze students' depth of mathematical thinking.

During two semesters, I, the principal investigator, led a nine-week intervention in four undergraduate Calculus courses in a small, mid-Atlantic college. Over the nine weeks, all students received instruction on average rate of change, limits, continuity, the derivative, and applications. Students were paired randomly by an outside researcher. As a preliminary analysis, problem scenarios created by six dyads with similar Calculus and problem-posing backgrounds were analyzed. For Phase 1 (five weeks), students were told to create problem scenarios for approximately 20 minutes per session based on the mathematical content taught that week. For Phase 2 (four weeks), students were instructed on the concept of problem posing, that is, the difference between analogous problems, "what if?" problems, and "original" problems (e.g., inversions), along with the incorporation of one, then two mathematical representations. Then, students created problem scenarios for approximately 20 minutes per session.

During Phase 1, almost 90% of the created scenarios were analogous to those received during instruction (not original), no matter the students' experiences with Calculus (if any) or with problem posing prior to taking the course. However, during Phase 2, most scenarios were somewhat original or original in nature. Such scenarios in Phase 2 were mostly more mathematically challenging than those in Phase 1. However, they varied in mathematical reasoning, understanding required by the solver, and in complexity. Phase 2 appeared to foster deeper mathematical thinking. Yet, as this did not occur for all student groups, more research is needed to explore ways to use the activity to foster greater originality.

Students' Perceptions and Academic Outcomes in an Active Learning-Based Calculus I Course: Insights From Mediation Analysis

Jerome Amedu
University of New Hampshire

Pei Geng
University of New Hampshire

Karen Graham
University of New Hampshire

Nigar Altindis
University of Alabama

Keywords: Active Learning, Calculus, Student Perceptions

Active learning can increase engagement, comprehension, and achievement in mathematics (Freeman et al., 2014; Fuchs & Sahmbi, 2024). Despite the widely reported benefits of active learning, students' perceptions remain mixed, with some studies noting resistance to these methods (Andrews et al., 2020; Finelli et al., 2018; Tharayil et al., 2018). This study investigates students' perceptions of the impact of active learning on their interest and enjoyment in mathematics and confidence in their mathematical abilities. Mediation analysis was used to explore whether students' perception of confidence mediates the relationships between interest in mathematics and academic achievement (grades) and interest and enjoyment. Research questions: (1) How do students perceive the impact of active learning sessions on their interest, enjoyment, and confidence in mathematics, and does this perception vary significantly depending on the teaching assistant? (2) Does confidence mediate the relationship between interest and academic outcomes (grades/enjoyment) in an active learning calculus environment?

Our analysis revealed that students' perception of the impact of active learning was positive overall. Specifically, out of the 142 students, over 40% of students reported an increase in their interest (65, 46%), enjoyment (63, 44%), and confidence (99, 70%) in mathematics after taking the calculus I course. Analysis of variance results indicated that teaching assistant (TA) was a significant factor for students' confidence, $F(3, 138)= 3.498$, $p = .017$, and enjoyment, $F(3, 138)=3.052$, $p = .031$, but not for students' interest, $F(3, 138)=2.571$, $p=.057$, at the .05 significance level. Correlation analysis shows the highest correlation (r=.86) between interest in mathematics and enjoyment in mathematics, moderate correlation (r =.60) between confidence in mathematics and the other two perception measures and weaker correlation (r=.37) between the course grade and the three perception measures. Mediation analysis was conducted to test the mediating role of confidence in the relationship between interest (independent variable) and grades and enjoyment as outcomes, respectively. Results showed that confidence partially mediates the effect of interest on grades, with a significant direct effect (b = .23, 95% CI [.05, .43], p =.02) and a significant indirect effect through confidence (b =.10, 95% CI [.01, .44], p =.04). Additionally, confidence significantly mediates the effect of interest on enjoyment, with both a significant direct effect (b = .84, CI [.74, .94], p < .01) and a significant indirect effect through confidence (b = .10, CI [.02, .18], p < .001). Pre-calculus experience, teaching assistant (TA), and small group participation score were control variables.

In line with prior research (e.g., Code et al., 2014), this study demonstrates that active learning positively impacts students' interest, enjoyment, and confidence in mathematics. Results also suggest that confidence is a crucial factor connecting interest to improved grades and enjoyment in addition to serving as a reliable predictor of success orientation and achievement (Kirikkanat & Soyer, 2018; Chue, 2020). Finally, although the TA was a significant factor on several student perception variables, further research is needed on the role of instructional support within active learning environments.

Comparison of Graduate Teaching Assistants' Ratings of Individual Program Components in a Multi-Component Pedagogical Training Program

Gary A. Olson
University of Colorado Denver

Leigh Harrell-Williams
University of Memphis

Scotty Houston
University of Memphis

Melinda Lanius
Auburn University

RaKissa Manzanares
University of Hawai'i

Keywords: graduate teaching assistants, post-secondary education, pedagogical training components

Sadera et al's (2024) scoping review on sustainable professional development (PD) of graduate teaching assistants (GTAs), teaching assistants, and tutors, noted that continuous, discipline-specific training, both before and during teaching, was important to the development of GTA's teaching identity and self-efficacy and their attitudes towards teaching-oriented PD and research. Designed to be a continuous, multi-component pedagogical development program using a framework of community of practice (Lave, 1991; Wenger, 1988), the National Science Foundation (NSF) funded *Promoting Undergraduate Success in Mathematics through Graduate Teaching Assistant Training* (PSUM-GTT) project (Harrell-Williams et al., 2020; Manzanares et al., 2024) provided (1) practical training, grounded in relevant literature, regarding issues in undergraduate mathematical sciences instruction prior to or during their first semester of teaching; (2) opportunities to mentor and be mentored by peers; (3) K-12 outreach opportunities to gain an understanding of the student pipeline, (4) a Critical Issues in Undergraduate STEM Education/Learning (CIUSE) seminar series; and (5) instructional support through a peer TA Coach. Hence, knowledge of how beneficial each component was to the GTAs is important information for the current institutions and for other institutions considering which component(s) they might adopt.

Due to the COVID-19 pandemics' impact on institutional policy and instructional format in the early project years, assessment of early outcomes heavily relied on GTA-provided data. Specifically, this poster focuses on quantitative data from end-of-year surveys administered in each of the four academic years of program implementation (2019-2020 to 2022-2023) by summarizing and comparing GTAs' ratings of how beneficial each of the five program components were to them. Results varied across the three universities and four years, indicating that the importance of each component could be dependent on the specific cohorts of GTAs as well as other factors such as institutional policy and changes in department culture. For example, at one university, the peer mentoring program had the highest average ratings component in the first year (4.39 out of 5), which was .74 higher than the other two schools. At the same university, the K-12 outreach had the highest average rating (4.5) in the last two years. However, average ratings for outreach were low at the other two universities, with means at or less than 2. Implications for program component adaptation and adoption will be discussed.

Keywords: Professional development, online workshops, teaching

Introduction

Online professional development (PD) workshops can be more accessible for math instructors whose responsibilities, constraints, or preferences do not align with participation in in-person PD (e.g., caregiving responsibilities, under-resourced institutions, concerns for environmental impacts of travel). In response, the MAA offered a series of online workshops that covered a variety of teaching topics (e.g., content-focused PD vs. pedagogy-focused PD) in the summers of 2022 and 2023. While the workshops appeared to be effective in helping instructors make changes to their teaching (Valadez Fraire et al., 2024), we also wanted to know how participants were changing their teaching and which workshop features, if any, were impactful in supporting these changes and how these supports and implementation may differ by workshop topic.

Methods

We surveyed math instructors who participated in any of 16 online workshops in the summers of 2022 and 2023. Surveys were administered about one year after instructors took part in the workshop. Respondents were asked if they had implemented anything in their classes that they had learned in the workshop, and if so, what, and which workshop features, if any, helped them to make these teaching changes. We computed descriptive statistics for quantitative items and conducted thematic analysis for open-ended items.

Results and Discussion

Respondents reported incorporating concrete examples, group work, and pedagogy changes (e.g., classroom activities and classroom materials). Respondents identified several workshop features that aided their implementation of what they learned at the workshop, such as access to resources, concrete examples, time to plan how they would use what they learned in the workshop in their teaching, and interactions with peers and facilitators. These findings demonstrate the different ways that participants implemented what they learned during an online PD workshop and the workshop features that helped them to enact their planned implementation in their classrooms. PD providers could utilize these features to create implementation-focused PD opportunities.

How Does the Level of Education of Students' Familial and Social Networks Influence Their Perception of Barriers to Applying to Graduate School in Mathematics?

Amelia Hogan
College of Holy Cross

Tim McEldowney
College of the Holy Cross

Keywords: Parental Education, Graduate School Applications, Social Capital

Graduate enrollment is heavily influenced by a student's parent's level of education, especially for doctoral programs (Mullen et al., 2003). One possible explanation could include the impact of students' familiar and social networks on the graduate school application process, due to the theory of social capital (Coleman, 1988). We use this framework to discuss our results. The following data was collected from 519 survey responses to a 57-question survey investigating student knowledge about applying to graduate school. The following two tables show selected results from two questions in the survey. Based on the first table, there is an association between students seeing graduate school application fees as a barrier to applying and their immediate members having less education. From the second table, one observes that students with someone in their social network with a higher degree are less likely to view obtaining letters of recommendation as a barrier to applying to graduate school. Due to the known association with educational attainment and social inequality (Blau & Duncan, 1967; Wells et al., 2011), not all students worry about the financial resources needed to apply to graduate school. Students with members of their social network who have graduate degrees are less worried about finding recommenders for their application and know what it is like to travel for graduate school. Therefore, these students who have people with higher degrees in their immediate circles have additional resources to apply to graduate school due to their social capital.

Table 1. Kruskal-Wallis test results for selected items for the question "To what extent are the following factors a potential barrier to your pursuit of graduate school?" using the level of education of immediate family member variable.

Item	Degree	*N*	Mean	Mean Rank	*H*	*df*	*p*	*r*
Graduate Application Fees	< Bachelor's	104	3.28	341.55	43.701	3	<.001	0.078
	Bachelor's	151	2.58	263.41

Introductory Students' Definition and Views Regarding Proof

Christina Koehne
SUNY New Paltz

Anthony Cooper
SUNY New Paltz

Keywords: introduction to proof students, student conceptions, importance of proof

In order to meet students where they are, we must first understand where they are at. As Rouhani and Zazkis (2023) noted in their RUME paper, "the existing research on conception of what a proof is and what counts as a proof is primarily focused on expert mathematicians (e.g., Inglis, & Aberdein, 2016, Weber & Czocher, 2019)". Complementary to Rouhani and Zazkis's work on students' conceptions about *proofiness*, we looked at how Introduction to Proof students defined proof and why they thought proofs were important.

Methods

The participants were undergraduate students in a public university, who were enrolled in an introduction to proofs course. Twenty students voluntarily agreed to participate and completed at least the initial reflective though prompts: 1) How would you define or describe the concept of proof? 2) Why do you think proofs are important in mathematics? We merged the students' initial and final reflective thought prompt answers to form our unit of analysis, since several students did not answer both the initial and final prompts. The authors independently analyzed and open-coded each entry before reaching an agreed upon final set of codes and themes. Independent coding was then revised before having a discussion to resolve differences.

Findings

These preliminary findings provide evidence that Introduction to Proof students reflected on four major components when defining proof and its importance: *Coherence*, *Community*, *Building Concepts*, and *Mental Processes*. Each of these four components is comprised of subcategories which will be discussed below.

In terms of *Coherence*, students primarily reflected on the importance of illustrating the validity of statements, the sequencing or logical ordering of statements, and argumentation. Although generalization, claims, and abstractions were mentioned, they were done by only a handful of students. Moreover, proof *coherence* was present for all students who reflected on communication to a *community*. However, the participants were not always explicit in the intent for communication; rather, they were vague in the notion that "You are proving…" for some purpose or would speak in terms of the collective "We", such as, "…concepts that we already know to be true". Additionally, of the students who mentioned using previous theorems, axioms, or definitions to help establish ideas, three (out of eight) did so without notions of communications. Similar to coherence, students would vaguely speak about the ideas of *Building Concepts*, which we noted as the regard of proof as a foundational component that mathematics is built upon or using known concepts to advance mathematics. Lastly, *Mental Processes* was prevalently seen as students noting the usefulness of proofs. However, several students also noted on their emotional experiences regarding proofs.

In conclusion, there is evidence to suggest that students find proofs important and useful for the foundation and expansion of the mathematical community knowledge. However, when it comes to communication and ideas of what a proof is, the notions, although present, could be more nuanced. Special attention in proof courses could be given for the importance of proof.

Graphing as a Tool to Support Covariational Reasoning

Chase Frater
Towson University

Audrey Gianelle
Towson University

Aidan Powell
Towson University

Kristin Frank
Towson University

Keywords: Covariational Reasoning, Student Cognition, Graphing

There are limitations to using graphing tasks to assess students' covariational reasoning since students' nonnormative graphing schemes can impede their ability to graphically re-present their images of covarying quantities (Frank, 2018; Moore et al., 2024). Thus, Drimalla et al. (2020) encouraged researchers to attend to students covariational reasoning in non-graphing contexts. In this poster we document the challenges in demonstrating advanced levels of covariational reasoning without normative mathematical representations, such as graphs.

Covariational reasoning entails an *anticipation* to track how two quantities magnitudes' change together. This involves three essential constructions: (1) constructing two quantities - measurable attributes of a situation, (2) imagining each quantity to vary (variational reasoning) and (3) coupling these images of variation through a multiplicative object (Thompson and Carlson, 2017). The multiplicative object is an essential construction in **co**variational reasoning. As Saldanha and Thompson (1998) explain, "As a multiplicative object, one tracks either quantity's value with the immediate, explicit, and persistent realization that, at every moment, the other quantity also has a value" (pp. 1-2). That is, as the student imagines variation in one quantity they necessarily imagine variation in the other.

One can conceptualize a point in the Cartesian coordinate system as a multiplicative object that simultaneously entails the magnitudes of two quantities. One can then construct a graph by tracking this point in the plane as they imagine the quantities to co-vary. Through this construction the graph is a record of the multiplicative object – the point – under variation. The physical construction of tracking point in the plane allows one to present and coordinate images of simultaneous variation. In contrast, there are linguistic difficulties in expressing one's anticipation to simultaneously attend to two quantities' magnitudes as they vary together: at any moment in time the language one uses will be focused on one quantity or another. One cannot simultaneously communicate variation of the constructed multiplicative object. This is a methodological limitation to studying students' covariational reasoning outside conventional representations, such as graphs.

In this poster we use the work of Sam, an undergraduate first semester calculus student, to document how his graphing activity supported and inhibited his construction of quantities, images of variation, and a multiplicative object. We report that while Sam's nonnormative graphing schemes inhibited him in graphing the gross covariation of two quantities, the activity of try to construct a graph supported him in constructing quantities from a dynamic situation and coordinating gross images of variation. We have no evidence that Sam constructed a multiplicative object to unite these images of variation. We caution this might be evidence of a linguistic challenge, and not a limitation to Sam's covariational reasoning. Sam's work illustrates some challenges of assessing students' covariational reasoning outside the context of graphing and suggests that the action of graphing might be necessary to enact advanced levels of covariational reasoning.

Designing With ChatGPT: A Critical Conversation

Matthew Mauntel
University of New Hampshire

Zack Reed
Embry-Riddle Aeronautical University

Keywords: Task Design, Undergraduate Mathematics, Technology, Artificial Intelligence

In recent years there has been an explosion of mathematics software supported by artificial intelligence that has supported the ways students think about mathematics. With the advent of generative AI (ChatGPT, NotebookLM, Gemini, etc.), the use of AI has steadily grown among the student population. This creates the demand to both understand the use and capabilities of AI by mathematics educators and how it can be leveraged for teaching (Frieder et al., 2023; Hodge-Zickerman & York, 2024; Sapkota & Bondurant, 2024; Wardat et al., 2023). Generative AI can take on several different supporting roles (Eager & Brunton, 2023; UNESCO, 2023) including being a creative engine, personal tutor, conversational buddy, etc. We approach the use of generative AI from the perspective of task design for an undergraduate mathematics educator. In this work we will address the research question: What are the affordances and constraints of the use of AI for undergraduate mathematics task design? We will be focusing on the capabilities of AI to provide background research for task design, generate code for use in task design, provide contexts for task generation, and create entire tasks and task sequences from user prompting.

For this research, we plan on doing a self-study approach (LaBoskey, 2004) – a qualitative approach of practice, analysis, and critical conversations – to reflect upon our designing and supporting the design of tasks for undergraduate mathematics students. Both authors are experienced task designers in undergraduate mathematics education, often make use of technology in task design, and have published work on the task design. For this analysis, each of us used ChatGPT in different ways to aid in the design of tasks. We shared our dialogues with ChatGPT, read through the dialogues, and then had critical friend conversations for each dialogue about how we used ChatGPT for different stages in task design. These conversations centered on the affordances and constraints of using ChatGPT for task design, the role of the task designer in the conversation, and the possible implications/uses for undergraduates using ChatGPT in a mathematics classroom. The transcripts of these conversations were transcribed, and we will present our initial analysis of these conversations on the poster.

The four dialogues that serve as a basis for this research include topics the following topics:

- Prompting ChatGPT to explore the mathematics behind the single value decomposition and related applications to data science from a mathematical source.
- Using ChatGPT to develop coding for Python and Matlab to illustrate different calculations in linear algebra.
- Exploring the use of ChatGPT to synthesize different frameworks for task design, modify the framework according for specific considerations of the instructor, and generate tasks using the modified framework.
- Generating realistic starting points for advanced mathematical topics such as Lie groups that can be leveraged for task design.

We will build on this work by examining the intricacies of task design more broadly, and particularly how technology and AI can be effectively integrated with current task design best practices.

Mapping Instructor Movement: Use of Classroom Space as a Communication Act

Elisha Hall
Western Michigan University

Tabitha Mingus
Western Michigan University

Keywords: classroom observations, interactions, socio-cultural norms, non-verbal communication

Storylines within discourse contain the imagined roles and interactions carried by the speaker (Herbel-Eisenmann et al., 2015). Participants in a classroom act out their storylines and in doing so negotiate roles. Positioning theory describes these roles as "positioning" actors (i.e., teachers and students) with agency and authority according to their role (Anderson, 2009; Herbel-Eisenmann et al., 2015; Langer-Osuna & McKinney de Royston, 2017; Wagner & Herbel-Eisenmann, 2014). Researchers examine discourse within teacher/student interactions to understand the student experience in the classroom (Adger & Wright, 2015; Chronaki & Kollosche, 2019; Herbel-Eisenmann & Wagner, 2010; Wagner & Herbel-Eisenmann, 2008).

Discourse (capital "D") includes verbal and non-verbal communication that contributes to messages of stance, power, agency, and authority (Bishop, 2012; Herbel-Eisenmann et al., 2015; Razfar, 2012). Non-verbal communication in this context includes gestures, facial expressions, and body language. In this poster, we purport movement is also a non-verbal discursive act that communicates positioning, agency, and storyline.

Classroom observations were done in a variety of courses (mathematics education content, mathematics, and statistics) as an exploratory phase of a larger research study at a Midwestern university. The recordings were played double-speed to focus on teacher movement. Examples of mapping the instructors' movements are provided below. Each map represents the first twenty minutes of instructional time for a single observation.

Every trip the instructor made from the front and around the room was given a unique color, and stops were shown as an "x." Looking at a map, one can identify whether the instructor stops to talk with students, centering themselves within conversations or standing to the side, or if they walk, pivot, and return to the front. The proposed poster will demonstrate many of these maps with details of the positioning displayed by each.

The information gleaned from these maps provides a glimpse of movement-as-communication, which informs storylines and impacts student positioning.

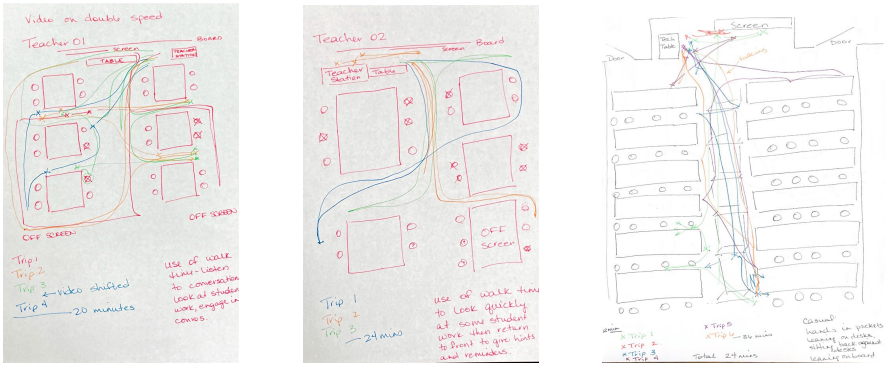

Figure 1: Examples of maps of teacher movement within the first 20 minutes of instructional time

Towards an Awareness of Instructional Approaches in Graduate Mathematics

Peter Karanevich
University of Colorado - Boulder

Keywords: Graduate Mathematics, Classroom Pedagogies, Instructional Practices

Mathematics teaching and learning research has occurred in elementary through secondary levels for at least the past century (Perry, 1901). Researchers have debated what mathematics should be taught (Romberg, 1992; Apple, 1992; McLeod et al., 1996), how content should be taught (National Research Council, 2001; Gutstein, 2016), and even who deserves to learn math (Guttiérrez, 2018; Schoenfeld, 2002; Louie, 2017). We have learned many things from these studies such as different perceptions of mathematics learning (Nasir, 2002; Sfard, 1998), and benefits of teaching strategies that center student participation (Boaler & Greeno, 2000). Recently, there have been efforts to research undergraduate math, namely the calculus sequence, abstract algebra, and linear algebra (Kogan & Laursen, 2014; Abdulwahed et al., 2012). These efforts have had impacts on how some universities (re-)structure their math courses and have resulted in greater student success in these courses (Laursen et al., 2014). All of these results came from investigating mathematics at various levels of a learner's trajectory, but there exists a higher level of tertiary mathematics where little research exists: graduate mathematics courses.

In many PhD mathematics programs across the United States, there is a common course trajectory for students. This trajectory involves a pillar sequence of classes, typically in Algebra, Analysis, and Topology. These courses are assessed using department-created tests, which the institution of study called preliminary exams, that are designed to evaluate student understanding of the concepts related to these core courses. Different schools have different expectations for the quantity/time frame for tests and testing windows and what are considered pillar courses. Overall, the trend for many students going into a mathematics PhD programs in the United States is to take course sequences that have high stakes assessment and then the courses beyond these are evaluated by instructor discretion.

This poster shows student/instructor responses about instructional practices during different stages of a students PhD program. Research has shared very little about course sequencing in graduate programs nor how this sequencing relates to student/instructor experiences in the classroom. Through interviews with PhD students and instructors of graduate mathematics courses, as well as classroom observations in multiple courses through the program at one PhD granting midwest university, I have had the opportunity to discuss teaching strategies and observe graduate classes in action. One finding from these data shows the difference in assessment strategies used and also instructional practices. For example, one student participant explained how"the pillar courses and the after pillar courses are very different", specifically pointing to her experience in a non pillar Analysis class where the instructor would "lecture at us [students] for a couple of days, asking us for our input [and] we got to ask questions and direct the lecture, depending upon our understanding." This contrasts with her pillar experience where, "There's no active learning. There's no group work. There's no discussions really happening in class for certain instructors." This shows one example of different teaching styles that are used.

Discussing differences between classroom instruction can begin conversations about mathematical achievement in PhD programs. Who benefits/struggles from the different instructional styles? How do the different approaches to teaching impact student retention? These questions and more are very important to consider when looking at classroom practices.

Gender, Rank, and Service: Unpacking Inequities Among Math Faculty at Research Universities

Sarah Otterbeck
Clemson University

Matthew Voigt
Michigan State University

Keywords: Service Responsibilities, Gender Identity, Math Faculty

Research consistently demonstrates that cisgender women faculty shoulder a greater service burden than cisgender men (CM), revealing a gender-based disparity in service performance and expectations (Guarino & Borden, 2017; Misra et al., 2021; O'Meara et al., 2017; Pyke, 2011). To address this issue, we aim to explore how tenure-stream faculty within mathematics departments at research-intensive institutions describe gender inequities through self-reports of time spent on service. We focused on mathematics departments and research-intensive institutions because of the absence of studies in this area and the significant underrepresentation of gender marginalized individuals (i.e., cisgender women and genderqueer (CWGQ)) (Blair et al., 2014).

Data for this analysis comes from the distribution of the Faculty Service Survey, developed and distributed via Qualtrics in the Spring 2024. We used convenience sampling through emails to reach tenure-stream math faculty at research-intensive institutions (high or very high) as defined by the Carnegie classification. Out of 218 responses, 75 participants met the eligibility criteria. We examined numeric responses on the time spent per month on various service activities. We measured these activities by a monthly timescale to capture a comprehensive view of faculty responsibilities and account for any service occurring on a once-a-month obligation. We analyzed the average hours on each type of service by academic rank (Assistant, Associate, Full), gender (CWGQ and CM), and the intersection of gender and ranks.

Preliminary findings indicate significant gender disparities in the performance of service responsibilities among tenure-stream math faculty. CWGQ faculty reported higher averages for service aligning with "feminized" service, i.e., "relational-oriented" service, (Hanasono et al., 2019) whereas CM faculty reported higher averages for service aligning with "masculinized" service, i.e., "goal-oriented" service (Hanasono et al., 2019).

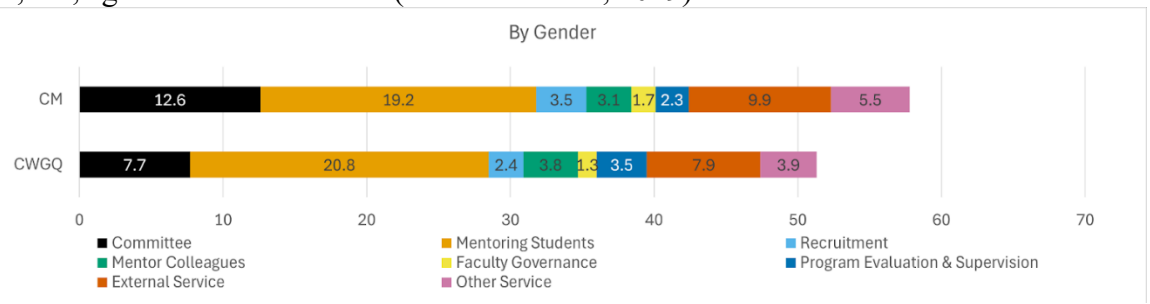

Figure 1. Stacked bar chart of monthly service hours by gender.

The data additionally revealed that Full Professors generally perform the most service hours, except in mentoring students and external service, where Associate Professors lead. Assistant Professors reported the least service overall, with notable exceptions in mentoring roles. These findings highlight the need for further analysis to understand these inequities and develop policies for more equitable distribution of service responsibilities.

Training AI Tutors: Tutor Training of the 21st Century

Eva Politou
Harvard University

Megan Selbach-Allen
Harvard University

Ari Kaufman
Harvard University

Milan Naropanth
Harvard University

Keywords: Tutor Training, Multivariable Calculus, AI Tutor

Introduction and Theoretical Framework

AI tools like ChatGPT and other Large Language Models (LLM) are here to stay, and already in use in educational platforms like Khanmigo. These tools show a lot of potential for use in education, but in their current form appear to be most useful for semi-supervised content generation (Nye et al., 2023). While AI tutors have potential to help students learn, provide personalized guidance and expand educational support they still require training and supervision. Using a lens of undergraduate tutor training (Johns, 2024) we sought to answer the questions: How does an AI tutor respond to training and how effectively does it support students?

Methods

This study was a case study of an AI tutor developed to support students in a multivariable calculus course. Students had the option of attending an in-person problem solving session led by an undergraduate course assistant or engaging with the same problems assisted by an AI tutor. The tutor was built on the TeachGPT platform which integrates ChatGPT 4 and 4o into educational tools for personalized learning (Kestin et al., 2024). The AI tutor was trained to be a friendly and encouraging persona focused on inquiry-based learning, guiding students through real-life applications of multivariable calculus. It was directed to avoid giving direct answers, instead offering hints or guiding questions like, "What do you think would happen if...?" to foster critical thinking and reflection. For each workshop, problems and solutions with detailed instructions, including learning objectives, solution steps, common misconceptions, and strategies to address them, creating a supportive and engaging learning environment were uploaded to the platform. Data for this study were the training prompts and logs of student tutor interactions over the course of the semester.

Results

After initial training, the AI tutor was helpful to students and did not appear to hallucinate or provide incorrect information. However, it appeared to be “too helpful” in that it was likely to provide a complete solution to the problem after a short question from the student. Further training from the course instructor was needed to direct the AI tutor to provide shorter hints and guide students via questioning rather than providing full solutions initially.

Discussion and Implications

This study demonstrates one potential use of LLMs in an undergraduate mathematics classroom. The course instructor felt the fully trained model performed well as a tutor and this modality was popular with students although many students still preferred to attend in-person sessions. Further research is needed to provide more general guidance for effective training of LLMs to act as mathematics tutors for students. With the current state of this technology the role of the human instructor remains central to the success of the AI tutor.

Supporting Playful Mathematical Problem Solving With Puzzles: Variant Sudoku

Jeremy Bernier
Clemson University

Eliza Gallagher
Clemson University

Neil J. Calkin
Clemson University

Keywords: mathematical problem solving, mathematical puzzles, play

The development of mathematical problem solving skills has been long-recognized by a variety of stakeholders as critical for all learners (English & Sriraman, 2010; Pólya, 1945). Additionally, solving mathematical problems can be a playful, enjoyable, and beautiful process (Holton et al., 2001; Su, 2020; Williams-Pierce & Thevenow-Harrison, 2021). Yet, many students who might have become excellent mathematical problem solvers are pushed out of mathematics early on in their educational experiences and may experience mathematics anxiety or other negative emotions when they participate in undergraduate mathematics courses (Maciejewski et al., 2024; Pajares & Miller, 1994), and may struggle to experience mathematics in the playful way that mathematicians do (Bernier, 2024).

Puzzles have long been suggested as a means of introducing students to enjoying mathematics and to engaging in mathematical problem solving (Burton & Burton, 1980). In general, a puzzle can be construed as a game or fun activity with a correct solution or right answer (Kim, 2006; Salen & Zimmerman, 2004). Puzzles can also involve mathematical problem solving and playful mathematics, particularly if they invoke mathematical structures, ideas, and objects directly in their presentation. A popular example is sudoku, a genre of puzzle where the solver must use given information to fill each row, column, and 3-by-3 box within a 9-by-9 grid with each of the digits 1 through 9. Sudoku has been used to support students engagement in and learning about mathematics in a variety of contexts (Butler & Butler, 2007; Lorch & Lorch, 2008; Tengah, 2011; Wanko, 2010).

In recent years, a community of puzzle solvers and setters has developed around what is known as "variant sudoku." Variant sudoku puzzles are sudoku puzzles which use additional rules and structures on top of the standard sudoku rules. For example, the "German whisper line" restriction indicates that adjacent in cells falling along a line must differ by at least 5. Under this condition, if two cells are joined by a line and one of them contains a 4, the other must contain a 9. These restrictions, combined with clever placement, allow the crafting of puzzles that provide few or no digits initially yet are still solvable through logical and mathematical reasoning. Moreover, these additional restrictions allow for the application of additional mathematical topics beyond those permitted in standard sudoku.

Our team is working to integrate variant sudoku into undergraduate mathematics coursework and to research that integration. Currently in the works is a study into the mathematical identity development of students who participate in variant sudoku solving and setting in an undergraduate honors course. Additionally, we are developing a design-based research project to craft open-access materials for a general education course centered around solving and setting variant sudoku puzzles. These projects are in early stages; as such, our poster will present information on the projects at their stage at the time of the conference. It will also include opportunities for attendees to participate in variant sudoku solving live.

The University of Alabama

Keywords: Instructional experience, gender, bold problem solving, college math

Curriculum and instructional modality are not neutral—each reflects individual choices and disciplinary norms that may be experienced differently by students depending on their background and identity (Leyva et al., 2021). The current work is preliminary work exploring ways to measure the influence of students' gendered attributes on their perceptions of their experiences in undergraduate mathematics classes. In particular, we ask: (a) What characteristics of interactions in mathematics classes result in different responses based on the student's binary sex and (b) which gendered attributes of the students relate to students' responses to surveys about mathematics classroom instruction?

Theoretical Framework

Gender is widely understood to be rooted in socialization, and we use it with this intent. Researchers have been attempting to unpack gendered attributes beyond the binary to understand the socialized tendencies associated with men and women. For example Stets et al. (2023) asked over 900 ethnically diverse undergraduate students about words in response to the phrases "Men usually are" and "Women usually are". They found that 30% of the descriptors describing men could be categorized as showing agency. In contrast, over half of the attributes found to describe women could be categorized as communal or competent. Taken together, it is evident that the concepts of personality and gender are conflated. This has implications for math experiences as Alcock et al. (2014) found that personality had predictive power above binary sex for math achievement, particularly the characteristics of agreeableness and conscientiousness.

Methods

A convenience sample of 67 students enrolled in undergraduate mathematics classes were surveyed via an electronically distributed survey link. The survey asked a battery of gender identification items and scales, including measures based on work by Stets et al. (2023). The survey also included slightly truncated versions of the "What Is Happening In the Class? (WIHIC)" questionnaire (Dorman, 2023) and the "Student Postsecondary Instructional Practices Survey in Mathematics (SPIPS-M)" (Apkarian et al., 2019; Creagar et al., 2022).

In order to answer research question 1, we used Kendall's W coefficient of concordance to determine if there are statistical differences in how males and females rate the mathematics class in the 6 subscales of the MCAQ. To answer research question 2, we looked at the correlations between the three gendered attributes and the 6 components of the MCAQ.

Results and Discussion

A variety of suggestive but small or non-significant relationships were evident that warrant further investigation and which will be elaborated on in the longer poster format. For example, Agency (from one of our gendered attribute scales) had a negative correlation with Teacher-Student-Content Interactions and positive correlations with Student-Student and Student-Student-Content Interactions. Further studies with a larger sample size may result in significance and additional qualitative analyses are also warranted to unpack observed relations.

An Undergraduate Student's Experiences with Mathematical Proof's Values and Norms

Jose Saul Barbosa
Michigan State University

Keywords: Proof, Norms and Values, Poststructuralism, Unstructured Interview

I use a poststructuralist stance to interrogate some of the discourses for mathematical proofs and their relationship to their author. Discourses are anything in our world that can be thought of and brought into existence through writing or creation which also influences the way that we think about or view social entities and/or relations or even what can be said, thought, or done in particular situations (Fendler, 2010; Walshaw, 2016). Scholars have adopted a poststructuralist perspective due to its ability to question the "normalities" in different social settings (Gutiérrez, 2013). While some mathematics education studies use poststructuralist theory (Dubbs & Herbel-Eisenmann, 2021; Johnson et al., 2022; Stinson, 2008, 2013), this perspective has not yet been widely used to explore questions related to the practices of mathematical proof. I view values and norms for mathematical proof as some of the discourses that inform the mathematics community about what is "normal" in mathematical proof.

Dawkins and Weber (2017) conceptualize some values for mathematical proofs, including the aim for mathematics that mathematical truth is purely objective and should not rely on the experiences of the author or their community. Norms upholding this value include omitting how an individual may have come to understand an object or concept in a particular way in a final proof or the norm that the author leaves out how they came to build their proof as the final argument should stand on its own without the experiences of the author. Researchers have worked to support students' *access* to these and other mathematical norms and values (Rupnow & Randazzo, 2023; Vroom et al., 2024; Vroom & Ellis, 2024); here, I aim to interrogate this value and associated norms. I address the research question: What are some ways that mathematics students respond to reading about norms that adhere to the value that mathematical proofs should be independent from the author and proofs which follow or breach these norms? During an unstructured interview, I presented an undergraduate student, Sherine, who completed an introduction to proofs course, with an excerpt from Dawkins and Weber's (2017) "Values and norms of proof for mathematicians and students" along with a theorem's textbook proof and a modified version of this proof which is meant to breach the norms mentioned above within an unstructured interview session setting. After I presented each material to Sherine, we discussed how she has experienced these values and norms.

From her reading of the excerpt, Sherine questioned the convention that an ideal mathematician should conceal that they are human. Sherine said, "We know that they are human, so why would we conceal that fact?" Despite this questioning, Sherine expressed her appreciation for the textbook proof which she said was "short and clear" compared to my personalized proof that, "makes sense and it's an explanation but that's not what a proof is." Instead, Sherine felt that the personalized proof sounded as if someone were verbally sharing the proof with another person or in a lecture. Sherine's recognition of my personalized proof as something to be shared in a lecture could have implications for how proofs are presented to students. In my future research, I will continue to investigate how more students in a focus group setting respond to this excerpt and different versions of proofs.

Undergraduate Students' Nature of Mathematics in an Introduction to Proof Course

Jordan E. Kirby
Francis Marion University

Keywords: Nature of Mathematics, Introduction to Proof, Student Reasoning

What is mathematics? This question, and the study of the nature of mathematics more broadly, are of interest to many mathematicians. However, many universities do not include dedicated coursework to studying the nature of mathematics. Reflecting on the nature of mathematics is important for both personal development as a mathematician (i.e., Hersh, 1998; Lakatos, 1976), as well as for the development of mathematical concepts itself (i.e., Ernest, 1985; Lakoff & Nunez, 2000).

Transition to proof courses offer a time for students to reflect on the nature of mathematics due to the shift from computational calculus courses to more abstract proof courses. Boyle and colleagues (2015) argued a transition to prof course may be the first time students are asked to become creators of mathematics rather than reproducing what they have previously seen. This course presents an opportunity to study what views these students hold of the nature of mathematics. In this study, I asked students in an introduction to proof course to respond to the prompt, "In your own words, what is math?" This question was asked multiple times through the semester after several intentional activities to force reflection were completed. Ten students responded to three prompts each over the course of the semester. Each batch of 10 responses were open coded for common responses. Nine of the ten students were math majors in their third or fourth years of the major, all having completed the calculus sequence. The remaining student was a computer science major with a mathematics minor.

As of the writing of this poster, the final writing prompt is being given to student participants. Initial results indicate an overwhelming majority (8 of 10) of students initially viewed the nature of mathematics as simply a "toolbox" to be used for other disciplines, or for problem solving. Seven of the 10 students remarked they had never formally considered the question "What is mathematics" before answering this prompt. Halfway through the semester when the question was asked again, responses started shifting slightly away from a toolbox approach to include more reasoning for validation or to answer questions mathematicians themselves ask.

Students were asked to reflect on what contributed to their evolving understanding of the nature of mathematics. Two students mentioned watching YouTube series, while the other students mentioned working with proofs in a general sense to shift their nature of mathematics. By February, I will have analyzed the third group of responses to see how this shift across the semester continues.

In this poster session, I hope to gain insight from attendees into what aspects of this research are most convincing, and any future directions such as intentional readings to include or classroom activities to include to help foster growth in the nature of mathematics.

An Intersectional, Quantitative Analysis of Undergraduate Students' Responses to Racialized and Gendered Instructional Events in Undergraduate Calculus

Megumi Asada
Rutgers University

Dan Battey
Rutgers University

Luis A. Leyva
Vanderbilt University

Maria Maria Castillo
Vanderbilt University

Keith Weber
Rutgers University

Keywords: Calculus; Equity; Black; Latin*; Women

It is widely agreed that undergraduate calculus is a gatekeeper to STEM degrees, weeding out Black and Latin* students and leading to a disproportionate loss of women (Ellis et al., 2016; Weston et al., 2019). Students' experiences in calculus classrooms can reveal how instruction reinforces inequities in mathematics learning opportunities (Leyva et al., 2021; Leyva, 2016). Our poster presents a quantitative analysis of the impact from two marginalizing events in calculus instruction on students' emotions and participation across race-gender intersections.

Previously, our team completed a qualitative study where cisgender Black students, Latin* students, and white women journaled about marginalizing instructional events in their calculus classrooms. Journaling responses were used to develop stimulus events for individual and group interviews to solicit student perceptions of these events as potentially racialized and/or gendered. We developed theoretical accounts for how seemingly neutral and commonplace events, such as ignoring a student's raised hand, can be marginalizing when accounting for broader influences of racism and misogyny (e.g., stereotypes of mathematical ability; Leyva et al., 2021). This work examines the extent to which our prior qualitative accounts generalize to a larger population.

The present quantitative study explores national survey data collected in Fall 2019 and Fall 2021 from students at 108 state colleges and universities with similar demographics to the state university where the qualitative study was conducted. Survey respondents included 322 Black, Latin*, American Indigenous, Middle Eastern and/or North African students, and multi-racial students. Our analysis focused on students' responses to two instructional events that our prior work identified as marginalizing (Leyva et al., 2021). The first event involves a student attempting to correct an instructor's mistake and getting interrupted by the instructor. The second event features an instructor laughing at a student and repeatedly not providing an answer to their question. For each event, our participants addressed if it would: (i) make them feel angry, frustrated or discouraged, (ii) impact their future participation, and (iii) make them aware of their race or gender. A factor analysis based on participants' responses to items in categories (i) and (ii) identified two scales. We report average scores on a scale (α=0.890) accounting for negative affective and participatory impacts of each event.

Results and Significance

On average, Black women (M=3.14, SD=0.60; M=3.08, SD=0.69) and white gender nonconforming students (M=3.11, SD=0.47; M=3.33, SD=0.36) were negatively affected by both events. (An average score of 3 corresponds to choosing "agree" to items indicating negative impacts on a 5-point Likert scale). Latin* women, white women, and Black men averaged above a 3 for one event. The results speak to the differential impact of instructional events by race-gender intersection and can help us create more affirming classroom spaces for historically marginalized students.

Immediate IBL Implementation With Minoritized Students as a Professional Development Activity

Bhargav Kale
The University of Arizona

Destiny Rivera
The University of Arizona

Aditya Adiredja
The University of Arizona

Keywords: classroom pedagogy, professional development, equity

Research has documented the benefits of Inquiry Based Learning (IBL) on student outcomes (e.g., Laursen et al., 2014). Even as new studies more carefully examine the differentiated benefits on minoritized populations (Johnson et al., 2020), professional development (PD) efforts, like the Academy of Inquiry Based Learning continue to attract many university educators nationally. The impact of such PD on participants' adoption of IBL practices have been a focus of study (e.g., Archie et al., 2022). The nature of PD usually involves workshops where people learn about teaching or how to adapt their teaching material to apply ideas from the PD. To different degrees, programs would incorporate student work or video data as a reflection material for participants. In this report we ask, *what are the impacts of immediately engaging PD participants in implementing IBL with minoritized students on the participants' teaching?*

This analysis was part of a larger project investigating instructors' development of teaching using active learning and anti-deficit perspective. Instructional faculty and graduate students at a research university applied to participate in the PD, and the year-long program went from the summer to the following spring semester. One core activity was the participants' leading a five-day IBL workshop in pre-calculus, calculus, or linear algebra. A month prior to the workshop, participants participated in four preparation meetings focusing on: 1) deficit discourse in mathematics education and teaching using IBL, 2) anti-deficit perspective and funds of knowledge, 3) writing an IBL worksheet (individual consult); 4) sharing the first worksheet and lessons about how to write worksheet; 5) sharing hopes and fears about the upcoming workshop. The five-day workshop was a part of a summer bridge program serving primarily first-year first-generation STEM students of color, and other interested minoritized students at the university. The instructors also received coaching on IBL teaching on their second day of the workshop.

Our findings come from analysis of exit interview data with a cohort of eight participants. We report on the significance of the immediate implementation of IBL with minoritized students by analyzing responses to two non-consecutive questions: "What is a major highlight of your experience participating in this program?" and "How do you view your role as a classroom teacher now?" Constant comparison (Glaser, 1965) revealed themes in the data. Four of the five common highlights pertain to implementing IBL in the workshop: *experiencing teaching using IBL, learning to design worksheets, playing a role of a guide in the classroom, broadening communication in the classroom*. Moreover, they aligned with the six themes of how participants viewed their role in the classroom eight months after the workshop, including *creating an empowering classroom community*, *shifting the thinking from instructor to students*, *actively listening to student thinking, affirming and honoring students' work, expecting students to communicate with one another, and expanding participation to include non-visible involvement.* Seven out of eight participants gave explicit examples on how they performed their roles in the classroom during their regular semesters, highlighting impacts on their practice. The emerged roles encouragingly align with many culturally responsive teaching practices (Zavala & Aguirre, 2024), which we connect to their actual experience implementing IBL with minoritized students.

The Disconnect Between Undergraduate Standard Mathematics and Modern Applied Mathematics: A Review of Integral Transform Research

Cory Wang
Middle Tennessee State University

Keywords: Applied mathematics, Information processing, Fourier analysis, Laplace Transform

Recent concerns highlight a shortage of engineering graduates to meet modern demands, in part due to the high drop-out rates in undergraduate engineering programs (Faulkner et al., 2019; Flegg et al., 2012). Various studies have attributed this to engineering students' struggles to transfer mathematical knowledge to engineering contexts (Ekici et al., 2020; Harris et al., 2015). This concern is further highlighted by Chui and Jiang (2013), who described a recent shift in modern applied mathematics from modeling through differential equations to information processing and data science, requiring a different set of mathematical concepts which have not been emphasized in the past, such as Fourier analysis and abstract linear algebra. This literature review aims to study the disconnect between the standard mathematics curriculum and modern applied mathematics. Due to the breadth of existing research, this review focuses on integral transforms (Laplace and Fourier Transforms), which provide a bridge between the standard mathematics curriculum and modern applied mathematics. The following two research questions guide the review: How are the Laplace and Fourier Transforms viewed differently between mathematicians and engineers? Is the standard mathematics curriculum effective in preparing engineers for their future studies, particularly in the field of Fourier analysis?

Methods

A literature search of mathematics education and engineering education journal articles and conference proceedings was performed with the keywords "Engineering Mathematics Education" and "Applied Mathematics Education". Articles not explicitly addressing differential equations, Fourier analysis, Fourier Transforms, or Laplace Transforms were excluded. A total of 57 articles were found, primarily in the *International Journal of Research in Undergraduate Mathematics Education*, *International Journal of Mathematics Education in Science and Technology*, and *IEEE Transactions on Education*. Open coding was performed on the 57 articles where key words and ideas along with specific excerpts were extracted. Themes and connections within the literature relating to the research questions were then identified.

Preliminary Findings

Integral transforms are viewed differently between mathematics and engineering due to the primary generating question, or question motivating integral transform use, in these contents. In mathematics, transform methods are a tool to solve differential equations. In engineering, transform methods are the key to characterizing and analyzing linear systems without finding closed-form solutions (Rønning, 2021; Rezvanifard and Radmehr, 2024). This results in key tasks, techniques, justifications, and theories involving the information processing dimension of mathematics, including complex numbers, functional analysis thinking, and the frequency domain, being underdeveloped in undergraduate mathematics courses (Ekici et al., 2020; Hochmuth & Peters, 2021). During the poster session, I plan to share findings and implications of this review. I also plan to obtain feedback regarding future directions and questions the RUME community would like explored regarding modern applied mathematics education.

The Impact of Physics Context on Student Thinking About Vector Product Directions

Allison Molinari
University of Maine

John R. Thompson
University of Maine

Keywords: Vector products, Student thinking

Introduction and Background

Although in mathematics curricula, vectors are typically not covered in depth until calculus 3 or linear algebra, vector quantities are used extensively in introductory physics (e.g., Knight, 2017); mathematical operations on vectors are prevalent in this context. The body of literature examining student understanding of vectors includes assessment instruments, but typically with significant focus on computational issues and/or the impact of context (Van Deventer, 2008; Mikula & Heckler, 2013; Heckler & Scaife, 2015; Barniol & Zavala, 2014; Carli et al., 2020). Other work has attended to more conceptual understanding about dot and cross products (Zavala & Barniol, 2013; Barniol, Zavala & Hinojosa, 2013). To more explicitly explore the role of context and aspects of task features on student performance, our research goals are to identify (1) how different contexts impact student ideas of vector concepts and (2) how performance on vector concepts varies with course level. We analyze how introductory physics students describe the direction of dot- and cross products in different contexts.

Methods

Multiple-choice, online surveys were administered in each semester of calculus-based introductory physics (PHY1, PHY2) after relevant instruction. Several prior tasks have had answer choices that are a mix of scalars and vectors, leaving some ambiguity about students' understanding of the vector or scalar nature of the products. To disentangle calculation errors from student understanding, we asked about the magnitude and direction of each product in separate questions. Surveys included several tasks asking about the magnitude and direction of dot and cross products, first as a pair of generic vectors in a 2-D coordinate system and second in a physical context. The physics contexts were mechanical work, magnetic flux, and the Lorentz force. We discuss the results of the direction tasks.

Results and Discussion

In the non-physics context, PHY2 students performed better than PHY1 students on both the dot- and cross product direction tasks. The most common incorrect answer, in both classes, was a direction *between* the two vectors; student explanations suggest the incorrect application of vector addition principles and ideas of combining vectors. From the non-physics to the physics context within each course level, there was no significant shift between correct and incorrect responses, for both the dot- and cross product tasks. However, there was a significant shift from *between* to other answers. The most common incorrect responses varied in the physics contexts in ways that reflect reasonable confusion with the physical quantities.

These results suggest that context does not impact overall performance but does impact which distractors students select. We are working on adopting or modifying existing analytical frameworks to explain the context dependence of student responses. Symbolic forms (Sherin, 2001), models of transfer (e.g., Lobato, 2008; Rebello et al., 2017), and dual-process theories of reasoning (Evans, 2006; Heckler, 2011; Kryjevskaia et al., 2014; Speirs et al., 2021) are three promising prospects that may provide insight on the impact of different contexts.

The Landscape of Research on the Meta-mathematical Aspects of Definitions

Rosina Andrews
Middle Tennessee State University

Cory Wang
Middle Tennessee State University

Keywords: Proof, mathematical definitions, literature review, meta-mathematical aspects

Meta-mathematical aspects of definitions (MMAD) are the general notions held about the nature, roles, functions, and characteristics of mathematical definitions (Gilboa et al., 2023). Mathematics education research has produced several rich branches of research exploring the meta-mathematical conceptions that proof learners, educators, mathematicians, and researchers hold about mathematical definitions (Edwards & Ward, 2008; Gilboa et al., 2023; Torkildsen et al., 2023; Zaslavsky & Shir, 2005). Researchers have found the MMAD play a role in students' success in producing mathematical proofs and developing their conceptions of mathematical definitions (Gilboa et al., 2023; Torkildsen et al., 2023). While the MMAD have been discussed both implicitly and explicitly in mathematics education literature, we have anecdotally noticed a trend of conflation in these aspects that may lead to confusion for novice researchers. In this project, we seek to review MMAD literature produced by the top ten mathematics education research journals to characterize the conceptions held about the MMAD by the mathematics education community. We seek to answer the questions: What MMAD have been most and least explored by mathematics education researchers? How has extant literature characterized these MMAD? What group has been most represented in research exploring conceptions of MMAD?

We conducted a systematic review of the top ten mathematics education journals, as identified by Williams and Leatham (2017). These include *Educational Studies in Mathematics*, *Journal for Research in Mathematics Education*, *Journal of Mathematical Behavior*, *For the Learning of Mathematics*, *Mathematical Thinking and Learning*, *Journal of Mathematics Teacher Education*, *ZDM: The International Journal on Mathematics Education*, *Mathematics Education Research Journal*, *International Journal of Mathematics Education in Science and Technology*, and *School Science and Mathematics*. The search was performed by identifying articles with the keywords "function of definition," "definition proof," "mathematical definitions," and "definition usage" in the body. A total of 108 articles were identified. The articles were coded separately by two researchers, searching for mentions of the meaning of mathematical definitions and concepts, with special focus on the meta-mathematical aspects (i.e. roles, functions, criteria, properties, and usage) of definitions. After disagreements were resolved, articles not implicitly or explicitly discussing the meta-mathematical aspects of definitions were excluded, resulting in 66 articles for further analysis in nine of the ten journals.

In this poster, we plan to share preliminary findings related to the implicit and explicit descriptions of MMAD as well as the meta-mathematical focus of the articles. These articles will be categorized according to the specific categories of the meta-mathematical aspects of definitions discussed. We offer a framework to clarify distinctions in the categories of MMAD, and thus aid in the streamlining of future MMAD research. Finally, we will describe the demographic (i.e. undergraduate students, pre-service teachers, mathematicians) that has been most-often featured in meta-mathematical definition research. During the poster session, we intend to gather feedback from the RUME community on future directions of the study and questions about mathematical definition research the community would like answered.

Shifting Perceptions: Using Stories to Understand Changes in Students' Attitudes After Completing an Introductory Mathematics Course

Samuel D. Reed
Lander University

Chase T. Worley
Lander University

Keywords: Mathematical Attitudes, Mathematical Narratives

Students' attitudes toward mathematics significantly influence their mathematical learning and achievement (Turgut & Bakir, 2024). Further, studies have suggested that mathematical achievement can be a predictor in whether students graduate from high school (McKee & Caldarella, 2016). These issues persist in college, with many students underprepared for their introductory mathematics coursework (Martinez et al., 2016) and drop/failure rates over 40% in these courses (Herriot, 2006). In a previous study (Reed & Worley, 2024), we investigated students' attitudes towards mathematics by examining their mathematical autobiographies or narratives in an introductory college mathematics course, akin to College Algebra. It was found that students' stories fit into four general categories: Friendly; Familial; Antagonist; and Frenemy, with a majority of students having a negatively leaning story (Reed & Worley, 2024).

The goal of this study was to examine and categorize the reasons which students expressed had shifted their attitude towards mathematics or their mathematical narrative in a more positive direction. To investigate this, we had students in a 'Launch into the University' initiative over the summer of 2024 to complete Pre- and Post-Narratives about their relationship with mathematics. The university offered introductory English and Mathematics courses, including English 101 and College Algebra, with integrated tutoring assistance. Many participants in these classes had experienced significant educational challenges during the COVID-19 pandemic disruptions, as mentioned in the Pre-Narratives. In examining these students' Post-Narratives, we found several factors which influenced their attitudes, and helped to promote a more positive outlook about themselves as mathematics learners. Despite the prevalent negative attitudes towards mathematics documented in prior research, our analysis of students' Post-Narratives revealed several key factors that contributed to positive attitudinal shifts. These factors included: (a) supportive and effective teaching approaches that create engaging learning environments, (b) students' development of resilience and help-seeking behaviors, (c) growing confidence and sense of mathematical empowerment, (d) recognition of mathematics' real-world relevance, and (e) challenging internalized negative perceptions about mathematical ability. By identifying these transformative elements, our study provides insights into potential interventions that may help mitigate the persistent challenges of mathematical anxiety and underachievement in higher education.

In this poster session, we hope to prompt the following discussion: *how do we leverage these results to continue to shift students' attitudes in a more positive direction?*

Sudoku: A Bridge to Proof Validation

Brittney Fahnestock
Texas State University

Sarah Hanusch
SUNY Oswego

Keywords: proof writing, proof validation, curriculum

It is well established in the literature that undergraduate students struggle when first learning how to write proofs, writing, and validating the proofs of others (e.g. Alcock & Weber, 2005; Selden & Selden, 2003; Stylianides, et al., 2017). The literature base hypothesized that explicit instruction on proof validation would help students improve their proof validating skills, and this study attempted to measure whether that hypothesis is true.

Curriculum Components

The curriculum introduced proofs through Sudoku, inspired by Greenhill's (2011) activity. This low-barrier experience allowed all students to engage equitably in the lessons. The second lesson focused on counterexamples and encouraged collaboration. The third lesson centered on identifying assumptions and conclusions as used in proof frameworks (Selden, et al., 2017).

Lesson four focused on proof validation and was emphasized due to its application in upper-level proof courses and everyday logic. This segment of the curriculum used the language of the Toulman scheme (1958) and included a handout that walked students through two guided examples on validating proofs. The students then tried examples on their own or in small groups.

Methodology

A pre-post test model was implemented. Twenty-three participants completed the pre-test, however only five participants had paired pre- and post-tests. The pre-test and post-test were identical assessments and consisted of 10 questions. Five questions provided proofs with unknown validity and asked the participants to choose if the proof was valid or invalid and explain why. One question gave the participants both a proof and disproof of the same statement and they had to determine which one was valid. The students were also asked to write their own proof of a statement and to then discuss the validity of their proof.

Results

On the pre-test, the participants in this study performed in ways consistent with the literature (Alcock & Weber, 2005; Ko, 2010; Weber & Ramos, 2014). The one result that counters previous research findings is that these participants demonstrated a conceptual understanding of counterexample with each counterexample question validated correctly at least 60% of the time. One notable finding is that although a majority of the participants wrote a valid proof, more than 50% of the participants did not answer the question asking them to validate their own proof.

Although the sample size is insufficient to make a statistical conclusion, there is some evidence that the students effectively learned proof validation techniques from the curriculum. Across the 50 questions, the scores decreased in two instances, improved in 20 instances, and stayed the same the remaining 28 times. Even more compelling is the changes in vocabulary observed from the textual analysis. On the post-test the participants made several references to the “warrants” for claims and to the “proof framework.” This result is triangulated by the survey given at the end of the course where the majority of the respondents said they used the proof framework every time or almost every time when writing their proofs.

Mathematical Modeling and Quantitative Reasoning: The Case of Task Design

Afaf Bahajj
Utah State University

Sindura Kularajan
Utah State University

Keywords: Math Education, Modeling, Quantitative Reasoning, Task Design

Mathematical modeling, the process of representing a real-world situation through mathematics, has gained increasing interest across K-16 education. Engaging in modeling requires certain competencies that are unique for solving modeling tasks. Despite the prevalence of modeling across curricula, numerous studies have documented the challenges students face as they engage in modeling (e.g., Klock & Siller, 2020). One promising approach for supporting learners' modeling competencies is to have students engage in quantitative reasoning as they construct models for real-world situations (Czocher et al., 2022). Quantitative reasoning entails conceiving a situation consisting of quantities and quantitative relationships (Thompson, 2011). Scholars have argued that quantitative reasoning not only supports students' understanding of *mathematical content* (e.g., Carlson et al., 2015) but also *mathematical processes* such as proofs and modeling (e.g., Belin & Akar, 2020). However, the first step in systematically supporting students' modeling competencies via their quantitative reasoning involves developing modeling tasks that are the ideal learning ecologies for students' quantitative reasoning to emerge. The central question that guides this study is: *In what ways can quantitative reasoning be integrated into the design of modeling tasks?* We address this question by designing a model development sequence (Lesh & Doerr, 2003) that integrates modeling principles with quantitative reasoning.

The model development sequence has three stages *Model Eliciting* (phase 1), *Model Exploration* (phase 2), and *Model Adaptation* (phase 3). In phase 1, students will develop strategies for building models and constructing quantitative relationships. In phase 2, students will analyze the models they constructed through examining the relationship between quantities and their variations. In phase 3, students will apply and refine the techniques developed in phase 1 and phase 2 to model a more complex, open-ended situation with limited information. We developed four sequences each consisting of three tasks. The sequences are *optimization*, *proportionality*, *flow*, and *growth*. In this poster we highlight the optimization sequence, where students use their algebraic knowledge to construct, analyze, and interpret functions that model real-world situations. Phase one (*food truck task*) involves modeling the relationship between demands and profit of a food truck business. Phase two (*catering*) involves modeling the profit for a catering company based on seating capacity. The instructional goal for the students is to construct a piecewise profit function for varying seating capacities. Phase 3 (*honey business*) involves modeling local business' profit changes due to COVID. The instructional goal for the students is to model the relationship between price, demand, and profit through building on and expanding on the quantitative reasoning strategies developed in earlier tasks.

To test the feasibility of our tasks, we intend to implement our tasks with undergraduate students in a clinical setting. Following a design-based experiment (Brown, 1992) methodology, results from the clinical interviews will be used to modify the existing tasks or design new ones if needed. This study ultimately will provide insights into the characteristics modeling tasks that have the capacity to elicit students' quantitative reasoning.

Not All (Former) Friends Are the Same

Candice M. Quinn
University of North Alabama

Anna Ary
University of North Alabama

Liviah Lash
University of North Alabama

Keywords: personification, math anxiety, reflection, mindset

Mathematics is often perceived to be a purely logical abstract field with no space for creativity, negatively impacting students' confidence and engagement (Boaler, 2016). Personification, attributing human characteristics to something nonhuman (Abrams & Harpham, 2012), helps students reflect on their personal relationship with mathematics and provides instructors insights into their students' mindset (Zazkis, 2015). By asking students to personify mathematics, educators encourage students to describe math as if it were a person in their lives, revealing their perceptions of the subject (Zazkis, 2015).

In this study, we analyzed students' perceptions by examining their responses to a personification prompt at the beginning and end of a Math Reasoning for the Arts course. Using Zazkis' (2015) framework of Monsters, Lovers, and Former Friends, we analyzed 80 pre- and post-personification responses across five semesters, identifying additional themes. We are still currently analyzing the data, however, preliminary results revealed categories such as Perfectionist, Mentor, Sibling, Antagonist, Current Friend, or Acquaintance. Additionally, we identified an extend theme of "Former Friends" that was combined with either Antagonist, Current Friend, or Acquaintance.

Out of 80 responses, 30 classified math as a Former Friend, defined as a friendship that has turned sour or dwindled, sometimes with the hope of mending, where an identifiable shift in or separation of the friendship is seen. Of these 30, the responses fell into one of three categories. Antagonist: (60%, n=18), where math is perceived as a bully who is hurtful, but not cruel; there is no intention of mending the relationship. Acquaintance (37%, n=11), where math is acknowledged as present in their life but is not considered a friend; there is no personal relationship. Current Friend (3%, n=1), where the friendship with math has been rekindled, or was maintained through hardships. These three extended Former Friend categories reflect distinct ways students perceive their evolving relationship with math, serving as a foundation for examining whether and how these perceptions shift over time. Building on this categorization, we investigated changes in students' views at the end of the Math Reasoning for the Arts course, after they had been exposed to mathematics in relation to art, music, and history.

Preliminary results indicate the following shifts in perception: Positive/Positive (49%), students express a new appreciation for math; Positive/Neutral (10%), students gain some respect or awareness; Neutral/Positive (23%), students show little change but develop a different perspective; Neutral (3%), students report minimal change in their feelings; Negative/Negative (1%), students feel worse and see no positive aspects; and No Change (14%), students continue to feel the same. Additionally, the content and structure of the Math Reasoning for the Arts course will be included in the presentation.

PAC-Math Protocol: A Framework for Assessing the Professional Development of Graduate Teaching Assistants

Emily Braley
Johns Hopkins University

Jack Bookman
Duke University

Jeneva Clark
University of Tennessee Knoxville

Keywords: Graduate Teaching Assistant, Professional Development, Program Assessment

Graduate Teaching Assistants (GTAs) play a critical role in undergraduate mathematics instruction across the U.S., and their preparedness directly impacts undergraduate student experiences (Ellis et al., 2016). Given the importance of Professional Development for Teaching (PDT) in preparing GTAs, stakeholders are increasingly interested in understanding the effectiveness of these programs (Braley et al., 2023). Key questions arise: Are these PDT programs improving GTAs' teaching performance? Are they adequately preparing GTAs for their future careers? Addressing these questions requires a robust, cyclical assessment framework that can guide departments in evaluating and improving their programs. This poster presents the PAC-Math Assessment Protocol, a new tool designed to systematically assess and improve GTA PDT programs.

The PAC-Math Protocol provides a flexible, iterative approach to assessment. It is built around six key phases: **Actions, Aims, Assessment, Analysis, Adaption, and Alignment.** These phases guide programs in defining their goals, collecting meaningful evidence, analyzing the outcomes, and making informed adaptations. The framework is intentionally adaptable, allowing programs to refine their aims and activities based on the evolving needs of their GTAs, departments, and institutions. This cyclical protocol also promotes alignment between program actions and intended outcomes, encouraging programs to sustain continuous improvement in their PDT efforts.

The PAC-Math Protocol has been piloted in a small-scale study with six mathematics department's GTA PDT programs. This initial phase asked pilot sites to focus on a specific component of their GTA PDT program (e.g. orientation, micro-teaching practice) and to use the PAC-Math protocol to guide their assessment. The pilot supported departments in initiating program assessment in a flexible way to meet their particular departmental goals. This poster will present the results of the PAC-Math pilot study, including feedback from program providers about the usefulness of the protocol. Visitors to the poster will gain insights into the effectiveness of the PAC-Math Protocol in capturing meaningful data and informing programmatic changes. By sharing these results, we aim to promote discussion about GTA PDT assessment and contribute to the broader conversation about improving the preparation of future educators in mathematics.

We would like to acknowledge the support of NSF (DUE-2306211), that made this work possible. This work was developed with input from participants in the 2023 PAC-Math workshop, founded on the principles of distributed leadership (Clark et al., 2022; Woods et al., 2004).

Collaborative Teamwork Builds Confidence and Independence in Discrete Mathematics

Rebeca Hernandez
San Francisco State University

Shandy Hauk
San Francisco State University

Paul Carmody
San Francisco State University

Keywords: equity, discrete mathematics, self-efficacy, agency, collaboration

For many students, discrete mathematics is a first exposure to formal logical reasoning, proofs, and proving. Undergraduates entering discrete mathematics have a long history with procedural problem solving and often attribute the authority for sense-making to textbook, instructor, or software (Herbel-Eisenmann, 2007). Like calculus, discrete mathematics shares a history of enormous disparities in outcomes correlated to demographic variables (Campisi et al., 2024). Research in undergraduate mathematics education, notably in calculus, has indicated that disparities can be addressed by linked changes in student materials and instructional methods (Bressoud & Rasmussen, 2015). Groupworthy learning opportunities for students combined with use of socio-culturally informed instructional approaches can build positive relationships among students, between students and instructor (and institution), and foster engagement in and outside of class (Archie et al., 2022; Laursen et al., 2014; Leyva et al., 2022; Yoshinobu et al., 2023).

As part of a project developing and researching the use of team-worthy lessons in discrete mathematics, the poster reports on a small study of 3 instructors (M, A, and P) and their 105 students. Classroom observations indicated that the use of team-worthy lessons changed the structure of classroom activity from primarily didactic lecture to at least 75% student-centered activity (e.g., group work, student presentation; Weston et al., 2023). However, a change in observed structure is only evidence of an affordance, not of students' experience of it (was it equitable? productive for learning?). After each team-worthy lesson students were surveyed about what went well (and not). Analysis of student responses used a framework based on social learning theory (Bandura, 1997) and dimensions of equity (Guitierrez, 2009).

The poster presents results about students' experience of equity, agency, authority, creativity, self-efficacy, and collaboration. The majority of students indicated collaboration as an aspect they deemed positive. Yet, collaboration was also the area they felt needed the most improvement! For example, two of the survey prompts were: "Share at least one aspect of your experience today with math teamwork that NEEDS IMPROVEMENT" and "Share at least one aspect of your experience today with math teamwork that was POSITIVE." For the first question, students in M's class felt mostly satisfied (60%), while A's and P's students highlighted needs for clearer instructions, improved participation, and better collaboration. For the "positive" question, students from all three instructors indicated collaboration most frequently, with at least 30% for each instructor (Carmody, 2024). As will be illustrated on the poster, these distributions reflect students' reports of their needs, both met and unmet, for establishing and sustaining a more equitable learning environment.

Poster-side conversations will explore next steps in research and practice. In particular, the project is developing a short-course for instructors who use the lessons. The short-course focuses on student-centered methods, particularly noticing student thinking, and the idea of how to balance the use of new and old instructional skills. A likely next research area is: What (re)balancing of instructor skills is needed to realize the potential of the (re)balancing of activity structures afforded by the lessons? Future work can examine how instructional skills, combined with the affordances of lesson content, contribute to the development of agency, self-efficacy, belonging, and engagement in mathematical sense-making among discrete mathematics students.

Acknowledgments

Based on work supported by the California Education Learning Lab. We are grateful to the many piloting instructors and hundreds of students who provided feedback on their lesson experiences.

Evidence of Equity Practices in Teaching-focused Professional Development

Jordan Guillory
San Francisco State University

Shandy Hauk
San Francisco State University

Sean Yee
University of South Carolina

Keywords: equity, novice instructor, professional development

Entry-level college mathematics classes are often taught by graduate students (about 35%) and most graduate students (more than 90%) will teach at some point (Blair et al., 2018). Research indicates that college mathematics instructors in effective undergraduate programs, particularly novice instructors such as graduate students, benefit from well-structured teaching-focused professional development (TPD) (Connolly et al., 2016; Friedlaender et al., 2014; Gehrtz et al., 2022). Those responsible for offering TPD, including those who lead workshops, courses, and seminars as well as those who facilitate TPD as course coordinators, have come to be known as *Providers* of TPD (Bookman & Murphy, 2019; Braley et al., 2023). Providers have a critical role, yet little is known about what they provide in TPD for novice instructors (Yee at al., 2023, 2024). At the same time, institutions vary in structure and resources in ways that are consequential for TPD. This leads to the questions: What are local Provider practices in the TPD they design and implement? In particular, what is the evidence that TPD is offering opportunities to learn equitable and effective practices?

This poster reports on a national effort to identify equitable practices promoted by and used in novice instructor TPD. Poster attendees will participate in refining the research design for a new extension to the project.

The two driving research questions for the new work:

1. TPD Content: What opportunities to learn about effective use of equity practices for teaching undergraduates are novice college mathematics instructors offered in TPD?
2. TPD Processes: In what ways do current Providers of TPD attend to equity practices themselves in the design and delivery of activities, formats, and topics in TPD?

Project research is driven by social cognitive theory (Bandura, 1997) and aligned with the five perspectives on instructional practices in the Mathematical Association of America's *Instructional Practices Guide* (IPG, 2018): *classroom, design, assessment, equity, and technology*. As published, the topic of equity practices was an appendix in the IPG. Subsequent research and development have refined and specified equity practices in detail for college teaching and learning in sciences, technology, engineering, and mathematics (National Academies, forthcoming).

The focus of the poster is designing research for gathering evidence of equity practices for research question 1 on TPD Content. The first step in the extension project is the development of a short (15-minute) survey for Providers. The research goal is collecting evidence about the current opportunities novice instructors have in local TPD programs to develop knowledge, skills, and productive dispositions related to equity practices (e.g., student-centered and instructor-decentered types and uses of formative assessment, identifying and leveraging "productive struggle," uses of roles in group activities). Given the time-constraint on the survey, it is especially important that items are written to gather information about Provider actions and actual in-use TPD formats, activities, and topics (rather than Provider or program intentions). Attendees will give feedback on potential survey items in support of design that will increase the feasibility of the survey to elicit information to address the two research questions.

Using Theory to Design Professional Development for Calculus I and II Instructors

Kaitlyn Stephens Serbin
University of Texas RGV

Baofeng Feng
University of Texas RGV

Roger Knobel
University of Texas RGV

Keywords: Professional Development, Calculus, Active Learning, Equity, Teaching Practices

Calculus courses are a gateway for students entering STEM fields, but they sometimes hinder students, especially those from historically marginalized groups, from pursuing STEM (Bressoud et al., 2015; Ellis et al., 2016; Kogan & Laursen, 2014; Seymour & Hewitt, 1997). Thus, there is a need for instructional innovation in Calculus and the creation of professional development (PD) programs to better equip instructors to support students' success. Researchers have identified characteristics of successful college calculus programs, some of which include the "use of student-centered pedagogies and active-learning strategies" (p. 145) and diversity, equity, and inclusion practices (Hagman, 2021). There is a need for researchers to design PD programs that train calculus instructors to implement active learning and equitable teaching practices. Our project contributes to this need by designing such a PD program for Calculus I and II instructors at two Hispanic Serving Institutions, a research university and a community college. For this poster, we report on how varied theoretical frameworks inform this PD's design.

The literature on active learning and equity in mathematics is vast. There are myriad theoretical frameworks and recommendations for teaching practices that instructors can use to equitably implement active learning (e.g., Freeman et al., 2014; Mathematical Association of America, 2018). Thus, it can be a challenge for PD designers to identify the main characteristics of active learning and equitable teaching practices that are essential for instructors to learn to implement. To address this, we employed a qualitative analysis on several articles and books (i.e., Bartell et al., 2017; Freeman et al., 2014; Gutiérrez, 2009; Kuster et al., 2018; Laursen & Rasmussen, 2019; Reinholz, 2023), as well as the National Council of Teachers of Mathematics' (2014) list of effective teaching practices and the Mathematical Association of America's (2018) Instructional Practices Guide, that outlined active learning or equitable teaching practices. We inductively coded (Miles et al., 2013) each manuscript to identify the active learning or equitable teaching practices listed in frameworks, examples, or recommendations for instructors. We then performed axial coding (Miles et al., 2013) to group the coded practices into broader categories, including: *(i) use meaningful engaging math tasks, (ii) facilitate student collaboration, (iii) elicit, notice, and use evidence of students' mathematical thinking, (iv) orchestrate class discussion on students' mathematical ideas, (v) attend to participatory equity and access in the classroom, (vi) foster an inclusive class community, and (vii) equitably assess student work*.

We used these categories to inform the design of our PD program for Calculus I and II instructors. The PD program consists of a workshop series over two days before the beginning of the course with follow-up biweekly meetings for the instructors in a professional learning community (Stoll et al., 2006) to reflect and receive feedback on their implementation of the equitable active learning teaching practices they learned. Each workshop was designed to train instructors to implement techniques pertaining to one of the broader categories of equitable active learning teaching practices. The literature-based categories we identified were productive for informing the design of our PD workshop series, so we recommend for researchers and practitioners to use this theoretical framework to inform the design of their PD programs for instructors. Future research can further refine this framework and address the effectiveness of PDs designed with this framework of equitable active learning teaching practices.

Distractor-Based Distractors: Adventures in Assessment Item Analysis

Russell Jeter
Georgia State University

Darryl Chamberlain Jr.
Embry-Riddle Aeronautical University

Kelvin Rozier
Georgia State University

Keywords: Assessment, Item-Level Analysis, Distractors

Motivation and Context

This poster presents a methodology for capturing underlying student conceptions based on their answers to a series of multiple-choice questions. We quantitatively and qualitatively examine publisher-supplied assessment items across four exams in College Algebra.

Item-Level Assessment Analysis

To appropriately capture students' mathematical conceptions, we perform an item-level analysis utilizing the following statistical measures: Item Difficulty (ID), Rasch Logistic Model (RLM) Estimated Item Difficulty (EID), and Point-Biserial Correlation (PBC). Item Difficulty (ID) refers to the proportion of students that correctly answered a given item. The PBC coefficient measures the correlation between students' performance on a single item and their performance on the exam as a whole. The RLM is a mathematical log function that relates the probability of a (correct) response on an item to the person's mathematical ability and to the item's difficulty. In this model, students have the highest probability of answering items with EID near their estimated ability (Krabbe, 2017). Unlike PBC, RLM takes into account a student's performance on each item in relation to the rest of the class' performance on the item. Example statistics are presented in Table 1 for two items on the exam.

Table 1. Item Response Analysis for two assessment items. Both items have similar difficulty, that is, Item Difficulty and RLM Estimated Item Difficulty are both consistent, but 4C22 is predictive of student performance on the exam (PBC close to 0.5), while 4C10 is not (PBC close to zero).

IRT Analysis			
Item	RLM EID	PBC	ID
4C10	2.91	0.03	0.36
4C22	2.75	0.38	0.39

Distractor Identification and Analysis

To investigate differences in item-level statistics, we investigate items' distractors – plausible but incorrect solutions (Chamberlain Jr. & Jeter, 2024). This leads to a classification of distractor types that can capture students' content misconceptions and provides evidence for distractor type impact on item-level statistics.

Discussion and Conclusions

These analyses and the items of interest they point to raise the following questions: What do these distractors tell us about student thinking? Why do high performing students get these questions right and low performing students get them wrong? To extend a multiple-choice assessment to fill a more formative role, it is important to align choices of distractors with the ways students might be thinking. Right/wrong dichotomy of questions in the analysis limits the amount of predictive power when it comes to student thinking.

Undergraduate Students' Conceptualizations of Four Big Ideas of Mathematical Modeling

Elizabeth G. Arnold
Montana State University

Elizabeth A. Burroughs
Montana State University

Keywords: Mathematical modeling, Thematic analysis, Big ideas

Mathematical modeling situates mathematical problem solving and critical thinking squarely in students' day-to-day experiences, broadening students' understanding of mathematics in everyday decision-making. Mathematical modeling is the *process* of creating mathematical representations to understand and make decisions about the world. When students model, they bring their individual experiences to understand a problem and inform their solution strategy. Thus, it is likely that the *modeling process* will unfold in different ways for different problems. Rather than focusing on modeling as a series of steps in a cyclic process, Arnold et al. (2021) described mathematical modeling in terms of four big ideas that characterize it.

1. Modeling begins and ends outside the mathematical world.
2. Modeling deals with situations that are open and complex.
3. Modelers exercise judgment when investigating problems.
4. Modelers decide when a solution is good enough.

We investigated how undergraduate students conceptualized these four big ideas during their study of and engagement with mathematical modeling. We designed and taught an upper-division, semester-long course in mathematical modeling at two different public land-grant universities. We created and implemented four modeling projects throughout the semester in our respective courses, with each project illuminating the four big ideas of modeling. We collected student work on these projects, along with survey data, and facilitated a written correspondence between undergraduates at the two universities. In those communications, our undergraduates reflected on their overall understanding of mathematical modeling and described their conceptualization of these four big ideas.

We conducted a thematic analysis (Braun & Clarke, 2006) on these data using an open and axial coding scheme (Strauss & Corbin, 1998). In our initial read of the data, we noted which of the four big ideas of mathematical modeling were prevalent. Then, using descriptions of the big ideas, we developed and used codes to describe the undergraduates' conceptualization of the four big ideas. Overall findings indicate that the big ideas were a tool to help undergraduates organize their own understanding of the process of mathematical modeling. We found that within undergraduates' conceptualizations, the four big ideas were connected and interdependent; when discussing one big idea, undergraduates also included connections to at least one other big idea. Tension also was evident between undergraduates' conceptualizations of Big Idea 2 and Big Idea 4; while they expressed excitement about the openness of a modeling problem, they also struggled with the notion of having to decide for themselves when their model and its solution were good enough. Lastly, we detected evidence of empathetic critical thinking skills in undergraduates' conceptualizations as they described how the modeling projects that focused on addressing justice in their own communities fostered their sense of mathematics and community.

In this poster, we (a) summarize the four big ideas of mathematical modeling, (b) describe the modeling projects we developed and implemented, (c) describe undergraduates' conceptualizations of the four big ideas, (d) summarize our findings, and (e) provide recommendations on how to facilitate undergraduates' learning of and engagement with the four big ideas of mathematical modeling.

Towards a Unified Theory of Abstraction: Abstracting and Reducing Abstraction as Reciprocal Categories of Mathematical Practices

Alice Mehalek
Colorado State University

Keywords: Abstraction, Reducing Abstraction, Unified Theory, Abstract Algebra, Disciplinary Practices

In the undergraduate classroom, abstract algebra concepts can be presented at varying levels of abstraction. Traditional lecture-based instruction presents concepts abstractly, and students often rely on their own cognitive strategies to make sense of them (Hazzan, 1999). Instructors using inquiry-based teaching methods often begin at a lower level of abstraction via concrete examples, guiding students to a higher level of abstraction through activities by which they discover and formalize the abstract properties of algebraic structures (for example see Ernst, 2016; Larsen et al., 2013). Many courses use a combination of teaching methods, requiring students to navigate between higher and lower levels of abstraction in both directions.

Existing theories of abstraction usually address activities and/or cognitive practices in one direction. Hazzan's (1999) reducing abstraction framework, expanded by Melhuish et al. (2018), classifies cognitive strategies that abstract algebra students use to *reduce* abstraction level. Other frameworks in the literature, including the generalization framework (Ellis et al., 2017) and Advancing Mathematical Activity (Rasmussen et al., 2005), describe ways in which students' understanding of mathematical topics *increases* in abstraction level through activities (referred to as disciplinary practices) such as generalizing, defining, and symbolizing.

Drawing on the existing literature and informed by my observations, I propose a unified theory of abstraction that connects multiple theories of learning through their approaches to abstraction. This unified theory comes out of my own need to make sense of observations of students' abstracting activities within the context of my dissertation study investigating abstraction in a groups first versus a rings first abstract algebra course, in which I observed the students and instructor moving fluidly between more and less abstract representations of abstract algebra ideas. Thus, this theory positions *abstracting* and *reducing abstraction* as reciprocal sets of linked disciplinary practices. This positioning reflects the bidirectional nature of navigating between levels of abstraction and conjectures that fluency in both directions is an indicator of student learning.

Abstracting encompasses the practices by which students move from less abstract to more abstract, including practices such as decontextualizing, relating, extending, generalizing, and symbolizing. *Reducing abstraction* encompasses the practices by which students move from more abstract to less abstract, and includes practices such as contextualizing, exemplifying, computing, and embodying. I define these practices within five categories of abstraction. Three of the categories (relationship between the object of thought and the thinking person; reflection of the process-object duality; complexity of concept of thought) were defined in Hazzan's (1999) original framework and the fourth (degree of precision/formality) added in the expanded framework of Melhuish, et al. (2018). I add a fifth category, interpreting abstraction as the degree of concrete embodiment of the concept of thought, based on observations and the literature on concreteness fading (Fyfe et. al, 2014). I define some of the practices by which students abstract and reduce abstraction within each category and provide examples of how students use these practices from my observations of an abstract algebra class.

Argument-Mirroring Proof-Texts: A Tool for Leveraging Students' Incoherent Thinking to Effect Greater Coherence

Steven Ruiz
Arizona State University

Keywords: calculus, chain rule, coherence, clinical interview, teaching experiment

This report details a teaching experiment (Steffe & Thompson, 2000) which consisted of clinical interviews (Clement, 2000) and exploratory teaching interviews (Sellers, 2020) designed to perturb selected students' incoherent thinking. In short, this study addressed the following research questions:

1) In what ways are students' understandings of the chain rule coherent with one another?
2) How do students respond to proof-texts which mirror their own incoherent thinking?

Theoretical Perspective

Glasersfeld (1988) describes schemes as quanta of knowledge held by an individual. Per Thompson (2008), incoherence is a lack of consistency between schemes. I used Toulmin's (1958) method to identify within students' arguments the claim – an assertion to be proven, data – evidence used to support the claim, and warrant – why the data is relevant to the claim.

Data Collection and Analysis

Ten students from a public research university in the American southwest participated in the initial clinical interviews, designed to examine the subjects' cognition regarding the chain rule of differentiation and its fundamental ideas e.g., continuity, differentiability, composition of functions, subjects were each presented with three functions and asked where each function was defined, continuous, and differentiable. The student was encouraged to think aloud and make annotations as appropriate.

Analysis focused on partitioning each student's transcript into arguments and identifying relevant claims, data, and warrants. These facets of a student's argument were then compared to one another and where appropriate (in my estimation), categorized as incoherent in one of four ways, including *incoherent claims* – two or more claims result in an impossibility and *justifications not broadly applicable* – the warrant from one argument would cause the claim from another argument to be altered. From each source of incoherence, *argument-mirroring proof-texts*, conditional statements and justifications built from the participant's reasoning were generated and presented to them to examine how they responded to their incoherent thinking and whether they take measures to resolve it.

Results and Discussion

The bulk of this report focuses on the four subjects who participated in both the clinical interviews and the argument-mirroring proof-text phase of the study and the effectiveness of the argument-mirroring proof-texts in particular. The latter method showed great effectiveness in a pilot study (Ruiz, in press). Furthermore, argument-mirroring proof-texts are highly individualizable, have the potential to be applied to a wide variety of contexts inside and outside of mathematics, and as such, the method represents a novel contribution to the field.

Exploring the Intersection of Social Justice and Quantitative Reasoning: Engaging Non-Stem Undergraduates With Payday Loans

Madhavi Vishnubhotla
The New School

Debasmita Basu
The New School

Keywords: Financial inequality, Social Justice, Compound Interest, Quantitative Reasoning

Social Justice Mathematics (SJM) represents a broad and evolving space within mathematics education. SJM integrates mathematical concepts with social justice issues and aims to achieve dual goals: enhancing students' mathematical understanding while fostering critical awareness of social injustices (Gutstein, 2003; Frankenstein, 1983). Much of the existing work on social justice mathematics has focused on middle and high school students (Gutstein, 2003; Stinson, Bidwell, & Powell, 2012), as well as preservice and in-service teachers (Gonzalez, 2009, 2003; Bartell, 2013). Although there are a few studies with undergraduate students in disciplines such as calculus (e.g., Erksine et al., 2022), computer science (Padiyath et al., 2024), and statistics (Conway & Nguyen, 2020)), there is limited research on how non-STEM undergraduate students engage with SJM, leaving a gap in understanding how these students respond to lessons designed to integrate mathematical content with social justice themes. Thus, we ask the question: "In what ways does integrating social justice themes, such as payday loans, impact non-STEM students' understanding of financial inequality and/or concepts of simple and compound interest?"

We draw from the work of Branson and George (2024), who explored the connection between payday loans and mathematical concepts, providing a framework for examining how undergraduate students relate to these concepts through the lens of financial inequality. This study was conducted at a university in the North Eastern U.S. Participants in the study were enrolled in a quantitative reasoning course for non-STEM undergraduate students, primarily from a business administration program. The aim of the course is to equip students with essential mathematical skills and apply them to real-world problems.

In this poster, we present a case study examining students' pre-existing perspectives on payday loans and their disproportionate impact on marginalized communities. We addressed our research questions through pre- and post-surveys assessing students' attitudes toward both mathematics and social justice, followed by interviews before and after the lesson. The data were coded, revealing key themes, such as students' views on financial systems and how these systems disproportionately affect marginalized groups. This poster will present emerging themes from our findings, illustrating how the integration of social justice issues into the quantitative reasoning course influenced students' understanding of both mathematical concepts and financial inequality.

Student Perceptions of Inequities and Benefits of Active Assessment Strategies in the Math Classroom

Sydney Belomy
California State University, East Bay

Anthony Chon
California State University, East Bay

Simone Sisneros-Thiry
California State University, East Bay

Keywords: active assessment, active learning, student experience

This study investigated student responses to active assessments in place of timed in-class exams in mathematics courses. *Active assessment* refers to assessment approaches that align with active learning paradigms (e.g., group presentations, portfolios; Katz, 2022). This research explored student perceptions of the benefits and the potential inequities of active assessment strategies. The poster will highlight both the student-identified advantages and areas of concern related to fairness, relevance, and resource availability. Findings contribute to ongoing discussions on equitable assessment practices in mathematics education for meeting the needs of all learners (Katz, 2022; Black and William, 2009; Laursen and Rasmussen, 2019).

Methods

Data for the study was collected through a two-stage process during the Fall 2023 and Spring 2024 semesters. Across the two terms, a total of 278 students from 13 different lower and upper division undergraduate mathematics courses completed a survey (during class time) which gathered their perceptions and experiences regarding the benefits and inequities of the particular active assessment strategies implemented in the course in which they were enrolled. The courses were taught by 8 participating instructors who implemented active assessment strategies. Following the survey, a subset of voluntary participants were selected for follow-up small-group interviews, for more in-depth discussions about their experiences. The qualitative data from these surveys and interviews was transcribed and analyzed to identify key patterns and insights related to the benefits and inequities of active assessments.

Results

Preliminary findings indicated the most common themes arising for perceived benefits included reduced anxiety, development of social skills, and connection to real-world applications. Common themes that emerged for potential inequities included uneven group dynamics (e.g., relative amount of work done by different group members) and format accessibility (e.g., assessments calling for advanced writing or linguistic skills). More than two-thirds of students responded that they preferred the active assessment strategy over a timed in-class exam. Overall, results suggest that, for students, active assessment benefits outweighed potential inequities.

Acknowledgements

This study is funded by NSF Research Grant #2225295.

Developing CALC: Developing Conceptual Assessments of Learning in Calculus

Beth Cory
Sam Houston State University

Taylor Martin
Sam Houston State University

Michael Oehrtman
Oklahoma State University

William Robertson
West Virginia University

Vicki Sealey
West Virginia University

Keywords: Calculus, Assessment, Productive Understandings, Integrals

Introductory calculus is a gateway to study in STEM disciplines. It introduces concepts about rate of change, accumulation, and co-variation, which are foundational concepts for modeling across STEM fields. Thus, assessing student understanding of calculus concepts is important to researchers and practitioners. Currently, no curriculum-independent concept inventory for introductory calculus has been validated and found to conform to accepted educational testing standards (American Educational Research Association, 2014; Gleason, White, Thomas, Bagley, & Rice, 2015). In 2007, Epstein and colleagues presented the first Calculus Concept Inventory (CCI) to evaluate the effectiveness of teaching methods on conceptual learning in calculus. However, the inventory was not research-based, was narrowly designed as a single multiple-choice summative exam (Epstein, 2007, 2013), and Gleason et al. (2015) found that the CCI failed a thorough psychometric analysis. Our purpose is to develop a reliable, well-validated curriculum-independent concept assessment to test productive understandings of calculus.

Instead of developing one assessment for all of calculus, we decided smaller, modular assessments for the various calculus topics would be more helpful. Initially, we focused on the topic of definite integrals and accumulation. We created a taxonomy of concepts related to definite integrals and further narrowed our initial focus to definite integrals involving area or other applications. Literature on student understanding of definite integrals shows two main themes. First, students who view integrals as adding up pieces and understand the pieces quantitatively are more successful in problem solving (e.g. Sealey, 2014; Simmons & Oehrtman, 2023). Second, many students over-rely on integrals as area without being able to unpack the meaning of the quantities that form the area (e.g. Sealey, 2006; Jones, 2015).

Productive understandings involve procedural and conceptual understandings. We utilize Hiebert and Carpenters' (1992) distinction between *procedural understanding*, where students solve problems using a predetermined sequence of actions, and *conceptual understanding*, where students solve problems by relying on their networks and relationships of ideas within the problem. Since many seemingly conceptual calculus problems are familiar to students and can be solved with only a procedural understanding, we aimed to create conceptual questions which, in particular, test students' ability to reverse-engineer why their problem-solving methods work.

We developed and refined seven initial assessment items which contained both standard tasks and slight variations, which were intended to disrupt application of memorized procedures and required application of conceptual knowledge. Based on clinical interviews with 15 students at 3 institutions, we observe that students' responses to these variations reveal insight that may further distinguish productive conceptual understanding from memorized procedures. Future research will involve designing additional small suites of conceptual questions on derivatives and limits. We will eventually invite other researchers to contribute to the development of these assessments in other areas of calculus.

Interdisciplinary Aspects of Linear Algebra: Student-identified Applications in STEM

Zhen Zhang
Florida State University

Christine Andrews-Larson
Florida State University

Keywords: linear algebra, Interdisciplinary Applications, STEM Education

Motivation and Research Questions. Linear algebra bridges abstract mathematical principles with advanced applications across diverse STEM fields (Stewart et al., 2022). Students often perceive its concepts as disconnected from their fields of study to their disciplines (Stewart et al., 2019). This study investigates: What is the nature of discipline-relevant examples identified by students at the beginning of an applied linear algebra course?

Literature and Theory. Existing literature highlights the importance of linear algebra in solving real-world problems across STEM and beyond. Stewart et al. (2019) emphasizes the need to connect abstract concepts like matrices and eigenvalues to practical applications, while Muhammad & Saidi (2024) demonstrate its role in data science through tasks such as dimensionality reduction and predictive modeling. Wang (2019) and Arangala (2023) emphasize the relevance of conceptual understanding in fields like machine learning, engineering optimization, and cryptography. Beyond STEM, linear algebra's applications in areas such as digital art and forensic psychology showcase its versatility (Stewart et al., 2022). This study aims to enhance teaching strategies that bridge theory and practice.

Data Sources and Methods. We analyze online discussion board responses from 66 U.S. undergraduate linear algebra students, grouped into five major-area categories: Applied Mathematics, Biomathematics, and Mathematics Education; Computer and Computational Science; Mechanical, Electrical, and Biomedical Engineering; Statistics, Actuarial Science, and Economics; and Non-STEM majors. Early in the term, students were asked to identify an example problem from their area of study that uses linear algebra. Data-driven codes capture the range of examples students provided (deCuir-Gunby et al., 2011). Examples provided by students were classified as Q&A (when a specific question and sample solution was provided, illustrative examples (when a demonstration of a particular idea was provided), or for descriptions of broad ideas (general principle in their discipline was provided). Examples were further analyzed for dimensional context (low or high) and core linear algebra concepts.

Results and Discussion. The representation of majors in our sample of 66 student responses was: Applied Mathematics (~16.67%), Computer Science (~24.24%), Industrial Engineering (~19.70%), Statistics and Actuarial Science (~34.85%), and non-STEM majors (~4.55%). The majority of responses were coded as Q&A (~39.29%) or illustrative examples (~44.64%), with about (~16.07%) coded as broad ideas. High-dimensional examples accounted for 62.5% of responses, prevalent in Computer Science and Statistics, while low-dimensional examples were more frequent in non-STEM fields and Engineering. The most frequently cited topics included Matrix (35 mentions, ~20%), matrix operations (29 mentions, ~16.5%), and eigenvalues (23 mentions, ~13%), with significant overlaps observed between disciplines. For instance, optimization techniques connected Engineering and Computer Science, while transformations bridged art and non-STEM applications. These patterns varied within and across disciplinary clusters, reflecting both shared and unique applications of linear algebra concepts. In our poster, we will feature a selection of examples across majors and linear algebra topics to highlight trends in dimensionality issues and overlap of discipline specific knowledge and linear algebra in endeavors focused on student selected topics.

Coding- and Spreadsheet-Integrated Tasks to Enhance Students' Quantitative Reasoning and Covariational Reasoning for Exponential and Logarithmic Functions

Margaret Sumera, U. of Alabama
Kayode Obafemi, U. of Alabama
Christopher Ocheni, U. of Alabama
Yan Tong, U. of Alabama
Nigar Altindis, U. of Alabama

Keywords: Coding-integrated tasks, Quantitative reasoning, covariational reasoning, logarithmic and exponential functions

Quantitative Reasoning (QR) is defined as a conceptualization of quantities as measurable attributes of an object(s), reasoning about and operating on quantities, and quantitative relationships in learning functions (Smith & Thompson, 2008). QR sets a foundation for covariational reasoning (CR); CR is the cognitive process involved in coordinating two quantities that covary while paying attention to how they change with respect to each other (Carlson et al., 2002). Studies have examined students' QR and CR skills across various mathematical domains, including exponential relationships (Castillo-Garsow, 2010; Confrey & Smith, 1995; Ellis, Ozgur, Kulow, Williams, & Amidon, 2012), trigonometry (Moore, 2010), rate of change (Johnson, 2012, 2015a, 2015b), functions (Carlson et al., 2002; Johnson, 2012, 2015a, 2015b), logarithmic-exponential functions (Ferrari-Escolá et al., 2016), the fundamental theorem of calculus (Thompson, 1994), graphs of functions (Carlson et al., 2002; Moore, Paoletti, & Musgrave, 2013), logistic function (Altindis et al., 2024), and differential equations (Castillo-Garsow, 2010). While research highlights the importance of QR and CR across various domains, these skills are complex due to the need to process multiple quantitative relationships simultaneously. Thus, we developed Python-integrated tasks to teach logarithmic and exponential functions.

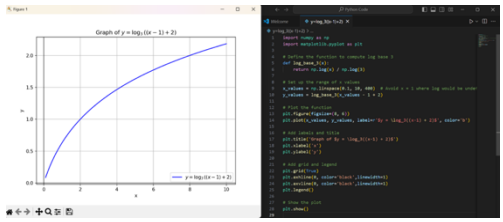

Figure 1. A Logarithmic Function Graph Created with Python Code

This poster will report on the affordances and challenges of coding and spreadsheet-integrated tasks and how these tasks allow students to model and visualize quantities and quantitative relationships. Using multiple representations (symbolic, graphical, numerical) enhances their understanding of function concepts. We will also report on preliminary testing of these tasks with high school students and their open survey responses. Additionally, we will discuss how students engage in multiple representations of mathematical phenomena, using Python codes to simulate and visualize the relationships between varying quantities. Furthermore, we will report that integrating coding into math lessons significantly increased students' engagement with the material, making abstract concepts more tangible and interactive. These findings highlight how Python coding can serve as a tool for enhancing students' quantitative reasoning and covariational reasoning skills, ultimately contributing to a meaningful understanding of logarithmic and exponential functions.

Undergraduate Students' Positions and Interactions during Group Work in a Calculus Class

Anna Robicheaux
Rhodes College

Erika David Parr
Rhodes College

Keywords: group work, student interaction, positioning, calculus

Group learning in the mathematics classroom aims to encourage deeper individual learning through creating a sense of autonomy and making space to negotiate new ideas. When a student proposes a new idea to the group, they reposition themselves with increased authority and autonomy; furthermore, the acceptance or rejection of new ideas may impact the success or failure of a group in reaching their desired goal (Barron, 2003; Cobb, et. al., 2009; DeJarnette & González, 2015). From this perspective, examining the positions of group members during collaboration may provide insight into what makes a group is successful. The central goal of this research is to evaluate how the interactions within groups of students impact individual learning. In this study, we examine undergraduate students' group interactions while learning to express distances within the Cartesian coordinate system.

The primary data set includes 31 videos that were taken in an undergraduate Calculus II course at a small, private college from 2022-2024. The recordings show groups of 2-3 students working on an "Interpreting Graphs for Calculus Activity" during a 50-minute class period. The activity begins with expressing distances on number lines and then advances to representing distances on the Cartesian plane. Data was collected from the same group of students in an individual pre-test, two questions on their third exam, and one question on their final exam. From these videos, we narrowed the dataset to 27 episodes involving pairs of students, roughly one to five minutes in length, which contained what we considered to be significant interactions. Significant interactions included discussions around the validity and certainty of a proposed solution, instances in which students shared different solution paths, and those in which students provided new ideas, or the students or instructor gave feedback on a proposed solution.

Currently, we are applying a coding scheme for interactional positions (Parr et al., 2023; in preparation) to identify the roles that students were taking on during these episodes of interaction, expanded from coding schemes developed by Lo & Ruef (2020) and González & DeJarnette (2015). The central codes that we have found to be relevant to this dataset are codes of primary knower (K1), secondary knower (K2), and primary uncertain knower (K1-U). Based on the application of these codes, we created categories to represent themes of interaction we found within the groups: Independently Working (each student displayed K1 and K2), Shared Understanding (each student displayed K1), Shared Uncertainty (each student displayed K1-U and K2), and Single Understanding (one student displayed K1 and the other displayed K1-U and K2). These categories capture both individual student roles and the nature of the students' interaction. Notably, of the first 16 coded episodes, we have identified 10 (62.5%) as Single Understanding, 3 (18.8%) as Shared Understanding, and 2 (12.5%) as Shared Uncertainty.

These differences in collaborative interaction between groups indicate the complexities of mathematical learning within a group. Analysis is ongoing to examine the relationship between these categories and positional codes with students' individual performance on related tasks following the group interaction.

An Examination of the Self-Regulation Strategies of Students in an Inquiry-Based Learning With ALEKS Support Course

Peter Sassman
Northern Illinois University

Keywords: self-regulated learning, inquiry-based learning, ALEKS, developmental

Extensive research has shown that a vital component of student success in mathematics classes is the ability to self-regulate (e.g., Bol et al., 2016; Isaacson & Fujita, 2006; Kramarski & Gutman, 2006; Ley & Young, 1998; Mevarech & Fridkin, 2006; Throndsen, 2011). Self-regulated learning (SRL) is the ability of a student to take an active part in their learning, by setting goals and motivating themselves, using different strategies to complete their learning task, and by reflecting on their learning and strategy usage (Zimmerman, 2002). A prominent model of SRL and the one being used for this project is Zimmerman's (2002) model, which has three phases: the forethought phase, the performance phase, and the self-reflection phase (Zimmerman, 2002). In addition, there has been research into different classroom practices to combat the issues of low academic achievement, such as more active-learning style classes (e.g., Freeman et al., 2014) and the use of technology (Cosyn et al., 2021). A specific type of active-learning model is known as Inquiry-based learning (IBL), where students are given investigative tasks that allow them to be engaged in the creation of important mathematics (Laursen & Rasmussen, 2019), and has shown promising results in university courses (e.g. Kogan & Laursen, 2014; Laursen et al., 2014). The intelligent-tutoring software ALEKS has also been adopted in many classrooms (Cosyn et al., 2021), where research has seen positive results when the software was used as a supplement to a regular classroom (e.g., Boyce & O'Halloran 2020; S. Sun et al., 2021). My project focuses on how students self-regulate their learning in classrooms that utilize inquiry-based learning (IBL) and ALEKS software.

This project integrates student questionnaires and classroom observations to determine how students self-regulate their learning in this novel classroom environment. The surveys include a numerical measure of students' SRL skills using a subset of the Motivated Strategies for Learning Questionnaire (MSLQ; Pintrich & De Groot, 1990). The classroom observations use the Toolkit for Assessing Mathematics Instruction – Observation Protocol (TAMI-OP; Hayward et al., 2018), while the intensity of IBL is measured using the Inquiry-Oriented Instructional Measure (IOIM; Kuster et al., 2019). I examine the self-regulated learning scores of students and the intensity of inquiry-based learning to look for relationships. This poster will present some of the observational data collected, along with the numerical values of the SRL skills, to answer the questions: (1) Is there a relationship between the intensity of IBL and students' self-regulated learning skills? (2) Are there differences in the intensity of IBL across sections? By analyzing how classroom practices may relate to self-regulated learning skills, we can then begin adjusting these practices to focus on improving the SRL skills of students in future courses.

For five different sections of this coordinated class with all different instructors, interesting differences were observed through the TAMI-OP, as well as differences in the implementation and intensity of IBL via the IOIM. For example, some sections had higher scores on the TAMI-OP, reflecting a more active-based classroom, but lower IOIM scores. In addition, some sections had higher IOIM scores but had lower self-regulated learning skills in students.

Developmental Math: Is A Traditional Approach Serving Underprepared Students?

Lily Glushakow-Smith
Towson University

Keywords: developmental, undergraduate, higher education, math education, co-requisite

This poster presents emerging results from a data-focused investigation of the effects Developmental Mathematics courses on student success at a large, comprehensive university. A growing research base about Developmental Mathematics suggests that effective Developmental Mathematics teaching requires a multifaceted overhaul from traditional models requiring multi-semester pre-requisite course sequencing, high stakes test placement, and front facing lectures by the professor. In particular, the literature suggests that co-requisite models, improving extracurricular supports, providing holistic placement methods, accelerating the developmental pathway, and enhancing professional development are all methods to support students progressing through the developmental pathway (Childers & Shi, 2021; Emblom-Callahan et al., 2019; S. S. Jaggars et al., 2014; S. Jaggars & Stacey, 2014; Miller, 2022; Park et al., 2018; Parker, 2019). Before implementing any changes, assessments need to be made on a case-by-case basis to determine which models are appropriate.

In the current study, I aimed to conduct a preliminary investigation of student success at a single university based on enrollment in a traditional algebra track developmental pathway. This institution's developmental math pathway is characterized as traditional because it is: a pre-requisite path from beginner to intermediate to college algebra; co-requisite offerings are only available to a specific subset of students; minimal active learning is utilized. My research question was: To what extent do students successfully proceed through a traditional developmental mathematics pathway? This research will add to the knowledge base of the field by contributing to the literature regarding failures of traditional pathways.

Methods

In order to examine student success rates, I accessed data from the Institutional Research board at the institution. I compiled demographic data, math course history and grades, and term GPA for all students enrolled in the algebra pathway (two sequential non-credit preparatory courses and College Algebra), during Fall 2021, Spring 2022, or Fall 2022. These data were analyzed to compare pass rates across demographics and various entry points to the pathway.

Results

Data analysis revealed that student success in this traditional developmental mathematics pathway is low. Students who enrolled in the lowest offered course only succeeded in passing college math in the minimum number of semesters seventeen percent of the time. The data also indicated that students that were failing the developmental courses had GPAs about a full letter grade lower than students that were passing the courses. These findings add to the research consensus that traditional developmental pathways do not well serve the aspirations of underprepared students. Future work will examine pathway interventions (such as course acceleration, implementation of active learning, providing more holistic placement methods, and enhancing professional development) to improve these outcomes and enable students to succeed.

Relationship Among Classroom Climate, Self-Concept, and Interest in Undergraduate Mathematics Courses: What Can We Learn From a Literature Synthesis?

Abel Sekone
San Diego State University & University of California San Diego

Keywords: classroom climate, classroom environment, math self-concept, math interest

Mathematics courses have become barriers for undergraduate students, including those pursuing STEM-related degrees (Olson & Riordan, 2012; Leyva et al., 2022). Some possible explanations for the difficulties that students have in mathematics coursework are the lack of belief in their mathematical abilities (Adlawon et al., 2022) and the lack of perceived relevance, as students wonder, "When am I ever going to use this?" (Chazan, 1999). The two aforementioned psychological processes, self-concept, and interest in mathematics, that influence learning are affected by several factors, including the multidimensional construct of the classroom environment.

Much research has focused on specific pedagogical practices teachers adopt, students' views of those practices, and the effect of particular practices on learning outcomes. Some studies explored the relationship between specific pedagogical or instructional practices and student learning outcomes in terms of achievement-related outcomes and affective outcomes (e.g., Kerrigan et al., 2020; Downing, 2020). For instance, culturally relevant pedagogy in college algebra positively affected students' attitudes toward mathematics and increased confidence in mathematics (Downing, 2020). However, a few studies have collected students' perceptions of the classroom environment more generally using established surveys (e.g., University Mathematics Classroom Environment Questionnaire) and evaluated the relationship between those perceptions and students' cognitive and affective outcomes.

In the present review, I synthesized quantitative studies examining how students' perceptions of their classroom environment are related to their interest and self-concept in math. In the poster, I include a table of the statistical evidence that the included papers showed of how different dimensions of the classroom environment are associated with constructs of students' self-concept and interest in college mathematics.

Results indicate that most studies used correlational, multiple regression, and structural equation modeling techniques on data collected using various measurement scales of classroom climate, self-concept, and interest in math. Findings demonstrated positive correlations (values ranging from 0.2 to 0.58) or absolute standardized path (values ranging from absolute 0.11 to 0.2) characterizing the relationship between students' perceptions of the components of classroom climate and their self-concept and interest in mathematics (e.g., Wang et al., 2017; Yin et al., 2020).

From the literature results on this poster, RUME researchers could identify research gaps of classroom conditions influencing affective outcomes and consider their classroom environment's impact on students' self-concept and interest in mathematics. This is an important avenue for future research as improving students' learning experience will positively impact persistence in pursuing STEM degrees. I discuss how future research could build and test a theoretical structural model to investigate the causal relationships between the various dimensions of the classroom climate and students' self-concept and interest in mathematics grounded in sociocultural theories, Krapp's (2007) person-oriented theory of interest, and Bronfenbrenner's (1977) ecological systems framework.

Mathematical Wellbeing as an Inclusive Framework for Equity: A Systematic Review

Marcelo Alonso Almora Rios
University of California, Los Angeles

Keywords: mathematical wellbeing, literature review, culture, organizational change

For many undergraduate students, navigating the demands of mathematics education can feel like navigating a pressure-cooker system. The term "mathematical wellbeing," coined in 2010, describes how individuals relate to mathematics in ways that are positive, functional, and sustainable throughout their lives (Clarkson et al., 2010; Part, 2012; Hill et al., 2021; Almora Rios, 2024; Hunter & Hill, 2024). Although relatively new, research on mathematical wellbeing has grown rapidly. This poster presents initial findings from a large-scale systematic review of the emerging literature on mathematical wellbeing, focusing on the rationales authors use to motivate its study. Specifically, this study highlights how centering mathematical wellbeing in organizational change efforts can promote student persistence in introductory math course sequences and foster positive, lifelong relationships with mathematical practice.

Methods

The Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines were used as a framework for data collection (Page et al., 2021). Following prior systematic review methods in mathematics education research (e.g., Darragh, 2016; Radovic et al., 2018; DiMartino et al., 2022; Cevikbas et al., 2022), the article corpus for review was constructed using databases in psychology and education research (ERIC, APA PsycInfo, ProQuest Dissertations & Theses Global, Web of Science Core Collection, Academic Search Complete, Education Source), international conference proceedings (2021-2024 International Group for the Psychology of Mathematics Education (PME) conference), citation searching, and gray literature found on Google Scholar (within first 300 results; see Haddaway et al., 2015). The search criteria used in this review was: (Keyword:Education AND Title:math*) AND Abstract/Title:(wellbeing OR flourishing OR happiness OR thriving OR satisfaction OR eudaemonia OR "mental health" OR "quality of life") after considering the usage and frequency of various synonymous search terms to 'wellbeing' in academic journals (see Iasiello et al., 2024; Butler & Kern, 2016; Veenhoven, 2015; Hill et al., 2021). Eligible studies were published in English and centered (not just utilized) the mathematics education context at any level. Articles passed screening by focusing on the conceptualization, measurement, or theorization of concepts related to the persistence of math learning or practice. Articles related to job satisfaction, in-service teachers, educators, the faculty workplace, or distance, online, computer-based, or e-learning, were excluded, as well as book reviews and oral communications from conference proceedings.

Native and Non-Native English Speakers in an Introductory Proof-Based College Math Course

Caelan Wang
University of Virginia

Keith Gallagher
University of Nebraska-Omaha

Sam Vancini
Penn State University

Keywords: Non-Native English Speakers, Introduction to Proof, English Learners, Language

Research on the influence of language on mathematics learning at the K-12 level (see de Araujo et al., 2018, for a review of this literature) suggests that in primarily English-speaking classrooms, perceptions of non-native English speakers as "deficient" can harm their learning of mathematics, but with appropriate supports, non-native English speakers can flourish. This study compares native and non-native English speakers' perceptions of the effects of their language status with their performance on proof-based assessments at the university level in a course taught and assessed in English. We sought to answer two questions: (1) to what extent do non-native English speakers perceive their language background as an advantage or a disadvantage in an introduction to proof course taught in English? And (2) to what extent do assessment outcomes between native and non-native English speakers align with students' perceptions?

Methods

Data were collected from a discrete math course focused on proofs at University of Manitoba where English was the language of instruction. Just before the end of the term, a questionnaire was sent to all students enrolled in all sections of the course. This questionnaire asked each student to indicate (Q1) whether they considered themselves a native speaker of English or a non-native English speaker and (Q2) whether they believed their English-speaker status contributed positively or negatively to their learning in their discrete math course. Respondents' itemized final exam scores were also obtained. The final exam in the course contained 12 questions with two questions consisting of two sub-parts; we treated these sub-parts as independent questions, yielding a total of 14 questions for analysis.

Respondents were sorted into two groups: native English speakers and non-native English speakers, as indicated in their response to Q1. Each respondent was then assigned a Perception Score (PS) of -1, 0, or +1 based on their response to Q2. A respondent was assigned a PS of -1 if they indicated a belief that their language status negatively impacted their learning, a PS of +1 if they indicated a positive impact, or a PS of 0 if their response was neutral.

A *t*-test was performed comparing the PS of native English speakers against the PS of non-native English speakers. Additionally, a *t*-test was performed on each final exam question, comparing the numerical scores earned by native English speakers against those earned by non-native English speakers.

Findings

The native English speakers ($n_1 = 40,\ M_1 = 0.675,\ SD_1 = 0.616$) had a significantly higher PS than the non-native English speakers ($n_2 = 52,\ M_2 = -0.0769,\ SD_2 = 0.788,\ p < 0.001$). There was a significant difference in scores on only two questions from the final exam: Q6(a) ($M_1 = 0.363,\ SD_1 = 0.660;\ M_2 = 1.010,\ SD_2 = 1.374,\ p = 0.00386$) and Q7 ($M_1 = 6.475,\ SD_1 = 3.772;\ M_2 = 8.298,\ SD_2 = 3.365,\ p = 0.0184$); in both cases, non-native English speakers outperformed native English speakers. These preliminary results suggest that, despite perceptions to the contrary, non-native English speakers perform at least as well as native English speakers on proof-based assessments in university math courses taught in English.

Exploring Students' Understanding of Belonging and Self-Efficacy in a Transformed Introductory Mathematics Course

Te'a Riley
The Ohio State University

Xingfeiyue Liu
The Ohio State University

Susan Olesik
The Ohio State University

Lin Ding
The Ohio State University

Raeshan Davis
The Ohio State University

Keywords: sense of belonging, self-efficacy, diversity, inclusion, culturally responsive teaching

Achieving diversity, equity, inclusion, and justice (DEIJ) remains a major challenge within STEM fields, especially at the higher education level. Particularly, at The Ohio State University, students from minoritized groups in STEM have felt othered and isolated within the STEM environments. To address disparities in participation and retention of minoritized students in STEM, our HHMI grant provides both financial and structural support to foster racial, ethnic, and gender justice. The HHMI-supported courses offer culturally responsive pedagogies (CRP), active learning opportunities, and smaller classroom sizes. As a part of the project, this poster focuses on accessing the pedagogical changes in one of the four foundational STEM courses, Math 1151, which has undergone integrated DEIJ-driven adjustments.

This poster investigates how students' experiences in a transformative mathematics course shape their sense of belonging (SB) and self-efficacy (SE). Research shows that higher SE and SB are key to student success and retention (Bandura, 1977, 1993; Hausmann et al., 2007; Zimmerman, 2000). Using the mixed-method approach, we compare pre- and post-class surveys results focused on these constructs, based on the Leibowitz et al. (2020) survey of SB, students' perceptions of CRP, and SE. Additionally, we analyzed open-ended questions to offer insights into how their course experiences impact their SB and SE.

The Fall 2024 study included a sample of 766 undergraduates who completed both pre- and post-class surveys, which included five-point-Likert-scale and open-ended questions. The sample was 82% first-year students, with 6% enrolled in HHMI sections. Analysis showed modest changes: students' SE slightly decreased, while perceptions of CRP increased. Group comparisons between HHMI and non-HHMI sections showed higher mean scores in HHMI, but not statistically significant pre-post changes. Further investigation of class standing revealed that first-year students reported significantly greater increases in CRP perceptions compared to upper-class students. Several themes emerged from the open-ended questions on how instructors have supported and could better support students' learning, including providing clear explanations and engaging environments which were cited for both improvement and appreciation. The most common response for improvement was that students already felt well-supported by their instructors suggesting that factors outside of this course (e.g. prior academic experiences, other course engagements, peer relationships) may have influenced the quantitative results. Although no statistically significant increases were observed in HHMI courses, the mean scores for SB and SE were already relatively high at baseline—4.02 and 4.14, respectively—aligning with participants' satisfaction with their instructors in open-ended responses. As the project progresses, we anticipate observing further improvements.

Introduction

Discrete mathematics lies at the intersection of mathematics and computer science and provides a landscape for mathematics education researchers to analyze the interaction between mathematical reasoning and computational thinking. In this poster, we provide preliminary findings from our analysis of undergraduate mathematics and computer science (CS) students' problem-solving strategies on a set of discrete mathematics questions.

Methods

Twenty-two students were interviewed in the Fall 2024 semester through think-aloud protocols (TAPs) to elicit their mathematical activity (e.g., Reinhart et al., 2022). In these TAPs, students were asked to verbalize their thinking as they solved mathematics problems. Mathematics and CS undergraduate students from four cohorts were interviewed. The first and second cohorts consist of 4 first- and second-year students in CS and 2 first- and second-year students in mathematics, respectively. The third and fourth cohorts consisted of 8 third- and fourth-year students in CS and mathematics, respectively. Students were presented with an assessment protocol consisting of 13 discrete mathematics problems. The problems included the following concepts: functions, combinatorics, game theory, recursion, set theory, logic, recursion, decision trees, and graph theory. As a preliminary pass through the data, all questions students answered were graded as either correct (1) or incorrect (0). A more detailed analysis will be conducted as we move forward with the project.

Results

For this poster, the analysis compares and contrasts how students from the four cohorts performed on the protocol questions. On average, mathematics and CS majors answered 7 out of the 13 questions on the protocol. Of the 7 answered, the math cohorts had a median score of 73%, while students in the CS cohorts scored 70%. A Wilcoxon rank sum test was conducted to evaluate differences in scores between math majors (n=10) and CS majors (n=12). The results indicated no significant difference in scores between the two groups ($W=59.5$, $p=1.0$). The CS cohorts exhibited larger variability in their assessment scores compared to the math cohorts. For a more in-depth analysis, a cluster analysis to inform the identification of natural groupings of students will be provided on the final poster.

Discussion

Preliminary analysis indicates that students from both majors performed about the same on the assessment protocol. However, interviews with the different cohorts of students revealed many different solution strategies and varying levels of sophistication. Our goal with this analysis is to yield fruitful insights into student reasoning in discrete mathematics and contribute to more effective mathematics education at the undergraduate level.

Examining Series Convergence via Script Writing: The Case of Jordan

Eduardo Torres Manzanarez
The University of Texas at Arlington

James A.M. Álvarez
The University of Texas at Arlington

Keywords: calculus, script writing, series convergence

Undergraduate students in the United States typically encounter the topic of infinite series in second-semester calculus courses (Kung & Speer, 2013). Students study techniques for determining convergence of infinite series which also rely upon leveraging prior knowledge about limits and convergence for both functions and sequences. As such, McDonald et al. (2000) assert the necessity for students to have "a rich sequence schema … to fully understand series as the limit of a sequence of partial sums" (p. 98). Similarly, Oehrtman et al. (2014) found students engaging in guided reinvention for sequence convergence capable of giving a definition for series convergence that aligned with its concept definition. Other research on student understanding of series convergence focuses on understandings of series and meanings for series-related concepts including ways students conceptualize and think about series convergence (e.g., Eckman & Roh, 2022; Martínez-Planell et al., 2012). In addition, Eckman and Roh (2024a, 2024b) and Larsen et al. (2024) explore how students interpret summation notation or develop notation describing partial sums of a series while Alcock and Simpson (2004) and Martin (2013) examine the type of imagery students rely upon when examining convergence of power and Taylor series. Researchers acknowledge that students face difficulties learning infinite series and that meaningful learning activities should facilitate the development of deeper understandings of series and series convergence (e.g., Lindaman & Gay, 2012; Martínez-Planell et al., 2012).

This exploratory case study aims to examine second-semester calculus students' understanding of series convergence and identify ways that script writing elicits aspects of their understanding. Script writing (Zazkis & Zazkis, 2014), used primarily with prospective teachers in mathematics courses for engaging in an imagined role-play through the process of writing a script, can also be used to explore or assess mathematical understandings (Zazkis, 2018). We examine student understanding through the theoretical lens of concept image and definition (Tall & Vinner, 1981). This poster presents findings related to the following research questions: (1) What aspects of student understanding of convergence of infinite series arise when working a scripting task versus a non-scripting-based task? and (2) In what ways do scripting task responses convey a student's concept image and definition regarding series convergence?

Jordan (pseudonym) participated in two interview sessions spaced two weeks apart, taking place in weeks 11 and 13 of a 15-week semester. Jordan completed the course midterm exam on series two weeks prior to the first session. The first session included a 75-minute task-based interview that involved general questions and tasks on sequences and series along with a 30-minute scripting training activity. The second session involved Jordan creating a script on series convergence within 45 minutes followed by a 45-minute interview focused on Jordan's script.

During the first task-based interview, Jordan confounds the sequence of partial sums of a series with the terms of the series. Jordan also claims that a series converges given that the terms of the series converge to zero. In the task-based script writing interview, Jordan's partial understandings persisted, but their script exposes these partial understandings in a more robust manner and provides distinct opportunities to convey their understandings of the concept definition. This exploratory work provides some evidence for using script writing as a viable alternative assessment of student understanding of series convergence.

Research-based Curriculum for Developing Mathematical Tools for Upper-Division Physics

Warren Christensen
North Dakota State University

Idris Malik
North Dakota State University

Keywords: Curriculum, Physics, Calculus, Differential Equations

As part of a larger project that investigates the gap between mathematics that is taught in math courses and the mathematics used in upper-division physics courses, we present curriculum on Separation of Variables and Taylor Series. While students are likely to be first introduced to these mathematical concepts in a math course, there exist specific instances where and how physics uses these tools in teaching content. Both mathematical tools are incorporated into the courses of Mechanics, Electricity & Magnetism as well as Quantum Mechanics.

Separation of Variables and the Taylor Series expansion, as used in a physics classroom, often have different emphasis and utility compared to when they are taught in math classrooms. For instance, the Taylor Series is used to expand a complicated equation about a small quantity within the equation in the limit as another quantity becomes very large, thereby simplifying the expression. The infinite Taylor Series is typically truncated to allow for further insight into an approximate expression that's useful for analyzing complex systems.

Methodology

The tutorials were developed to allow students work through the relevant mathematics using a sequence of physics examples from different content areas (the aforementioned Quantum Mechanics, E&M and Upper-division Mechanics). Despite using course-relevant symbols and phrasing, the tutorials attempt to avoid the use of sophisticated physics content. This is intended to alleviate the need to get caught up on physics concepts so that students can gain experience and focus on the complexities of the mathematics at play. Additionally, multiple versions of the tutorials have been created, such that the first topic encountered would be most relevant to the course in which it was given, with additional, less scaffolded examples are intended to boost students' familiarity and skill with each mathematical tool. The tutorials were vetted by experts in mathematics and physics at several points in their development. Furthermore, one-on-one interviews with undergraduate and graduate students were conducted with numerous modifications made to address areas of confusion. Finally, both tutorials have been used in classroom settings where independent student groups working through the tutorials were recorded, transcribed and analyzed.

Results

While initial results are positive–both tutorials were successfully deployed in a classroom environment and generated desired discussion among students–the level of student activity and interaction varied. Engagement in the Separation of Variables Tutorial was limited compared to the Taylor Series Tutorial; however, it is unclear if this was a result of existing classroom dynamics or an indication of needed modifications in the tutorials.[1]

Investigating Outcomes for Students Repeating Calculus I

Prairie Wentworth-Nice
Johns Hopkins University

Emily Braley
Johns Hopkins University

Keywords: calculus, repeated course

In the undergraduate STEM research community, research has focused on interventions to decrease DFW (students earning grades of D, F, or withdrawing from a course) rates in introductory courses (Norton et al., 2018) or has delved further into why students leave STEM pathways in college. (Seymour & Hewitt, 1997). Johns Hopkins University (JHU), like many universities, has had a number of initiatives focused on supporting students taking introductory STEM courses, including the Gateway Sciences Initiative, and the To, Through, and Beyond initiative focused on students who are first generation and low-income students. Both initiatives focused on interventions to increase student success in introductory STEM courses including calculus.

One set of students we are specifically considering is students retaking calculus because they don't pass the first time. Work has been done studying students retaking developmental math at community colleges (Canfield, 2013; Bickerstaff et al., 2022) and those retaking calculus at a mid-sized public university (Dibbs, 2019). We hope to add to this growing literature by considering students retaking calculus at a small private and research-focused university.

At JHU, students can drop a course without a transcript mark until the seventh week of the fifteen-week semester, likely encompassing students facing challenges similar to those with DFW outcomes. To include this broader group, we will track these students as well, referring to them collectively as DDFW students. This approach represents a key divergence from existing literature, which typically focuses solely on DFW outcomes.

Through the examination of placement data, surveys, and interviews with DDFW students, we aim to describe the what, when and why of the DDFW students' experiences and gain insight into what helps these students succeed.

By documenting commonalities among students who successfully pass calculus on the second try, and identifying factors that contributed to failing, we hope to propose interventions to help increase the pass rate of calculus for both first time takers and repeating students. This poster will present an overview of the literature to date and research questions posed to investigate the outcomes for students who retake calculus.

Keywords: playful mathematics, calculus, teaching assistants, professional development

Our team has been conducting research on mathematical play and learning for some time. Recently, we began examining how Calculus I undergraduate students enrolled in a large lecture class can be supported in experiencing mathematical play during their sections. The first author implemented playful calculus tasks focusing on covariation in five different sections, and we have been analyzing that data to identify what teacher moves supported or discouraged playful mathematical engagement. In our discussions, we have identified a key tension between *establishing a playful environment* and *supporting mathematical content goals.* Particularly, the low-stakes nature of mathematical play (Williams-Pierce & Thevenow-Harrison, 2021) may sometimes be in conflict with the explicit mathematics learning goals, and vice versa. In this poster, we share some preliminary findings from this pilot study, with a particular focus on teacher moves. Our future plans involve conducting professional development (PD) with teaching assistants (TAs) so they can implement mathematical play opportunities in their sections. We consider a key part of that PD to be teacher moves that carefully thread that tension between establishing playful environments and facilitating productive mathematical learning.

For example, a key part of mathematical play is establishing an environment students are comfortably *playing* in. Play often involves exploration, agency, and learning from low-stakes failure ((Ellis et al., 2024a; Ellis et al., 2024; Williams-Pierce, 2019), which can be quite the contrast with the more traditional format of large lecture classes. Even the much smaller class sizes of the sections in this study served as more intimate extensions of the lecture, with desks arranged to face the TA at the chalkboard. In fact, in multiple of our sections, students walked into the classroom, saw that the desks had been rearranged into collaborative groups, and walked out again to double check the room number. In each section, we saw evidence that the first author engaged in ***nonjudgmental teacher moves*** that supported students in experiencing a more playful environment by the end of class. For example, a common teacher move was nonjudgmental contrasting of different student responses, such as following up a student sharing their graphed line by choosing the next student to be one who graphed a curve. By the end of class, students were more likely to be working loudly together, laughing, and taking ***public mathematical risks*** by volunteering to share their work even when they were unsure of the work or themselves. Fostering a newly playful environment is a sensitive process that works in tension with more explicit mathematical guidance – nonjudgmental teacher moves supported playfulness, but may not have efficiently improved covariational reasoning. We are continuing to explore this highly productive tension between play and content learning, and will discuss this in more detail in our poster.

Developing a Coding Scheme to Analyze Instructor Questioning in Mathematical Discussions

Ryan Gabriel Aniceto
San Diego State University

Anne Cawley
Cal Poly Pomona

Seth Ricarte
Michigan State University

Keywords: instructor questioning, large group discussion, active learning

Mathematical discussion is a central feature of mathematics instruction, which is shaped by the types of questions an instructor poses and the ways that students respond. Existing literature has introduced frameworks delineating types of questions that an instructor can pose, such as open and closed questions (Sullivan & Lilburn, 2002), higher-order and lower-order questions (Brahier, 2020), and open questions not calling for reasoning (Vacc, 1993). Additional work has also looked at the types of questions that could be asked that connect to relational practices (Wood et al., 2015), e.g., "How are we feeling about this?". Yet, we do not know how an instructor's questions impact the way students begin to develop rich, self-prompted responses.

We aim to investigate the following research question: How can an instructor use questioning and evaluation to motivate students to autonomously contribute toward mathematical discussions in more meaningful ways? In this poster, we outline the development of our coding scheme, present preliminary findings on mathematics classroom instruction, and discuss the nuances of the coding scheme. As a theoretical framing, we adopt one of Anthony's (1996) constructivist formulations for active learning, which characterizes students as mentally engaged in active thinking which promotes intellectual involvement (Kyriacou & Marshall, 1989). Incorporating this perspective into instructor-facilitated mathematical discussions, we assume that if a student provides a high-level response to questions posed by the instructor (i.e., by supporting an answer with details about their process or reasoning), then they are demonstrating an internalized understanding of the mathematical material.

The dataset used for this study consists of two 30-minute class recordings of an undergraduate mathematics content course for future elementary teachers taught by Author 2 taken from the middle and end of the semester. From the transcripts, each solicitation of input from Author 2 and each student's contribution was logged using the developing coding scheme. The coding scheme was then developed through multiple iterations of data analysis. The EQUIP tool (Reinholz & Shah, 2018) served as an initial coding scheme, including codes for Solicitation Type (*What*/*How*/*Why*), Length of Talk, and Student Talk Type (*What*/*How*/*Why*/*Other*). After a first iteration of coding, we created codes that accounted for non-mathematical types of questions, such as personal questions fostering relationships with students and logistical questions. After a second round of coding, we created codes that accounted for whether a *What* question was *Open-Ended* or *Closed-Ended* as well as codes that allowed us to identify non-verbal ways of participation.

Preliminary findings show that students demonstrated richer (e.g., more contributions coded as *How* or *What* codes) and more extensive mathematical responses later in the semester, which featured more varied types of instructor solicitations. There were multiple instances in both segments where students provided higher-level responses than the solicitation type. Through this data, we aim to stimulate conversations about the multiple ways instructors can facilitate high-level mathematical discussion and further refine the coding scheme. Subsequent work will incorporate this revised scheme into a larger analysis of an entire semester of the course.

Critical Consciousness Activation Through Undergraduate Mathematics Curriculum

Nicholas Witt
The University of Arizona

Guadalupe I. Lozano
The University of Arizona

Cynthia O. Anhalt
The University of Arizona

Keywords: critical consciousness, curriculum, teacher education

Critical consciousness (CC) has been advocated as a necessary part of mathematics learning through culturally relevant pedagogy (Ladson-Billings, 1995). The ways in which CC is conceptualized varies greatly (Freire, 1970; Ladson-Billings, 1995; Jemel, 2017; Watts, Diemer, & Voight, 2011). Furthermore, the idea of *critical* mathematics is also approached from various ways in literature (e.g., Gutiérrez, 2009; Skovsmose, 2013). Thus, operationalizing CC in mathematics education research can occur from a variety of lenses leading to challenges for researchers. In this poster we present our approach to identifying evidence of prospective mathematics teachers' (PTs) CC through a construct that we call *critical consciousness resources* (CCRs; Witt, Lozano, & Anhalt, 2024) as they engage with a culturally responsive precalculus curriculum. Our prior work (Witt, Lozano, & Anhalt, 2024) presented CCRs as, "ideas that elevate a person's awareness or sense of agency to 'engage the world and others critically'" (Ladson-Billings, 1995, p.162). In this poster, we present our expanded methodology for analyzing CCRs.

Methods

Prior work on CC in mathematics, and critical mathematics education have been primarily theoretical in nature. This study can be situated alongside others who have worked on critical mathematics curriculum (e.g., Brantlinger, 2013; Gutstein, 2006; Gutiérrez, 2013). However, we aim to contribute a conceptualization of what makes an emergent idea about contextually-rich mathematics *critical* while engaging with such curricula. Our poster will present our approach to analyzing how two cohorts of prospective mathematics teachers activated CCRs in various ways through engaging with a precalculus task *grounded in place* (Lozano, 2023). The task we feature comes from a place-based, mathematically authentic and rigorous curriculum that centers the identities and cultures of students from the Southwestern United States. Through PTs' "I-statements" (e.g., "I will try to inspire [my students] by talking about the possibility of change, and how they can better the world."), we coded whether the statement was *critical* or *dominant* (cf. Gutiérrez, 2009), centered mathematics or the context, and determined a level of agentic disposition (e.g., awareness or agency). Through a thematic analysis (Clark & Baun, 2017), we describe broader salient ideas represented in the CCRs across multiple PTs.

Findings and Discussion

We offer this conceptualization as an analytic tool to help mathematics education researchers consider the kinds of CCRs that may be activated while teaching with asset-based, contextually and culturally rich tasks such as those featured in our poster. Our findings indicate that several levels of agentic dispositions were uncovered as PTs engaged with the task. We argue that teaching to activate CCRs contributes to equitable and affirming learning environments in undergraduate mathematics classrooms. These are important research considerations for gaining insights into how mathematics curriculum can critically impact the students who engage with it.

GTA's Categories of Perception of Precalculus Students' Covariational Reasoning

Irma E. Stevens
University of Rhode Island

Keywords: graduate teaching assistants, covariational reasoning, student thinking

Herbst et al. (2023) published four categories of perception teachers use when considering student contributions: normativity, serviceability, responsiveness, and framing. The authors argue that though attending to the mathematical sophistication of a students' work is important, the task of teaching requires teachers to attend to more, stating that these categories provide additional relevant insights teachers can and should make. Though described with a geometric problem, the authors argue their relevance to other topics. In this study, I used this framework to identify potential categories of perception when interacting with students engaged in tasks offering opportunities to engage in constructing and interpreting graphs via covariational reasoning—reasoning about two quantities changing together. Thompson and Carlson (2017) argued for the importance of this reasoning in supporting students' conceptions of rate of change in precalculus courses and beyond. The Bottle Problem (Carlson et al., 2002), in which students are given a bottle and asked to construct a corresponding volume-height graph, has been widely used to support this end. In this study, I analyzed how graduate teaching assistants (GTAs) reason about various bottle problems and then assess video of precalculus students working on the same problems to understand how these GTAs perceive these students' reasoning.

The group of 11 graduate students were enrolled in a one-credit hour seminar on teaching undergraduate mathematics. In a course assignment, the GTAs first read an introduction to procedural vs. conceptual understanding, which includes an introduction to Carlson's Precalculus Concept Assessment (Carlson, Oehrtman, and Engelke, 2010) and potential student responses to a bottle problem (Abell et al., 2024). Then, the GTAs completed 8 total bottle-graph pairs and submitted a 3-5 minute video of their reasoning. Then, the GTAs watched two precalculus students explain their reasoning on the same problems and submitted their reflections on those videos, including sharing how they would respond to those students. The student videos were strategically selected; one student exhibited amounts of change reasoning, and another student used phenomenological language about "speed".

To attend to the GTAs' responses to students' covariational reasoning, the following analysis occurred. First, GTA responses were coded for correctness (final graph shape), framing (color coding, labeling), normativity (production of reasonable responses), and serviceability (attention to covariational reasoning/mathematical relationships). Second, GTA responses to the precalculus student videos were analyzed according to the same categories of perception.

Results show that the GTAs do attend to various categories of perception, though at varying degrees. The poster will detail overall patterns in the categories of perception as well as consistency between what the GTA attended to in their own work vs. the students' work. Overall, this study points to a continued need to learn about how to support students' covariational reasoning at the undergraduate level by considering what current categories of perception instructors attend to, and particularly how we can support GTAs in intentionally considering a broad range of categories when analyzing student work.

Acknowledgments

Thank you to Jessica Tolchinsky for her ongoing research with GTAs in this project.

Exploring How Educational Math Videos Affect Student Motivation

Samuel Lippe
Rhodes College

Erika David Parr
Rhodes College

Keywords: online learning, student motivation, epistemic messaging, YouTube videos

Finding ways to generate and sustain student motivation for learning mathematics is a beneficial endeavor. Researchers have begun to examine how to measure student motivation over time in an undergraduate course (Alibek, 2024), as well as how to motivate students through problem sets aimed at promoting intellectual need (Weinberg et al., 2022). Current work to both measure and promote student motivation is primarily focused on classroom settings. However, research shows that students increasingly consult external online resources, including videos on YouTube, to support them in their math courses (e.g., Muir, 2014). Although studies have looked at how such videos may benefit students' learning of mathematical content (e.g, Esparza Puga & Aguilar, 2023; Radmehr, 2024), researchers have yet to examine how online math videos can influence motivation. This project aims to begin to address this gap by asking the question: How do popular online math videos affect undergraduate student motivation?

Three popular mathematics YouTube channels include Khan Academy, Professor Dave Explains, and 3Blue1Brown. We view such popular math videos as existing on a spectrum from conceptual to procedural, based on the goals and approaches taken by these different content creators. From our perspective, a highly conceptual video may focus more on broad math concepts and developing a general mathematical intuition (i.e. many 3Blue1Brown videos), whereas a largely procedural video may focus more on how to solve specific math problems that would be relevant to assignments in a math course (i.e. Khan Academy, Professor Dave Explains). For this study, we have selected one video from each end of this spectrum. We have begun conducting interviews with undergraduate students and ask questions to gauge their interest in and view of mathematics before, during, and after watching each of these videos.

To frame our study and support our data analysis, we apply the lens of epistemic messaging, which describes the ways in which teachers convey to students what ideas are valued in a classroom and what ways of thinking are important (Russ, 2018). By applying this concept to videos, we are able to observe how the specific epistemic messaging within each video affects student interest in mathematics. With this lens, we are additionally able to observe trends in epistemic messaging between the videos at either end of the conceptual-procedural spectrum.

This poster will describe the structure of the interviews and report findings from our grounded analysis. Although data collection and analysis are ongoing, initial findings suggest the potential for a conceptual video to influence a student's perception of mathematics. However, we have not found this across the board for students from a variety of backgrounds. Thus far, we have found that a student's mathematical background and STEM-related interests may prime some students to be more receptive to the messages contained in the videos. Additionally, a student's inherent disposition towards learning may also impact the extent to which a video may impact their perceived motivation. These initial findings suggest that students may have very different take-aways from the videos, meaning that video recommendations may need to be tailored for individual students in order to affect student motivation.

Analyzing Student-Advisor Interactions During First-Year Undergraduate Mathematics Advising

Elena Crosley
University of Michigan

Keywords: Gender, Advising, Women, Identity, Embodiment

This poster reports on findings from a larger research project focused on a mathematics department's advising practices for incoming undergraduate students. This analysis explores how talk and gesture in student-advisor interactions play a role in how students are given particular mathematics course recommendations and explores the mediating role of gender in the interaction.

Recent trends show men and women are earning bachelor's degrees at near equal rates, however women only account for about one-third of undergraduates earning bachelor's degrees in a STEM discipline. Furthermore, women account for an even smaller fraction when compared to men among those earning bachelor's degrees in math-intensive STEM majors (Canaan & Mouganie, 2023; Jiang, 2021; Louten, 2022; Suárez & Beatty, 2022). While examinations of the gender gap in math-intensive STEM majors is not a novel research area, existing research has largely focused on in-classroom, faculty-level, and curriculum-specific interventions while minimizing the role of one-on-one interactions and outside-of-classroom contexts. One such overlooked site for intervention is undergraduate, pre-course-enrollment mathematics advising.

The mathematics advising explored in this study takes place at a large, public, midwestern university. Incoming undergraduate students opt in to meeting one-on-one with a member of the mathematics department (i.e., tenured faculty, postdoctoral researchers, graduate students) while they consider which math class to take. The sessions are short, lasting just 5-10 minutes on average and conclude with the student and advisor reaching a non-binding math course recommendation. Advisors and students have had no prior interactions. Advisors receive minimal to no training prior to engaging in the work of advising (Gholson et al., 2021; Margolis et al., 2023).

In a very short amount of time, students must provide information about their math background, academic desires, and future goals, and advisors must absorb this information and leverage their understanding of course details and major requirements to reach a course recommendation. Initial analyses of the advising sessions uncovered that students with similar mathematics backgrounds are sometimes given quite distinct math course recommendations that differ widely in terms of their ambitiousness (e.g., Statistics versus Honors Calculus I). Why is this happening? The analysis reported on in this poster examines paired sessions where students with similar mathematics backgrounds are given distinct course recommendations and is guided by the following questions:

1. How is student mathematical competence co-constructed through student-advisor interaction in undergraduate mathematics advising sessions?
2. How, if at all, does gender mediate the co-construction of a student's mathematical competence and the final course recommendation a student receives?

Student and advisor talk are examined in tandem with an embodied analysis based on video recordings of the advising sessions and corresponding transcripts to answer these questions. The layering of discourse analysis and embodied analysis provides a fuller picture of the advising interaction compared to either method in isolation and offers multiple avenues for exploring how gender might mediate interaction.

The Effect of an Activity-Based Quantitative Reasoning Course on Students' Perspectives About Mathematics

Lisa Driskell
Colorado Mesa University

Tracii Friedman
University of Wisconsin – Madison

Keywords: quantitative reasoning, non-STEM, activity-based, anxiety, relevance

Previous studies identify that student-centered approaches to teaching and learning result in academic outcomes that are as good or better than more traditional lecture-based approaches and that the positive effect is more evident for previously low-achieving students (Freeman et al., 2014; Kogan & Laursen et al., 2014). These results have driven change efforts toward course design and content delivery in introductory mathematics courses nationwide (Smith et al., 2021). In light of such results, we redesigned our non-STEM quantitative reasoning course to be activity-based and interactive. Studies also investigate students' attitudes in a variety of active learning courses including calculus and linear algebra (Duran et al., 2022; Murphy et al., 2015). We aim to know whether students in our quantitative reasoning course, who often hold a negative view and prior experience with math, have changed perspectives after completing the course. In particular, has this course impacted students' views about mathematics, learning, and the relevancy of mathematics to their lives?

The redesigned course, *Mathematical Investigations*, is required for all students at our institution seeking a 4-year degree that is not in a Bachelor of Science or Bachelor of Business Administration program. Approximately 200-250 students enroll in the course each semester. The sections are capped at 25 students and are primarily taught in person by full-time, non-tenure-track faculty with some sections offered on a satellite campus and others offered asynchronously online. In Fall 2020, we introduced the course redesign which transformed our traditional, computational, lecture-based course to a course that emphasizes relevant, real-world applications through classroom activities and course projects. We collected anonymous responses to identical pre-course and post-course surveys to informally gauge the effectiveness of the redesigned course. After early indicators of success, we shifted to distributing the surveys through Qualtrics, using personalized 5-digit codes to link the anonymous pre-course survey responses to the individual's anonymous post-course survey responses.

The complete survey includes three open-response questions and seven Likert scale questions. Across four semesters beginning with Spring 2023, we have approximately 795 pre-course and 490 post-course respondents including 392 paired survey sets. The current analysis focuses on the paired responses to a subset of the Likert scale questions. We see favorable results in response to the statement "I feel anxiety about math" (n=392). While 48 students disagreed or strongly disagreed with the statement in both surveys, 166 students who did not initially disagree with the statement indicated improvement, shifting in the direction of "strongly disagree" in the post-course survey when compared to their pre-course response. In response to the statement "Mathematics has no relevance to my life" (n=391), 191 students disagreed or strongly disagreed with the statement in both the pre- and post-course surveys. An additional 111 students indicated improvement, shifting in the direction of "strongly disagree" in the post-course survey.

Our results indicate that students' perspectives were improved after completing the course. Our future work is to conduct a qualitative analysis on the paired responses to the open-ended survey questions which are tied to students' feelings about math and making mistakes in math.

Acknowledgments

We thank former undergraduate students, Moira Hilton and Declan Atwell, who conducted preliminary qualitative analysis of open-ended responses from the initial survey results. Their work, which included literature reviews, inspired the authors to pursue this study. We also thank the instructors involved in teaching the redesigned course and administering the course surveys.

Building Metaphors That Describe Mathematics Identity and Experiences among Mathematics GTAs: Locks to Change

Kristin Tenney
San Diego State University

Mary E. Pilgrim
San Diego State University

Sue Doe
Colorado State University

Keywords: Mathematics; Graduate Teaching Assistants; Reflection; Identity; Professional Development

Graduate teaching assistants (GTAs) hold unique positions in higher education as they take on roles of both learner and instructor. Kress (2020) found that GTA identity includes not only their sense as a teacher and student, but also their own relationship with mathematics and how they may - or may not - align with the field. In this poster, we share data from a GTA professional development (PD) activity focused on race. We analyzed work from seven mathematics GTAs who responded reflectively to short biographies of mathematicians of color and to at least one other GTA's writing. Reflections focused on their own racial identities and lived experiences. While this study was not driven by a predetermined research question, the responses from the GTAs on the reflective writing assignment were more complex than expected, which prompted further investigation. In particular, we wondered: *How do biographies of mathematicians of color prompt GTAs to reflect upon their own lived experiences in mathematics?*

Women and students of color are underrepresented in STEM fields (Fry et al., 2021) and thus their mathematics experiences are often viewed through windows of white others, with notably few opportunities for mirrors (Leyva, Quea et al., 2021; Guiterrez, 2018). Motivated by this discrepancy, we leveraged Style's work (1996/1988), which focuses on the concepts of a window and a mirror, where windows allow for one "to see the realities of others" and mirrors provide opportunities for one to "see her/his own reality reflected" (p. 1). Abo-zena et al. (2019) expand on the windows and mirrors metaphor by including doors: a way to foster engagement between diverse individuals and provide opportunities for sharing of ideas and perspectives among those with different backgrounds and lived experiences. Aligning with the house metaphor, we added our own construct, *locks*, to capture statements that highlighted obstacles, challenges, or adversity that the GTAs described.

Our findings show the application of the a priori codes windows, mirrors, doors, and locks. The mirror code occurred in all seven discussion board threads, many of which contain posts by more than one GTA. In relation to the mirror codes, every time a lock code was identified it was linked to a mirror. Five of the six locks occurred where GTAs were looking for a connection to autobiographers through personal challenges. In these cases, they saw the obstacles that they themselves had faced in their mathematics career reflected back by successful mathematicians who looked like them. Often locks were followed up by doors in discussion threads.

Our exploratory study, which emerged from a pedagogical experiment, suggests that GTAs, who are both students and emerging educators, may be positively affected by the reading of biographies of successful mathematicians from underrepresented populations, especially when accompanied by self-reflexive writing. Exploring the reflective practice of this PD may create more inclusive and equitable mathematics classrooms by supporting GTAs in considering personal and systemic experiences of marginalization.

Designing Courseware for Equitable Access, Engagement and Learning in Gateway Mathematics: Centering the Experiences and Perspectives of Students and Faculty

Ann Edwards
WestEd

Tanner Higgin
WestEd

Keywords: Gateway mathematics, learning technology, user-centered design

Postsecondary math faculty are facing several related challenges that existed prior to but were accelerated by the COVID-19 pandemic (Lopez et al., 2021). At the institutional level, concerns over declining enrollment and budget cuts have led to staffing declines and increased workloads. Faculty have had to teach in a wider array of classroom scenarios, including fully online synchronous or asynchronous, hybrid/hyflex, and in-person, with some teaching courses in all of these scenarios. Furthermore, faculty are finding that, compared to prior to the pandemic, students are entering gateway math courses with greater challenges in mathematical knowledge and skills, surprising gaps in fundamental technology skills, and under-preparation in college-ready organizational skills. Students are also experiencing anxiety and trauma related to mathematics. As a core component of many gateway mathematics courses, digital courseware has the potential to help faculty address these challenges but also presents barriers and challenges to faculty and students (Ganimian et al., 2020; Viberg et al., 2020).

This poster reports on a nationwide study of the perspectives, experiences, and needs of math faculty and students regarding courseware technology (i.e., digital content and tools/platforms designed to support learning) in gateway mathematics courses. The goal of the study, funded by the Gates Foundation, is to inform the design and implementation of mathematics courseware technologies that can improve the mathematics learning experiences and outcomes of Black, Latinx, Indigenous, and low-income students. The study focuses on Quantitative Reasoning, College Algebra, and Calculus and draws upon equity-focused and user-centered design research methods. Data include interviews, surveys, and diary studies, with intentional sampling of the priority student populations (Black/Latinx/ Indigenous/Low-Income) across institution types (2-year and 4-year, particularly TCUs, HSIs, and HBCUs), as well as faculty (teaching, research, adjunct). The analysis draws upon approximately 75 hour long semi-structured interviews of instructors of the selected courses and 75 interviews of students. Seven faculty participated in diary studies, providing daily logs of activities involving mathematics and uses of courseware.

The poster reports on findings from the faculty analysis related to three key themes: (1) Equity: pertaining to issues of access to and proficiency with technology as well as the capacities of courseware to promote inclusion; (2) Engagement: barriers to and features supporting student engagement with courseware content; and (3) Effectiveness: insights related to how courseware can support meaningful mathematics learning and identity development. The poster also presents products to inform design and development of courseware derived from the study analysis, including faculty personas, journey maps, and a map of the ecosystem of resources, supports, barriers, and obstacles in faculty's use of courseware in gateway mathematics.

Acknowledgments

This work was supported, in whole or in part, by the Gates Foundation [INV-069032]. The conclusions and opinions expressed in this work are those of the author(s) alone and shall not be attributed to the Foundation.
