Graduate student instructors (GSIs) in mathematics play a pivotal role in shaping undergraduate education and are the future of collegiate mathematics faculty. As part of their development, GSIs are expected to engage in teaching-focused professional development (TPD), particularly in evidence-based strategies like Active Learning (AL) methods. However, higher education is only beginning to explore how to effectively measure GSIs' growth in teaching skills through such TPD. This study examines the learning process of 47 novice GSIs from three universities, specifically focusing on their evolving understanding of AL before and after participating in TPD. By analyzing the GSIs' own definitions of AL, the research highlights changes in their knowledge and alignment with the intended TPD outcomes. The findings provide insight into the effectiveness of TPD on AL, while also offering recommendations for structuring future evaluations of TPD impact on GSI teaching knowledge and skills.

Keywords: Active Learning, Graduate Student Instructors, Teaching Assistants, Professional Development, Assessment

Mathematics graduate students are a substantial proportion of the undergraduate teaching workforce in the United States (Belnap & Allred, 2009; Speer et al. 2010) and their pedagogical knowledge and methods are greatly influenced during this time as novice college mathematics instructors (Deshler et al., 2015; Speer and Murphy, 2009). During their experiences as graduate student instructors (GSIs, graduate students who are instructors of record for a mathematics or statistics course), research has indicated that teaching-focused professional development (TPD) improves GSIs' knowledge and skills for effective teaching (Deshler et al., 2015; Yee & Rogers 2017; Hauk & Speer, 2023). Decades of work have also demonstrated that active learning (AL) approaches—using teaching strategies that actively engage all students in the classroom—are among the most effective (Freemen et al., 2014; Gobstein et al., 2016). AL has received significant discussion on its value within the classroom, with overwhelming recognition of its success *with appropriate TPD* (Reinholz, 2023). For example, Reinholz et al. (2022) reported on how and why supervision of collaborative learning is critical for AL strategies to be effective. Indeed, without addressing a classroom culture, student collaborations may include microaggressions that drastically limit the effectiveness of AL. Thus to prepare GSIs for implementing AL well, they need equitable and effective TPD (National Academy of Science, Engineering, and Medicine, 2023).

How can we know if TPD is effective? Specifically, how can we gather data and assess the impact among GSIs of AL-focused TPD opportunities? It requires data upon which to evaluate effectiveness, which, in turn, requires data collected around the objective or aim of the TPD (Yee et al., 2024; Deshler et al., 2015). In recent years, research in undergraduate mathematics

education has begun exploring ways to evaluate the effectiveness of TPD (Yee et al, 2023; Yee et al, 2024).

Purpose and Rationale

The purpose of this study was to research how collecting and analyzing data on GSI learning in an AL-focused TPD activity might be part of evaluation of TPD effectiveness. Prior research has indicated that to improve practical understanding of AL, instructors need to (1) recognize exemplars through readings about AL methods (McConnell et al., 2017), (2) visualize and imagine themselves using varying AL methods (Yee, 2021), and (3) become aware of the nuances inherent in the enactment of AL (Laursen & Rasmussen, 2019). Our approach was to focus on how GSIs' *definitions of AL* changed during their TPD experience.

Unpacking GSIs' meaning making for educational definitions is important particularly for GSIs in mathematics where deductive and axiomatic structures put significant weight on definitions. For example, a series cannot both converge and diverge because the definition of convergence and divergence is binary, founded in the logic that a mathematical statement is either true or false, hence *dependent upon the definition* (Vinner, 2002). Thus a mathematical definition's utility is uniform. However, definitions in educational research rely on human participants and evidence, as seen in the diverse use of AL across different disciplines. How a chemistry lab uses AL is distinct from how a mathematics classroom uses AL because chemistry labs inherently engage students through lab experiments, resulting in facilitating labs being the focus for AL. Our rationale for this study emphasizes GSIs' definitions of AL as dynamic and not static. To this end, our research question for this study was: *How do novice GSIs' definitions of AL change after participating in an AL-focused professional learning activity?* For this study, novice refers to GSIs who are within their first two years of teaching.

Relevant Literature for Framing the Professional Development

Dimensions and Pillars of Active Learning

Four pillars for AL support instructors in developing a definition of AL: (1) Students engaging deeply with coherent and meaningful mathematical tasks, (2). Students collaboratively processing mathematical ideas, (3) Instructors inquiring into student thinking, (4) Instructors fostering equity in their design and facilitation choices (Gobstein et al., 2016; Laursen & Rasmussen, 2019; Smith et al., 2021; Yee et al., 2024). Recent work in developing TPD for operationalizing a definition of AL has come out of the SEMINAL project (and coding of over 100 mathematics instructor definitions of AL; Williams et al., 2020). In leveraging this previous work, we sought to attend to novice GSIs with their beginning understanding of AL. This led to another dimension of interest: interconnectedness. Together with the four pillars, the dimensions reflected on and considered in our AL-focused TPD and research were: (1) Role of students, (2) Role of mathematics, (3) Role of the teacher, (4) Role of equity, (5) Interconnectedness of the other roles. The fifth dimension was added because our research team agreed that how the four roles are connected is just as important as any single role. For example, the interconnectedness dimension focused on if novice GSIs could recognize that the role of equity affects the role of the teacher and students.

Critical Reflection by Assessing Definitions

The larger scope of this work strives to understand how GSI conceptions of AL for productive use in the classroom change over time. This study focuses on definitions for multiple

reasons. We understand how educational definitions can be perceived differently from mathematicians' use of definitions (Tall & Vinner, 1981). Ultimately, learning to integrate definitions for teaching is a process. This study is not trying to argue or search for a "right" or "correct" definition of AL. Indeed, Williams et al.'s (2022) work shows the diverse ways in which experienced mathematicians view AL. The goal of this study was for GSIs to reflect on how their AL definition might change as they built experience as instructors. Consequently, the AL-focused TPD activity was designed to have GSIs critically reflect (Brookfield, 2017) on AL definitions by actively engaging in assessing their own and others' definitions. To that end, similar to other classroom practices used to help novice GSIs use AL (e.g. Observation Protocols, Yee et al., 2022), this study did not use assessment *of* AL understanding, but rather assessment *for* AL understanding.

Description of Module, Lessons, and Activities

The AL-focused TPD module included two 50-minute sessions with novice GSIs as (Lesson 1 and Lesson 2) as well as pre- and post-lessons assignment. Figure 1 describes the module.

Overarching Goal of Module*: The goal of this unit is to have novice GSIs grow their definition, understanding, and implementation of AL. *Full description of activity is at (Yee et al. 2024)*	
Pre-Module Assignment: 1. **Read** Active learning in the college classroom by Faust and Paulson, 1998. 2. In the context of Mathematics teaching and learning, please type **your own definition** of active learning in as much detail as possible.	
Lesson 1 Objectives:	**Lesson 1 Activities (50 Minutes)***
● GSIs will Identify what students and instructors can do with a selected set of active-learning strategies. ● Justify their decisions on what students and instructors can do with a selected set of active-learning strategies in their classroom.	● GSIs are given a list of 10 common GSI strategies ● GSIs are given a table with rows indicating ways students are engaging during the activity and columns about how the instructor is engaged during the activity. GSIs then work in small groups to list each AL strategy in what cells they find most relevant. ● GSIs negotiate with one another how they would enact the activity relative to what the instructor is doing and what the students are doing. ● GSIs recognize that direct instruction is just one of many teaching methods and quite limited within the scope of what students can and can't do.
Lesson 2 Objectives:	**Lesson 2 Activities (50 Minutes)**
● Notice and articulate distinctions and dimensions of definitions of Active Learning ● Revise their initial definition of Active Learning.	● GSIs review the rubric (see Figure 2) and practice evaluating three pre-generated definitions according to the rubric. ● GSIs then review their own definition ● Classroom discussion is had around any issues of confusion with the rubric and what they notice and wonder about their own pre-module AL definition

Figure 1. Active learning module structure and components

GSIs began by reading a collegiate AL article (Faust & Paulson, 1998) and creating their own initial definition of AL. Lesson 1 had them engage with 10 AL strategies by asking the GSI to envision (1) what the student is doing and (2) what the instructor is doing for each. Lesson 2 had the GSIs see a rubric for evaluating definitions of AL along the five dimensions using a scale from 1 to 5 (see Figure 2). GSIs then practiced and made sense of the rubric with three AL definition examples that were pre-generated to identify how the dimensions of AL are used. Finally, GSIs reviewed their own definition and discussed what GSIs noticed and how they might want to change their definition.

This report focuses on the Lesson 2 objectives. The activity was designed after multiple iterations of a smaller activity (Lesson Plan 1) so that results could be used to interpret and justify conclusions about GSI's change in definitions. By looking for changes in definitions (especially relating to equity), we collected data to determine if the TPD objectives had been met. Furthermore, through assessment and reflection, we could determine how to improve the TPD itself. Ultimately, the rubric is not just to rate definitions, but a means to understand the components of the definition (i.e. assessment *for* AL understanding).

Methods

To answer our research questions, this study used a sequential mixed methods approach where qualitative coding was followed by quantitative analysis. GSIs' original definitions (pre-module assignment) and the GSIs' revised definition were qualitatively coded using the rubric by the research team after the entire module TPD was completed (post-module assignment). Figure 2 offers an abridged rubric, while the full rubric can be found at https://bit.ly/RUME2025.

	(1) Missing Element (α)	(2) Basic Definition (α)	(3) Specific Example(s) (β)	(4) Sufficient Definition (γ)	(5) Rich and Nuanced Definition (γ)
Role of Students	No mention of students or what students are doing	Includes broad mentions that students are active or actively engaged	Can articulate what the student is doing during a specific example of active learning	Describes what students are doing inside and/or outside the classroom; definition may include active engagement with mathematical learning, or peer-to-peer interaction	Describes what students are doing inside and outside the classroom, including active engagement with mathematical learning, peer-to-peer interaction to communicate mathematical reasoning
Role of Mathematics	No mention of the mathematics	Mention of math class or doing math (in general)	Gives examples of specific mathematics content (e.g., chain rule)	Reflect on the mathematical content that was difficult to understand, that has become clearer conceptually than it was.	Defines how specialized mathematics knowledge for teaching is directly involved with the active learning strategy, including how mathematical reasoning is embedded to build student understanding
Role of Teachers	No mention of the teacher or what teachers are doing	Mention of the teacher in general ("the teacher plans active learning")	Gives specific examples of active learning strategies such as think-pair-share	Describes formative assessment(s) and how student feedback will be incorporated to inform teaching	Describes what the teacher is doing to orchestrate active learning, including planning considerations, instructor use of student thinking, and how the instructor engages students
Role of Equity	No mention of equity	Mention equity within the classroom around content, student, or teacher access; reference to "all students" such as active learning	Gives specific inclusive teaching strategies related to implementing active learning	Illustrate how the specific strategies will provide equitable access to the learning activity. May provide examples linking ideas to practice such as equity versus equality	Describes equity considerations and intentionality for using inclusive teaching practices, such as norm setting for engaging students in discussions; includes discussion of how active learning is not automatically equitable; may talk about other equitable or inclusive teaching strategies.
Interconnectedness	No connections among the four different roles	Defines active learning by what it is not ("not lecture"), and does not connect across dimensions	At least one connection is stated between two of the roles (teacher, students, math, equity)	Definition touches on more than one connection across more than two of the roles (teacher, student, math, and equity)	Definition touches on roles of students, teachers, and mathematics, with attention to equity, interactions, and mathematical sense making and communication; acknowledgement that the roles are interconnected

Figure 2. Abridged rubric used to assess active learning definitions by graduate student instructors

The data was then quantitatively analyzed to determine what changes, and frequency of those changes, occurred among participants' definition components and qualities. α, β, and γ are categorical codes described further in the findings.

Participants and Data Collection

47 novice GSIs from three universities in the midwestern and southeastern United States participated in the GSI TPD. All novice GSIs had just begun as full instructor-of-record in introductory mathematics and statistics courses. All three providers of the TPD were researchers in this study. Participants submitted their initial and final definitions of AL via an online form, either during a TPD activity or as homework. Participants' prior understanding of AL from the providers was limited. Students had perhaps heard the language around students should be "active," but AL was never formalized beyond personal experiences with teaching.

Data Analysis

Three members of the research team completed the qualitative coding of all 47 GSIs' pre- and post-definitions using the rubric (Figure 2). They all coded 20 GSIs' pre- and post-definitions along all five rubric dimensions, then met to compare, discuss, and agree on initial codes. They discussed how to align the rubric, then discussed and revised their individual codes

until the whole research team agreed on coding for the initial set of 20 GSIs. The remaining 27 GSIs were split evenly among this same group so that each researcher coded for 9 GSIs' pre- and post-definitions along all five rubric dimensions on their own. Inconsistencies were discussed until interrater reliability was 95%.

For example, one student wrote in their pre-definition, "My own description of it would include things such as collaborative problem solving, hands-on activities, flipped classroom, peer teaching, project based or discovery learning," which the research team agreed was a score of 1 in all categories, except Role of Students (score 5). The post definition for the same student was:

> Multiple participants are involved in AL inside a classroom: the instructor creates learning opportunities with equitable access points and then facilitates tasks so that everyone in the class is involved with the task, while simultaneously collecting feedback from the students to navigate and decide on the next learning actions and goals. All students have an opportunity to be actively involved in the learning process, while following the established classroom norm of promoting the construction of their own knowledge and ideas simultaneously respecting others' experiences and perspectives. Students engage in tasks to develop understanding and become an active participant/ a primary stakeholder in their learning and further investigate their understanding in and outside of the classroom by taking ownership of their own learning outcomes.

Researchers scored this student's post definition as still a 1 in Role of Mathematics and a 4 for Interconnectedness, but a 5 for the Role of Student, Instructor, and Equity.

Findings

Pre- and Post-Definition Descriptive Discussion

Upon completion of the initial coding, the research team decided to group some rubric score values into broader categories. The α category comprises scores of 1 (Missing Element) and 2 (Basic Definition), representing, at best, the inclusion of a rubric dimension in a GSI's definition with little specificity. The β category represents a score of 3 (Specific Examples(s)). And the γ category comprises scores of 4 (Sufficient Definition) and 5 (Rich and Nuanced Definition), representing the inclusion of a rubric dimension in a GSI's definition at a level of complexity beyond a basic statement or concrete example. These three broader categories were introduced to help identify trends via quantitative analysis, both in describing pre- and post-definitions individually and in understanding changes from pre- to post-definitions overall.

Table 1 provides a summary of how GSIs' pre- and post-definitions were coded and organized by rubric item category (ranging from less rich in the α category to more nuanced in the γ category). This provides evidence for the initial and end states of GSIs' definitions through the activity.

Table 1. Number of GSIs' pre- and post-definitions by category

	Pre-Definition (N=47)			**Post-Definition (N=47)**		
	α	β	γ	α	β	γ
Role of Students	25	9	13	6	11	30
Role of Mathematics	44	0	3	36	2	9
Role of Teachers	28	17	2	9	32	6
Role of Equity	46	1	0	38	5	4
Interconnectedness	20	20	7	0	12	35

α = rubric score of 1 or 2; β = rubric score of 3; γ = rubric score of 4 or 5

As seen in Table 1, the category with the largest number of GSIs' pre-definitions was the α category for every rubric dimension. Pre-definitions were especially highly concentrated in the α

category for both Role of Mathematics and Role of Equity, meaning that the Roles of Mathematics and Equity were either missing or included in a basic way for nearly all GSIs' pre-definitions. The other rubric dimensions (Role of Students, Role of Teachers, And Interconnectedness) were distributed more widely across all categories.

Regarding post-definitions, Table 1 shows that Role of Mathematics and Role of Equity remain relatively highly concentrated in the α category, but these are the only rubric dimensions for which the α category had the largest number of post-definitions. Researchers expected that GSIs' definitions would change after having worked with the rubric in Figure 2, but it is noteworthy that no post-definitions fell into the α category for Interconnectedness. This is likely because many of GSIs' pre-definitions completely lacked mention of certain rubric elements (such as the "Role of Mathematics" or the "Role of Equity") and therefore had fewer opportunities to make connections between roles. The rubric prompted GSIs to think about and include all roles (and naturally make more connections among the roles) in their definitions.

Changes in Definition

We observed a deepening in richness of GSIs' definitions of AL by observing their change in category from their pre-definition to their post-definition. For simplicity, a GSI's definition became *richer by category* if it was assigned rubric scores for pre- and post-definitions that represented a shift in category from α to β, from β to γ, or from α to γ. Among the 47 GSI participants, it was most common (17 of 47 participants, 36%) for a definition to become richer by category in three different rubric dimensions. Two GSIs saw their definitions become richer by category across all five rubric dimensions (15%), while seven GSIs saw no increased richness by category in any rubric dimension.

Researchers note that since GSIs' were given the rubric prior to constructing their post-definitions, one might expect to observe GSIs' definitions becoming somewhat uniformly richer by category across all rubric dimensions (after considering rubric dimensions where GSIs' pre-definitions were concentrated in richer categories, see Table 1). This was not the case at all. The "Interconnectedness" rubric dimension saw the most substantial enrichment of definitions, with 35 of 47 participants' definitions (74%) becoming richer by category, even though this rubric dimension started with the fewest pre-definitions in the α category. Conversely, the "Role of Mathematics" and "Role of Equity" rubric dimensions began with the most pre-definitions in the α category and yet saw the least amount of enrichment by category.

Role of Mathematics and Role of Equity: All but three GSIs' pre-definitions fell into the $\boldsymbol{\alpha}$ category for the "Role of Mathematics" rubric dimension, yet only nine definitions became richer by category in this dimension through the activity. Looking at the "Role of Equity" rubric dimension is even more extreme—all but one pre-definition fell into the $\boldsymbol{\alpha}$ category, yet only eight definitions became richer by category. To better understand the changes in richness for the Role of Mathematics and the Role of Equity, a more granular analysis of the participants' post-definitions was done with participants' whose pre-definition was an $\boldsymbol{\alpha}$ category. Table 2 details the exact change in rubric score (not just category) for all pre-definitions within the $\boldsymbol{\alpha}$ category.

Table 2 illustrates 8 out of 47 post-definitions (17%) received a score of 1 to represent the Role of Mathematics as being a "Missing Element." However, 23 of 35 of the GSIs' definitions (65%) that started at a pre-definition score of 1 ("Missing Element") grew to a post-definition score of 2 ("Basic Definition"). These GSIs' definitions became richer within the α category. Ultimately, pre-definitions that began in the α category lacked concrete examples of how

mathematics takes a role in the AL process (β category) or how mathematical content and reasoning shapes or is shaped by the AL process more broadly (γ category).

Table 2. Number of GSIs pre- to post-definition rubric score shifts in α category

	Pre-Definition Rubric Score (α category)	Post-Definition Rubric Score 1	2	3	4	5
Role of Mathematics	**1 (N=35)**	6	23	1	5	0
	2 (N=9)	2	4	1	2	0
Role of Equity	**1 (N=41)**	20	15	2	2	2
	2 (N=5)	1	2	2	0	0

Table 2 also states 21 out of 47 post-definitions (45%) received a score of 1 to represent the Role of Equity as being a "Missing Element." 15 of the 41 (37%) post-definitions began with a pre-definition of score of 1 shifted richness towards a "Basic Definition" (score 2) for the Role of Equity, yet 20 of the 41 (49%) had a pre- and post-definition score of 1 within the Role of Equity. Even more so than for the Role of Mathematics, GSIs' definitions infrequently incorporated specific examples or sufficiently rich/nuanced conceptualizations of the Role of Equity in AL.

Discussion & Implications

Despite limited research on GSI learning (e.g., Deshler et al. 2015; Yee et al., 2023) this study represents a transferable model for assessing the impacts of GSI TPD. Like Williams et al. (2022), we found that AL definitions rarely included any mention of equity or mathematics, much less nuanced and rich treatments of these complex topics. In answering our research question, this AL-focused TPD, overall, did lead to more nuanced and richer GSI AL definitions. Although one might expect that exposure to the rubric for AL definitions would result in uniform improvements to GSIs' definitions of AL, we did not see that. Instead, we saw that most GSIs improved in their definition with the Role of the Teacher, Role of the Student, and Interconnectedness. Although the considerations of mathematics and equity did not show overall categorical growth beyond the α category, we did see more mentions of mathematics and/or equity. The surface attention to equity was not surprising; it typically takes far more equity-focused TPD for GSIs to develop nuanced conceptualizations of equity (Reinholz, 2023; Reinholz et al., 2022). Thus, one implication for GSI TPD is that GSIs need longitudinal TPD experiences focused on developing their conceptions of equitable mathematics teaching and learning.

An additional implication for TPD providers is that the model we used for assessing the impacts of the AL TPD on GSIs' definitions is transferrable to other pedagogical topics. Thus, this study answers the call of many for more research on what makes for effective TPD (e.g., Deshler et al., 2015; Hauk & Speer, 2023; Yee & Rogers, 2017; Yee et al., 2023; Yee et al., 2024). One limitation of our study is that we just focused on GSIs' definitions of AL; future studies should look for connections between growth in GSIs' AL definitions and enactment practices of AL. We recommend some longitudinal future studies to look at more lasting impacts, and to assess if sustained TPD can further improve not only GSIs' AL definitions, but also their AL practices.

Exploring Women-Identifying Graduate Students' Values Related to Teaching and Learning Mathematics

T. Royce Olarte
University of California Santa Barbara

Ciera Street
Cal Poly, San Luis Obispo

Graduate students' values related to teaching and learning are critical in shaping their professional identities and future careers as faculty members. These values encapsulate instructors' convictions about what is important or worthwhile as it relates to mathematics teaching and learning. Research suggests that mathematical discourses reflect and empower dominant masculine values. Thus, we explore three women-identifying graduate students' values related to teaching and learning mathematics to highlight their voices and emphasize ways in which their values align with or challenge dominant masculine values. Utilizing interview data, we found four values across the three participants: collaboration, student-instructor perceptions, humanizing mathematics, and compassion and care for students' wellbeing. We discuss how these values interact with dominant masculine mathematical discourses and the ways in which these values may help foster equitable mathematics pedagogy.

Keywords: Graduate Teaching Assistants (GTAs), gender, values, equity

The values that women-identifying mathematics graduate students hold about teaching, student learning, and pedagogy are critical in shaping their professional identities and future careers as faculty members (e.g., Clarke et al., 2013; Austin & McDaniels, 2006). As many graduate students transition from learners to educators, their beliefs and values will not only influence their teaching practices but also contribute to the evolving landscape of mathematics education in postsecondary institutions. Given the underrepresentation of women in mathematics, especially in faculty positions (Casad et al., 2021; Kessel, 2014), it is essential to understand the perspectives and values they bring to their academic and professional lives (National Science Foundation, 2021). Research suggests that values related to teaching and learning are central to the development of a teacher identity and can profoundly influence career trajectories (Beijaard et al., 2004). For women in mathematics, these values may encompass a commitment to equity, inclusivity, and student-centered pedagogy, which are often in contrast to the more traditional, content-focused values historically dominant in the discipline (e.g., Hottinger, 2016; Leyva, 2017; McMinn et al., 2022; Mendick, 2006; Reinholz et al., 2019). Understanding these values is essential not only for supporting the professional development of women-identifying graduate students but also for illuminating how their values align or misalign with the longstanding norms and discourses of the mathematics discipline (Leyva, 2017; Mendick, 2006; Street, 2024).

The alignment or misalignment of these values with the traditional expectations of mathematics faculty can significantly impact the career pursuits and retention of women-identifying mathematicians. For instance, research has shown that when there is a mismatch between personal values and the prevailing culture of the discipline, individuals may experience role conflict, reduced job satisfaction, and a heightened likelihood of leaving the profession (Gardner & Holley, 2011). Conversely, when institutions recognize and support diverse values, it can lead to more inclusive teaching practices, innovative pedagogical approaches, and a more welcoming environment for both students and faculty (Casad et al., 2019). Therefore, examining the values of women-identifying mathematics graduate students provides critical insights into

how these emerging educators may challenge or reinforce existing pedagogical norms and helps to identify potential areas of misalignment that could be addressed to promote greater inclusivity within the discipline. In this preliminary work, we seek to illustrate values that women-identifying graduate students hold related to student learning and teaching. In particular, we asked: What do women-identifying mathematics graduate students value about mathematics teaching and learning? In what ways, if any, do their values align with or challenge dominant values in postsecondary mathematics education?

Conceptual Framing

We ground this study within the position that mathematics education is a values-laden space (Adiredja & Andrews-Larson, 2017; Ernest, 2016; Swanson, 2010). Values represent semi-stable convictions one holds about what is important or worthwhile, influenced by both individual experiences and societal factors, such as gender (Bishop et al., 2003; Seah & Andersson, 2015). Research suggests the values imbued within mathematics spaces often reflect dominant masculine values, such as individualism, rationalism, and competition (Ernest, 2003; Leyva, 2017; Mendick, 2006). Therefore, doing mathematics can produce value tension for those unable or unwilling to assimilate into the masculine culture of mathematics (Levya, 2017; Mendick, 2006). This tension can force women in mathematics to either conform or sacrifice components of their gender identity to be a mathematician (Hottinger, 2016). While a growing body of work relates to how marginalized students' values contrast with and challenge the dominant masculine values in undergraduate mathematics (e.g., Fong et al., 2019; Levya, 2021; Street, 2024), limited, if any, examine graduate students' and instructors' values related to teaching and learning mathematics.

Seah et al. (2016) operationally defined mathematics education values as tools that are "use[d] to define the relative importance of different attributes of mathematics and of its pedagogy" (p. 14) which are "inculcated through the nature of mathematics and through the individual's experience in the socio-cultural environment and in the mathematics classroom" (Seah, 2005, pp. 146-147). For example, research within K-12 mathematics suggests teachers highly value activities that focus on consolidating materials in class, problem-solving and investigative activities, and small-group collaboration (Akyildiz et al., 2021; FitzSimons et al., 2000). As one of the only, if not sole, article that focuses on graduate students' teaching values, Schwartz et al. (2022) found that graduate teaching assistants across disciplines (with 8.7% of the sample in a STEM department) most valued higher-order thinking skills in their teaching, including fostering students' written communication, critical thinking, and information literacy skills. Their results also reflect how gender may influence values of teaching and learning mathematics, finding that women GTAs in their sample valued components of ethics and diversity (e.g., adapting course content to reflect different cultures) more so than men, and that this value was associated with higher use of student-centered teaching practices. Given the highly contextualized nature of values related to teaching and learning mathematics, instructors play a major role in emphasizing the central values in the classroom. We focus the present work on women-identifying graduate students' values to highlight their perspectives in a masculine domain and connect to emerging work challenging exclusionary gendered mathematical discourses.

Methods

Context and Participants

This study was conducted at a large, research-intensive university in the West Coast of the United States. We used convenience sampling (Miles et al., 2020) to recruit graduate students in the mathematics department. Sixteen doctoral students completed a survey that elicited self-identified/self-selected demographic information and requested their participation in a 90-minute interview. A total of six students participated in the interview, but in the present work, we focus on the three women-identifying graduate students from the sample (See Table 1; all demographic information was self-selected or self-described). At this department, serving as a teaching assistant (TA) involved planning for and facilitating sections (i.e., recitation hours). All participants had experiences as TAs and as instructors of record for lower division mathematics courses. Each of the three participants researched theoretical mathematics (Kayla was interested in geometric group theory, Kendall was focused on lower dimensional topology, and Morgan was researching quantum algebra and knot theory) and all expressed intentions to continue their careers as faculty members in a mathematics department at a postsecondary institution.

Table 1. Participant information

Name	Race and/or Ethnicity	Year in Ph.D. Program	Other self-described identities
Kayla	White/Caucasian	1st	Underrepresented student, Christian
Kendall	White/Caucasian	5th	
Morgan	White/Caucasian	5th	Underrepresented student

Aligning our work with transformative feminist theories and approaches (e.g., Creswell & Plano Clark, 2011; Du Bois, 1983; Kitzinger & Wilkinson, 1997, etc.) we chose to engage with the experiences and values of women-identifying graduate students without any direct comparison to the experiences and values of men in mathematics. Centering women's experiences in mathematics and illuminating the values they hold is important in its own right. With a special focus on their gender identities, we aim to contribute to and expand the field's understanding of mathematics graduate education by describing some of the values that women-identifying graduate students hold regarding teaching, student learning, and pedagogy. However, it should be noted that our analytical focus on Kayla's, Morgan's, and Kendall's values is not intended to homogenize nor generalize to women-identifying graduate students in mathematics doctoral programs.

Data Collection and Analysis

We utilized Zoom to conduct one-hour semi-structured interviews (Rubin & Rubin, 2011) focused on students' experiences in graduate school, including the supports and barriers they encountered, their perceptions of the mathematics professoriate, and their understanding of mathematics teaching. We analyzed the interview transcripts using Saldaña's (2013) method of pre-coding, first-cycle, and second-cycle coding. We engaged in pre-coding by first independently reading through each transcript and identifying instances that participants articulated values related to mathematics teaching, student learning, etc. Our first-cycle coding process involved reading through the transcripts together and sharing and reconciling the codes

we established individually during pre-coding. Our second-cycle coding process included discussing how the codes represented themes related to participants' values related to teaching and learning mathematics. Throughout this analysis process, we wrote notes and memos (Miles et al., 2020) capturing the progression of our themes and ideas. For the present study, we highlight four themes related to participants' values about teaching and learning mathematics: *Collaboration*, *Student-Instructor Perceptions*, *Humanizing Mathematics*, and *Compassion and Care for Student Wellbeing*.

Results

Given the limited scholarship on mathematics graduate students' values about teaching and learning mathematics, we utilize a descriptive approach to illustrate these women-identifying graduate students' values. It is important to note that the following values are not mutually exclusive, and we observed participants expressing values that encompassed multiple themes.

Collaboration

Kendall, Morgan, and Kayla all valued collaboration in mathematics and reported implementing instructional practices that encouraged students to engage with one another, converse with peers, and make sense of the mathematics together. Although some of their efforts to foster collaborations were similar (e.g., group work during sections), the underpinnings of why they valued collaboration in mathematics classrooms differed. Kendall and Morgan understood collaborative sensemaking and interactions with others during class as aspects of instruction that advance students' learning of the mathematics content. They considered group work to be most beneficial because it affords opportunities for students to explain their thinking to others and teach their peers. To explain why she utilized group work in her teaching, Morgan said, "[The students] best learn by doing and teaching others…I think it's when you work together, and kind of talk about it with your peers, that's probably when you learn the most." Similarly, Kendall shared, "I do think math classes need more group work, because I think it's super important for people to explain how they think about something and compare that to how other people think about it." For Morgan and Kendall, collaboration is an aspect of mathematics instruction that supports students' learning.

Alternatively, Kayla valued collaboration in mathematics because it encouraged interpersonal relationships among the students and allowed her to foster connections with students. For example, she acknowledged while doing mathematics homework that, "I think working with other people to solve problems helps. It might not be the best to do it in a classroom setting, but I think outside a classroom works." However, Kayla did implement collaborative activities in the classroom, emphasizing how those activities helped bolster connections with her students. She reflected, "I usually would just say like, 'Alright, break up into groups of two and three. And I'm gonna just walk around, and I'm going to sit with you guys and have you talk about the problem to me… I always like trying to sit with them at the table and make it a level playing ground.'" Thus, Kayla valued group work as a means to immerse herself with students and better connect with them.

Student-Instructor Perceptions

A notable value that participants held around mathematics teaching and learning centered around how the members of the learning community viewed each other. They acknowledged the impact of students' perceptions of them, and conversely their perceptions of students, on the broader dynamics of the classroom. Morgan shared,

> Energy level is not necessary, but it helps a lot. I think for a professor who's engaging and who is willing to involve his students as much as possible, who takes the time to get to know the student, to know where they're at in the class and things like that. I think those professors are the best, and the ones who you can genuinely tell that they care. That's the truth.

She valued the student perception that professors and instructors genuinely care about their students. Additionally, participants described other pedagogical practices that would result in positive portrayals of themselves to students. For example, Kayla explained, "I think being organized is a good one...it adds that level of respectability to where if you're not organized, it just kind of gives off the wrong vibe." She made sense of how students perceived TAs and instructors and understood preparedness and organization in the classroom to be related to levels of respect. Similarly, Morgan valued providing clarity in the classroom expectations. She said, "I have a very detailed syllabus, I have a calendar up. I think students should know all the dates of the exams and everything, what's expected of them. I think that they know that in my class." Again, the notion of being clear and organized emerged and suggests that these graduate students are actively making sense of how students perceive them as TAs and instructors in the classroom.

Interestingly, we also found evidence of participants valuing students' engagement because it supported their connections with the students. Kendall shared, "I got to know [my students] really well, and they were super chill kids." She elaborated on these students, saying, "I had a really great group of students. They wanted help, they wanted to learn, they wanted to do well. They were motivated. I didn't have any students who just refused to show up to things and refused to participate." Kendall recognized and valued the students' efforts and motivation, and this made connecting with them easier and more enjoyable for her. Overall, we found that participants' value of connecting with students was deeply intertwined with their values of humanizing mathematics and exhibiting compassion. We unpack these in more detail below and recognize that participants considered these practices to collectively foster positive connections with students.

Humanizing Mathematics

Kendall, Morgan, and Kayla all discussed pedagogical components that reflect valuing humanizing mathematics, including presenting themselves as relatable to their students and presenting mathematics as a human endeavor. Kayla recollected her own experience as a student, and how she valued "professors who are more personal and kind of come in and tell you about themselves," rather than "all I know about you is you do math." In particular, she mentioned while the students were in groups, how she "like[s] trying to sit with [the students] at the table … so I come off more relatable to them." Kendall similarly valued relatability in her classroom. She noted that just being a graduate student, "especially as a TA… [the students] feel more comfortable with us." When thinking about her overall approach towards teaching, Kendall revealed she "take[s] an approach that [she] is the student, like trying to be in their shoes."

This also transitioned into how Kendall thought about the human aspects of mathematical learning, saying how "putting [herself] in [the students'] shoes, remembering how hard it was to grasp concepts can be super helpful to students." She acknowledged that mathematical learning is difficult and planned her teaching to reflect this. Similarly, Kayla recognized mathematics as a human endeavor by valuing mistakes in the learning process, saying "owning up to your mistakes [as the instructor], if you're wrong, it's fine. It's actually pretty encouraging for students to see when you do make a mistake, to be able to take accountability for it." Morgan

also discussed the value of practicing mathematics and learning through mistakes, while also emphasizing there is a point in which as the instructor, "even if you make a plus or minus mistake, and if you do that every class, then that can, even it it's not about the concepts, that can hurt the students." Thus, the participants recognized a balance, whereby mistakes are integral and inevitable in learning and teaching mathematics, but there is value in preparing for each lesson to minimize small mistakes. Morgan and Kayla also positively spoke about connecting mathematics to areas beyond the classroom. Kayla valued this as a student, saying that she really appreciated when professors "[gave] expert exposition to what they're doing" that connected the mathematical concepts to a real-world application or previously learned mathematical concepts. In her teaching, Morgan "tries to incorporate some applied things" to make the students feel more connected to mathematics.

Compassion and Care for Student Wellbeing

Each participant also emphasized valuing students' emotional wellbeing and their role as supportive and compassionate instructors. When asked about what characteristics make a successful undergraduate mathematics instructor, Kayla responded that "having compassion for students, just as people, is a pretty big one." Similarly, Kendall shared that "our role [as instructors] is to guide [the students] along in more of an emotional sense and a math sense." Morgan specified that this could look like "someone who's very available for their students, who, you know, you feel comfortable going to their office horse, and they are very supportive… and really encourage students even if they're not the best students in the class." Thus, we see how each participant valued aspects of compassion and support for students in teaching mathematics.

For Morgan and Kendall especially, this valuing of compassion frequently arose in direct challenge to traditional mathematical discourses that value innate mathematical ability over hard work and effort (Jaremus et al., 2020; Mendick, 2006). In their interviews, they recognized the prevailing mathematical discourses that paint the discipline as extremely difficult with little support and widespread stereotypes that position people as unintelligent if they perform poorly in mathematics (Leyva et al., 2021; Reinholz et al., 2019). Morgan talked about how important it was to her to be a supportive instructor to those struggling in the course, referencing professors she had who were "not supportive enough" and "who teach to the top 1% of their class." She shared how she saw how "a lot of people have that issue with math where they're like, 'Oh, I'm too dumb to be in math' and that's just not the case… like, there's too many people telling people that they're not good in math." Kendall similarly portrayed her valuing of compassion, noting how "part of [her] approach is also being forgiving in a sense." She discussed how "a lot of students get disheartened" when they fail tests, and "part of our job as an instructor… is to be there when they need a mentor and then to remind them that they can still get this stuff." Both Morgan and Kendall's interviews highlight their belief that mathematical knowledge can be learned through hard work as opposed to a solely innate skill, and they valued their role as supportive and compassionate instructors towards students in this learning.

Discussion and Conclusion

The findings above detailed four values of teaching and learning mathematics held by women-identifying graduate students. While these do not encompass all mathematics education values held by women-identifying graduate students, the ways in which similarities in values emerged across these participants suggest challenges to the sociohistorical dominant masculine values in mathematics. In particular, we see tensions within the traditional Western

feminine/masculine dichotomies of collaboration/competition, collectivism/individualism, emotional/logical, and hard work/innate ability. Mendick (2006) posits that mathematical values emerged from these dichotomies, firmly aligning mathematics with dominant masculine values. However, the four values above position mathematics along the more feminine side of these dichotomies. While mathematical environments often reflect the masculine value of competition (Hottinger, 2016; Mendick, 2006; Reinholz et al., 2019), the participants valued collaborative aspects for mathematical learning and interpersonal relationships. Collaboration alongside the values of humanizing mathematics and compassion suggest the importance of instructor-student and student-student relationships, reflecting a collectivist view of mathematics rather than the traditionally masculine individualistic view (Lane et al., 2019; Mendick et al., 2008). The valuing of compassion and concern for students' wellbeing coincide well with values related to emotional aspects of learning mathematics. While dominant masculine discourses pose mathematics as purely logical and emotionless (Mendick, 2006), the participants acknowledged the ways mathematics can be difficult and laden with emotions such as frustration or loneliness and valued their role as understanding and compassionate instructors. Lastly, the participants also valued students' effort in their courses and the ways in which, as the instructor or TA, they could support students' perseverance in mathematics, countering perceptions that mathematical ability is innate and challenging stereotypical hierarchies that position men as more innately mathematically able (Hottinger, 2016; Reinholz et al., 2019). These examples demonstrate ways in which these women-identifying graduate students' hold values that conflict and challenge traditional masculine mathematics values as mathematics instructors.

Implications and Future Work

Morgan's, Kendall's, and Kayla's values highlighted in this work resonate with and reflect existing characterizations of pedagogical practices that advance equity in undergraduate classrooms (e.g., Pai et al., 2024; Rubel, 2017). For example, their values point to the notion that mathematics teaching is an interpersonal, social activity that builds connections between people. Additionally, their values and reported practices echo our contemporary understanding of the experiences of women-identifying faculty in STEM. For example, they are seen as caregivers and feel pressure to be perceived as nice and nurturing (Guarino & Borden, 2017; Hart, 2016). Women faculty also report being more student-centered in their pedagogies than their male counterparts (McMinn et al., 2022). Future work will more closely examine how graduate students' values align with the values that underpin equity-based practices, which may potentially misalign with historically dominant values in mathematics education. We conjecture that values alignment and misalignment can influence how graduate students come to learn about and take up these practices, and this can have significant implications for how mathematics graduate programs prepare students for careers as faculty. Research has shown that integrating equity-based pedagogies into a teacher's regular practice can be a slow process (e.g., Shadle et al., 2017; Walter et al., 2021), and we suggest that examining and leveraging graduate students' values is one way we can better support their pedagogical development. Our findings revealed that these women-identifying graduate students hold values that may be conducive to developing their understanding and expertise of equity-based practices. Providing opportunities to articulate and make sense of one's values related to teaching and learning mathematics can equip graduate students, mathematics departments, and institutions with new insights and framing on how to better support their pedagogical development and transition to faculty positions.

Not-so-Secret Watchers: What Students Can Tell Us About Teaching

Sandra Laursen
University of Colorado Boulder

Tim Archie
University of Colorado Boulder

Projects to improve teaching as a means to improve learning need good tools to measure shifts in the use of effective research-based instructional strategies. We describe a survey tool to assess active and collaborative learning practices in college STEM by asking students to report what practices are used commonly in their course. Student reports correlate with their experience of the learning environment, and with their self-reported learning outcomes. Student means by section are corroborated by instructor-reported use of these practices and external observations.

Keywords: teaching, professional development, survey measures, research-based instructional strategies (RBIS)

A basic question in education research is the linkage between teaching and learning. This is surprisingly difficult to measure, however. To study how teaching activities relate to learning outcomes, we must have ways to describe teaching in diverse settings (AAAS, 2013). This need surfaces, for example, in studies of interventions to improve teaching (e.g., Manduca, et al., 2017; Archie, et al., 2022). Efforts to increase college instructors' uptake of research-based instructional strategies (RBIS) need tools to assess the initial state of participants' teaching, to measure changes over time, and to know if their change strategies are working or not.

Surveys and observations are commonly used methods for studying teaching. Instructor surveys can be efficiently administered to large numbers of instructors, but they pose challenges including sampling, internal validity, and potential biases in instructor self-report (Iverson, 2012). Social desirability bias is particularly concerning in self-reports of teaching. Williams and coauthors (2015) review properties of existing instruments for instructor self-report.

Classroom observations offer detailed, naturalistic information about teaching, but they are time-consuming and costly. Hora and Ferrare (2013) and Campbell (2017) discuss strengths and limitations of classroom observation in higher education, with particular attention to validity and reliability concerns. Weston, Hayward and Laursen (2021) discuss additional challenges to reliability when time sampling is applied to make inferences about term-long courses.

As regular occupants of classrooms, students can offer insight about the teaching taking place, especially when combined with other measurement methods. In evaluative uses, student ratings of teaching are often derided as popularity contests with known, serious biases (Kreitzer & Sweet-Cushman, 2021; Heffernan, 2022). Others find that "student ratings tend to be statistically reliable, valid, and relatively free from bias or the need for control, perhaps more so than any other data used for faculty evaluation" (Benton & Cashin, 2014, p. 315). The MET study (2012) found clear connections between student ratings of their teachers and student achievement gains: "Students know an effective classroom when they experience one." (p. 1) The key is asking "the right questions, in the right ways" (p. 1), probing aspects of teaching that students are qualified to evaluate, and doing so in ways that minimize threats to validity.

Mindful of these caveats, we developed a brief student survey to characterize the teaching in recitations of large STEM gateway courses, in the context of an institutional project to infuse active and collaborative learning into those recitations. Importantly, we did not survey students to measure course outcomes, such as attitude or learning. Rather, we capitalized on students'

everyday presence in the classroom to report on the teaching they experienced, and we used their reports to describe and measure change in teaching over time. The simple student survey focuses on the frequency of specific teaching practices and is aligned with other instruments that we have developed (Hayward, et al., 2018; Weston, et al., 2021, 2023). Alongside this measure, we also measured students' perceptions of the classroom environment and a small set of student self-reported learning gains, to assess whether these experiences were related to the teaching practices that students described. We describe results for three research questions (RQ):

1. How does student-reported use of ACL practices relate to (a) their experience of the learning environment, and (b) their self-reported learning gains?
2. How does student-reported use of ACL practices relate to instructor practices, from (a) instructor self-report and (b) observation?
3. How can these student metrics inform formative and summative evaluation?

Conceptual Framework

We follow Neumann (2014) in viewing the purpose of higher education as learning "how to live a full and democratic life," exerting essential freedoms with the abilities "to argue and write, to inquire and imagine, and to act ethically and humanely" (pp. 249-250). This view contrasts with notions of the purpose of higher education as developing a labor force to compete in the global economy. Substantive learning requires that students encounter new subject-matter ideas and connect them to their existing personal knowledge. The teacher's job, Neumann argues, is to orchestrate and bring about these encounters. Doing this well requires sophistication, and thus we recognize teaching as a complex human activity that invokes individual beliefs, values, knowledge, and behaviors, and that takes place within nested cultural and operational contexts that include the classroom, the institution, and the wider community (Schoenfeld, 1998).

Our perspective on measurement draws on Guskey's framework for evaluating teacher professional development (PD; 2000, 2002). The evaluation framework begins with two near-term outcomes, teachers' experiences of the PD and the learning they take away, and it ends with student learning, the desired ultimate outcome. Connecting near-term outcomes to downstream learning are teacher context and implementation: how supportive is teachers' context to implement what they learn in PD, and how does their classroom behavior change in ways that will lead to stronger student learning. Both these mid-stage outcomes are more complex to measure, but influence whether and how the student learning outcomes are accomplished.

Here we focus on development of a tool to measure elements of implementation of active and collaborative learning, a suite of RBIS linked to student learning (Freeman et al., 2014). While our tool yields a picture of teaching much simpler than Neumann's portrayal of complex classroom interplay, both have at heart teachers' choices about how to use class time to more or less actively orchestrate students' encounters with subject matter (Campbell et al., 2017). Effective use of active learning techniques focuses students' attention on course material and creates opportunities to connect to their own knowledge and learning needs, as students engage with each other and the instructor over the course material. We do not assume that teachers are equally skillful at implementing these approaches, nor indeed at lecturing, but we do assume that their choices are agentic and that they matter for student experience and outcomes.

Context for the Study

The study context was offered by Gateway2STEM, an NSF-supported project at George Mason University (GMU). The project sought to incorporate active and collaborative learning (ACL) into recitation sections of gateway courses in mathematics, physics and computer science

(CS). Gateway courses are foundational to a variety of educational pathways, high in enrollment, and high-risk for students (Koch, 2017). Here the gateway courses were two two-term calculus sequences, two two-term sequences in introductory physics, and introduction to programming in CS. In 2023 a new two-term intro sequence in CS was added.

Recitations were targeted as a foot in the door, seeking to give instructors concrete experiences with ACL approaches, develop their expertise and interest, and build local teaching cultures that would spur broader changes. In large courses, ACL was implemented by graduate assistants who teach recitations in math and CS; term and tenure-track faculty, who teach physics presentations and blended recitation/lecture courses in math and CS. Each department chose a guided inquiry approach, in which students worked in small groups on sequenced tasks, called worksheets (mathematics), tutorials (physics), or programming assignments (CS). Common tasks were prepared and recitation instructors were encouraged but not required to use them.

GMU is a large public institution, with about 23,000 undergraduate students. Many are non-traditional students who are working, studying part-time, resuming education after military service, or preparing for a second career. Many are in the first generation of their families to attend college. The students are ethnically diverse, like the metro area where GMU is located.

Research Methods

We surveyed students and instructors about their experiences of recitation across the whole term, and observed single class sessions for a sample of recitation sections and blended courses.

Surveys and Observations

The short survey (≤10 min) focused on student experiences. We used three blocks of items (Table 1)—two existing instruments plus our instrument, called the TAMI-SS (Toolkit for Assessing Mathematics Instruction: Student Survey) in keeping with our other TAMI instruments. The instructor survey (TAMI-IS) asked teachers to estimate their use of the same five teaching practices, by percentage of total class time, across the whole course.

Table 1: Overview of Survey Item Blocks Used in this Study

Use of ACL practices: TAMI-SS (Hayward, Weston & Laursen, 2018; Weston, Laursen & Hayward, 2023)	Learning environment: WIHIC (Dorman, 2003; Hoover & Pelaez, 2008; Skordi & Fraser, 2019)	Learning gains: SALG (Seymour et al., 2000; Laursen et al., 2011)
frequency of 5 teaching practices: lecture, small group work, individual work, student presentation, whole class discussion (0=never to 4=almost always)	frequency of experiences in 7 areas (8 items each): student cohesiveness, teacher support, involvement, inquiry/ investigation, task orientation, cooperation, equity (0=almost never to 4=almost always)	learning gains in 5 areas common to all 3 disciplines (0=no gain to 4=great gain)
S-ACL = mean for 3 practices: small group work, student presentation, whole class discussion (0-4)	WIHIC: mean (0-4)	Gains: mean (0-4)

Surveys were administered online near the end of fall term, to 112 sections in 9 courses in 2021 and to 94 sections of 11 courses in 2023, to over 3000 students each time. Student surveys were distributed by recitation instructors to protect student anonymity. We gave instructors a script to explain the survey and asked them to provide class time to respond.

In all, about 2200 students responded at least in part. Overall student response rates were 36% in 2021 and 46% in 2023, ranging by section from 96% to 0, depending on how the survey was shared with students. Because of this variation in response, we do not directly compare courses. We were able to match 25 instructor responses to student sections across both years.

We also conducted on-site observations for single class sessions of 16 recitation sections and six blended sections. Along with detailed field notes, we recorded the elapsed time for the same core teaching activities as on the surveys (lecture, small group work, etc.). Summing the time for each activity enabled comparisons with instructors' self-report and student report.

Data Analysis

We computed three composite variables. The student ACL score (S-ACL) is the mean frequency of class discussion, student group work, and student presentation, for one student. The section ACL score is the mean S-ACL score for sections with ≥10 responses. The instructor ACL score (I-ACL) is the total percentage of class time for the same three activities. For each, higher values indicate more frequent use of the ACL strategies. Internal reliability of WIHIC subscales was verified with all subscales showing a Cronbach's alpha of 0.9 or greater. Independent sample t-tests were used for statistical comparisons of courses targeted or not by the intervention. For most analyses, we combined data across both years to increase statistical power and learn about the behavior of the items. To answer RQ3, we separated data sets by year.

Results

We used descriptive statistics to report on the behavior of the survey items, and used correlations and linear mixed models to answer RQs1-2.

Descriptive Statistics

Table 2 provides the mean and standard deviation for each composite item. On average, ACL practices were reported to occur 'seldom' and the distribution was moderately platykurtic, while student-reported WIHIC items occurred 'seldom' to 'sometimes' on average, and the scale was negatively skewed. Student reported 'moderate' to 'good' gains on average, and this scale was moderately negatively skewed.

Table 2. Descriptive statistics for S-ACL, WIHIC, and Gains.

Scale	N	Mean	SE	SD	Skew	Skew SD	Kurtosis	Kurtosis SD	Alpha reliability
S-ACL	2056	2.15	0.02	1.04	-0.07	0.05	-0.68	0.11	NA
WIHIC	2236	2.70	0.01	0.70	-0.48	0.05	0.17	0.10	0.97
Gains	1973	2.82	0.02	0.92	-0.64	0.06	-0.07	0.11	0.91

Cronbach's alpha coefficient was used as a measure of the internal consistency for Gains and WIHIC scales. ACL practices are discrete, mutually exclusive practices that can be used independently, thus are not expected to show an expected relationship or response pattern connecting individual practices. Therefore, we did not measure the internal consistency of ACL practices. The internal consistency of both Gains and WIHIC scales was good, with alpha coefficients of 0.91 and 0.97 respectively.

RQ 1a: How does student-reported use of ACL practices relate to learning environment?

We tested the relationship between student ACL (S-ACL) and WIHIC scales. From correlation analysis of all student cases, we found a moderate positive correlation (0.51), indicating that students report more positive environments in courses that include more active learning. We also tested the consistency of this relationship across disciplines and found similar, low to moderate correlations across math, physics, and CS (0.40, 0.54, 0.33, respectively). Figure 1 shows both the correlation of individual scores for all student responses that include responses to every item in the scale (L), and of section means for sections with at least 10 students (R).

Lastly, we conducted a linear mixed model to test this relationship with WIHIC scale as the dependent variable, student ACL as a fixed effect, and course section as a second-order random effect. Controlling for the influence of section-level data is necessary as section responses ranged from 1 to 169, which would bias the correlations based on student reports from larger sections. For this analysis, we excluded student responses from sections with fewer than 10 responses, as larger class sizes have been shown to be more reliable (Benton & Cashin, 2014). The resulting analysis of 1640 student responses from 93 course sections revealed a moderate positive effect (0.33, t (73) = 18.64, $p < 0.001$) of ACL practices on WIHIC, when controlling for the random effect of course sections.

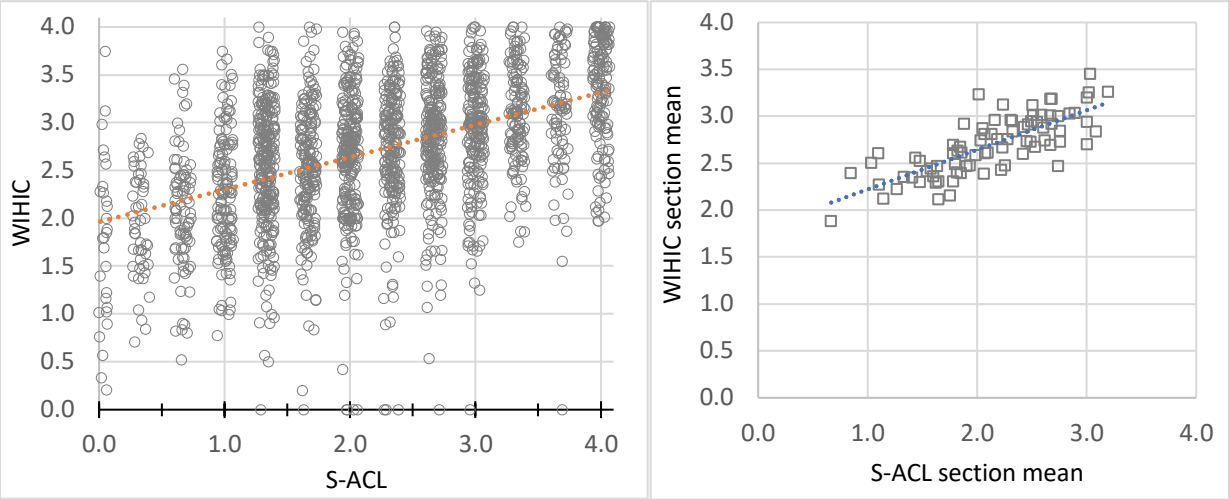

Figure 1. WIHIC score correlates positively with S-ACL, for individual students (L) and section means (N≥10) (R).

RQ 1b: How does student-reported use of ACL practices relate to students' learning gains?

We tested the relationship between student reports of the ACL practices they experienced and their perceived learning gains. A correlation analysis of all student cases revealed a statistically significant moderate positive correlation (0.25) between ACL and gains, indicating that students report greater learning gains in courses that include more active learning. We tested the consistency of this relationship across disciplines and found similar minimal correlations for math and physics, 0.25, and 0.27, respectively, but no statistically significant relationship for CS.

We then conducted a linear mixed model to test this relationship with learning gains as the dependent variable, ACL as a fixed effect, and course section as a second-order random effect. As above, we excluded student responses from sections with fewer than 10 responses. This analysis revealed a moderate positive effect (0.23, t (86) = 8.93, $p < 0.001$) of ACL practices on student reports of their learning gains when controlling for the effects of class sections.

RQ 2a-b: How does student-reported use of ACL practices relate to instructor practices?

We tested the relationship between student- and instructor-reported use of ACL practices, by instructor and course, for the subset of cases where both types of data were available. We compared the mean student reports of ACL practices for each recitation section (section S-ACL) with that section's instructor response (I-ACL). A correlation analysis of section S-ACL and I-ACL revealed a statistically significant, strong positive correlation (0.60, $p > 0.05$), indicating that students' and instructors' reports of the ACL practices in a given class are well aligned.

Similarly, we tested the relationship between instructor-reported I-ACL, and observed proportion of time spent in ACL practices from a single class observation. In general, there is good correlation between what instructors say they do, and what we saw them do (0.76, $p = 0.16$). The outliers in Figure 2 (R) are two GTAs who used the whole observed class session for a guided inquiry task, but reported using much less time for ACL on average.

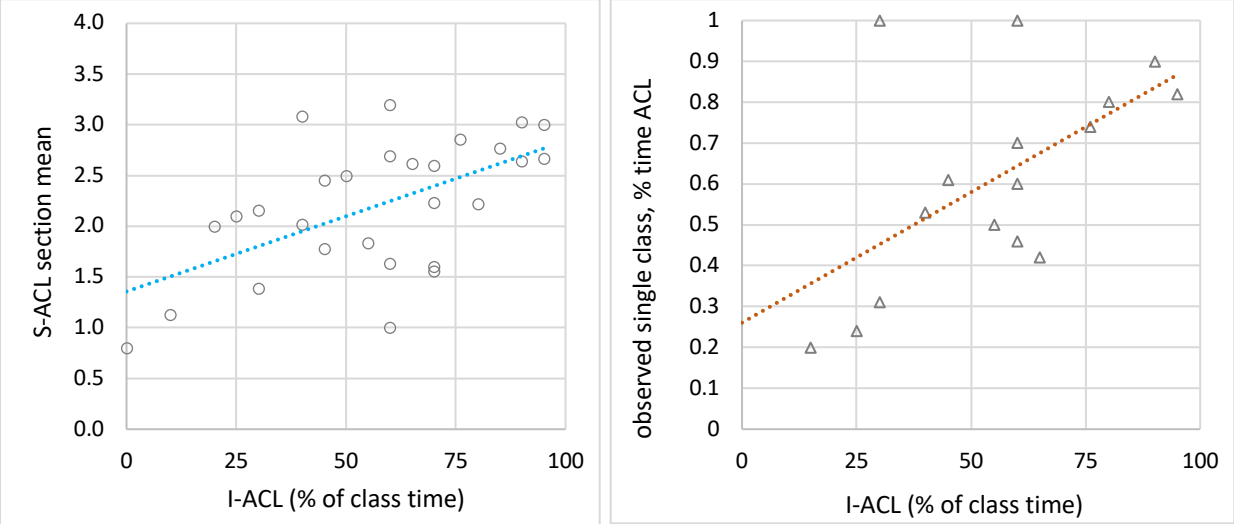

Figure 2. S-ACL section means correlate with their instructor's report, which in turn correlates with observation.

RQ 3: How can these metrics inform formative and summative program evaluation?

Figure 3 (left side) compares mean S-ACL for target courses actively involved in the project versus nontarget courses that had not yet implemented ACL in 2021. The S-ACL metric clearly distinguishes courses that had and had not implemented ACL with an effect size of 1.05.

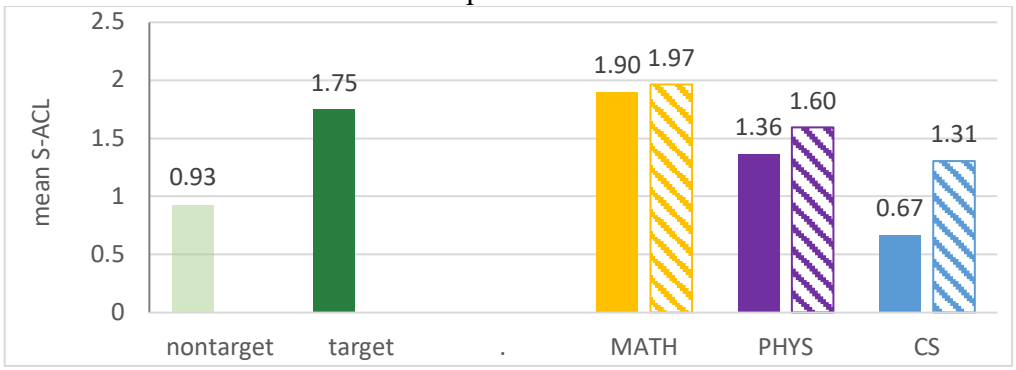

Figure 3. Project-wide and department means for S-ACL in 2021(solid), and 2023 (stripes)

Figure 3 (right side) shows department means for 2021 (solid) and 2023 (stripes). These student data corroborate the PIs' reports about implementation levels: math had already

implemented ACL in target courses in 2021 and sustained that work in 2023; physics' implementation increased from 2021 to 2023; and CS was not active in 2021, but had begun to implement ACL by 2023.

Discussion

Students responded to the items in the TAMI-SS block and were able to discriminate them on the response scale provided. Nearly all students responded; we filtered out responses missing any of the items, as the composite variable S-ACL is not meaningful without answers to each item. Over 95% of students reported coming to class most or all of the time: they are observers who have experiences to report. The S-ACL scale is normally distributed, indicating that most students reported experiencing some ACL practices, with smaller proportions reporting either high or low levels of ACL practices. Analyses are ongoing, but we have found no systematic patterns of difference in response to these items by student subgroup (Apkarian, et al., 2024).

Drawing on student observations to assess implementation of ACL strategies has several affordances. There are many observers to describe the teaching experience across the full term, not just one day. The measure is simple, behavior-focused, and not evaluative. It aligns with other measures we have developed to facilitate triangulation among measures to characterize teaching, and/or to combine with other survey or non-survey measures (exams, grades, etc.). Student-provided evidence can be a golden spike linking a specific initiative to longer-term or harder-to-measure outcomes established in the literature (Brown Urban & Trochim, 2009). However, good response rates are needed to compare courses or sections or pre/post time points. Both student and instructor response rates limited the matching of data for course sections.

The correlation of S-ACL with WIHIC suggests a positive relationship between active learning and students' classroom experience. This alone may be a benefit, if having more positive experiences encourages students to persist in their STEM studies. Further, ACL is linked to stronger learning, as measured by the smaller positive correlation of S-ACL to learning gains. However, in this setting, the impact of these benefits may be modest, given that the intervention focuses on recitations only (and a small group of blended lecture-recitation classes). It remains to be seen if the culture of ACL will "trickle up" to lecture sections as the PI team postulated.

Results from the CS courses offer an example of how these data may be useful in program evaluation and research. The increase in S-ACL (Figure 3, far right) reflects a strong implementation signal as CS joined the project work. Slightly weaker relationships of S-ACL to student experience and learning variables in CS may reflect this earlier stage of implementation. Students may not perceive benefits of ACL teaching until instructors' ACL implementations are less tentative, consistent and clearly communicated. Indeed, class observations in CS displayed less frequent cooperation among students. Moreover, in write-in comments, CS students expressed stronger preference for learning on their own, compared to math and physics students. Instructors may need to actively reshape norms about learning in CS to strengthen student buy-in. Norms can shift quickly as instructors adopt active facilitation practices that students notice—and likely share via the student grapevine (Turpen & Finkelstein, 2010).

As a metric for assessing progress on an institutional effort to increase use of active and collaborative learning, the S-ACL composite from TAMI-SS items was responsive to change over time and sensitive to differences in implementation. We do not recommend using this tool to evaluate individual instructors. Rather, it is useful to indicate progress on efforts to support instructors to shift their practices toward RBIS, at an institutional scale (Laursen, et al., 2019).

Acknowledgments

The study was funded by the National Science Foundation (NSF-DUE award #1821440). The authors thank the many instructors and students who took part in the study, and the GMU PI team for their assistance in acquiring data.

Student Meanings for $\hbar/2$ in a Quantum Mechanics Expectation Value Problem

Julia Truman
University of Colorado Boulder

Megan Wawro
Virginia Tech

In modeling physical phenomena and solving associated quantitative problems, students reason about constants in various ways. These symbols represent elements of mathematical structures with embedded algebraic operations and are imbued with contextual physical meaning. In this paper, we report on what meanings for the constant ħ/2 students conveyed in a quantum mechanics expectation value problem from a spin-½ context. Through analysis of interview data with 12 students from two different universities, our analysis documents eight different meanings for ħ/2: part of expression in problem setup, part of calculation, result (either consistent or not consistent with unit interpretation), eigenvalue, measurement, average, and bound. This analysis highlights both the cognitive complexity of reasoning with symbols and the impressive ability of students to flexibly and fluidly leverage multiple meanings for symbols at this content level.

Keywords: linear algebra, quantum mechanics, student thinking

How symbols are used in mathematics and physics can differ. For example, in contemporary mathematics the term "constant" often refers to numbers of interest such as π, $\sqrt{2}$, or the golden mean φ (Wolfram, 2024). In physics, "constant" is additionally used in ways not necessarily needed in pure mathematics, such as for fundamental physical constants that have stable values derived from experimental measurement (e.g., the gravitational constant G). As Redish (2005) states, "We have many different kinds of constants – numbers (2, e, π, …), universal dimensioned constants (e, h, k_B, …), problem parameters (m, R, …), and initial conditions" (p. 2). We note that Redish cleverly included the literal symbol "e" twice, with the first referring to the number and the second referring to elementary charge[1]; we note that e can also be considered as the unit of electric charge. The constant of interest in this study is $\hbar/2$. Planck's constant h describes the behavior of particles and waves on the atomic scale; the reduced Planck's constant[2] $\hbar = \frac{h}{2\pi}$ is the quantization of intrinsic angular momentum, or spin.

In this study, we investigate students' meanings for the constant $\hbar/2$ as they engaged with an expectation value problem from a spin-½ context. For instance, at times students were engaged with $\hbar/2$ as the measured value of spin along an axis, as a quantity with units, or as an eigenvalue of the operator associated with a spin observable. This work is part of a larger project that investigates students' understanding, symbolization, and interpretation of eigentheory and related concepts in quantum mechanics. In particular, we investigate the following research question: *what meanings do students demonstrate for* $\hbar/2$ *in a quantum mechanics expectation value problem from a spin-½ context*?

Theoretical Perspective and Literature Review

In this paper we analyze students' *meanings* for $\hbar/2$. We view an individual's mathematical meaning for a concept not to be inherent or intrinsic to a concept itself but rather be personal to the individual. Furthermore, an individual's meaning for a concept is dynamically formed through the individual's continual interaction and interpretation within their given cultural

[1] $e = 1.602176634 \times 10^{-19}$ coulombs

[2] $\hbar = 1.0546 \times 10^{-34}\ J \cdot s$ or $\hbar = 6.5821 \times 10^{-16}\ eV \cdot s$

settings (Blumer, 1969). Particular to research on students' meanings at a given time, Thompson (2013) offers that "the meanings that matter at the moment of interacting with students are the meanings that students have, for it is their current meanings that constitute the framework within which they operate" (p. 62-63). In this paper, we analyze the meanings in the moment that students are operating with for $\hbar/2$ during their work on a particular expectation value problem within an interview setting. Because we cannot access a person's meanings directly, we infer students' meanings from what they say and write during the interviews. In this way, we "delimit categories of responses according to particular mathematical meanings that we discern from them," and we categorize students' responses "based on meanings we believe might underlie the response based on the best available evidence of interviews" (Yoon & Thompson, 2020, p. 4).

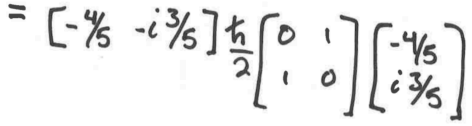
The idea of particular symbols like $\hbar/2$ having a variety of meanings for students has been examined in the literature with other more prominent symbols, such as the equal sign (e.g., Carpenter et al., 2005; Falkner et al., 1999; Kieran, 1981; Knuth et al., 2005). There has also been research that considers the importance of student interpretations of the equal sign in physics contexts. For example, Alaee et al. (2022) break down the relational interpretation of the equal sign into multiple physics-specific categories depending on the relationship described, such as definitional, causality, and assignment. This illustrates a variety of student meanings for this same symbol including ones that may not appear in purely mathematics-focused research. Based on this, when considering the meaning of symbols in physics, it follows that examining and categorizing not only the field-specific meanings of standard mathematical symbols but other symbols which are entirely field-specific could provide some of this same importance.

For such an examination, we began with Arcavi's (1994, 2005) notion of symbol sense. For our purposes, we particularly focus on four of Arcavi's aspects in the specific context we are analyzing: reading symbolic expressions involving $\hbar/2$ in different ways, consideration of the meaning of $\hbar/2$, recognizing the meaning of $\hbar/2$ during intermediate (both calculational and conceptual) steps, and how it has different meanings for the students across different contexts. In Rodriguez et al.'s (2018) analysis of students' mathematical reasoning in chemical kinetics, they state, "Symbols mediate the connection between the physical world and how we think about phenomena" (p. 2115). In our study, the ways that the symbol $\hbar/2$ mediates the connection between physical interpretation and mathematical calculation are central to how students work through the expectation value problem and explain their reasoning.

Methods

The data come from individual, semi-structured interviews (Bernard, 1988) with students enrolled in a Quantum Mechanics course from two different public research-active doctoral universities. All interview participants were recruited during class, gave informed consent before being interviewed, and received compensation for their time and effort. Four interviewees (students labeled A#) were from a junior-level course at a large university in the northwestern US; the course met for seven hours a week, and interviews occurred one month into the semester. Eight interviewees (students labeled C#) were from a senior-level course at a medium-sized university in the northeastern US; the course met for three hours per week, and interviews occurred two months into the semester. Both courses used McIntyre et al. (2012) as the textbook.

This study is part of a larger research project focused on student use of and student thinking around the concepts of basis and eigentheory, as well as their use of and meanings for various notation. In this paper, we consider student responses to the following interview question: "Consider the state $|\psi\rangle = -\frac{4}{5}|+\rangle_x + i\frac{3}{5}|-\rangle_x$ in a spin-1/2 system. Calculate the expectation



value for the measurement of S_x." Students were encouraged to think aloud as they engaged in the problem, with the interviewer asking clarifying questions along the way as needed.

The results presented in this paper started as one portion of a broader analysis. That analysis considered the correctness of students' solutions, what problem-solving approaches were used, what alternative approaches were discussed (if any), whether certain meanings and terminology were observed in the data, and whether certain concepts were discussed (e.g., basis, eigenvalue). One element we noticed in broader analysis was that some students had written their responses in forms like $\frac{7}{25}\frac{\hbar}{2}$, which prompted us to wonder about their meanings for $\hbar/2$. We then focused on how they interacted with $\hbar/2$, considering all their mentions of "h bar" and what meanings they seemed to correspond to. For our initial analysis, we focused on every instance of the students saying "h bar" in any context (or verbally referring to where they wrote it, but not if they wrote it and did not talk about it). We used open coding (Miles et al., 2013) to classify the students' statements. One of the first apparent divisions was between the use of $\hbar/2$ in a purely mechanical or calculational way, its use in a more conceptual way, and its use in a statement of a result. This led to further categorical divisions, primarily in the conceptual categories based on what was discussed by each student. The meaning categories were developed by considering each of the students in turn and either making new categories (describing what student meanings seemed to be) or grouping them into existing ones. The meaning categories were then cross-checked, combined or refined, discussed, and used to recode the data until we reached agreement.

Results

Our analysis revealed eight meanings for $\hbar/2$ in students' work with the expectation value problem: as part of expression in problem setup, as part of calculation, as part of result consistent with unit interpretation, as part of result not consistent with unit interpretation, as eigenvalue, as possible outcome of an operation or a measurement, as average measured value or weighted average, and as an aspect of positional bounds. In Table 1, we give examples of each of these meanings. In the remainder of the Results section, we share detail regarding the meanings for $\hbar/2$ as a unit with a dimensioned constant, as well as an outcome. We then conclude with an example of student reasoning that utilized many of the meanings for $\hbar/2$ in quick succession.

Table 1. Summary of the 8 meanings for $\hbar/2$ with examples.

Category Name	***Examples***
[Setup] As part of expression in problem setup	(C11) This is the h bar over two times 0 1 1 0 is the spin operator in the x direction. [The matrix used is incorrect here.] 
[**Calculation**] As part of calculation	(A8) "...so S sub x acting on plus x is equal to h bar over 2, include both vector, x, so we're just gonna use that, so then this, is equal to negative four fifths h bar over 2 plus, plus, minus i h bar over 2 three fifths minus."
[Result-Unit] As part of result with unit interpretation	(C6) "And now I like my answer. Um, then it's h bar over two 7/25, um, is the expected value of S sub x." (C5) "...you'd get zero h bar over two as your expectancy value. So, yeah."

[Result-Nonunit] As part of result not with unit interpretation	(C8) "...7, h bar out over 50 is the expectation value for spin x." (A25) "So your expectation value ends up being, uh, 7 h bar over 50, I think."
[Eigen] As eigenvalue	(C1) "And so you'd expect the average, overall the measurements to be halfway between the two eigenvalues, which are h bar over 2 and negative h bar over 2."
[Outcome] As possible outcome for an operation or measurement	(C5) "We only know this, because if I'm already in the x state, and I'm operating on x, I'm going to get an h bar over two or a minus h bar over two with these probabilities, so." (A30) "Um, so, basically when you measure psi for Sx in the Sx direction you can either get h bar over two or minus h bar over two and this is like the average of the probabilities of one or the other."
[Average] As average measured value or weighted average	(C2) If the sample was large enough for you to take, um, the average value you would get would be 7 fiftieths, 7 h bar fiftieths, would be your average measured value, [Int: Okay.] which is an impossible value for you to get with, as, or for a, which is an impossible value for you to actually measure on each individual one [...]"
[Bound] As an aspect of positional bounds	(C1) "And so the average over all measurements would be, uh, positive. It'd be something between zero and h bar over two, and that's not what I'm seeing here."

Student meanings for ħ/2 as a unit

Two of the meanings found in our overall analysis for ħ/2 are distinct but related: as part of a result consistent with a unit interpretation [Result-Unit] and as part of a result not consistent with a unit interpretation [Result-Nonunit]. The Result-Unit meaning is consistent with considering ħ/2 as a universal dimensioned constant (Redish, 2005), but also with considering ħ/2 as the unit itself. As stated by Norton (2024), "(extensive) quantities rely on a unit for measuring them. Whatever we take as a unit becomes 1, and when 1 becomes an iterable unit, every other number in the number sequence becomes some measure of 1s" (p. 466). In our context, a Result-Unit meaning of ħ/2 would be consistent with treating $\hbar/2$ as a 1 for which other numbers – in this case, the expectation value – are measures of this contextual 1.

A notable example comes from C5, who, after completing the question in Figure 1, was asked to change the state vector from Figure 1 to have the same coefficients but now in terms of the z-basis and calculate the expectation value of measurement of S_x. Immediately after correctly getting 0 as their answer, C5 stated, "So, hey I suppose, that's equal to zero h bar over two. And that's a good um, way to write that because it's well, zero with respect to what? With respect to h bar over two …" We note that C5 keeps the $\hbar/2$ in their solution even though it is not necessary in a strictly algebraic context. C5 emphasizes this explicitly by pointing out their solution can be interpreted as no $\hbar/2$'s, implying C5 can hold meaning for $\hbar/2$ as a type of object, namely a unit. By contrast, other students do not give evidence that they were treating $\hbar/2$ with a unit meaning, as seen in the two examples in Table 1.

Student meanings for $\hbar/2$ as an Outcome

In the data set, we documented instances in which students seemed to assign $\hbar/2$ a meaning of being an outcome of either a mathematical operation or the outcome of a physical

measurement. If it was unclear from the context of the utterance in the interview which of these two meanings for outcome was aligned with the student utterance, we only assigned it the category of general outcome. Overall, this was the second-most common meaning for $\hbar/2$ in our data set, behind only the Calculation meaning. Furthermore, all but two of the students made utterances that we coded as conveying an Outcome meaning.

Almost all utterances coded as Outcome were consistent with an Outcome-Measurement meaning for $\hbar/2$. For example, as C12 was beginning their solution process, they considered the measurement values associated with spin up and spin down, stating: "this measurement [points to $|+\rangle_x$] is going to be h bar over two, and this [points to $|-\rangle_x$] is minus h bar over two." A25, also while explaining how they were approaching the problem, stated "you're measuring the x component of the angular momentum and you can either get positive h bar or minus h bar over 2." In both of these examples, the students discussed the act of measuring $\hbar/2$ and $-\hbar/2$ as the result of those measurements. An example in which it was unclear if the student meant the outcome of a mathematical operation or the outcome of a measurement comes from A9: "...it's just the, like, if you did, a histogram result, right, you tabulate your results to be nine twenty-fifths of the time you got negative h bar over 2, and h bar over 2." The student uses the words "results" and what you "got," but the student does not explicitly mention either a measurement or a mathematical calculation. In the context of when the Outcome meanings occurred, namely, as students were explaining why their answer to the expectation value problem was sensible to them, the frequent Outcome-Measurement meaning is appropriate.

Only one student, C5, had meanings in the Outcome category that were consistent with an Outcome-Operation meaning. One example is included in Table 1: "We only know this, because if I'm already in the x state, and I'm operating on x, I'm going to get an h bar over two or a minus h bar over two with these probabilities, so," which was given when C5 shared their problem-solving approach to the question in Figure 1. Although the Outcome-Operation meaning is less appropriate in this context, there is precedence for it in the literature in that students may sometimes conflate mathematical operation and measurement (e.g., Gire & Manogue, 2012; Wawro et al., 2024). Gire and Manogue (2012) offer an explanation for why this could be an understandable conclusion that students might make as they are learning: "In mathematics, operators transform vectors; in physics, measurements change the state of a quantum system; but these are two different uses of the idea 'to change'" (p. 1), and that "it is common for textbooks to say that observables are represented by operators" (p. 4).

Examples of Multiple Codes Together

We conclude our Results section with a vignette highlighting how multiple meanings of $\hbar/2$ are employed in concert with each other by students to convey their problem-solving and/or explanation of an expectation value problem. While all students employed multiple meanings of $\hbar/2$ in some way, this vignette with A30 is a point where they are particularly intertwined. After reading the question, A30 writes $\langle\psi|S_x|\psi\rangle$ (see Figure 1), and says:

A30: I think I'm going to keep this in ket notation because I know what Sx does to the x, uh, kets [...] so the bra so [mumbling] sixteen over twenty, twenty five h bar over two plus nine over twenty-five which is h bar over two!
Interviewer: Okay so, what does that mean physically? What's going on?
A30: Um, so, Sx can either be, oh whoops I made a mistake [laughing] uh this should be a minus x ket and this should be a minus h bar over two which makes this minus … [corrects their answer to 7/25 $\hbar/2$]

A30: Um, so, basically when you measure psi for Sx in the Sx direction you can either get h bar over two or minus h bar over two and this is like the average of the probabilities of one or the other.

Interviewer: Okay. Okay. Do you have any way to look at that and like that seems about right? [...] I don't know if when you got h bar over two you changed your mind if something seemed wrong about it or how'd you see that mistake?

A30: Uh, well, I just I looked up here and I saw that, mm, how I put Sx on the minus x operator was h bar over two rather than minus h bar over two. I was like, oh. that's not correct.

Interviewer: Gotcha. And why - where did the minus come from?

A30: Oh, cause the eigenvalue of Sx times the minus x ket is minus h bar over two.

Interviewer: Okay. Okay, so if you look at the seven h bar over twenty five times two is there any way to look at that and think, oh that seems about right? [...]

A30: Well, I know it's - it can only be between h bar over two and minus h bar over two and so, uhh yeah if it's anything outside of that I know oh that's wrong or, I guess if you have something like this and you're measuring Sx you should not have, solidly one h bar over two or minus h bar over two.

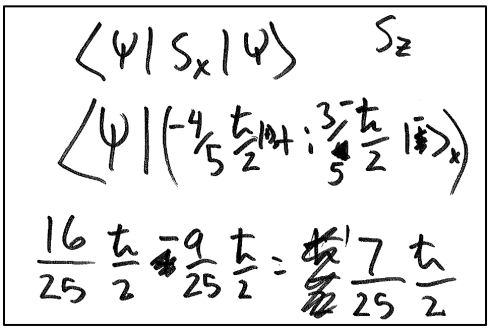


Figure 1. A30's work on the question.

In these 24 lines of transcript, A30 had 13 utterances of $\hbar/2$ or $-\hbar/2$ that show a variety of different meanings in a short span of time. First is one use of $\hbar/2$ with a straightforward Calculation meaning (line 2), where A30 substitutes in the linear superposition of psi in terms of $|+\rangle_x$ and $|-\rangle_x$. Next is A30's statement of their solution (line 3), which has a Result-Unit meaning. After explaining their error and correcting it with a Calculation meaning (line 6), we observe them interpret their solution using an Outcome - Measurement meaning twice (line 9) and an Average meaning (with "this," line 9). When asked if there was a way they knew their first answer was incorrect, they mentioned their error via a Setup meaning for $\hbar/2$ (line 15). When asked about why the negative sign was needed in that setup, A30 uses an Eigen meaning (line 18). Finally, when asked again about evaluating the plausibility of their solution, A30 uses $\hbar/2$ twice in a way consistent with a Bound meaning (line 21), and finally goes back to Outcome - Measurement (line 24). In this case, we observe A30 fluently switching between a variety of different meanings for the same symbol, including multiple procedural and conceptual ones.

Conclusion

In this paper, we report on what meanings for $\hbar/2$ students conveyed in a quantum mechanics expectation value problem from a spin-½ context. Through analysis of interview data with 12

students from two different universities, our analysis documents eight different meanings for $\hbar/2$: part of expression in problem setup, part of calculation, part of result (either consistent or not consistent with unit interpretation), eigenvalue, measurement, average, and bound. This analysis highlights both the cognitive complexity of reasoning with symbols and the impressive ability of students to flexibly and fluidly leverage multiple meanings for symbols at this content level. We illustrated this with data with from A30, an exemplar of a student quickly and seamlessly moving between several different meanings.

Additionally, the use of $\hbar/2$ in ways that algebraically and conceptually work like a unit is a notable result. Further research could point to a difference in the type of understanding held by students who use $\hbar/2$ as a unit and those who do not. We note that this split in the Result-Nonunit and Result-Unit codes has some similarities to the broader calculational/conceptual dichotomy, given the difference is whether the students' statements simply report a calculational result or suggest a related conceptual interpretation of the numerical value of the result. Accordingly, it also corresponds to Arcavi's (1994, 2005) symbol sense category of the ability to read symbolic expressions in different ways, here more focused on the consideration of meaning. Further questions could not only examine this, but also use it in contrast to other instances of units in order to gain a greater understanding of students' concepts of various units in math and physics.

Our results regarding two meanings for $\hbar/2$ related to outcome, either outcome of a measurement or of an operation, are consistent with prior research (Gire & Manogue, 2012; Pina et al., 2024; Wawro et al., 2024). We see this as further evidence that emphasizes the complexity encountered when introducing new symbols with new meanings. This variation in developing or desired meanings is also consistent with the findings of previous work related to the meaning of other symbols, such as the equal sign (e.g., Carpenter et al., 2005; Kieran, 1981; Knuth et al., 2005). In terms of symbol sense (Arcavi, 1994; 2005), developing a conceptual understanding of the mathematical equations, calculational steps, and results in terms of the related physical referents involves ability to understand the different kinds of meaning that different symbols can have across various contexts.

Limitations to our study include focusing our analysis on students' verbalized instances of $\hbar/2$. Our eight meanings for $\hbar/2$ were drawn exclusively from analysis of students engaging in one expectation value problem in a spin-1/2 setting. Future research could analyze student meanings of $\hbar/2$ from other problem contexts (other than expectation value) or settings (such as spin-3/2, which would introduce additional multiples of $\hbar/2$), which could further refine the existing meanings or introduce additional meanings.

Harpeth Hall School

This study explores the crucial issue of attrition in the undergraduate mathematics major. In this report, we thoroughly examine open-response survey data from seven former mathematics majors describing why they chose to major in mathematics as well as when and why they chose to leave. We situate these data within findings from the 2019 study Talking About Leaving Revisited. *Findings from the present study indicate students may leave mathematics because they are intrinsically drawn to a new discipline, or they may feel pushed out of mathematics due to perceived poor instruction and/or lack of outreach and support.*

Keywords: mathematics major, retention, recruitment, enrollment

Undergraduate major enrollment is a nationwide topic of discussion in university STEM (science, technology, engineering, and mathematics) departments, especially in the mathematical sciences, in which many mathematics major programs are being eliminated due to low major enrollment (e.g., D'Agostino, 2023). It is imperative to recruit students to major in the mathematical sciences for both the preparation of the STEM workforce and the vitality of university mathematics departments, yet the true issue of enrollment in the mathematics major may lie in retention; mathematics has the highest attrition rate of any undergraduate major at 52% (Leu, 2017). The question remains, why are students, who at one point chose mathematics as their major, walking away? In an effort to answer this question and provide recommendations for how mathematics departments can support retention in their majors, we launched the **Ma**thematics **J**ourneys **o**f **R**etention: **W**hy **I**ndividuals **S**witch **E**ducational Paths (MAJORWISE) Survey Study. In this report, we detail the stories of seven former mathematics majors, including why they chose mathematics as a major, when and why they chose to leave, what majors they changed into, and what supports might have retained them in the major.

Background Literature and Framing

Recruitment and retention in undergraduate STEM majors has been a topic of concern for over three decades (Seymour et al., 2019; e.g., McDade, 1988; Seymour & Hewitt, 1997). One line of research of STEM majors (broadly) has investigated trends among students leaving STEM majors, including demographic variables, college readiness, and instructional methods experienced. These quantitative studies have indicated women, students from minority racial groups, students with low mathematics standardized test scores, students who receive lower absolute (or relative) grades in university STEM courses, and students who take courses taught through strict lecture methods may be at a higher risk for leaving a STEM major (e.g., Belser et al., 2018; Chen & Soldner, 2013; Cundiff et al., 2013; Rask, 2010; Watkins & Mazur, 2013). Although quantitative data may allow researchers to find patterns and speculate why students chose to leave their major, research drawing upon qualitative data and the student perspective may help to identify the circumstances and reasons students remain in or leave STEM. A major effort to conduct large-scale qualitative research on reasons students leave undergraduate STEM

began in 1990 with the study *Talking About Leaving: Why Undergraduates Leave the Sciences* (TAL; Seymour & Hewitt, 1997; Seymour & Hunter, 2019). In this study, researchers interviewed 460 students who had either switched from or persisted in STEM majors from ten undergraduate institutions. Seymour and Hewitt (1997) classified *switchers* as those students who entered their university as STEM majors and then switched to non-STEM majors and *persisters* as seniors who were persisting to graduation in their original STEM majors. This study resulted in a framework of explanations for student academic and career decisions; this framework was characterized by a complex push-pull decision making process. *Push* factors are defined as "problems in students' precollege and college experiences that made it difficult for them to persist with their original choices of majors and career aspirations" (Seymour & Hunter, 2019, p. 7). *Pull* factors are defined as "perceived attractions or advantages that drew students to alternative majors and career possibilities" (Seymour & Hunter, 2019, p. 7). The TAL project team conducted a follow up study, *Talking About Leaving Revisited* (TALR; Seymour & Hunter, 2019) from 2013 to 2014 in which they interviewed 96 switchers and 250 persisters from six different undergraduate institutions.

TAL and TALR shared many results with respect to the reasons students chose to leave STEM. These shared top reasons included *loss of incoming interest and motivation* (push factor), *rejection of STEM careers and associated lifestyles* (push factor), *shift to a more appealing career option* (pull factor), and *poor quality of STEM teaching* (push factor). The more recent TALR study identified a few new reasons (or a dramatic increase in the prevalence of reasons identified in TAL) for switching out of STEM, such as *discovery of an aptitude for a non-STEM subject* (pull factor), *discouraged/lost confidence due to low grades in early years* (push factor), and *competitive, unsupportive STEM culture makes it hard to belong* (push factor).

The TAL and TALR studies provided a unique student-centered and qualitative perspective on attrition and issues in undergraduate STEM majors. Yet, this research neglected to investigate (a) issues specific to the mathematics major and (b) reasons students might switch from one STEM major to another. The TALR study sample was predominately life science, engineering, or physical sciences majors, with only 7.4% of participants from mathematics, even though the authorship team identified the mathematics major as having a higher-than-expected switching rate compared to other STEM majors (Seymour & Hunter, p. 76). Seymour and Hunter's assessment of mathematics students as especially high risk for leaving STEM mirrors the NCES Beginning Postsecondary Students Longitudinal Study data, which indicate that of students who declare a mathematics major only 43% (NSF/NCSES, 2012) to 48% (Leu, 2017) will complete their degree in mathematics, which is the lowest retention rate among all degree programs.

There is a need to investigate reasons students leave the mathematics major not only because it leads undergraduate majors in attrition, but also because mathematics students may encounter challenges which would not be identified as reasons for attrition in STEM more broadly. For example, students may struggle with their mathematical identities and self-efficacy as they transition from computational mathematics courses to more abstract and theoretical proof-based mathematics courses (Civian & Schley, 1996). The mathematics students learn become increasingly advanced, and the transition to abstract mathematical thinking and theoretical concepts in university mathematics can challenge students' view of the nature of mathematics and competency in the subject (DiMartino & Gregorio, 2019; Liebendörfer & Hochmuth, 2013).

A few international qualitative studies from the United Kingdom (Rodd & Bartholomew, 2006; Ward-Penny et al., 2011) and Australia (Hall et al., 2022) have investigated retention in the mathematics major specifically. These studies indicated students may become disaffected

with mathematics at the undergraduate level because they dislike lecture-based instruction and feel as though their courses place a strong emphasis on memorization. Many chose to major in mathematics because it was easy for them in secondary school, but it became a challenge at university. We seek to contribute to this extant research by focusing specifically on (a) math majors, and (b) the context of higher education in the United States. In particular, we aim to understand the journeys of students who chose to leave their mathematics majors at four-year undergraduate institutions in the U.S..

Methods

Data Collection and Recruitment. During Fall 2023, our team carried out a nationwide survey, using Qualtrics, with free-response items of students who have been enrolled in a mathematics major at four-year institutions during the years 2013-2023. In addition to general demographic information (race, gender, age, etc.), this survey solicited information such as: reasons for enrolling in a mathematics major, mathematics courses taken at the university level, type of institution attended, instructional methods experienced in university mathematics courses, and timing of and reasons for considering leaving, actually leaving, or staying in the mathematics major. We recruited survey participants through dissemination of our survey through professional networks, social media, and snowball recruitment (requesting participants share the survey with others). Participants were offered an opportunity to provide their contact information to enter a chance to win one of four $50 Amazon gift cards.

Survey Participants. The MAJORWISE online survey received 147 applicable responses from a total 176 responses, which were filtered for responses from participants meeting our sampling criteria. We removed responses when, for example, individuals did not indicate they were enrolled in a mathematics major during the years 2013-2023, the quality control question was not answered correctly, or individuals did not complete survey questions beyond providing consent to participate.

Among the 147 survey respondents, 92 (62.5%) were still pursuing a mathematics major, 48 (32.7%) had graduated with a degree in mathematics, and 7 had previously been enrolled as a mathematics major but had switched into a different degree program. We have reported on findings from the participants who are still completing a mathematics major or who graduated with a mathematics major in other publications (e.g., Heath et al., 2024), and for the purpose of this report we restricted our sample to the seven participants who left their mathematics major.

Data Analysis. Survey responses from the seven participants who left the mathematics major were analyzed by first compiling all responses from a single participant and using their responses to each question to compose an analytic memo (Saldana, 2016) summarizing the chronology of a given participant's journey through their decision to major in mathematics and eventually change that major. These analytic memos were then categorized as describing *push* journeys or *pull* journeys in leaving the mathematics major, according to the scheme presented by Seymour and Hunter (2019) in *Talking About Leaving Revisited.* In the present study, we defined a ***push journey*** as a story in which a student left mathematics primarily due to negative experiences in their undergraduate mathematics major. We defined a ***pull journey*** to be when a student left mathematics primarily because of a draw or allure to a different topic or degree program.

Findings

In what follows, we describe the journeys of the seven survey respondents who decided to leave their mathematics majors. These stories reflect a variety of reasons students may choose to change out of the mathematics major into another degree program. We report these journeys by

first presenting the participants who indicated they felt *pushed* out of their mathematics majors (Allen, Brody, Cora, Danielle, and Erika) and then presenting the participants who reported they were *pulled* into or drawn to another discipline and major (Yosef and Zanab).

Push Journeys

Participants' experiences deciding to leave their mathematics majors classified as *push* journeys were characterized by a disaffection with mathematics, their instruction, or their degree program and course requirements. The first three participants, Allen, Brody, and Cora, all expressed they left their mathematics major because they felt as though they could not succeed. The following two participants, Danielle and Erika, both expressed they left the major because they did not enjoy it.

Allen. Allen was a white, male student pursuing a B.S. in Mathematics from a large, public R1 institution in the Southeastern United States. He was enrolled as a mathematics major for three years until he decided to change his major to Business after his junior fall semester. Allen decided to major in mathematics before he began college, and he described that he chose mathematics as his major because he had wanted to be a mathematician since his childhood and an intrinsic love of the discipline. Allen wrote,

> I wanted to be a mathematician since I was a kid. I see math as a study that is trying to make sense of the universe instead of trying to make sense of man-made things. I love analyzing data and trying to find a pattern.

While enrolled as a math major, Allen took many different mathematics courses, including upper-division courses like Abstract Algebra I and Numerical Analysis. Allen attributed his experience in Numerical Analysis to his decision to change his major. He claimed the university and the mathematics department faculty had not prepared him to succeed because he was expected to know a coding language in numerical analysis, yet he did not. After his experience in Numerical Analysis, Allen changed his major to Business. Allen said if there had been different instructors teaching his course, or different requirements set up to take certain courses, he may have been supported enough to stay in the major.

Allen's story depicts a *push* journey because despite his intrinsic passion and love for mathematics as a topic, he felt there were barriers to his success embedded in his mathematics degree program, specifically with respect to how the major prepared (or did not prepare) students to take subsequent required major courses.

Brody. Brody was a white, male student pursuing a B.S. in Mathematics Education at a large, public R1 institution in the midwestern United States. Brody decided to major in mathematics before starting college, and he was enrolled as a math major for one year before changing his major to Social Studies Education. Brody said he chose to major in mathematics because he was successful in mathematics in high school, enjoyed teaching, and wanted to be like the great mathematics teachers he had in high school. Brody took College Algebra and Precalculus at the undergraduate level, but when he enrolled in Calculus I, he struggled and decided to drop the course and change his major. Brody said, "I struggled a lot in calc 1. [I] did not want to put myself through the rigor of the program and have my mental state be worsened by math classes." Brody indicated he could not think of any supports that might have helped him stay in the major.

Brody's story illustrates how a student might initially feel drawn to mathematics because of success in the subject in high school. However, Brody perceived that the challenge of Calculus and an extended study of mathematics would worsen his mental state, and thus *pushed* him out of the major.

Cora. Cora was a Black/African American, female student, pursuing a B.S. in Mathematics at a small, private HBCU in the Southeastern United States. Cora chose to major in mathematics as a first-year student, having originally declared a Computer Science major. Her decision to pursue a mathematics major was motivated by her dislike for coding in computer science and her enjoyment of learning mathematics and solving problems. Cora took Discrete Mathematics and Calculus I as an undergraduate, but she changed her major to Education during the middle of her second year at the university while taking Calculus II. Cora attributed her decision to leave mathematics to poor instruction in her mathematics courses. She wrote,

> I decided to switch when I realized that my professor and many others in the mathematics department were not efficient in teaching math courses. I did not think it was fair for me to stay in a major that did not have great professors.

When asked what supports might have helped her stay in mathematics, Cora responded that more support from her mathematics department chair and dean as well as making tutoring available for higher-level mathematics courses may have changed her journey.

Cora's story highlights how perceived poor instruction in mathematics courses and a lack of infrastructure (e.g., tutoring for upper-division courses) can *push* a student out of mathematics. Cora provided a unique perspective as a student who did not begin college as a mathematics major, and during her time as a computer science major she had potentially experienced different quality or type of instruction in another department before joining the mathematics department.

Danielle. Danielle was a white, female student pursuing a B.S. in Mathematics with a concentration in Applied Mathematics at a large, public R1 institution in the Southeastern United States. She chose to major in mathematics before starting college and she chose mathematics because she loved the subject in high school and wanted to pursue a career in applied mathematics. Danielle was enrolled as a mathematics major for three semesters; she took a variety of mathematics courses at her university: Calculus II and III, Linear Algebra, Introduction-to-Proof, Probability and Statistics, and Partial Differential Equations. Danielle's decision to leave her mathematics major was primarily motivated by frustration with her degree program and course requirements. She wrote,

> The applied mathematics concentration focused too heavily on theory, in my opinion. It seems like everyone is taking the exact same classes overall, with about 3 or 4 electives to differentiate between concentrations. The degree felt poorly designed and very rigid in what students could or could not take.

Danielle's discontentment with her degree program depicts a *push* journey because, although she still enjoyed what she considered to be "applied" mathematics, she perceived her major as requiring too many theory-based courses and the concentration as not distinct enough from the standard mathematics major at her university.

Erika. Erika was a white, female student seeking a B.S. in Mathematics Education at a large, public R1 institution in the midwestern United States. She decided to major in mathematics before beginning college because she wanted to be a mathematics teacher but changed her major from mathematics to Business at the end of her second year of her undergraduate studies. Erika decided to leave mathematics because, "Awful professors made [her] very disinterested." She noted that if the mathematics courses were structured better or if she had gone to a different institution with "better professors" she would have stayed in the mathematics major.

Erika's story highlights another example of a student leaving mathematics because they considered their course instruction inadequate, *pushing* them to a different major and department. Erika did not provide a detailed account of what made the instruction she experienced poor.

Pull Journeys

Participants' experiences deciding to leave their mathematics majors classified as *pull* journeys are marked by an allure or draw to another discipline or department. Two students, Yosef and Zanab, described their decision to leave mathematics as pull journeys.

Yosef. Yosef was a multiracial, male student seeking a B.S. in Mathematics and Statistics at a large, public R1 institution in the northwestern United States. Yosef decided to major in mathematics after transferring to his new R1 Institution. Yosef majored in mathematics for three academic years before switching to computer science. Yosef expressed lack of direction with his career, and ultimately decided to major in mathematics because he enjoyed solving problems and proving statements. Yosef took several mathematics classes before struggling in Calculus II. Yosef remarked, "After I realized that math was difficult, I fell in love with arguably something even more difficult and equally as reliant on math: computer science."

Yosef expressed he preferred the instruction in his computer science courses, which involved large projects with writing and problem solving, and his mathematics courses, in comparison, felt like "busy work." Yosef said he may have wanted to stay in math if it were taught differently. He wrote,

> I think the entire way we teach math would need to change. I think a project focused and problem-solution focused way of teaching math would've helped me. It was hard for me to think that integration techniques would help me in the real world, but knowing how to create a hash table felt more applicable.

Yosef's story depicts a *pull* journey because he was attracted to the instruction he experienced in another discipline and felt drawn to a more interesting and applicable major in computer science. Yosef indicated the instructional methods used in mathematics classes may be a deterrent to the retention of some mathematics majors.

Zanab. Zanab was a Black/African American, female student pursuing a B.S. in Mathematics at a large, public R1 institution in the northeastern United States. Zanab chose to major in mathematics because she liked the concepts and ideas of mathematics. She took many mathematics classes, including complex analysis and topology, before she switched to a computer/information sciences major during her second year of her studies. Zanab decided to leave the mathematics major due to a preference for her new major, writing, "I just preferred the new major. I wanted an intersection between compsci and psychology. I like the challenge of programming."

Zanab's story depicts a *pull* journey because she felt pulled to her true passion. Zanab said there was nothing that could have changed to make her stay.

Discussion

Across the journeys of the seven participants who left their mathematics major, there were many factors influencing their decision to leave, including: (1) challenge and struggle, (2) instruction, (3) curriculum, and (4) passion and interest. These align with and supplement the findings from *Talking About Leaving Revisited* (Seymour & Hunter, 2019) to help understand why students may leave mathematics majors.

Several of the participants mentioned challenge and struggle as a factor influencing their decision to leave mathematics. Allen, Brody, and Cora, all mentioned struggling in a mathematics course as push factors influencing their decision to leave. Researchers in TALR similarly found that students across STEM disciplines may leave STEM because they were "discouraged/lost confidence due to low grades in early years" (Seymour & Hunter, 2019, p. 92). Interestingly, although Brody and Cora did change their majors during Calculus, Allen's journey

illustrates a case in which it was not courses in early years that discouraged him. Challenge was not only associated with push journeys; both Yosef and Zanab also mentioned challenge and difficulty level in their responses. Thus, for some students, difficulty, challenge, and struggle pushed them away from mathematics, while others perceived difficulty and challenge as something pulling them to a subject, whether mathematics or their new discipline.

In addition to facing challenge in mathematics courses, students discussed instruction of their courses with respect to choosing to leave mathematics. Allen, Cora, and Erika cited poor instruction of their mathematics courses as pushing them out of mathematics. TALR also found this to be a common reason for leaving STEM majors, with 96% of switchers referencing "poor quality of STEM teaching" as a concern contributing to their switching (Seymour & Hunter, 2019, p. 92). Limited by the survey format of these data, our team could not inquire further about what "poor quality instruction" meant to Allen, Cora, or Erika. Yosef, however, described being pulled to computer science because he experienced teaching he found more engaging. He noted he enjoyed instruction based in projects, problem-solving, writing, and stated if mathematics were taught more from this perspective he may have wanted to stay. Aligning with the TALR study, Seymour and Hunter also found students may switch from STEM because they "prefer teaching approachs in non-STEM courses;" (p. 92) however, Yosef's experience of teaching he preferred was in another STEM subject.

Three students, Danielle, Allen, and Erika mentioned issues related to curriculum and program of study as pushing them from their mathematics majors. Danielle's complaint regarding her major program was that even the applied mathematics concentration required too many theoretical mathematics courses, and Allen was frustrated he was expected to know a coding language without having been required to take a programming course. The TALR study mirrors these complaints in the concern they found, "STEM curricular design problems: pace, overload, labs, alignment" (Seymour & Hunter, p. 92). It could be debated whether or not Allen and Danielle's programs of study were actually poorly designed, but it is also possible the intentions of the program design and expectations of students in those programs were not clearly communicated to the students.

Finally, passion and interest were primary reasons Yosef and Zanab found themselves pulled to other subjects. This aligns with TALR's finding that students left STEM if they discovered an "aptitude for a non-STEM subject" and "non-STEM major offers better education, holds more interest" (Seymour & Hunter, 2019, p. 92). The latter of these concerns identified in TALR also resonates with Erika's comment she "had awful professors that made [her] very disinterested," as she indicated another major would offer a better education and hold her interest.

Conclusion

The seven stories highlighted in this report provide examples of the many different factors affecting retention and attrition issues in mathematics departments across the United States. The results from this study support that some of the findings from TALR are also applicable to the discipline of mathematics, yet it is notable that three participants in this study (including both of the pull stories) switched to a different STEM discipline, rather than out of STEM. Common across both push and pull journeys is discontentment with teaching in university mathematics. As our sample of students who left their mathematics major was small and the survey format of data collection inhibited us from inquiring into further detail regarding participant comments, we intend to continue this research and gain a larger sample of students who have switched out of the mathematics major and include more in-depth qualitative data such as interviews or written narratives to gain a deeper perspective on students perceptions' of their mathematics programs.

Acknowledgments

This project was funded through the Middle Tennessee State University College of Basic and Applied Sciences.

Real Analysis Professors' Noticing of Equity Gaps and Minoritized Students' Perspectives

University of Nebraska-Lincoln

Addressing equity and opportunity gaps in undergraduate education requires change across systems, including the pedagogies and orientations of the undergraduate faculty whose courses and departments perpetuate these gaps. Hence research on how undergraduate faculty notice quantitative and qualitative evidence of inequitable experiences has the potential to advance reform efforts. We conducted an interview-based study of 5 mathematicians who were presented with data analytics indicating equity gaps in proof-based courses at their university, and statements from minoritized students in these courses about their experiences. We found that the faculty may hold split inclusive and exclusionary frames about students and mathematics; that there may be a persistence of personal experience as an interpretive lens; and that qualitative and quantitative evidence may elicit different frames of instruction and students. We discuss these findings through the lens of a noticing framework.

Keywords: proof-based course, equity, mathematicians, noticing

Background

Equity and opportunity gaps are well-documented in undergraduate mathematics education (e.g., National Academies of Sciences, Engineering, and Medicine [NASEM], 2016; Solomon & Craft, 2016; Leyva, 2016). Recent scholarship points to the need for centering minoritized students' views of undergraduate instruction (e.g., Larsen et al., 2016; Leyva et al., 2021a, Leyva et al., 2021b). Yet systemic change requires not only articulating mechanisms of marginalization, but also change in the orientation of undergraduate faculty whose courses and departments may reinforce gaps. Thus, research on how undergraduate faculty may view evidence of inequity can advance reform efforts. Such research can identify affordances and barriers to using qualitative and quantitative evidence regarding equity to shift instructor orientation.

This study contributes to this area by examining how undergraduate faculty frame and attend to data on equity gaps or data about minoritized students' perceptions. We focused our study on mathematics faculty who had taught real analysis, a course with a widespread 'weed-out' reputation (e.g., reddit r/math, 2018) and yet also recommended for inclusion into mathematics major programs (Mathematical Association of America, 2015). We act on the theory that a course with this kind of reputation and role may be one that amplifies impact on identity, particularly for minoritized students. We address the research question: *What do real analysis professors notice in data about the performance and experiences of minoritized students in real analysis courses where equity gaps exist?* By investigating this question, we aim to gain insights into how instructors may interpret and address equity issues in their classrooms.

Conceptualizing Equity

Equity can be viewed from dominant and critical perspectives, and we use both here. From a

[1] The second, third, and fourth authors contributed equally and are listed alphabetically.

dominant perspective, equity can be conceptualized as "the inability to predict mathematics achievement and participation based solely on student characteristics such as race, class, ethnicity, sex, beliefs, and proficiency in the dominant language" (Gutierrez, 2002, p. 153). Equity 'gaps' can be quantified from this perspective, for instance via disparities in performance or persistence among students of different backgrounds (which may be perpetuated within an instructional and institutional environment) (e.g., National Center for Educational Statistics, 2011). For all that such "gap gazing" (Gutierrez, 2008, p. 357) may obscure asset-based views and perpetuate a static view of equity, these statistics can call attention to inequity and are often used to substantiate calls to action (e.g., NASEM, 2023).

From a critical perspective, equity concerns identity and power. This perspective "builds upon the idea that mathematics is a human practice that reflects the agendas, priorities and framings that participants bring to it" (Gutierrez, 2011, p. 21) which complicates the desire to quantify 'gaps' within. Instead, this perspective aims to document the experiences of individuals as they face situations which diminishes their identity or their power. A critical perspective is needed in cultivating asset-based – and anti-deficit – views, and to humanize the experiences of those from historically marginalized populations.

Inequitable Experiences in Departments of Mathematical Sciences

As a report of the American Mathematical Society (2021) detailed, departments of mathematical sciences have had a long history of racial discrimination, and this discrimination continues to impact equitable participation in the mathematics community today. Recent scholarship making deliberate efforts to elicit and situate the perspectives of minoritized students largely underscore three arguments. First, minoritized students continue to encounter negative experiences that impact their identities in mathematics (Apkarian et al, 2024; Leyva et al., 2022; Leyva et al., 2024). Second, researchers and practitioners can and must find more ways to recognize and showcase the creativity and cultural assets of students from historically marginalized populations (Adiredja et al., 2020; Valdovinos Gutierrez & Ko-Wong, 2024). Third, instructors can disrupt or reinforce inequities, through their actions (Ball, 2024; Cawley & Wilson, 2023; Reinholz et al., 2024).

Building on this scholarship, an emerging area of work examines what happens when departments and instructors are asked to engage with evidence toward these arguments. For instance, Bolick and Voigt (2023) used data analytics to document inequities for undergraduate mathematics leadership teams to consider in transforming mathematics at their institutions. Adirejda et al. (2024) showed preliminary evidence that professional development of undergraduate mathematics faculty such as critical conversations around race and gender and funds of knowledge interviews may lead to instructors taking a more humanizing view of instruction. These efforts show promise that programmatic consideration is possible through engagement with qualitative and quantitative data. At the same time, one area that has received less attention is instructors' framing of forms of evidence toward particular courses that they have taught and are likely to teach in the future, and over which they have relative autonomy. This focus is important to understand because it explicitly leverages instructor agency.

In courses such as real analysis, instructors often hold primary responsibility for managing and shaping the classroom experience. In this sense, instructors are on the 'front lines' of education, with the autonomy to foster an inclusive learning environment – or not. Given that instructors have significant control over classroom dynamics, meaningful change in addressing equity gaps requires a deep understanding of how instructors perceive and interact with these issues. Specifically, it is essential to explore how instructors frame, recognize and respond to

data indicating performance disparities and to accounts detailing the experiences of minoritized students–in sum, how they *notice* signals of inequity.

Theoretical Framework

We use Louie et al.'s (2021) Frame-Attend-Interpret-Respond (FAIR) framework to conceptualize *noticing.* This framework embeds the practices of attending, interpreting, and responding (e.g., van Es, 2011) within a broader action of framing. Following the work of van Es and colleagues, in teaching and reflecting upon teaching, an instructor *attends* to particular features of instruction (and does *not attend* to other features), whether consciously or subconsciously; *interprets* these features, such as in terms of student identity, potential, and competence; and *responds* to this attending and interpreting in what they say or do in the classroom or how they plan for teaching.

Louie et al. (2021) argued that *noticing* necessarily occurs within sociopolitical contexts, for classrooms are social environments where power dynamics exist (with the instructor and among students), thus learning environments are neither socially isolated nor politically neutral. As such, those who have the responsibility of noticing in learning contexts should be aware of their framings of the situation, including the local, institutional, and cultural aspects. Other framings may be related to the students, the discipline of mathematics, or interactions that occur in the learning environment, and these framings may come from a deficit or anti-deficit perspective, albeit unknowingly at times. *Frames* create "expectations for how the emerging activity should unfold" (Hand, 2012, p. 251) and may draw on unseen, dominant assumptions and cultural values that guide the actions within noticing (Louie et al., 2021); and hence *framing* shapes *attending*, which in turn shapes *interpreting* and *responding*.

Mathematics and mathematical ability may be framed in exclusionary and inclusive ways (Louie, 2017). For instance, framing mathematics as a "fixed body of knowledge to be absorbed" can serve to exclude learners, whereas framing mathematics as "about making sense of ideas and understanding connections" may promote inclusion through meaning making; and framing mathematical ability as "hierarchical" is exclusionary, whereas framing mathematical ability in terms of the potential for "everyone [to have] both intellectual strengths and areas for growth" can lead to naming and seeing competence in students (p. 496). Instructors may also frame their observations of teaching from a deficit- or asset-based view of their own teaching capabilities.

Study Context

At the University where the study took place, the mathematics department hosted a presentation of data analytics that analyzed "DFW rates" for the department's courses over a three-year period. Here, a DFW rate of a course means the percentage of students in that course who received a D or F in the course, or who withdrew from the course. The analysis revealed that underrepresented students—defined by the University as those identifying as African American, Hispanic, and/or Indigenous—had higher DFW rates in an introductory real analysis course compared to their represented peers. Specifically, at the time, the DFW rate for real analysis was 25% for represented students and 35% for underrepresented students. In this same period, the DFW rate for real analysis for continuing college-going generation students was 24%, whereas it was 27% for first generation students.

Following this presentation, two of the authors surveyed and conducted interviews of underrepresented students about their experiences in real analysis. We discuss these surveys and interviews here because the data from these protocols were written into the protocols of the study presented in this report. Given that the University is predominantly white, students who identify

as Black/African American, Hispanic/Latinx, Asian/Asian American, Native American, or Native Hawaiian/Pacific Islander are often visible minority groups on campus. In line with Shah's (2019) recommendation to avoid treating Asian identities as a monolithic "model minority," we included Asian students in our study to better understand their experiences in upper-level mathematics courses.

In all, 27 students participated; all were current or former undergraduate mathematics majors who identified as Black/African American, Hispanic/Latinx, Asian/Asian American, Native American, or Native Hawaiian/Pacific Islander and who had taken or planned to take at least two of the following junior-level, proof-based courses: introduction to proof, introduction to abstract algebra, and real analysis. Data collection consisted of three phases: informational survey, primary interview, and secondary interview. The brief informational survey included background items related to students' identity, work obligations, and school obligations (cf. Jett, 2009). This survey asked questions about the number of hours students worked while taking these math courses, if they had to commute to campus, and whether they identified as a first generation college student. Similar to Herzig (2002), we structured the primary interview as a chronological mathematical autobiography. The secondary interview allowed us to co-construct a narrative with participants based on their responses to the primary interview. This narrative structure provided a space for students to clarify and further elaborate on their stated experiences in mathematics (Leyva et al., 2021a). The secondary interview also allowed us to conduct a member-check for validity purposes.

Overall, 13 students completed the survey and both interviews, and an additional 14 students completed an extended survey where selected interview questions were written as multiple choice questions. The surveys and interviews highlighted ways that real analysis was felt as gate-keeping; that students have responsibilities outside of class that influence their participation and engagement; and how students' experiences of the class depended heavily on the instructor, including how they attended–or seemed not to attend–to students' questions and contributions. A more comprehensive description of this part of the study is found in Bennett and Lai (in press).

Methods

The participants of the present study were five instructors spanning assistant, associate, full professor levels at the University. All five taught at least one of the three courses for mathematics majors in the past three years; most had taught more than one of these courses during multiple semesters. The professors (with pseudonyms N, P, T, V, Z) completed an informational survey and participated in a hour-long, semi-structured interview. Four of the five professors identified as white (the fifth chose not to respond), and all five answered "English" for the primary language that they think about or "do" math in, although this was at times different from their "native" language. None of the five identified as first-generation college students.

In the interview, we presented professors with quantitative and qualitative data in the form of DFW rates from Fall 2018-Summer 2023 and quotes from students in the above-described interviews. In particular, we showed them four responses to the question "What do you wish your professor knew?", which students interpreted broadly, and two responses to "What does it take to succeed in real analysis?" As the professors viewed the quantitative data, we asked probing questions, such as, "What drew your attention to this part?", "What do you think is the 'problem' that is being addressed?", and "Are there things that could change this outcome?" We allowed professors to choose which student quotes to which to attend. We asked questions such as, "What drew your attention to that student's experience?", "What's your understanding of what this student is trying to convey?" "Do you think a student might feel this way in your

course? What would you do?" These questions were meant to elicit a talk-aloud of acts of noticing, in particular *attending*, *interpreting*, and *responding*.

To analyze responses, we organized professors' noticings of the quantitative and qualitative data into tables structured by the FAIR framework (Louie et al., 2021), focusing first on how they *attended* to, *interpreted*, and *responded* to the data presented. Similar to Hand (2012) and Louie and colleagues (2021), we then analyzed the noticings to look for themes to help us understand how professors *framed* students' experiences in real analysis. In articulating frames, we described how professors noticed in deficit or anti-deficit ways and the impact on frames about students, mathematics, and interactions, using Louie's (2017) exclusionary and inclusive frames as an analytic starting point.

Findings

In this section, we present three main findings from our analysis of professor noticings.

Split of Asset-based/Inclusive and Deficit-based/Exclusionary Frames

A key finding in the analysis is the complicated nature of asset-based/inclusive frames and deficit-based/exclusionary frames; how a professor can hold both kinds of frames when discussing the qualitative evidence. Professor N enjoyed teaching real analysis. He loved his real analysis course when he was an undergraduate and attributes it as being his inspiration "to be a math major and become a mathematician," affirming the view that real analysis can be a gateway. Furthermore, he shared that he tells this story with his students whenever he teaches real analysis. In this way, Professor N holds an inclusive frame of mathematics.

When asked how real analysis compared to other similarly advanced undergraduate mathematics courses, Professor N pointed to his experience teaching a linear algebra course. While he does not teach linear algebra as proof-based, he shared:

> I have them justify things, but I'm not looking for what I would consider to be a properly written form of proof. I'm just looking for something kind of a weaker level of justification... [Real analysis] has been quite a bit harder for the students. I mean, there's some that just seem to really struggle with understanding epsilon-delta proofs, and it's a real challenge to get them past the class sometimes.

We understood Professor N as having framed students as either capable or not. While the gap in DFW rates was "disturbing" to him, it was also "unsurprising" that there was a gap, as students will have varied levels of preparedness and capabilities. Professor N is an example of how two opposing frames can coexist simultaneously yet not create a disequilibrium of personal beliefs about mathematics or students when discussing the quantitative performance data.

Persistence of Personal Experience as Interpretive Lens

A second central finding in our work is how professors primarily relied on their personal experience as an interpretive lens for noticing the presented data. This manifested as professors attending to and interpreting the student quotes in light of their own teaching experiences, sometimes regarding the goals or improvements they have in mind for their classes.

In his response to "What do you wish your professors knew", a student, Vince, shared how the "lack of representation of underrepresented students in math courses could discourage a student from organizing study groups or reaching out to others for support." When prompted to discuss one of the four student quotes, four of the five professors said that Vince's response "caught my attention" or were interesting in some way. Professor N said,

> I think what Vince wrote is the one that most caught my attention just because again,

> affirming this fear I have that underrepresented students are still kind of left out. But the guilt I have about the fact that I don't really know how to solve that or at least I haven't figured out a way and I haven't really done a great job of addressing this very real issue.

Professor N connected Vince's statements to his own beliefs and feelings about teaching, particularly about being inclusive in his classroom. In addition to his feelings of "fear" or "guilt", other professors conveyed their personal emotional reactions to what students shared, feeling "crushed" or "shocked" by some of the students' experiences. Similarly, Professor T attended to what Vince was saying in light of his own musings about teaching: "I think that Vince's was the most thought provoking to me, just because I think Vince talks about some of these things that have been on my mind the last couple of semesters."

We also found it noteworthy how the professors made evaluative statements of the presented student quotes based on their own perceptions and experiences. For instance, comments such as, "I think I agree with [student]", or "I absolutely believe the things she's talking about with her experiences" emphasized the (in)validity of students' accounts. At times, the evaluative statements seemed to justify dismissing what students said, like "I think his impression…is somewhat unrealistic." However, this perception of "unrealistic" is based on the reality of the professor, not on the lived experiences of the student.

We likened this phenomenon to the notion of listening to respond rather than listening to understand. When personal experience is the listener's primary lens, they bring what others say back to their own context.

Qualitative and Quantitative Evidence May Elicit Different Frames

When reading the statements of students' experiences, the professors seemed to acknowledge that people's stories are complex and there does not exist an immediate solution to address the challenges experienced. After reading that some students expressed feeling unsupported and underrepresented in their mathematics courses, Professor V said, "I know there's no magic solution and I don't know that there's anything short term that we can do, but maybe there's things that we can put in place to support and represent the students." Similarly, Professor T underscored the importance of seeing Vince as a whole person in the classroom:

> I think what Vince is talking about is having professors that really fundamentally don't understand his experience. [...] Vince wishes that professors understood his experience, what experiences and what aspects of his life and identity are coming along with him to this classroom.

Professor T expressed that professors should get to know students on an individual level in order to understand their experiences and full selves, not just as learners of mathematics.

In contrast, four of the professors viewed the quantitative data from a classroom level, rather than an individual level. This led to ponderings about what solutions might exist "for all" students in proof-based courses. Professor Z said, "There are things that work well for everybody. I don't know things that would work well for a specific student population, but what works well for everybody is additional support inside and outside the classroom." Four of the five professors mentioned that "getting students to talk to each other" or implementing active learning strategies were a viable solution to the institutional performance gaps presented in the quantitative data. In most cases, the qualitative data helped the professors problematize and shift away from "for all" solutions for the challenges that minoritized students face, to viewing and listening to students on an individual level.

Discussion and Conclusion

We discuss our three main findings through the lens of the FAIR framework (Louie et al., 2021). In Table 1, we illustrate professors' framing of students, mathematics, and the presented student narratives. Our analysis revealed that it was important to understand professors' framing of students and mathematics *prior* to analyzing their FAIR noticings of the data. During our session, we will share similar tables for each professor analyzing their noticings of both the qualitative student narratives and quantitative student achievement data (i.e., DFW rates) and how these align with or draw on their framings of students and mathematics in the context of proof-based courses for mathematics majors. We found that frames of students, mathematics, and data differed depending on the type and presentation of the data (i.e., qualitative narratives or quantitative rates and graphs). For instance, our third finding suggested that although professors interpreted student quotes as complex puzzles that should be addressed on a personal level alongside students, they interpreted quantitative performance data needing a "for all" solution (e.g., Leyva et al., 2022). We will share how the two tables compare across professor framings and noticings of the two data types.

Table 1. Noticings of students' real analysis experiences with the FAIR framework

Students	**Framing** students as people with many responsibilities, different capabilities, and intersecting identities		
	Attending to students' experiences and their (un)success in math	**Interpreting** student challenges as complex puzzles to solve	**Responding** inclusively to the identities of individual students
Mathematics	**Framing** real analysis and proof-based courses as rigorous and necessary		
	Attending to the difficulty of the subject shared by students	**Interpreting** the difficulty of the course as unavoidable	**Responding to** quotes with worry, but not knowing a remedy
Qualitative Data (Student Narratives)	**Framing** qualitative data from students as sometimes trustworthy, valid, and compelling and sometimes unbelievable or unhelpful		
	Attending to the validity of what students say	**Interpreting** student quotes in light of their own experiences	**Responding to** quotes with an evaluative statement

Finally, the protocol we used to prompt professors to notice (i.e., to state what stood out in the student quotes, rephrase what the student is trying to convey, and describe how the account could inform their own practice) was effective in focusing the discussion on the students' experiences while rooting the conversation in practical implications for teaching. We wonder how conversations about institutional performance gaps and improving student experiences are facilitated in meetings of departmental stakeholders, and if attendees are similarly given the space and structure to attend to, interpret, and respond to presented data. We encourage those working toward equitable changes in mathematics departments to first attend to and understand what students are sharing in their accounts of classroom experiences before looking for large-scale solutions and implications for teaching.

Students' Generalizing Activity While Using Determinant Applets

David Plaxco

Matthew Mauntel
University of New Hampshire

In this article, we share results from a series of interviews with a pair of undergraduates using an applet designed to support students' understanding of determinants. We identify four generalization clusters that the participants developed, and we share our analysis of the activity types that led to these generalizations. We used Ellis et al.'s (2022) Relating, Forming, and Extending framework to characterize the participants' generalizing activity. We share results from this work and discuss the implications for applet design, instruction, and future research.

Keywords: Linear Algebra, Determinants, Generalizing, Dynamic Geometry Software, Inquiry

This paper extends prior work developing inquiry-oriented curricular materials for linear algebra instruction. We designed two web-based dynamic geometry software (DGS) applets intended to provide students with real-time geometric representations of the determinant of a matrix, visualized by the parallelogram/parallelopiped image of the standard basis vectors under a user-determined 2×2 or 3×3 matrix, respectively (Wawro et al., 2023; Mauntel et al., 2024). In the applets, users can manipulate the matrix entries and observe, in real-time, the effect these changes have on the parallelogram/parallelepiped and a dynamic "determinant" value calculated by the applet. Initial implementations of the applets showed strong potential for students' generalizing activity (Wawro et al., 2023). We aim to better understand students' in-the-moment generalizing based on their experiences with the applet and how students' use of the applet might inform design changes to the curricular materials. In service of these goals, we conducted semi-structured interviews with students as they used the applets, prompting them to discuss broader relationships they identified through their activity. We sought to identify (1) what generalizations and generalizing activities do students engage in as they use the determinants applets? and (2) how do these insights into students' generalizing activity inform our applets' design?

Literature and Theoretical Framings

We draw from several research areas to contextualize our work. We first situate our work relative to existing research on student thinking about determinants and dynamic geometry software. We then detail a framework for students' generalizing activity that we use for analysis.

Determinants and Dynamic Geometry Software

In our literature search, we found few studies that attend to student understanding of the determinant concept (e.g., Chagwiza et al., 2021; Ndlovu & Brijlall, 2016). For example, Kazunga and Bansilal (2018) focused on identifying misconceptions and errors used by in-service secondary mathematics teachers. Although most correctly solved determinants of 3×3 matrices, few were successful with 4×4 matrices because many tried to extend or generalize a 3×3 procedure. Some participants also conflated the determinant of a matrix with the matrix itself (evidenced, for instance, by using $|A^T|$ to symbolize the matrix A^T), and many did not use known properties to compute the determinant of a matrix created from one with a known

determinant (e.g., the columns were swapped). Through examining pre-service teachers' understanding of determinant using numeric, algebraic, or geometric representations, Durkaya et al. (2011) found that participants employed numeric and algebraic representations of the determinant, but not a geometric one, in answering computational questions; however, during interviews, geometric representations were helpful to improving their understanding.

Some research has focused on integrating technology to support students in developing a conceptual understanding of the determinant. Research shows that Dynamic Geometry Software (DGS) applets allow students to investigate, visualize, make predictions, calculate, simulate, and generalize certain situations, all of which are critical practices for inquiry (e.g., Gol Tabaghi & Sinclair, 2013; Gol Tabaghi, 2014; Greefrath et al., 2018; Hollenbrands, 2007; Paoletti, 2020). In linear algebra, DGS has been used to explore key topics such as linear combinations (Mauntel et al., 2021), linear transformations (Turgut, 2022), eigentheory (Gol Tabaghi & Sinclair, 2013; Gol Tabaghi, 2014), and determinants (Donevska-Todorova, 2012, 2016, 2017). Through applet and task design, Donevska-Todorova (2012) focused on conceptualizing the determinant of a 2×2 matrix as area of the parallelogram defined by the points corresponding to the matrix's row vectors, helping students discover the property $\det(A) = \det(A^{\mathrm{T}})$ and the relevance of parallelogram point orientation for the determinant's sign. The author attributes the DGS's ability to simultaneously display numeric and geometric feedback as important for connecting to students' prior geometric understanding. Donevska-Todorova (2017) further elaborates on the benefits of DGS in student learning of dot product and determinants, indicating that students took initiative in forming questions and developed a more in-depth conceptual understanding of determinant. Through interaction with the DGS, students indicated evidence of a schematic understanding of determinant by relating it to other mathematical concepts or providing different interpretations of determinants. These studies possibly indicate a potential for DGS as a viable alternative approach to support student understanding of determinant concept, providing them with visualizations of determinant.

In our own design research (Wawro, 2023), we reported on student thinking from interacting with GeoGebra applets designed to leverage students' knowledge of linear transformations in $\mathbb{R}^2$ and $\mathbb{R}^3$ to support an understanding of determinant as a measure of (signed) multiplicative change in the area or volume caused by the transformation. Consistent with the cited literature, we designed the applets so that students contextualize the DGS relative to their existing notions of linear transformations. The goal was to provide students with a foundation for the connections they make while using the applets; in particular, the applets were designed to support students' explorations of how the matrix components [M] relate to the transformed object's graph [G] and to the determinant [D]. In our analysis of students giving observations from the applets and initial explanations for them, we found that most common observation type was [MDG], meaning "[M] implies [D], which makes sense because of [G]." For example, one student wrote, "If any of the columns in the 3×3 are LD [linearly dependent] with another, the det(M) will be zero due to there being no volume, only area or a line." It was sensible that most student observations began with [M] because the most interactive aspect of the applet was adjusting the matrix component values. This potentially hindered students from conjecturing the biconditionality of the determinant generalizations. Thus, we refined the applets to include two additional features: swapping rows and columns, and dragging the graphed images of the basis vectors that define the parallelepiped or parallelogram.

Generalizations and Generalizing Activity

A core goal of this project is for linear algebra students to extend their reasoning beyond particular empirical examples and develop generalizations that can be used for a broad set of problems and further students' conceptual understanding. The process of generalizing has been highlighted in a number of mathematical areas including algebraic reasoning (Carraher et al., 2008; Ellis, 2007; Kaput, 2008), calculus (Dorko, 2023), computational thinking (Lockwood & De Chenne, 2020; van Borkulo et al., 2021), and linear algebra (Harel, 2017). There are several different theories about how students generalize material. Generalization can begin with students recognizing and continuing a pattern in early algebra (NCTM, 2000). Carraher et al. (2017) highlighted the idea of conjectural generalization, which is "treating an instance (e.g., $7 + 1$) as a case of something more general (e.g., $a + b$)" (p.264). Harel and Soto (2016) explored the idea of structural reasoning, a five-step process that ended with students exploring general structures through a process of pattern recognition and reflection.

To characterize students' generalizing activity, Ellis et al. (2022) developed the Relating-Forming-Extending (RFE) Generalization Framework, which can be used to analyze how students engage in generalizing activity:

> Relating is the identification of similarity across situations, problems, or strategies that the learner perceives as distinct contexts. Forming is the development of an initial, sometimes tentative generalization, and extending is the use of that generalization, sometimes to a broader domain. (Ellis et al., 2022, p. 362)

The relating category involves generalizing based upon a prior context, problem, or situation and can encompass the idea of transfer. The forming category is primary method for creating new generalizations and involves associating objects, finding and isolating consistent features across a number of scenarios, and anticipating or extracting regularities. The extending category encompasses continuing an existing generalization to new situations or cases, making minor or major alterations to the generalization, transforming a generalization through extension, and removing particulars. Technology can aid in the development of generalizations by providing empirical grounding for deductive reasoning and pattern recognition (Turgut, 2022).

Methods

Adopting the instructional design theory of Realistic Mathematics Education (Freudenthal, 1991), the IOLA curricular materials (Wawro et al., 2013) build from experientially real task settings to foster active student engagement in the guided reinvention of mathematics through student and instructor inquiry (Rasmussen & Kwon, 2007). Our research is guided by the Design Research Spiral (Wawro et al., 2022), in which we iteratively draft, implement, and refine task sequences, guided by various design research theories at each phase. The IOLA determinants task sequence (Mauntel et al., 2024) leverages students' knowledge of linear transformations to support an understanding of determinant as a measure of (signed) multiplicative change in the area or volume caused by the transformation. To support students' shift from situated activity to more generalized activity, we leveraged DGS GeoGebra applets that synchronously display dynamic representations of numeric, geometric, and algebraic aspects of the determinant. This makes DGS a suitable tool for supporting students' exploration of determinants, connecting to their existing geometric and algebraic knowledge. DGS applets promote mathematical curiosity (Rumack & Hunker, 2019) as students explore, observe, conjecture, and justify. This centers students' activity as the foundational mathematics to be leveraged and extended. Adopting the RME design heuristic of guided reinvention, the instructor's role includes facilitating students'

open-ended activity toward more organized and focused generalizations connecting changes in matrices to changes in the distortion of the space and how they relate to determinants.

Context

We conducted a paired teaching experiment (Steffe & Thompson, 2000) in five interviews with two undergraduates from a small, four-year university in the American Southeast: Ruby and Ahmed (pseudonyms). Authors 1, 3, and 4 identified goals for each interview, which were conducted by Author 1 and assisted by Author 4. In interviews 1 and 2, we oriented the participants to the 2×2 applet and how it depicts aspects of determinants. In interviews 3 and 4, we supported the participants in identifying mathematical relationships through their use of the applets. Toward the end of interview 4 and throughout interview 5, the team focused on eliciting as many generalizations about determinants from the participants as possible.

For this teaching experiment, we used the applets from the initial task sequence (Mauntel et al., 2024, Wawro et al., 2023) and new applets designed for these interviews, which included updated features (Figure 1). First, buttons were added to allow students to switch rows, switch columns, or take the transpose of a matrix (see (a) in Figure 1). Second, randomize and identity matrix buttons (b) were added to facilitate students generating a large assortment of matrices or testing conjectures. Finally, manipulable points were added to the images of the unit square and unit cube (c), allowing students to move the images of the basis vectors that define the parallelepiped or parallelogram (automatically changing the matrix accordingly). The modified applets are found at www.geogebra.org/m/v8hw88fs (2D) and geogebra.org/m/fppgz9q2 (3D).

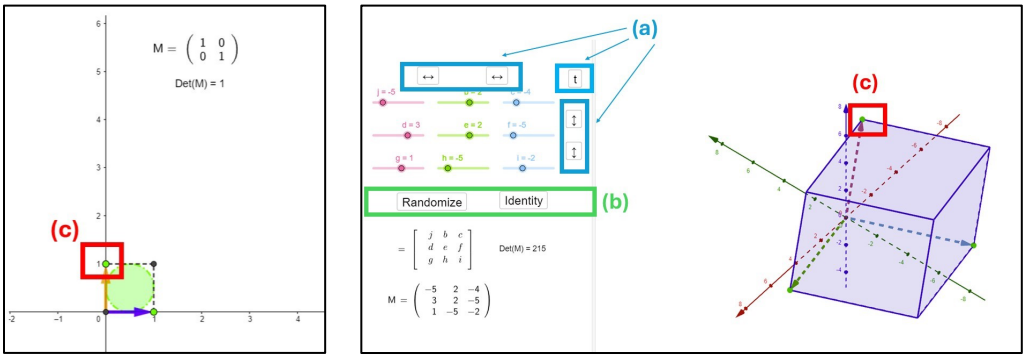

Figure 1. A screenshot highlights the new features of the updated applets.

Analysis

We individually reviewed the transcripts for interviews 2-5 and identified any statements the participants made about determinants that had a conditional or bi-conditional structure. In doing so, we centered the participants' perspectives as they generalized. We holistically categorized these student statements as generalizations through two rounds of coding: open coding and focused coding (Saldana, 2015). The first author combined the identified generalizations onto a single document, merging any instance of repeated identifications. The author team then discussed similarities and differences between the student generalizations. From this, we formed four different generalization clusters (see Table 1) based upon our perceived change to the determinant and used these to categorize participants' activity in later iterations of analysis.

We chunked the transcripts into Episodes of Mathematical Reasoning (EMR) to facilitate the coding process (Andrews-Larson et al., 2024). Each EMR was identified by what we perceived to be the major question the students were trying to answer during that portion of the interview.

The EMRs in the transcripts were primarily separated by a transition between two topics initiated either by the interviewers or the participants' goal-directed activity. For each EMR, we identified which generalization clusters were addressed by the participants' activity.

Using the RFE framework, we coded the participants' generalizing activity according the three broader categories (relating, forming, or extending) and the applicable subtypes of those categories (e.g., within extending: continuing, operating, transforming, or removing particulars). The coding process was divided into three stages. In the initial stage, our goal was to create a shared understanding of the framework's (sub)categories. We then engaged in a second coding phase, during which we noted that codes sometimes repeated across speaking turns due to the nature of the participants' dialogue. Thus, in the third stage, we grouped related chunks together with a single code. Each author coded individually on a cloud-based spreadsheet. During each coding phase, we met regularly to discuss and come to a consensus. We agreed on most codes. In other instances, one or two authors found multiple codes suitable or the interview did not provide enough information for a definitive code; we noted such cases.

Results

Generalizations

Across interviews 2 to 5, we identified four clusters of mathematical activity related to generalizations about determinants (Table 1). These clusters emerged as we sought out specific generalizations and broadened our focus to include the participants' generalizing activity while using the applets. We differentiated clusters by the described effect on the determinant. Cluster A relates to scaling the determinant by k, k^m, or k^n (e.g., if you scale a row by a number k then the determinant is scaled by k). Cluster B includes activity related to negating the determinant (e.g., switching the columns of the matrix). Cluster C mainly consists of characteristics of the matrix that make the determinant zero or nonzero (e.g., vectors are linearly dependent). Cluster D includes descriptions of the determinant remaining unchanged (e.g., swapping rows twice). Although we witnessed Ruby and Ahmed make several distinct, nuanced generalizations that consisted of multiple statements within a given generalization cluster, we do not intend these clusters to indicate that the participants consistently viewed each statement as immediately related to any other within the cluster. Instead, these generalization clusters are an organizational tool used to help identify potentially related generalizing activity across the interviews.

The first two interviews were primarily focused on supporting students' use of the applets and understanding of their connection to determinants and completing the other activities in the unit (Mauntel et al., 2024 (PRIMUS)). The fifth interview was primarily focused on soliciting as many broad, established generalizations from the participants as possible. The excerpts we discuss in this paper are from interviews 2 and 3, which consist of early, initial generalizing activity. Specifically, in this paper, we focus on the participants' generalizing activity that led to Cluster B and explore how this supported generalizing activity toward Cluster A.

Table 1. Clusters of generalizations

Cluster	Effect on Determinant	Mathematical Action/Activity/Statement (Examples)
A	The Determinant is Scaled by k, k^m, or k^n	• A vector is scaled by k • Area/volume is scaled by k. • Multiply a [row/column] by a number k • Multiply m [rows/columns] by a number k

		• Matrix A is scaled by k
B	The Determinant is Negated	• Image is flipped/reflected across an axis • Columns or rows of a matrix are switched • Vectors are swapped (geometric), either instantaneously or dynamically • Vectors cross over each other • Color of the parallelogram/parallelepiped changes • [row/column] is [multiplied by -1 / scaled by -1 / negated]
C	Determinant = 0 or Determinant ≠ 0	• Concepts related to the Invertible Matrix Theorem • Linearly (in)dependent columns/rows • Nonzero volume (3×3) or nonzero area (2×2) • Scaling a row/column by zero/having a [row/column] of zeroes • Rows/columns/vectors are multiples/linear combinations of each other • Cube turns into a plane or a line segment
D	The Determinant Doesn't Change	• Det(I) = 1 • Swapping two rows and swapping two columns • Area/volume stays the same /doesn't change • Determinant stays the same / doesn't change • Changing only an off-diagonal entry • Pushing/leaning the box/cube

The Development of Generalization Cluster B and Cluster A

Reflecting across an axis, scaling rows, and negating the determinant. In Interviews 2 and 3, we asked participants to negate the determinant of given two-by-two matrices. Near the end of Interview 2, Ruby found that the determinant could be negated by reflecting or "flipping" the image of the parallelogram across the y-axis. In interview 2, she accomplished this by negating each entry in the top row, saying, "I wanted to flip it across the y-axis," later adding, "I changed a and b [the entries in the top row] to be negative." Ruby also noticed that the color of the parallelogram changed from red to green when she negated the determinant. Around the same time, Ahmed suggested changing the signs of a and c (the entries of the first column), explaining that doing this causes the result of the 2×2 determinant formula, $ad - bc$, to change from 2 to -2 (in this case). Throughout the episode, we saw several instances in which the participants recognized connections between their actions on two different mathematical objects (here, the geometric image and the entries of the matrix) and changes in the determinant. Consistent with Ellis et al.'s (2022) RFE framework, we coded these as various types of **forming** activity, especially *associating objects*. This is based on their actions on both the geometric (G) and matrix (M) parts of the applet and their observations on how these actions affected the determinant (D). This culminated in a generalization shared by both participants and expressed by Ahmed, saying, "…if you multiply by a negative by the top half of the matrix, you'll get a y reflection. If you multiply by a negative by the bottom half [of] the matrix, you get an x reflection." Throughout these excerpts, the participants consistently scaled rows by -1, which led us to believe that Ahmed intended "multiply by a negative" to mean -1 in this generalization.

Composition of multiple reflections. In Interview 3, the participants reproduced and extended their reasoning from Interview 2, with Ahmed pointing out that the top row determines the x-coordinates for the vectors that define the parallelogram, saying, "when you multiply the top row by -1, then you get the flipped image on all flip across stuff y-axis." Ruby added, "[to]

reflect over x, you change y and to reflect over y, you change x." Ahmed and Ruby explored this connection by generating examples, which we coded as **extending** by *continuing*. Ahmed then restated their prior generalization, replacing "negative" from before with "negative number."

> *Ahmed*: …if you multiply the top row by a negative number, you will produce a matrix that is flipped across the *y*-axis, and if, subsequently, if you multiply the bottom row by a negative number, you will produce a matrix that is flipped across the *x*-axis.

In this quote, Ahmed is subtly **extending** his and Ruby's prior generalization. We note that Ahmed's statement conflates the matrix itself with the parallelogram image of the unit square under the transformation defined by the matrix. Also, as before, this quote does not mention the determinant. However, Ruby's activity before and after this quote indicates she was attending to the determinant's calculation and the color of the parallelogram produced by the applet. Indeed, when pressed by the interviewer a few minutes later, Ahmed stated, "…the determinant would be multiplied by that negative scalar." Ahmed also clarified that he is applying the negation twice, once to each row, adding, "But if you multiply that negative scalar by both axes, the *x* and *y*, then you'll end up with the same determinant just multiplied by a positive scaling." Here, Ahmed applied the generalization twice, scaling the top and bottom rows by a negative scalar. This newly formed generalization is structurally different from the former ones because it considers scaling two rows in sequence and anticipating the compounded result. We coded this instance as **extending** by *transforming* because the generalization itself changed for Ahmed.

Scaling by k and extending to k^n. Later in Interview 3, Ahmed asked to update the prior generalization, saying, "So when you're only multiplying the one row by some value, k. k times [row 1], you end up with a determinant times k." We coded this as **extending** by *transforming,* based on his explicit request to change the language of the prior generalization. Ruby and Ahmed explored this generalization using a specific matrix and scalar to test the statement, which we coded as **extending** by *continuing*. Ahmed then provided an algebraic rationale using a generic matrix with components a, b, c, and d; generic scalar k, and the 2×2 determinant formula. Like their prior generalizing activity when negating the determinant, Ahmed **extended** this generalization by applying it to each row in a 2×2 matrix, which he stated will cause the determinant to be scaled by k^2 and alluded that this should extend to larger matrices.

Discussion

The most direct result from analyzing Ruby and Ahmed's generalizing activity has been the four clusters of mathematical activity and statements, providing a foundation for understanding the generalizations that these applets can support. We have also gained insight into how students' interaction with the applet informs their generalizing activity. Specifically, we recognize that the applet first provides students with examples of matrices to explore during their **forming** activity. Students also often return to the applets during **extending** by *continuing* activity to explore more specific cases to check established but untested generalizations. This suggests potential design changes. For instance, we could incorporate features that can be toggled on once students have developed a specific generalization so that the applet might support students' **extending** activity. Though space limitations prevented us from exploring it much here, we have found some evidence that the updates to the applet supported some of the generalizing activity.

Another contribution of this work is the application of Ellis et al.'s (2022) framework in a new content area and with an additional focus on generalizing with DGS applets. Most notably, we have identified a clear instance of **extending** by *transforming*, which Ellis et al. state "are not well specified in the literature" (p. 377). This demonstrates a meaningful contribution to the field's understanding of undergraduates' generalizing activity.

Undergraduate Student's Voices and Achievement in a Purposefully Designed Calculus Active Learning Setting

Nigar Altindis
University of Alabama

Karen J. Graham
University of New Hampshire

Jerome Amedu
University of New Hampshire

Pei Geng
University of New Hampshire

We explore undergraduate students' perceptions of and the impact of implementing active learning in calculus recitations. Analysis of Likert-scale items indicate that speaking up in recitation helps clarify students thinking, suggesting that calculus instructors should create opportunities for students to speak up in the classroom. Qualitative analysis of two open-response questions indicates an increasing trend over time of students responding that working on problems in small groups was one of the most helpful aspects of recitation. Although students responded that dissatisfaction with group work was one of the least helpful aspects of recitation, this response was never as prominent as group work being the most helpful aspect. An independent two-sample t-test on students' course grades indicate no statistically significant difference ($p = 0.14$) between the treatment group (active learning) and control group. Results suggest that active learning with structured group discussions enhances student engagement and collaboration in learning Calculus concepts.

Keywords: Active Learning, Calculus, Collaborative Small Groups

Introduction

Undergraduate Calculus courses are foundational for all STEM disciplines. Success in the course is critical to retention since many students who struggle tend to leave STEM majors (Bressoud, et al., 2015). For students who are underrepresented in STEM, like women and people of color, having positive learning experiences in Calculus courses has been especially linked to their success and retention in STEM-related careers (Ellis, et al., 2016; Laursen et al., 2014). To address these challenges, over the last few decades, mathematics departments nationwide have invested in revamping their calculus courses (Rassmussen et al., 2019; Smith and Funk, 2021). These revamped courses include implementing a more student-centered culture that values active learning to improve student learning and engagement with mathematics (CBMS, 2016; Uhing et al., 2021).

Based on these recommendations and with support from an NSF grant (Award No. 2013427) we have substantially transformed the teaching of Calculus over the last four years. The Calculus I course at our institution is offered in the lecture-recitation format. All lectures and recitations are closely coordinated, following a common curriculum, calendar, and assessments. Starting in Spring 2022, we restructured our Calculus I course by introducing evidence-based practices. In recitations, students work in small groups collaboratively solving problems and a graduate teaching assistant (GTA) and an undergraduate learning assistant (LA) circulate the room and support student learning by responding to questions, orienting students to learning resources, and encouraging students to collaborate, share, and present their ideas. In revising the course structure and recitation materials we adopted The Conference Board of the Mathematical Sciences (CBMS) statement that defines active learning as "classroom practices that engage students in activities, such as reading, writing, discussion, or problem-solving, that promote

higher-order thinking" (CBMS, 2016, para. 1). This paper highlights the voices of the students and the potential impact on their learning throughout four semesters of implementation.

Literature Review and Theoretical Orientation

The Impact of Active Learning in Undergraduate Mathematics Classrooms

Research has consistently shown that active learning settings, broadly defined, positively impact both students' experiences (Uhing et al., 2021) and academic performance (Fuchs & Sahmbi, 2024). Freeman and colleagues (2014) specifically found that students in active learning environments outperformed their peers in traditional settings, with an average performance increase of 6%. Additionally, students in traditional, lecture-based classrooms were 1.5 times more likely to fail compared to those in active learning environments.

Delving into the reasons behind these positive outcomes, scholars report that active learning enhances comprehension and promotes higher achievement, fosters conceptual understanding (Code et al., 2014; Maciejewski, 2016; Roop et al., 2018), and reinforces mathematical competency and confidence (Kogan & Laursen, 2014; Lenz, 2015). Such findings indicate the effectiveness of active learning in mathematics classrooms and its potential to reduce failure rates while improving overall student engagement and performance.

Students Voices and Experiences with Active Learning Calculus Course Design

Research has consistently documented students' perceptions and experiences with active learning in mathematics courses, with most students indicating a high level of engagement and perceiving these courses as beneficial to their learning (Bowers et al., 2019; Reinholz, 2018; Weurlander et al., 2017). Collaborative group work has effectively promoted student engagement and success in Calculus classrooms (Hitt & Dufour, 2021; Code et al., 2014). However, some studies have reported student resistance to active learning methods (Tharayil et al., 2018), highlighting the need for continued investigation into students' perceptions of active learning environments in Calculus courses.

Even when students were neutral or did not favor the active learning classroom settings, they still found the course structure beneficial for their understanding of mathematics (Smith & Cardaciotto, 2011; Rosenthal, 1995; Weurlander et al., 2017). These findings suggest that while active learning generally enhances student outcomes, there is variability in how students perceive and respond to these methods. This emphasizes the importance of understanding students' voices and integrating them into active learning designs that are tailored to students' needs.

Active Learning

Active learning is defined as a method of teaching mathematics through student-centered pedagogies (Faust & Paulson, 1998; Weiman, 2014). It involves students engaging with the learning process in ways that require active participation and involvement (Prince, 2004), and it is a pedagogy that immerses students in the practice of doing mathematics (Fuchs & Sahmbi, 2024). In this context, active learning is about the practice of students' engagement, instructional routines, and the learning process and its outcome. This study aims to explore students' perceptions of and the impact of implementing active learning in undergraduate calculus recitations. With the following questions: (1) What are students' perceptions of an active learning environment in Calculus 1 recitations? (2) Is there a difference in students' final course grades before and after the introduction of active learning in calculus recitations?

Method

Context of the Study

This project focused on active learning in Calculus I as part of a larger research and development project to revamp introductory STEM courses at a research-intensive university in the northeastern United States. Starting in Spring 2022 a purposefully designed student-centered. active learning approach was implemented in the recitations using a particular structure (brief introduction/review by the GTA, group work on problems, student presentation of solutions), researcher-created activities, and undergraduate learning assistants working with the GTAs to facilitate discussion. Prior to Spring 2022, most of the recitation sections were instructor-centered, with whole group discussions led by the GTA; they highlighted problems from the textbook similar to the assigned homework, with the GTA answering student questions related to the concepts being covered in the lecture.

Data Collection

At the end of each semester, we collected survey data from students enrolled in the Calculus I course (a total of 694 students across four semesters, 154 students in Spring 2022, 212 in Fall 2022, 159 in Spring 2023, 169 in Fall 2023). The survey was comprised of seven Likert scale questions and several open-ended questions. Students were asked to respond on a 5-point Likert Scale (5- strongly agree to 1-strongly disagree) to each of the following statements: (1) The recitations helped me learn Calculus better (Help_learn); (2) I would like other courses to have small group work available as an option (SG_Other_Courses); (3) Ideas in this course became clearer after I heard other students in my small group explain them (S_Ideas); (4) I would recommend group work at Calculus recitations to other students (SW_Calculus); (5) When I spoke up in recitations, it helped me clarify my thinking (SR_Helped); (6) I looked forward to coming to Calculus recitation sessions (CR_Sessions); (7) I collaborate on Calculus related work with people from my group outside of class time (CC_Group).The two open-response questions analyzed for this paper are: (1) Please comment on the aspects of the recitations you think were most helpful for your learning; and (2) Please comment on the aspects of the recitations you think were least helpful for your learning.

Method of Analysis

The current analysis focuses on students' perceptions of the structure of the active learning environment in the recitation sessions and how it influenced their learning experiences both qualitatively and quantitatively. By analyzing students' final course grades, we aimed to examine the impact of the active learning approach on students' course achievement. Specifically, a two-sample t-test is applied to the final course grades to compare the traditional learning and active learning. Moreover, correlation analysis is conducted on the Likert scale survey questions to study students' perceptions about the active learning environment. In addition, we conducted a qualitative analysis to identify the aspects of the active learning environment that students found most beneficial and the factors that contributed to their engagement and motivation.

To analyze the open-ended responses, two members of the research team developed a codebook using both theory and data-driven approaches as described in DeCuir-Gunby et al. (2011). The codebook contained code labels, code definitions, and example responses to describe the individual codes. First, theory-driven (a priori) codes were developed based on Uhing et al. (2021) in their analysis of students' learning experiences with active learning mathematics in Precalculus through Calculus courses at six institutions. The three broad codes in this first stage

were helpful instructional practices, positive recitations experiences, and negative recitation experiences. During the second stage, data-driven (emergent/inductive) codes were developed to capture core issues that repeatedly showed up in student responses but did not fit under existing a priori codes. The researchers first coded the data independently, then they met to compare results; discrepancies were resolved by consensus. A summary of the final codes is presented in the results section below.

Results

Reliability Measures

We established the reliability of the perception of student active learning for the seven Likert-scale items (Altindis & Oyeniran, 2024) for both 2022 and 2023. Reliability measures (estimated reliability within the range of 0.81 to 0.87; Cronbach alpha 0.81 for both years; omega alpha 0.85 for 2022 and 0.84 for 2023) indicated that the seven items and the whole scale are equally reliable (Van den Brink & Mellenbergh, 1998). Additionally, we proved that the survey items measure a single construct: the students' perception of active learning (c.f., Altindis & Oyeniran, 2025).

Correlation Analysis of Students' Perception

With the Likert scale data from the 7 survey questions, Pairwise Spearman correlations were computed for each of the four semesters that implemented active learning activities. All the pairs of the seven survey questions produced positive correlations. Table 1 shows the Spearman correlations of those pairs with correlation value greater than 0.30 for each semester. Across all the four semesters, S_Ideas and SW_Calculus produced the largest correlation compared to all other pairs, followed by SG_Other_Courses and SW_Calculus.

Table 1 Pairwise Spearman correlations of the seven Likert scale survey questions (Likert survey, pairs > 0.30)

Scales	Spring 2022	Fall 2022	Spring 2023	Fall 2023
S_Ideas & SW_Calculus	0.671	0.679	0.724	0.624
SG_Other_Courses & SW_Calculus	0.526	0.562	0.503	0.578
Help_learn & SW_Calculus	0.460	0.539	0.335	0.539
Help_learn & CE_Sessions	0.434	0.489	0.420	0.455
SW_Calculus & SR_Helped	0.402	0.436	0.307	0.494
S_Ideas & SG_Other_Courses	0.382	0.420	0.407	0.515
S_Ideas & CE_Sessions	0.322	0.407	0.306	0.316
SR_Helped & CE_Sessions	0.316	0.442	0.431	0.467
Help_learning & S_Ideas	0.312	0.411	0.359	0.402

The correlation coefficients between the scales S_Ideas (students' perception of clarity of ideas after group discussions) and SW_Calculus (students' willingness to recommend group work in Calculus) across four semesters are as follows: 0.671, 0.679, 0.724, and 0.624. These findings suggest a robust positive relationship between how much students feel that group discussions clarify their understanding of Calculus concepts and their likelihood to recommend group work. This trend has been consistent over the four semesters, showcasing the value of group work in supporting students' learning experiences.

The correlation coefficients between the scales SG_Other_Courses (students' preference for having small group work available in other courses) and SW_Calculus (students' willingness to recommend group work in Calculus) across the four semesters are as follows: 0.526, 0.562, 0.503, and 0.578. This means that students with a positive experience with group work in Calculus recitations are moderately likely to prefer similar group work opportunities in other courses. This suggests that successful group work experiences in one course can positively influence students' attitudes towards group work in other courses.

Students' Perception of Active Learning

We calculated the mean values of survey scales for each semester to analyze the overall trends in students' perceptions of active learning, examining whether these perceptions increased or decreased over the four semesters (Table 2).

Table 2. Mean Scores and Standard Deviations of Students' Perceptions of Active Learning Across Four Semesters

	Spring 22	Fall 22	Spring 23	Fall 23
Help_learn	4.39 (0.778)	3.98 (0.920)	3.89 (1.032)	3.86 (0.999)
SG_Other_Course	4.04 (0.858)	3.88 (0.942)	3.71 (0.895)	3.93 (0.920)
S_Ideas	3.83 (0.932)	3.54 (1.036)	3.49 (1.030)	3.53 (1.023)
SW_Calculus	4.14 (0.905)	3.86 (0.974)	3.74 (1.026)	3.96 (0.937)
SR_Helped	3.95 (0.858)	3.72 (1.002)	3.82 (0.889)	3.78 (0.928)
CR_Sessions	3.37 (1.060)	3.06 (1.125)	3.02 (1.090)	3.14 (1.053)
CC_Group	2.65 (1.300)	2.63 (1.368)	2.60 (1.287)	2.72 (1.318)

Overall, responses to the 7 survey questions indicated that while students generally find value in small group work and recommend it to others, their feelings about how much it helps them learn and clarifies ideas have gradually declined. The "CR_Sessions" and "CC_Group" scores indicate that students are less enthusiastic about attending recitations and collaborating outside of class, suggesting that the structure or effectiveness of these sessions may need re-design to re-engage students. Most importantly, students' realization that speaking up in recitations helps clarify their thinking, suggests that fostering more opportunities for student participation could be beneficial.

The graphs in Figure 1 provide the results for the qualitative coding of two open-response questions (aspects that were most helpful and aspects that were least helpful) and represent the number of students who responded in each subcategory across the four semesters. It should be noted that student responses may fall into more than one category. Subcategories of responses to the question about what aspects of recitations were most helpful were further subdivided into two broad categories: (1) helpful instructional practices that include working on problems in small groups (GW), presenting solutions (PW), creating individual help space (IHS); and (2) positive experiences with group work/recitation that include working on problems (WP), TA/LA support (TAS), small class size/community building (SC). Responses to the survey question asking about aspects that were least helpful were subdivided into the following three categories: dissatisfaction with group work (DGW), concerns about recitation work/content (CRW), and class format & scheduling (CF). From the graphs we see an increasing trend over time in students responding that group work (GW) was one of the most helpful aspects of the recitations. We also note that even though students noted that dissatisfaction with group work (DGW) was a

least helpful aspect, the number was consistent across the semesters and not as prominent a response compared to group work being one of the most helpful aspects.

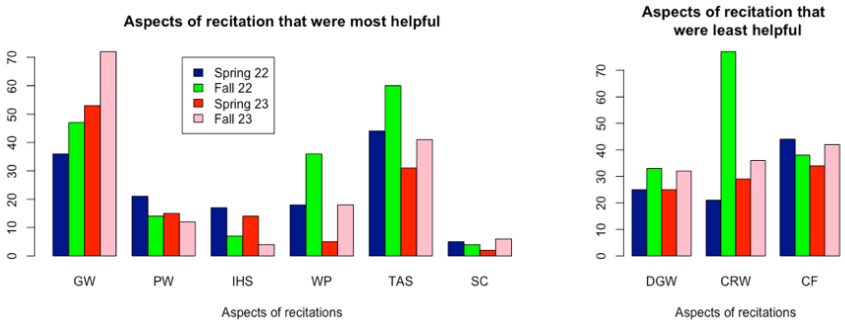

Figure 1. Distribution of codes for student responses to two open-response questions by semester

Comparing Student Achievement in Calculus

This study aims to determine if there is a significant difference in students' final course grades before and after the introduction of active learning in calculus recitations. To assess this, we collected data from students enrolled in Calculus during the following semesters: Fall 2021, where a traditional instructor-centered learning approach was employed, and Spring 2022, Fall 2022, Spring 2023, and Fall 2023, where an active learning approach was implemented.

Through preliminary examination, we found that there was a statistically significant difference (p-value < 0.001) in student achievements between the Spring semesters (n=402, mean 2.10 and sd. 1.25) and Fall semesters (n=456, mean 2.43 and sd. 1.22) where the active learning approach was implemented. Therefore, to reduce confounding effects and ensure a fair comparison, we focus on the analysis in the Fall semesters for the effect of the active learning approach with group work in recitations.

To ensure the validity of combining the data from the two Fall semesters (Fall 2022 and Fall 2023), an independent two-sample t-test showed no statistical significance (p-value = 0.84) in the difference in student achievement between the two semesters. Therefore, we combined the data from Fall 2022 and Fall 2023 to serve as the treatment group for active learning, while Fall 2021 serves as the control group.

The treatment group utilizing active learning shows an increase in average course grades (n=456, mean 2.43, sd. 1.22) compared to the control group (n=226, mean 2.31, sd. 1.43). To assess the effect of the active learning approach, a one-sided independent two-sample t-test produced a p-value of 0.14 between the control and treatment groups, indicating that the treatment's effect is statistically insignificant at the 0.05 significance level. Additional data from future semesters could further enhance the understanding of the treatment's impact. Figure 2 below shows the grade distributions for two types of learning methods.

We note that instructors in the experimental groups were not the same as in the control groups. However, the course materials, homework assignments, tests and exams, and grading policies were used uniformly by all instructors in the control and treatment groups.

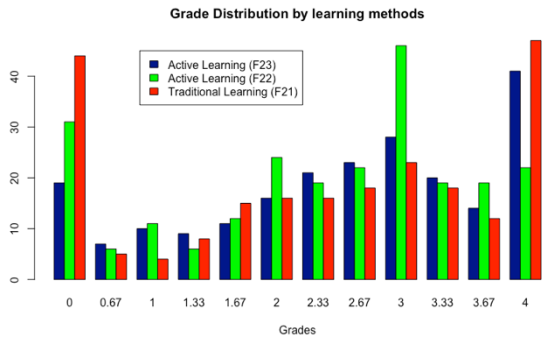

Figure 2. Grade distribution for Fall 2021 (traditional format), Fall 2022, and Fall 2023 (active learning format).

Discussion

We found a strong positive correlation between students' perceptions of the value of group discussions in clarifying their understanding of Calculus concepts and their likelihood to recommend group work to their peers, confirming previous work (Uhing et al., 2021). This indicates that as students engage more deeply in group discussions and gain clarity on calculus concepts, they recognize the benefits of collaborative learning and are more inclined to promote small group work in recitations and other courses.

These results are supported by the coding of the two open-response questions. There was an increasing trend over time of students responding that working on problems in small groups was one of the most helpful aspects of recitation. This increase over time might be a natural result of the instructional team adapting to the more student-centered process. Responses in the dissatisfaction with group category might be more related to how the groups were structured rather than group work not being helpful, e.g., the student did not like "switching groups multiple times", or how groups were assigned "random groups – I would have learned the most from my first group, but it got switched." Student concerns about recitation work/content (CRW) are consistent with results from the SEMINAL survey (Uhing et.al (2021). That is, students found some of the recitation work unrelated to the lecture or course assignments and wanted more practice, "For me recitation should be about practice problems and solving them in order to get used to them", "the recitation work felt incredibly out of sync and off topic compared with what we were learning in the main course."

An independent two-sample t-test indicated no statistically significant difference ($p = 0.14$) in students' course grades between the treatment group (active learning setting) and the control group at the 0.05 significance level. These findings do not support the claim that students participating in active learning environments achieved better final grade outcomes in Calculus compared to those in traditional lecture-based settings. Instead, we argue that we think there are other variables that affect students' achievements in calculus courses, yet our test does not measure them.

In summary, the results suggest that integrating active learning, particularly through structured group discussions, can enhance the student learning experience by promoting engagement and collaboration in understanding Calculus concepts. These findings necessitate further exploration into the long-term effects of active learning on student success and motivation in STEM courses.

Can a Single Placement Test Effectively Place Students Into Different Math Pathways?

Kristin Frank
Towson University

Alexei Kolesnikov
Towson University

Xiaoyin Wang
Towson University

Math placement policies are intended to match incoming freshmen with an appropriate math course. At our four-year institution, the same placement test is used to place students into nine courses across three pathways. In this paper we use institutional data to analyze the effectiveness of test-based placement into different courses requiring similar (and sometimes the same) cutscore. We use the classification power metric to evaluate and compare the effectiveness of three placement policies. We report that that placement tests provide minimal information about students' readiness for mathematics courses that are not algebra intensive, such as basic statistics.

Keywords: Placement, Classification Power, Math Pathways

Improving student success in entry-level college mathematics courses is a high priority for many higher education institutions. One of the approaches to improving student success involves developing and refining the process that matches incoming students with an appropriate mathematics course. In many cases, this process involves incoming students taking a placement test where the students' performance on the test, possibly in conjunction with other measures like high school GPA, determines which mathematics course(s) they are eligible to take.

Much of the research on mathematics placement has been conducted in the context of two-year institutions with a focus on the distinction between remedial and college-level coursework. Our study extends this body of research to evaluate placement at a four-year institution utilizing a test-based multi-level placement system. Placement policies at our institution are intended to simultaneously assess a student's readiness for college-level mathematics and differentiate between a student's readiness for various levels of mathematics courses. To further complicate the placement decision, there are three mathematics pathways students can choose depending on their major and career goals. Thus, the same placement test score can place students in different college-level courses. In this paper we use the classification power metric to compare the effectiveness of multi-level placement policies based on different placement-tests. Our results highlight that the placement process at our institution provides little information about students' readiness for non-algebra intensive courses.

Background

There are two main strategies to evaluate the effectiveness of a placement policy: comparative analysis of observable outcomes and classification error analysis. Researchers conducting comparative analysis of observable outcomes focus on the relationship between placement decisions and observable outcomes such as students' grades in their first math course, retention, and time to graduation (see, for example, Barnett et al., 2018, Chen, 2016, Rodriguez, 2014; and Thornton et al., 2019). Frank et al. (2022) found that the placement decision has low explanatory power for both short- and long-term outcome variables and argued that such comparative analysis of observable outcomes is not sufficient to meaningfully evaluate placement policies.

Another strategy is to treat the placement decision as a classification problem where the goal of placement is to identify, with as high accuracy as possible, the students who are ready to take

the target course and those who need to take a prerequisite (see Belfied & Crosta, 2012; Scott-Clayton, 2012). The quality of the decision can be measured with the *severe error rate* (SER). Scott-Clayton (2012) defines the SER as the sum of the percentage of students who were placed into developmental math but would have been able to pass college-level math with the grade of B or higher and the percentage of students who were placed into college-level math but earned a failing grade (F). Researchers report SERs between 16% and 28% in the context of mathematics placement at two-year institutions (Belfield & Crosta, 2012; Scott-Clayton, 2012).

Frank et al. (in press) identified three methodological challenges associated with using the SER to evaluate and compare placement decisions: (1) challenges associated with determining whether a given SER is evidence of an effective placement policy when there is no benchmark for comparison, (2) challenges associated with comparing SERs across placement policies; and (3) interpretational challenges due to possible variation in the magnitude of the SER due to chance. They propose a new metric, the *classification power* (CP), which quantifies the amount of information provided by the placement policy about students' readiness for a given course. The CP measures the reduction in the number of severe errors from implementing a given policy instead of a hypothetical placement policy that provides no information about students' readiness (imagined as a weighted coin-flip). Since the classification power compares the number of severe errors between the implemented policy and a hypothetical policy that places the same cohort of students, the classification power can be compared across courses and across placement periods.

Since the classification power measures the reduction in severe errors, the greater the classification power the more effective the policy. A policy is deemed ineffective if the 95% confidence interval for its classification power includes 0 since a classification power of 0 indicates that the implemented policy provides no improvement compared to a hypothetical policy that can be imagined as using a weighted coin-flip to place students.

To inform policy decisions, it is advantageous to consider separately the CP for both ready students (i.e., students who are able to earn a grade of B or better in a given course without taking the prerequisite) and not ready students (i.e., students would earn a failing grade in a given course if they do not first take a prerequisite). The CP for ready students (CP_R) can be interpreted as the percentage of ready students appropriately placed by the placement policy while the remaining ready students are imagined to be placed with a weighted coin-flip where the coin is weighted to match the overall placement rate. Similarly, the CP for not ready students (CP_{NR}) can be interpreted as the percentage of not ready students appropriately placed into a prerequisite while the remaining not ready students are imagined to be placed with a weighted coin-flip. Frank et al. (2024) analyze placement into Precalculus at their 4-year institution. They report lower classification powers for not ready students suggesting that placement at their institution is better at identifying ready students than not ready students.

Methodology

To evaluate and compare placement policies that place students into multiple college-level courses (e.g., Basic Statistics, College Algebra, Precalculus, etc.), we determine the CP for a single course at a time. We call this the *target course*. Each student who eventually takes the target course as part of their program of study – the *target course population* – was either placed or not placed into the target course when matriculating into our four-year institution. A student is placed into the target course when they have met the qualifying score on the placement test. Our data consists of institutional records for students in the target course population including measures of academic preparation (high school GPA, SAT/ACT) as well as demographic factors

(race, gender, age).

In order to estimate the unobserved severe errors, we follow the process described by Scott-Clayton (2012) to perform a statistical matching between students who took the target course without taking prerequisites and those who took the target course after a prerequisite. The process is fully described in (Frank et al., in press). We fit two regression models on the group of students who took the course without prerequisites. The first model estimates the probability of a student earning higher than a B in their first attempt in the target course given a vector of academic and demographic data. The model is applied to students who earned at least a B in the target course on their first attempt. Students with a predicted probability of passing over 50% are classified as underplaced; this produces an estimate of unobserved underplaced students. The second model estimates the probability a student fails the target course without prerequisites; this model is applied to students who took a prerequisite and earned at least a D on their first attempt in the target course. Students with a predicted probability of failing over 50% are classified as overplaced. These estimates, together with the students observed to be severely misplaced give an estimate for the SER since the SER is the sum of all observed and estimated severe errors.

The classification power is defined as the reduction in the number of severe errors made by the implemented policy and a hypothetical policy where the placement decision is independent of a student's readiness (Frank et al., 2024). We use ρ_R (and ρ_{NR}) to denote the SER for ready (and not ready) students for this hypothetical policy. We separately compute CP_R and CP_{NR} where:

$$CP_R = 1 - \frac{\mathbf{P}(\text{Ready and Not Placed})}{\mathbf{P}(\text{Ready})\mathbf{P}(\text{Not Placed})} = 1 - \frac{SER_R}{\rho_R} \text{ and } CP_{NR} = 1 - \frac{\mathbf{P}(\text{Not Ready and Placed})}{\mathbf{P}(\text{Not Ready})\mathbf{P}(\text{Placed})} = 1 - \frac{SER_{NR}}{\rho_{NR}}.$$

The overall CP is a weighted average of CP_R and CP_{NR} where each metric is weighted by the relative proportion of severe errors made by the hypothetical policy.

Institutional Context and Data

At our four-year institution, a student's score on a math placement test and their declared major are used to place students into one of nine math courses, eight of which offer college credit. The courses are organized into three pathways: a non-algebra pathway culminating in basic statistics, an algebra pathway culminating in Calculus for Applications (a business calc course), and an algebra intensive pathway culminating in Calculus I (this is the only pathway requiring precalculus).

Since 2014, our institution has implemented two placement tests. Between 2014 and 2018 we administered the Mathematical Association of America's Basic Algebra Test (BAT) and Calculus Readiness Test (CRT). Students wishing to take either business calculus or calculus needed a qualifying score on the BAT (17) and a qualifying score on the CRT (see Table 1). In 2018 our institution adopted the Assessment and Learning in Knowledge Spaces Placement, Preparation, and Learning Test (ALEKS PPL[1]). Both placement tests were administered to all incoming students without college math credit in an online and unproctored environment. Cutscores for a subset of courses considered in this paper are provided in Table 1. Notice that in 2016 our institution changed the cutscores for the BAT/CRT test thus we consider separately the students placed under each set of cutscores.

[1] The ALEKS placement test is an adaptive test consisting of 25 questions designed to assess students' knowledge across 314 topics (McGraw Hill, 2024).

Table 1. Cutscores for BAT/CRT placement test and ALEKS placement test.

	BAT/CRT v1 F14-S16	BAT/CRT v2 F16-S18	ALEKS F18- present
Basic Statistics	BAT 17	BAT 14	ALEKS 30
College Algebra	BAT 12	BAT 14	ALEKS 46
Precalculus	BAT 17	BAT 20	ALEKS 61
Business Calculus	CRT 11	CRT 11	ALEKS 61
Calculus I	CRT 11	CRT 15	ALEKS 76

Recognizing that there are three math pathways at our institution, the same placement test score could place students into three different courses depending on their declared major. For example, an ALEKS score of 62 would place a sociology major into basic statistics, an economics major into business calculus, and a physics major into precalculus.

Data

Our data consists of the academic records for all first-time freshmen who enrolled in Towson University, a large public university in the mid-Atlantic region, between Fall 2014 and Fall 2018. We exclude students who enrolled in/after Fall 2019 due to confounding effects of the COVID pandemic. We evaluated the CP for four courses across three pathways (college algebra, precalculus, basic statistics, and business calculus). Table 2 summarizes the demographic characteristics of these target course populations and provides the percentage of students in the target course population who were placed into the target course by the placement test. We partition the data by cohort based on the placement policy at the time of a student's enrollment.

Table 2. Summary of demographic and academic preparation for each target course.

		Sample Size n	White %	Black %	Asian %	Hispanic %	Other %	Placement Rate %
College Algebra	BAT/ CRTv1	1,076	58.27	19.42	6.41	7.90	7.99	88.85
	BAT/ CRTv2	1,566	50.13	24.58	6.90	10.09	8.30	83.21
	ALEKS	850	48.35	29.18	8.24	7.06	7.18	74.71
Precalc	BAT/ CRTv1	679	54.64	21.94	8.25	7.66	7.51	82.62
	BAT/ CRTv2	483	38.51	33.54	9.32	9.11	9.52	60.46
	ALEKS	262	38.17	37.79	8.02	8.02	8.02	59.92
Basic Stats	BAT/ CRTv1	875	59.54	18.63	7.89	6.86	7.09	71.89
	BAT/ CRTv2	939	52.82	22.15	9.16	8.09	7.77	85.20
	ALEKS	582	45.53	29.38	9.45	8.25	7.39	95.02
Business Calc	BAT/ CRTv1	635	63.62	14.33	6.93	6.61	8.50	36.85
	BAT/ CRTv2	617	56.08	21.23	7.29	9.24	6.16	45.71
	ALEKS	336	51.79	25.60	7.14	6.55	8.93	60.71

We recognize some demographic shifts in the sample over time. We do not see this as problematic since we perform the analysis on each cohort of students and the demographic characteristics are more uniform within a cohort. Additionally, we note sample sizes greater than 260, sufficiently large to perform the statistical matching described in the methodology.

Results

In this section we provide the results of the statistical matching procedure described in the methodology. Tables 3 and 4 present: the CP, the CP for ready students (CP_R), and CP for not ready students (CP_{NR}) for four courses across math pathways. We also provide 95% confidence intervals (CI) computed using bootstrapping techniques. We selected these four courses from the eight credit-bearing courses because they share similar (sometimes identical) cutscores (see Table 1). Table 3 provides the results for two courses in the algebra-intensive pathway and Table 4 provides results for two courses not in the algebra-intensive pathway.

Table 3. Comparison of classification power for courses in the algebra intensive pathway.

		BAT/CRTv1		BAT/CRTv2		ALEKS

Effectiveness of Test-Based Placement

Across these four courses and three placement policies we report estimates for the CP between -15.7 and 46.1. As we will discuss in the next section, we take this wide range in CPs across courses as evidence that the amount of information provided by a placement test varies based on the nature of the target course and the placement test administered.

Before comparing the effectiveness of a placement test across courses, we begin with a brief discussion of the evidence of test-based placement focusing our discussion on ALEKS based placement into precalculus. For ALEKS based placement into precalculus, we report a CP of 13.9 and associated CI of (-5.5, 33.5). We interpret this CI as evidence that we can expect substantial variability in the classification power due to chance and the specific characteristics of the enrolled student population. We note that we see large confidence intervals for the SER as well. We take this as evidence that small, single percentage point, variations in any measure of the effectiveness of a placement policy may be simply attributed to chance.

We see that for placement into precalculus both BAT/CRTv2 and ALEKS made about the same proportion of severe errors (SERs around 15%). However, we see different CPs for these policies; we report a CP of 30.8 for BAT/CRTv2 and 13.9 for ALEKS. This provides evidence that two policies can make the same proportion of severe errors while providing different information about students' readiness for a course. We attribute the difference in these estimates to variation in the percentage of students ready and not ready for the course in each cohort: the SER does not take into consideration differences in the sample characteristics while the CP attends to these differences by comparing an implemented policy to a hypothetical policy that places the same population of students.

We now consider the CP for ready and not ready students separately. For ALEKS based placement into precalculus we report an estimate for CP_R of 24.3 and an estimate for CP_{NR} of -20.5. The magnitude of these results can be interpreted as the percentage of ready (and not ready) students we confidently placed correctly. That is, we estimate that ALEKS based placement correctly placed 24.3% of ready students into precalculus and *incorrectly* placed 20.5% of students not ready for precalculus into the course while placing the remaining with a coin-flip weighted to match the placement rate (here 59.92%). That is, the negative estimate (for either the CP_R or CP_{NR}) implies the implemented policy made more severe errors than using the hypothetical coin-flip policy for all students.

We emphasize that the benchmark here is a weighted coin-flip policy – an obviously suboptimal placement policy. Looking across courses most often we report CPs for ready and not ready students around 25%. That is, most often we are confidently placing 25% of ready and not ready students. We take these reported CPs as minimal evidence for the effectiveness of test-based mathematics placement in providing information about students' readiness for a target course.

Comparison of Classification Power across Courses

At our institution, the same placement test is used to place students into nine different courses. In this section we evaluate the ability of a placement test, even an adaptive test like ALEKS PPL, to provide information about students' readiness for such a variety of courses. Specifically, we compare the effectiveness of placement into College Algebra and Basic Statistics as well as Precalculus and Business Calculus since these courses share similar (sometimes identical) cutscores across placement cohorts.

Across all three placement periods, the CP for Basic Statistics is less than the CP for College Algebra. These are significant differences for both BAT/CRTv1 and ALEKS as there is no overlap in the confidence intervals. Additionally, we report negative estimates for the CP for Basic Statistics under BAT/CRTv1 and ALEKS suggesting that a hypothetical policy using a weighted coin-flip would have made fewer errors than these implemented test-based policies. We also note that Basic Statistics has the lowest estimate for CP_R across all courses. Furthermore, this estimate is negative (-33.6). Together, we interpret this as preliminary evidence that test-based placement could serve as a gatekeeper in non-algebra intensive courses as the tests are incorrectly underplacing a larger percentage of ready students than a weighted coin-flip. We do not interpret this as evidence that there should be no placement policy for such courses as we estimate around 10% of students are not ready for basic statistics and would benefit from taking a prerequisite. Our results highlight the need for better placement mechanisms.

Next, we directly compare placement into precalculus and business calculus[2]. Across all three placement periods the CP for business calculus is less than the CP for precalculus. This difference is significant for placement under BAT/CRTv1; there is no statistically significant difference under the ALEKS policy which uses the same adaptive test and cutscore for both courses. This is noteworthy since under BAT/CRTv2 students took different placement tests to place into these courses, yet these different tests did provide statistically comparable amounts of information for each course. It is also worth noting that the CRT underplaced many students ready for business calculus as evidenced by the low CP_R (15.5). This suggests that utilizing different placement tests for different target courses is not necessarily an effective way to implement a multi-level placement policy.

Impact of Cutscore on Policy Effectiveness

We notice that changing the cutscores between BAT/CRTv1 and BAT/CRTv2 had different impacts across courses. For both college algebra and precalculus, increasing the cutscore reduced the percentage of students placed into the course (see Table 2). However, this change did not improve the policy's ability to identify students not ready for the course as we see no noticeable change in CP_{NR}: the slight decrease in the reported point estimates can be attributed to variation due to chance). In contrast, decreasing the cutscore for basic statistics did improve the policy's ability to identify ready students as we see an increase in CP_R. This is a noteworthy change since the initial cutscore of 17 on BATv1 resulted in a policy less effective than a weighted coin flip, as indicated by the negative estimate of CP_R. However, after decreasing the cutscore the estimates for CP_R and overall CP increased so that we can say the policy is more effective than the hypothetical coin-flip.

These results echo Leeds and Mokher's (2020) finding that changing the cutscore can impact placement accuracy. In fact, our data suggests that increasing the cutscore does not necessarily result in improved placement accuracy but can instead serve as a gatekeeper for ready students.

Discussion

At our four-year institution, a placement test is used to place students into nine courses across three different math pathways. We questioned the effectiveness of a single test (even an adaptive test) in placing students into multiple courses. Our findings provide preliminary evidence that test-based placement serves as a gatekeeper for courses outside the algebra intensive pathway (i.e., courses not leading to Calculus I). We do not interpret this as evidence that there should be no placement policy as we estimate that there are students not ready for these courses (about 10% of students who need to take basic statistics need a prerequisite and about 20% of students who need to take business calculus need a prerequisite).

We recognize that these findings could be the result of the established cutscores. Thus, we plan to use the institutional data to construct a proposed policy that sets cutscores to maximize the CP. Evaluating the CPs associated with such a proposed policy would allow us to distinguish whether it is the placement test or the cutscore that limits the information the test score is able to provide about students' readiness for a given course.

"Algebra shouldn't be this hard": How Developmental Math Student Perceptions of and Prior Experience With Algebra Influence Course Relearning Experiences

Kristen Amman
University of Nebraska-Lincoln

Juan Pablo Mejía Ramos
Rutgers University

We report results from a longitudinal case study of Elementary and Intermediate Algebra students' perceptions of what it means to "relearn" algebra, and the consequences of such perceptions on relevant behaviors and affective states. This data comes from a larger project investigating student experiences relearning individual topics and reflections on relearning across two semesters of developmental math courses. We found that students often conflated their perceptions of algebra as a familiar and "simplistic" subject with the notion that they understood it, leading to the idea that relearning it should be easy. This perception was held even in the face of poor course performance and was used to motivate unproductive patterns of behavior. In identifying the unique factors that informed and reinforced students' perceptions of relearning, this report provides useful insights for educators who are currently grappling with high rates of failure and attrition in such courses nationwide.

Keywords: developmental mathematics, relearning, algebra

This report describes students' perceptions of what it means to relearn algebra in traditional developmental math courses, i.e., semester-long college courses whose content mirrors that of United States middle and high school pre-algebra and algebra courses. Such courses continue to make up a significant portion of developmental math offerings (Kosiewicz, Ngo & Fong, 2016) and are subject to the greatest scrutiny in the developmental math space. In a series of prior reports on *relearning* in this space (i.e., when current learning goals are essentially the same as those of a previous learning experience for a given student), we have demonstrated the utility of focusing on *student perceptions* of their current understanding of algebra and how such understanding is impacted by learning about it again in college (Amman & Mejía-Ramos, 2021, 2022, 2023). We have argued that such perceptions may be crucial in explaining student behaviors and learning outcomes related to specific topics in those courses. Our work contributes to a long-standing call for research on developmental mathematics education to open the "black box" of teaching and learning in such courses (Grubb, 2001; Sitomer et al., 2012; Mesa, Wladis & Watkins, 2014) to better understand what factors may contribute to their historically high failure rates (Chen, 2016; Bailey, Jeong, & Cho, 2010).

The data presented in this report come from a larger longitudinal study that sought to capture how college student perceptions of relearning evolved over two semesters in a developmental mathematics program. In this report, we present results about (1) the ways students perceive their overall experience relearning in a developmental mathematics course, and (2) the relationship between a student's perception of their developmental mathematics course experience as a whole and their evolving relationship with relearning across individual topics. In addressing these issues, we also seek to contribute to educational theory regarding relearning—a phenomenon that is present in a variety of first-year college mathematics courses. Indeed, by identifying the facets of students' perceptions of relearning that may be tied to the topic of algebra itself, we become better able to understand how student experiences might vary when relearning in courses such as college-level Precalculus or Calculus.

Literature Review

Studies seeking to describe student experiences in developmental mathematics courses typically focus on one of four areas: placement into or rates of passing developmental math courses (Moran, 2008; Benken et al., 2015; Ngo, 2020; Ngo & Velasquez, 2020; Bahr, 2012; Fong, Melguizo & Prather, 2015; Xu & Dadgar, 2018); non-cognitive variables associated with placement or passing such as academic mindsets or self-efficacy (Silva & White, 2013; Ironsmith et al., 2003; Baxter, Bates & Al-Bataineh, 2016; Hall & Ponton, 2005; Zientek et al., 2013; Higbee & Thomas, 1999; Guy, Cornick & Beckford, 2015); describing instructor perceptions of student experiences (Mesa, 2012; Er, 2018; Reichwein, Schneider & Onwuegbuzie, 2014; Grubb & Gabriner, 2013); and describing student perceptions of their own learning experiences (Cox & Dougherty; 2019; Benken et al., 2015; Mesa, 2012). The current study is of the fourth type. Studies of this type are sparse, but critical to understanding and explaining students' motivation for patterns of behavior and course engagement.

Cox and Dougherty's (2019) end-of-semester interviews with 25 community college pre-algebra students indicated that 15 of the 25 students perceived the course to be useful in "refreshing" their preexisting knowledge of pre-algebra. These students identified the overall function of the course as "reviewing" or "remembering" algebra as opposed to helping them to better understand the mathematics they had seen before. In fact, even though 18 of these students indicated that they "wanted to 'really understand'" the reasoning behind their use of procedures in the course in way that they had not accomplished previously (p. 256), only three of these students indicated that they felt this had been accomplished by the end of the course. Thus, it seems that there was some distinction between what participants may have desired from a relearning experience and what they felt the course was ultimately capable of providing to them.

Benken et al., (2015) surveyed 306 first year students placed into Intermediate Algebra at California State University. A smaller sub-finding of this study concerned student perceptions of what it meant to gain a "better" understanding of mathematics in a developmental math course in which they had already seen the material before. The authors found that some, although not all, students perceived a better understanding to mean that they had recalled material they had already learned previously. Interestingly, instructors who were also surveyed in this study indicated a perception that most students approached the course as a "review" rather than an "opportunity to learn new content". Instructors perceived such an impression negatively, and assumed it stemmed from an overconfidence in skills. However, it is important to note that studies in this category involved interviewing (Cox & Dougherty, 2019) or surveying (Benken et al., 2015) students at the end of their course experience. Thus, while each of these studies gives us important insight into students' perceptions of learning in a developmental mathematics course, they are limited in their ability to explain why such perceptions are formed by students, or how they might influence student experiences learning course content. The current study sought to complement this prior work by identifying exactly such mechanisms.

Contrary to current depictions of developmental mathematics students having one uniform "type" of learning need (for example, a "refresher" of course material or an intensive review of "basic skills", Grubb & Gabriner, 2013; Cox & Dougherty; 2019), in our own previous work (Amman & Mejía-Ramos, 2021; 2022), we have found that developmental math students' learning experiences differed substantially across time and across course topics. This was because students' judgements regarding how and when to integrate their prior algebra understanding with what they were learning in their current course were dependent on their perceptions of the similarity of the topic in the developmental math context compared to their

previous algebra classes, and their confidence in their understanding of the topic at that time. Due to variations in perceptions of similarity and confidence throughout the semester, we found that existing categories from the literature were not all-encompassing descriptors or labels for a "type" of experience (e.g., a "refresher" experience) that fit each student. In subsequent work (Amman & Mejía-Ramos, 2023) we substantiated the connection between students' expectations for what relearning might look like at different points of the course and their methods of engagement with course content. The results of this previous work departed significantly from studies that advocated for the use of broad labels to describe student experiences due to the difference in relearning experiences based on topic. However, these results do not contradict the idea of students holding more holistic impressions of what it means to relearn in a course (Cox & Dougherty, 2019; Benken et al., 2015). Rather, they motivate the necessity of research that seeks to understand the relationship between students' topic- and course-level perspectives on relearning. The current study sought to do just this—to understand how students' holistic perceptions of relearning algebra were formed and how they evolved as the course progressed.

Theoretical Framework

Traditionally, conceptualizations of relearning have been oriented around the author's notion of a successful experience. For example, in her work on learning experiences in mathematics content courses for future teachers, Zazkis (2011) describes relearning as "the learning-again of concepts and ideas that are familiar or that are perceived as familiar by the learner," (p. 9). She goes on to orient this notion around a particular successful outcome. In contrast to "simply adding knowledge to what was previously incorporated into a learner's repertoire," relearning is described as *reconstruction*—a process that involves a reframing and reorganization of prior cognitive structures from K-12 learning for the purpose of teaching (p. 12). While we have found the notion of reconstruction to be useful in prior work (Amman & Mejía-Ramos, 2023), we found that orienting the conceptualization of relearning around this outcome was less useful in understanding student learning experiences in developmental mathematics courses. We were interested in characterizing what was happening to student understanding in these courses—how their cognitive framing of algebra content was impacted by their relearning experience, even if it could not be characterized as a "successful" reconstruction.

Accordingly, we define relearning in mathematics broadly as the experience (happening at a time T2) of learning about content one has already tried to learn about in a previous mathematics course (happening at an earlier time, T1). Importantly, the second learning experience cannot be simply a review of the content for the purpose of teaching something else (this would be better characterized more simply as the activation of prior knowledge in a relevant learning experience); the learning of such content must be *the target* of learning experiences happening at both T1 and T2. We do not orient our conceptualization around specific successful learning outcomes at T1 or T2. Instead, we treat the "learning" of relearning more generally to allow for a focus on describing *how* students' existing understanding of content can be (or be perceived to be) impacted by the T1 experience, without the necessity of comparing these impacts to a successful norm. Under this conceptualization, one may study relearning at multiple grain sizes: relearning a particular topic (such as relearning *solving systems of equations*) or relearning an entire course (relearning *Algebra*). Topic-level relearning was the focus of our earlier work in developmental mathematics (Amman & Mejía-Ramos, 2021, 2022, 2023) and resulted in a broader range of possible relearning outcomes than had previously been noted in the literature. This report focuses on the "course-level" relearning—students' holistic perceptions of what learning is like overall in a course. In a previous report (Amman & Mejía-Ramos, 2023) we

presented findings that described the relationship between one Intermediate Algebra student's topic-level and course-level perceptions of relearning as she continued to encounter content involving the sub-topic of factorization throughout a developmental math course. In the current study, we focus on course-level perceptions, demonstrating how such perceptions evolve over time and come to influence students' behavioral patterns and affective responses in developmental mathematics.

Methods

We conducted a multiple, longitudinal case study over a period of three semesters, following six students enrolled in either Elementary Algebra or Intermediate Algebra at a four-year university. Elementary and Intermediate Algebra are non-credit-bearing courses whose syllabi reflect those of a typical high school algebra course. Each participant spent two consecutive semesters in the study, with three participants beginning the study in Elementary Algebra in Spring 2021 and the other three beginning in Intermediate Algebra in Fall 2021. All participants were recruited at the beginning of the semester via email for a study focused on their experiences learning about algebra in their current course. Interested students completed a survey in which they were asked about their algebra course-taking history, then shown a list of topics (and related problems) that would be taught in their current algebra course. Students described how well they remembered and how confident they were in their current understanding of each topic.

Each semester, we chose participants whose survey responses varied in terms of how well they thought they remembered and understood the given topics, and their level of experience with college algebra courses. While some participants like Jina were taking an algebra course in college for the first time, all participants reported taking at least one algebra course in middle or high school prior to their enrollment in the study. Other participants had substantial course-taking experience with college algebra, such as Danasia who had failed Elementary Algebra twice before her recruitment into the study, and Becca who had passed Elementary Algebra and subsequently failed Intermediate Algebra once prior to recruitment. This abundance of prior algebra learning experiences meant that all participants were likely to characterize at least some of their upcoming learning experience as relearning. Data collection consisted of six one-hour interviews per student, surveys, grades on course exams and responses to exam questions whenever possible. Interviews 1-4 occurred in the first semester of study enrollment and focused on student experiences relearning specific topics in their algebra course as well as larger holistic reflections on the task of relearning algebra. Interviews 5 and 6 occurred the following semester and focused more on how students' perspectives on relearning evolved over time now that they were in a different course context. Details on topic-level interview questions may be found in previous reports (Amman & Mejía-Ramos, 2022; 2023). For the sake of space, we describe the components of interviews 1-4 that focused on course-level relearning for this report.

At the end of every interview, we asked students to describe, overall, how they thought the experience of relearning in their math course had been different from learning new content in mathematics for the first time. Each student's responses to this item were carried over into subsequent interviews to probe for further reflection throughout the semester. During the fourth interview, it was not uncommon for participants to be presented with three or four responses that they had previously given to this item and asked to discuss their perception of the relationships between them. This feature of the interviews served two purposes. First, it allowed us to better understand students' evolving perceptions of relearning throughout the semester and to discuss these perceptions with them in their own words. Second, it served as a member check of preliminary codes that we might use to describe course-level relearning perceptions.

Formal analysis proceeded in multiple rounds of qualitative coding. Again, for the sake of space, we only describe analysis as it is relevant to our course-level relearning data. The first round of analysis on this data proceeded once we had already built descriptions of individual cases at the topic-level. We then coded student responses to the questions at the end of each of the four interviews in the first semester of the study in which they were asked to describe their perspective on relearning algebra and how it might differ from learning something new for the first time. Subsequent rounds of analysis involved cross-case comparisons resulting in preliminary themes that either grouped various students' course-level relearning perceptions or sought to associate a course-level perception with larger patterns of behavior and affective states across the data set. This process involved engaging in explanation-building utilizing all data sources for an individual participant, then moving to the next participant to locate commonalities across experiences and produce evidence of rival explanations if that participant experienced a similar outcome despite different combinations of the study variables (Yin, 2009). The result of this stage of analysis was a set of preliminary themes that were refined over a period of several further rounds of analysis for consistency.

Results

Discussions around relearning at the course-level centered were mainly dominated by the perspective that relearning algebra should be easy due to its familiarity and perceived simplicity relative to later topics in mathematics. All six students discussed this perspective in all four of their first semester interviews and used it to justify their level of engagement with course material. However, as will be discussed in subsequent sections, students began to experience increasing moments of cognitive dissonance around this perspective when confronted with their course performance as the semester went on.

Conflating Perceptions of Algebra Familiarity and Simplicity With Understanding

All six participants persistently described the task of relearning algebra as something that should be easy because they had learned about it before. We use the word "should" to reflect the persistence with which students held this belief even in the face of substantial difficulty with the course material. This perspective influenced the behaviors and course experiences of all participants but is perhaps best exemplified by Cara and Jina's experiences throughout Elementary and Intermediate Algebra, respectively, due to their tendency towards exposition and high degree of reflection in their interviews. Additionally, Cara and Jina serve as excellent focal points for the data set given that both participants began the study with very different levels of algebra relearning experience, with Cara having taken two prior semesters of college algebra at other institutions and Jina having Intermediate Algebra as her first math course in college.

When discussing this perspective, participants often conflated the notion of algebra being a familiar subject with the perception that they either already understood it or with the expectation that they would achieve an appropriate level of understanding in the class easily. For instance, in her first interview, Jina stated, "I've already learned [algebra], so I'm not really sure what the most difficult topic would be, whether we have gone over it in the past or not. If it was something that we went over, it would be a little bit easier to understand just 'cause I have a basic knowledge of how it would go versus if it's something completely new I think I would have a bit more trouble trying to understand." In this way, Jina describes her perception of relearning as inherently easier than learning something new due to her foundation of "basic knowledge" in the subject. This perspective was often bolstered by participants' view of algebra as a more simplistic subject in mathematics. This was exemplified in Jina's case when she

described algebra as a "very straightforward" subject, one in which problems could be solved simply by "memorizing a formula." Cara echoed this sentiment in her first interview, stating that for her almost all math at this level was memorization, adding "I know once you get further into it, it's more than that and it takes a lot, but right now it's just 'remember how to do this." In this way, students expected that their experience relearning algebra would mostly be an exercise in recalling algebraic procedures. Given that the subject of algebra was highly familiar to them, this appeared to be a task that would be easy for them to complete successfully.

As the semester went on, participants continued to hold onto this perspective, even after finding it to be at odds with the actual understanding of algebra developed during their T2 learning experience. For instance, Jina reported feeling confident that she would perform well on an Exam 1 topic that would be taught in the course because she "remember[ed] that those rules were easy to remember." That is, Jina did not have any recollection of the topic itself, but rather a sense of general familiarity with it along with a perception that understanding algebra was as simplistic as memorization and recall. However, Jina often found herself frustrated when attempting to reconcile her relearning perspective with actual course experience, stating in her fourth interview, "I keep contradicting myself cause it's like I've seen these [topics], so I'm like 'I remember it being easy, so it'll be easy' but then at the same time when I'm learning it it's kind of like, 'oh this isn't what I learned'. Cara echoed similar sentiments when she indicated on her recruitment survey that she had seen systems of equations before and remembered some of what she was taught. However, after learning about it in class, she found this perception to be false. In explaining this, she reflected, "it's probably just because like at face value it's just, you know, an easy [topic], it's not that complex." In this way, Cara and Jina, like the other participants, conflated their familiarity with algebra, along with its early introduction in the K-12 curriculum, with an actual understanding of the material. As we will see in the following section, this often led to undesirable or frustrating outcomes due to its influence over students' behaviors.

Persistent Impacts on Behavior

This conflation of perceived familiarity and simplicity with understanding of algebra was critical to participants' experiences throughout the semester, given that it was often used as a motivator for patterns of in-class behavior. For example, at the end of the semester during her fourth interview, Jina noted that despite evidence from her first exam that her understanding of algebra was often not correct or unreliable, "by exam two, I still had that mindset in the back of my mind. Like 'oh algebra shouldn't be this hard.' So then it was like some things [in class] I would listen to, but some things I would just kind of be like I like, 'I already know this' like 'I don't need to be like listening' I guess." Here we see Jina explicitly conflating her perception of algebra as something that should be easy with the notion that she already understood course material. This served as a way of motivating a pattern of disengagement from the course that she mentioned for five out of seven major course topics in Intermediate Algebra.

Cara discussed a similar association between perceptions of relearning algebra as something that should be easy and patterns of disengagement from the course. For example, in her second interview, Cara emphasized that in Elementary Algebra, "we're adults and supposed to learn quickly…faster than we did when we were younger…like you already learned this but now you're just going over it and it should be like a 'oh duh' kind of moment you know?" Like Jina, Cara's perception of the task of relearning algebra as something that should happen quickly and with relatively little effort resulted in an over-reliance on memory and a lack of engagement with course material. For example, when reflecting on her lack of success with problems involving systems of equations on a course exam, Cara stated, "I think that because of how easy it was,

once I realized what you're supposed to do, I was like 'I don't need to remember this, it's gonna be fine, I could see this anywhere and be able to solve it any day of the week.' Not the case. Not the case at all." Here, Cara seemed to initially perceive the content as almost obvious, something that she could reason through without even having an explicit memory of it. In fact, Cara stopped going to class soon after the second course exam because she felt she could recall the material on her own regardless of whether she was in class or not. This decision seemed to contradict the fact that she had scored more than 10 points lower than the class average on the first two course exams, and speaks to the persistent influence of this perception of relearning algebra on student decision-making.

Conclusions

We intend to contribute to broader literature that seeks to characterize the unique challenges inherent in the teaching and learning of developmental mathematics courses that have caused them to become the target of countless reforms (e.g. Hodara, Jaggars & Karp, 2012; Yamada & Bryk, 2016). Specifically, we focus on describing how students are interpreting the task of relearning in these courses—what, exactly, they are meant to do when learning about material they have already tried to learn about in a previous course. We believe that such a focus on student perceptions is critical given previously-noted differences in the literature between instructor's perceptions of developmental math students and students' perceptions of themselves. For instance, developmental math students are often characterized by their instructors as engaging in unproductive learning behaviors such as self-handicapping strategies (Mesa, 2012) and having poor study and time management skills (Reichwein, Schneider, & Onwuegbuzie, 2014). In contrast, students in Mesa (2012) have described themselves as preferring mastery over performance goals, a lack of engagement in self-handicapping behaviors, a disposition towards hard work, and an expectation that instructors would challenge them. Likewise, students in Cox and Dougherty's (2019) study indicated a desire to form a deep understanding of the material they were relearning, and were sometimes even disappointed by the ultimate function of the course as a "review" or "refresher." In this way, it seems that developmental math students and their instructors may hold different understandings and expectations regarding the work of relearning and how they are meant to productively engage their previously-developed understanding of algebra in this new college course context.

In addressing these concerns, it seems crucial for developmental math instructors to examine the features of their instruction or of the structure of their courses that might unintentionally support students in forming perceptions of relearning algebra that ultimately do not serve them. For instance, in this report, we stress the importance of students' judgements of algebra as a "familiar" subject. Students were often unsuccessful in making accurate judgments of familiarity on their own, believing particular topics or procedures to be something they had already learned about or understood sufficiently, then finding this to be inaccurate after receiving feedback on course exams. Given this information, it would seem reasonable for instructors to build course activities that explicitly disrupt these assumptions of familiarity, either by presenting course materials in a non-standard way (see work on restructuring college algebra around the notion of structure sense; Wladis, Sencindiver & Offenholley, 2023) or by explicitly asking students to interrogate their sense of familiarity around a topic shortly after it is introduced. Likewise, instructors may want to reflect on the way that they frame the subject of algebra while teaching, noting that suggesting that students "should" already understand the material, or should come to understand it quickly (e.g. Cox, 2015), may unintentionally support students' disengagement with course content and overreliance on their own memory of their prior understanding.

The Role of Exploring and Conjecturing When Introducing Derivatives in Calculus: To Prove or to Verify?

Saba Gerami
California Polytechnic State University - San Luis Obispo

In this report, I present how eight experienced college calculus instructors used exploring and conjecturing to frame their instructional tasks for introducing derivatives. During semi-structured interviews with each instructor, I prompted them to propose instructional tasks for introducing derivatives. The tasks were broken down into their smallest calculus-specific problems, which I refer to as calculus-specific task units or CTUs. Using the notion of instructional situations by Herbst (2006), I categorized the exploring/conjecturing CTUs into a single instructional situation: Exploring or conjecturing to verify statements or relationships. I further describe how the CTUs were invoked in the tasks and the kinds of mathematical works they were expected to engage students in. To conclude, I discuss why the exploring/conjecturing CTUs revealed in the study either did not, or could not, converge to proving situations.

Keywords: Calculus, exploring and conjecturing, derivatives, instructional situations, tasks

Mathematical disciplinary practices, or activities commonly undertaken by professional mathematicians—such as exploring, conjecturing, defining, and proving (Rasmussen et al., 2005)—have been promoted to enhance students' engagement with mathematics in the classroom and improve their conceptual understanding. In the context of calculus education, the reform movement of the 1980s led to emphasizing conceptual learning and active student engagement in the classroom by relying on graphical, numerical, and technological elements for exploring and illustrating ideas, while reserving algebraic manipulations more for computational purposes (Bressoud et al., 2016; Kidron, 2020). Researchers, mathematics departments, and individual calculus instructors continue to explore, study, and implement these innovations to improve student outcomes in calculus (Borji et al., 2018; Bressoud et al., 2016; Code et al., 2014; Gerami et al., 2023).

In this paper, I focus on how college calculus instructors utilize the disciplinary practices of exploring and conjecturing. I define exploring as examining mathematical objects and relationships among them, and conjecturing as a particular case of exploring, during which one produces a generic or conceptual statement after exploring relationships among some mathematical objects. To better capture the learning opportunities the instructors create in their classrooms, I turn my attention to one concept—the derivative—examining how instructors present it through their instructional tasks (i.e., problems and activities designed to "focus students' attention on a particular mathematical idea;" Stein et al., 1996, p. 460). This paper addresses the following research question: What roles do exploring and conjecturing play in calculus instructors' instructional tasks when introducing the concept of derivatives?

Theoretical Framework

By conceptualizing teaching as a social activity, Brousseau's (1997) *theory of didactical situations in mathematics* assumes that every mathematics class operates under a didactical contract, referring to "shared expectations of what it means to study mathematics in school" (Herbst et al., 2023, p. 402). Although often implicit, the contract defines the roles of the teacher

and students, governs the classroom relationships, and regulates the work of teaching and learning mathematics through social content-related norms (Brousseau, 1984).

Relying on the notion of didactical contract, Herbst (2006) introduced *instructional situations* as local or specialized didactical contracts for specific instructional exchanges within a course of study. Herbst et al. (2020) defined *task framing* from the perspective of the teacher in mathematics instruction as choosing a way of handling a problem about the knowledge at stake; once recognized by students, the task framing allows students to know what kind of mathematical work they should perform and what kinds of interactions they can have. In other words, for instruction, teachers choose how to frame a problem, so that students know the task at hand and how they are expected to handle the problem. For example, Herbst et al. (2023) provided an example of how a teacher, with respect to the same piece of knowledge—the tangent segments theorem that states "a circle is tangent to two intersecting lines if and only if the points of tangency are equidistant from the point of intersection" (Herbst et al., 2023, p. 403)—can both frame the work as a construction and as a proof. In this way, instructional situations are both each of the distinct problem framings used in a course of studies, as well as "the specific norms that regulate the teacher's and students' work on them" (Herbst et al., 2020; 2023, p. 402). Researchers have identified various customary instructional situations, or distinct types of framing tasks, mainly in high school geometry and algebra (e.g., exploring or examining a figure, shape, or solid constructing; constructing a shape, figure, diagram, or solid including physical models; geometric algebraic calculation; solving equations in one variable). This line of work highlights that teachers can select from the available set of instructional situations to frame their instructional tasks, consequently launching, organizing, and scaffolding students' work (Herbst et al., 2018; 2020).

Methods

The data for this report comes from a larger study (Gerami, 2024) in which I purposefully selected and interviewed eight experienced calculus instructors from across the United States, who reported using various patterns of inquiry in their teaching. The instructors chose their own pseudonyms: Justin, Adrian, Barry, Matthew, Gopher (he/him); Monica (she/her); Max (they/them); and Alex (any pronouns). During four semi-structured 1–2-hour long interviews with each instructor, the instructors were asked to propose eight tasks for introducing derivatives. To ground the instructors' proposed tasks in students' conceptions of derivatives, I organized the interviews using Zandieh's framework (2000, Table 1) in two ways: 1) each interview was dedicated to one representation of the derivative (graphical, verbal, physical, or symbolic), and 2) The instructors were asked to propose two tasks within each representation that would help transition students' conception from one process-object layer to the next (the first task from ratio to limit, and the second task from limit to function).

Table 1. Zandieh's (2000) adapted framework for the concepts of derivative.

		Representations			
		Graphical	Verbal	Physical	Symbolic
Process-Object Layer	Ratio	Slope of the secant line	Average rate of change	Average velocity	Difference quotient
	Limit	Slope of the tangent line	Instantaneous rate of change	Instantaneous velocity	Limit of the difference quotient
	Function	Graph of the derivative function	Rate of change of a function	Velocity as a function of time	Derivative as a function

The instructors collectively proposed 56 tasks. Because most of the instructional tasks comprised of multiple parts, I suspected that the instructors often used multiple calculus-specific instructional situations to frame the multi-part instructional tasks. Therefore, I broke down the instructional tasks into their smallest calculus-specific problems, which I call *calculus-specific task units* or *CTUs*. By this, I mean that if I further divided a CTU into smaller tasks, the results would not be recognizable as calculus tasks; instead, they would be recognized as tasks from algebra, arithmetic, or other content areas preceding calculus in a standard mathematics curriculum sequence. After finalizing the CTUs of all kinds (calculating, graphing, exploring/conjecturing, etc.), I used thematic analysis (Saldaña, 2021) to achieve two main objectives: 1) identify the calculus-specific instructional situations, as defined by Herbst and Chazan (2012), by reducing the list of CTUs; and 2) synthesize the findings. During these processes, I heavily relied on Herbst et al.'s (2010) descriptions of instructional situations developed in geometry to guide myself on what to pay attention to within each instructional situation. To identify the calculus-specific instructional situations, I asked myself *how can I identify meaningful new categories for them if I looked past the specific mathematical objects within each CTU? How are the mathematical work and the norms of such work that students are expected to do similar/different if I looked past the specific mathematical objects within each CTU?* Essentially, to define the instructional situations, I differentiated between and categorized different CTUs based on the nature of mathematical work and the norms that regulated such work by relying on my own knowledge as a calculus instructor. This process resulted in five calculating, one exploring/conjecturing, two graphing, two installing, one proving, and one solving equation instructional situations (see Gerami, 2024 for complete description). I foregrounded each instructional situation across all instructional tasks to uncover patterns and themes about situation use. In doing so, I gathered tasks with similar codes for comparison to address the following questions: *How did instructors invoke these situations? How frequently and diversely were they employed? In what sequences and patterns did situations from this category typically appear in the tasks?* In this study, I focus only on the exploring/conjecturing findings.

Findings

All instructors used exploring/conjecturing calculus-specific task units (CTUs) in their instructional tasks for introducing derivatives. Given that conjecturing is a particular case of exploring, indicating when students are expected to produce hypotheses based on their perception (or contextualized conjectures) or reasoning (or reasoned conjectures), I included them in one category. I identified 11 distinct exploring/conjecturing CTUs across all the proposed instructional tasks. These CTUs with their frequency of use are listed in Table 2 (see Gerami, 2024 for detail of how the instructors used them in their tasks). I reduced all the exploring/conjecturing CTUs to one instructional situation: *Exploring or conjecturing to verify statements or relationships*. This instructional situation requires students to confirm that a statement or relationship is true, either based on perception or by making connections between multiple mathematical representations, without deductively proving it.

Table 2. Exploring/Conjecturing CTUs identified across the tasks, their engaged layer of derivative, and their frequency of use

Layer	Exploring or conjecturing CTUs to verify statements or relationships	*n*
Ratio	**E1.** Exploring the pattern among rates of change on consecutive intervals of one unit of length	1
	E2. Conjecturing the relationship between average rate of change of a function on an interval and the slope of the secant line	1
Limit	**E3.** Conjecturing the existence and/or value of instantaneous velocity or slope of a tangent line or a best estimate for rate of change at x_0 • given a table of values for various x_i and $f(x_i)$ including x_0 and values to the right and left of x_0 • between x_1 and x_2 (to the left and right side of x_0), given a table of values for various x_i and $f(x_i)$ including x_1 and x_2 • from a pattern of slopes of secants h-units distanced to the right side of x_0, with h decreasing • from a pattern of slopes of secants to the left and right side of x_0 • from a pattern of Δx-units distanced to the right side of x_0, with Δx decreasing with formal limit definition $\lim_{\Delta x \to 0} \frac{f(x_0+\Delta x)-f(x_0)}{\Delta x}$ • using average rates of change from a pattern of Δx-units distanced to the right side of x_0, with Δx decreasing	8
	E4. Conjecturing a formula for instantaneous velocity at x_0 from a pattern of Δx-units distanced to the right side of x_0, with Δx decreasing with informal limit definition $\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x}$ as $\Delta x \to 0$ with formal limit definition $\lim_{\Delta x \to 0} \frac{f(x_0+\Delta x)-f(x_0)}{\Delta x}$	3
	E5. Exploring the slope of a tangent line of a cusp	1
Function	**E6.** Conjecturing how a smooth function's graph looks like if we zoom in enough	2
	E7. Exploring the graph of difference quotient $\frac{f(x+h)-f(x)}{h}$ with sliding h going to zero	1
	E8.1. Exploring the relationship between graphs (of $f(x)$ and $f'(x)$)	4
	E8.2. Conjecturing the algebraic relationship between graphs of $f(x)$ and $f'(x)$ for $f = x^n$ (e.g., f is quadratic implies that f' is linear)	
	E9.1. Exploring the physical journey of an object given the graphs of $f(x)$ and $v(x)$	2
	E9.2. Exploring the physical journey of an object given the graph of $v(x)$	
	E10. Conjecturing the shape (trend—i.e., increasing, decreasing, constant—and concavity) of a function given the sign (positive, negative, zero) and change (increasing, decreasing, constant) of its instantaneous rate of change	1
	E11.1. Exploring $f'(x)$ using patterns of $f'(x_0), f'(x_1), f'(x_2), \ldots$	4
	E11.2. Conjecturing the power rule ($f'(x)$ for $f(x) = x^n$ for all integers) using the patterns of derivatives of $f = x, f = x^2, f = x^3, \ldots$	

Note. The different terms that instructors used in their tasks to refer to the same concept are wave underlined to indicate their equivalence.

At times, the instructors used explicit expressions, such as *explore*, *hypothesize,* and *make a prediction*, in their task descriptions to evoke these CTUs (e.g., "Can you make a prediction about what will happen when you zoom in on any point on this graph?" Justin, Prompt 5's task). However, they more often directed students towards the object of inquiry by asking them: whether they could do something (to imply the possibility of performing a mathematical action, rather than assessing students' mathematical abilities), to explain their thinking, or to consider what might occur under specific conditions (e.g., "Is there a 'best' AROC [average rate of change] estimate?"; Alex, Prompt 5's task; "Can you write down the exact number of the speed at $t = 2$?", Matthew, Prompt 1's task; "Talk about the relationship between these average velocities and what [do you] think would happen if [the windowpanes became smaller?]", Monica, Prompt 1's task). The rather indirect use of language to evoke exploring/conjecturing situations suggests that instructors may have to clarify the situation in class to convey to students what they are expected to do.

The instructional situation was presented in the form of two learning opportunities in the instructional tasks:

a) Exploring graphical representations of derivatives to make sense of, or conjectures about, symbolic representations and relationships between, functions, derivative values, and derivative functions (E2, E5, E6, E7, E8.1, E8.2, E9.1, E9.2, E10), and
b) Inductively constructing symbolic representations (including definitions) to model derivative patterns (E1, E3, E4, E11.1, E11.2).

The first group—exploring graphical representations of derivatives to make sense of, or conjectures about, symbolic representations and relationships between, functions, derivative values, and derivative functions—includes CTUs in which students are expected to make connections between graphical and/or symbolic representations of objects that are related to derivatives. In these CTUs, students rely on graphs of functions, secant and tangent lines, and derivative functions to explore and conjecture how they are related to one another or to make sense of numerical or symbolic representations related to derivatives, such as the derivative value at a cusp at in E5 and the limit of the difference quotient in E7.

The second group—inductively constructing symbolic representations (including definitions) to model derivative patterns—includes CTUs in which students are expected to detect mathematical patterns about changes and/or derivatives among some mathematical objects, and to possibly come up with procedures or formulas that model the pattern. These situations, like E3, E4, and E11, can precede installing (i.e., defining) situations by allowing students to develop intuition about definitions or formulas before they are formally installed.

I identified two recurring patterns in how exploring/conjecturing CTUs were integrated into the instructional tasks: after requiring students to calculate and graph things, or before installing a new definition, formula, or procedure. In the first pattern, the instructional tasks with exploring/conjecturing CTUs required students to perform calculations and graph things via calculating and graphing CTUs. Subsequently, students were prompted to explore or make conjectures. For example, in Alex's task for Prompt 1, students were initially asked to use average velocities to estimate instantaneous velocity (C1 and C4). They were then asked to conjecture a formula for instantaneous velocity at a point by "continuing to make their estimate better." Similarly, in their tasks for Prompt 3, Max, Alex, Adrian, and Monica used combinations of graphing and calculating CTUs related to average or instantaneous rate of change at a point before E3, in which they asked students to conjecture about the existence or the value of instantaneous rate of change at a point. In another task for Prompt 5, Gopher first asked students

to estimate the rate of change at a point, and then followed the instructional task by asking students to use an applet to conjecture the slope of tangent line at a cusp (E5). As these examples demonstrate, it appears that these preceding calculating and graphing CTUs would make room for students to observe, visually inspect graphs or sequences of numbers and identify patterns. Thus, in these exploring/conjecturing CTUs, at stake are making sense of the graphs and/or calculations, connecting various concepts/representations of derivatives, or discovering how graphs or calculations would change under specific conditions. Although the role of the teacher in exploring/conjecturing situations is often to give students the object of explorations and possibly legitimize the resources and tools that students can use (Herbst et al., 2010), in these cases the work of the teacher was more directive because the tools and resources were already given in the instructional task via students working on them through explicit graphing/calculating CTUs beforehand. This limits students' free choice in selecting the representations and operations for their exploration. There were only a few instances where the exploring/conjecturing CTU did not proceed any other CTUs. Although this suggests that students were granted more autonomy, the instructional tasks already provided the related representations for their explorations (e.g., Alex's task for Prompt 6; Justin's task for Prompt 4).

In the second pattern, some exploring/conjecturing CTUs led to CTUs that stated a new definition, formula, or procedure or validated students' findings from the exploring/conjecturing CTUs for future use. For example, in their instructional tasks proposed for Prompt 5, after asking students to conjecture the existence of instantaneous velocity at t_0 given a table of values for various t_i and $f(t_i)$ with Δt decreasing (E3), Matthew used E4 to ask students to conjecture a formula for instantaneous velocity at t_0 using their explorations from E3, and Alex used I4 to formally install instantaneous rate of change. In another example, Alex and Monica installed the power rule (I7) in their instructional tasks for Prompt 8, after having students calculate derivatives of $f = x$, $f = x^2$, $f = x^3$, … (C7 and C11) and conjecture a formula for the derivative of x^n (E11). Thus, in this pattern, the exploring/conjecturing CTUs seem to create opportunities to legitimize the new knowledge gained from the CTUs. Therefore, at stake in these CTUs is introduction to or becoming familiar with new general formulas and procedures about derivatives (limit definition of instantaneous rate of change at a point, finding slope by zooming in, power rule).

Discussion

In this report, I demonstrated that although the calculus instructors in the study relied on a diverse and engaging range of exploring/conjecturing calculus-specific task units (CTUs) in their instructional tasks when introducing derivatives with inquiry, the CTUs were all to verify statements or relationships. Despite the instructors' reliance on these CTUs when framing their tasks, the instructional situation either did not, or could not, converge to proving situations. Although Herbst et al. (2010) asserted that exploring/conjecturing situations in geometry "often converges to the formulation of conjectures, or the proofs of those conjectures," it seems that calculus instructors in this study use exploring/conjecturing CTUs to have students reason abductively and inductively. It seems that in the CTUs identified in this study, deductive inferences (i.e., proving) were either: not appropriate given students' existing knowledge (e.g., proving E6 without students' knowledge of infinitesimals), not called for because these CTUs were designed to lead to installing situations (which could not be proved deductively; e.g., E3 and E7), or that even when proving conjectures were possible, the instructors chose to not

pursue them. Regarding the latter category, I suspect that six CTUs could lead to proving situations that student could work on with using their existing mathematical knowledge:

- E2: Conjecturing the relationship between average rate of change of a function on an interval and the slope of the secant line—could lead to proving that the two quantities are equal.
- E5: Exploring the slope of a tangent line of a cusp: proving that the derivative at the cusp does not exist—could lead to demonstrating that the right-hand limit is not equal to the left-hand limit.
- E8.2: Conjecturing the algebraic relationship between graphs of $f(x)$ and $f'(x)$ for $f = x^n$)—could lead to proving that $f'(x) = nx^{n-1}$ using a limit definition of the derivative, indicating that the function loses a power when differentiated.
- E10: Conjecturing the shape (trend—i.e., increasing, decreasing, constant—and concavity) of a function given the sign (positive, negative, zero) and change (increasing, decreasing, constant) of its instantaneous rate of change—could lead to proving what happens to slope of the tangent line, written using the limit definition, at a random point on any of those intervals.
- E11.1: Exploring $f'(x)$ using patterns of $f'(x_0), f'(x_1), f'(x_2), \ldots$—could be followed by using a limit definition of derivative to calculate $f'(x)$.
- E11.2: Conjecturing the power rule ($f'(x)$ for $f(x) = x^n$ for all integers) using the patterns of derivatives of $f = x, f = x^2, f = x^3, \ldots$—could lead to proving that $f'(x) = nx^{n-1}$ using a limit definition of the derivative.

Of these CTUs, however, only three—E8.2, E10, and E11.2—were about general statements. While the other CTUs could also lead to proving, they were specific to particular functions and the conclusions would not always be useful for other functions. The absence of deductive reasoning following the CTUs can be attributed to the CTUs being either about particular examples, or because when they were generic enough, the instructors found inductive reasoning more appropriate than deductive reasoning, possibly due to time-consuming or challenging algebraic manipulations.

Indeed, the instructors in this study used a high number of exploring/conjecturing CTUs, which aligns with associating inquiry in undergraduate mathematics education with authentic problem solving and the exploration of novel ideas. However, despite the emphasis on conceptual mathematical reasoning in inquiry-oriented contexts, instances where exploring/conjecturing situations could have been followed by reasonable proving situations were, in fact, not followed up with proving situations. One explanation could be that instructors perceived proving situations, especially with student-centered activity structures, as too challenging for calculus students. Paradoxically, it may be the case that more lecture-oriented instructors might use more proving situations via lecturing. It is also possible that college instructors simply do not consider calculus an appropriate subject to engage students in the work of proving, given that 'formal' proving is often introduced in linear algebra, following the calculus series. Nonetheless, my coding of proving CTUs was rather broad, encompassing deductive mathematical justifications, which researchers have shown could be done in any mathematics class (Stylianides, 2007).

Learning Linear Algebra Through Instrumentation of Interactive Figures: Analysis of Student-Generated Mathematical Observations and Conjectures

Ryan Peffer
Washington State University

Judi McDonald
Washington State University

Sepideh Stewart
University of Oklahoma

Linear algebra is an important topic with many in-demand applications. In this paper, we consider a set of digital interactive figures created for introductory linear algebra students. The figures were designed to scaffold student experimentation with linear algebraic objects in the process of making observations and conjectures. We analyzed a collection of student reflections written about their experience and observations from the interactive figures through the theory of instrumental genesis. Based on the results of this pilot study, we believe that these interactive figures can be effective in promoting cycles of observation and conjecture as pre-proof activity.

Keywords: Linear algebra, CAS, eigenvalues, conjecture, instrumental genesis

Literature Review

Linear algebra has been and continues to be a crucial foundational topic for many other disciplines. More recently, the modern era of data-driven and machine learning innovation has only increased its relevance. As a deeply theoretical yet also readily applied subject, the way that linear algebra is taught is of critical importance as it needs to lead students to conceptualize and yet think pragmatically.

Since the early 1990's the Linear Algebra Curriculum Study Group (LACSG), and contemporarily the LACSG 2.0 in 2022, have set forth an educational agenda for the teaching of linear algebra in the university mathematics curriculum (Carlson et al., 1993; Stewart et al., 2022). Among this guidance, of primary relevance to this project are the recommendations to implement and integrate computer algebra systems (CAS) learning support, and to further attend to the theoretically based content common to second courses in linear algebra.

In keeping with this movement, modern linear algebraic texts often encourage and integrate the use of CAS support such as MATLAB or Maple (Lay et al., 2016; Leon, 2010) Using CAS support to assist students in performing computations involving vector and matrix manipulations, solving systems of equations or computing matrix determinants, inverses, and eigenvalues and eigenvectors allows for fast and accurate calculations. The intent is to leverage CAS to reduce a student's cognitive load on routine arithmetic, thus computing should provide an arena for experimentation and tinkering that can help reinforce conceptual ideas, such as by "generating computational justifications for claims and making strategic choices to limit [complexity]" (Bagley & Rabin, 2016). This experimental mode of doing mathematics via computation also possesses affective consequences, as students may be able to shed restrictive, formulaic views of what "doing" mathematics is (Castle, 2023). Conversely, using CAS may distract students from focusing on linear algebra and shift their attention to the coding itself. As such, in implementing CAS support in the teaching of linear algebra, it is important to understand what impact it is having on student learning.

In order to connect ideas of computation and experimentation with productive modes of mathematical activity, we utilize an emergent model for the process by which mathematicians engage with mathematics, Observation-Conjecture-Proof-Theorem (Peffer, McDonald, & Stewart, 2024). Rooted in traditional Definition-Lemma-Proof-Theorem-Proof-Corollary

(DLPTPC) models, which can be opaque and intractable to introductory mathematics students (Uhlig, 2002), the Observation-Conjecture-Proof-Theorem model of doing mathematics seeks to delineate a simple path by which students can generate, critique, and validate mathematical ideas. In an introductory linear algebra course, we further wish to primarily engage students in routines of observation leading to conjecture, which can be motivated and facilitated by CAS-automated algebra and computation.

Theoretical Perspectives

In this study, we will use Trouche's (2020) model of instrumental genesis to understand how students come to understand and utilize technology (interactive figures) to perform a task. The theory of instrumental genesis describes a codependence between a subject (prototypically the student learner) and the artifact (e.g. a calculator, graphing tool, or digital intractable).

In quantifying the artifact, the affordances/potentialities and constraints of the artifact become the relevant leverages by which the subject and artifact interact. The affordances/potentialities of an artifact are "what it offers [the student], what it provides or furnishes," and the possibilities for mathematical activity that are opened to the student. In contrast, the constraints of an artifact are those limits that bound the space of action and perception available to the subject.

Thereafter, the theory of instrumental genesis describes twin processes of instrumentation and instrumentalization, which describe the mutual changes elicited in the subject by the artifact, and vice versa upon the artifact by the subject. Instrumentation is "the action by which a subject acquires an artifact, and the effect of this action on the subject, who develops, from this artifact, an instrument for performing a task. An instrument is thus made up of an artifact component and a cognitive component (knowledge necessary for/from using the artifact for performing this type of task)" (Trouche, 2020). Conversely, the process of instrumentalization describes how a subject adapts an artifact to their intentions, via stages of discovery (of functions), personalization, and customization.

Within this study, the artifact(s) in question are a collection of interactive figures developed by the second author, meant to host a space for exploratory linear algebraic arithmetic action and observation. These interactive figures primarily feature concrete, number-valued matrices and vectors, and different calculations are performed by the figures. The affordances of the figures include the mechanisms for control at the student's disposal, largely the "new matrices," "size of matrices," or scalar setter buttons. In addition, the automatic display of the example matrices generated and their relevant sums, products, scalings, and exponentiations, as well as their corresponding calculated eigenvalues constitute intended structural constraints of the figures.

As identified by the interactive figures' constraints, the interactive figures leave very little room for personalization as the source code is unavailable to students, and the discovery process is intended to be near immediate to a population of students who are familiar with mechanisms such as buttons and sliders. As such, we will not explore the instrumentalization process and instead primarily emphasize the artifact level affordances and constraints as well as the instrumentation process, by which a subject's understandings and strategies evolve as a result of working with the artifact.

Thus, we seek to utilize the framework of instrumental genesis, in conjunction with our Observation, Conjecture, Proof, Theorem conceptual framework of doing mathematics to investigate the in-situ affordances/potentialities and constraints experienced by the students, and what observable effects upon the student via the instrumentation process can be observed.

Our research questions are:

- How did the interactive figures facilitate (or not) students to participate in the Observation-Conjecture-Proof-Theorem model of doing mathematics?
- What was the process of instrumentation of interactive figures for linear algebra students, and what were the experienced affordances and constraints of the interactive figures?

Method

This case study was conducted in an honors section of a first course in linear algebra at a large public land-grant R1 university in the northwest USA. Out of 16 enrolled students, 13 participated, with most of those students interested in quantitative degrees in STEM fields and medicine.

With the intention of developing a conceptual framework by which to evaluate the interactive figures' merits, such as by collecting student perspectives on the interactive figures' instrumental affordances and constraints, a single digital worksheet activity was assembled consisting of five interactive figures related to the algebraic properties of eigenvalues (See Figures 1-4 below). As intended introductory or pre-introductory materials, the interactive figure activity was administered to students over a weekend's time to complete following a brief first lecture on eigentheory. As such, students had been shown the definitional equation of eigenvalues and eigenvectors of a matrix as well as basic necessary conditions such as non-zero eigenvectors and uniqueness of eigenvalues for an eigenvector. By the time of participation, students had not seen nor practiced how to compute eigenvalues or eigenvectors, nor had any of the eigenvalue properties displayed in the worksheet been discussed in class.

The student participants were assigned to spend approximately 15 minutes manipulating the digital figures and look for any observable patterns or trends. For course extra credit, the students then submitted one to three paragraph reflections on their observations made based on the following open-ended prompt: Write out your thoughts in a few paragraphs about whatever you found interesting or noteworthy while in the worksheet. These reflections were gathered via the course space in Canvas, which were collected and de-identified in a OneDrive file.

From these reflections, the authors used open coding (Strauss & Corbin, 1998) to establish themes and build a codebook, which include the following main codes: Descriptive language, Eigenvalue, Eigenvector, "Why" Questions, Worksheet (Figures, Features, Design), Affect, Mental Acts, Agreement/Believe as Fact, and Examples. Furthermore, we have extracted all mathematical statements included in the student reflections to analyze the stage of mathematical activity present in the Observation-Conjecture- Proof-Theorem model of "doing" mathematics.

Results and Discussion

Students' Construction of Mathematical Statements

Of the 13 participants in this study, 12 students attempted to discuss in some capacity the algebraic relationships given in the interactive figures. Of these students, 7 produced most or all of the desired relationships (or non-relationships, in regard to sums and products of matrices), with three others largely stating that they did observe patterns without explicating them and the final two stating that they did not understand how to interpret the figures and could not construct any of the relationships.

Scalar multiple and matrix exponentiation. Each of the 7 identified participants were able to construct valid relational statements about the eigenvalues of matrices cA or A^k from the interactive figures shown above in Figure 2, such as the excerpts below. We noticed a variety of

levels of generalization demonstrated by students, such as S1 who states the property for scalar multiples for any scalar c, while S2 only constructed the relationship for c = 2. Whether or not that student understood that the property extended to any other constant and used 2 as a prototype is unclear. Furthermore, we can observe that even though the worksheet only allowed students to select scalar values from integers between -4 and 4, students such as S1 were comfortable extending this observation to include any scalar.

> S1: "Multiplying a matrix by a scalar scales the eigenvalues by that same value"
> S2: "The eigenvalues of 2A are twice the amount as the eigenvalues of A."
> S5: "When the matrices were put to a specific power, the eigenvalues were also put to that same power."

Sum and products of matrices. Consider the more open-ended figure relating the eigenvalues of sums and products of matrices (Figure 3 above). Seven of the participants commented in some capacity that there is no identifiable pattern from the eigenvalues of A and B to the eigenvalues of the sum A+B or product AB. Nebulously, two students reflected that they could see the pattern between sums and products of matrices without explicating what pattern they were or were not seeing.

Of those students who correctly observed a lack of relationship in the matrix sum and product example, we notice a distinct difference in the style and conviction of the statements themselves. For example, S3 phrases their statement definitively whereas S5 couched their language in more uncertain terms, in particular leaving room for the possibility that they just couldn't find the intended relationship.

However, this uncertainty seemed to only be present in the case of non-patterns that the students might have expected to find, as all 7 conjecturing students presented definitive statements about the relationship between the eigenvalues of AB and BA or $B^{-1}AB$ and A, as with the final two excerpts from S4 and S6 below.

> S3: "When you add two matrices together, the eigenvalues do not correspond to the addition of the eigenvalues."
> S5: "I could not find the relationship between eigenvalues when the matrices they stemmed from were added or multiplied to each other."
> S6: "Multiplying two matrices together [does not necessarily] multiply the eigenvalues. The resulting eigenvalues always seem to be slightly greater in magnitude than the result one would anticipate."
> S4: "If a matrix A is multiplied by a matrix B, it's eigenvalues will be the same as Matrix B times Matrix A. Also $B^{-1}AB$ has the same eigenvalues as just A."

Extent of observation-conjecture-proof-theorem activity. We have seen evidence of students effectively engaging in observation and conjecture style mathematical activity through participation with the interactive figures. The below two excerpts thus demonstrate where students have stopped in the process of Observation-Conjecture- Proof-Theorem.

> S1: "As to the specific eigenvalues of matrixes, we haven't discussed how to find them, so I'm taking the worksheet's values as fact."

S3: “I also liked the brief explanations that they gave, however, I would like to have some more in-depth discussion about how to solve eigenvalues.

As expected, the students were not able to leverage the interactive figures in order to glean further conceptual meaning or computational technique about eigenvalues and eigenvectors. In this way, the domains of verification and justification as proof-type activity are not currently accessible to students following their time with the interactive figures, however by their remarks we believe that the interactive figures have helped to prime students for these further deeper conversations.

Artifacts of Instrumentation: Affordances and Constraints

The below three excerpts each contain some language relating what the student was able to “do” with the interactive figures. For S2, changing the size of the matrix being exponentiated helped to identify the relationship, at least to them. S3 remarked about the ability to change matrices, which likely came from the ability to either modify the matrix dimension or change parameters such as the scalar multiple or exponent. Finally, S9 used embodied language “scale the vector with my hand” when referring to the geometric interactive figure, indicating a level of experienced control. All of these comments indicate that the designed features of the interactive figures were largely experienced as affordances of the figures that students were able to leverage to help make sense of the encoded relationships.

S2: “For the powering up a matrix … When I made it a 3x3 matrix, it looked like the the eigenvector/the matrix of A^k is the product of A times A, and the eigenvalues of A^k = the eigenvalues of A to the power of k, but I don't know why some of the signs changed from positive to negative if it was being squared.”
S3: “I found the worksheet to be useful in that it allows you to change the matrices and see what happens to the eigenvalues.”
S9: “It was interesting to scale the vector with my hand and check the gradual change of the values on my own.”
S8: “For number three [Figure 3], I also get the products of eigenvalues and the different ways you can add or multiply them together, but like before I do not get how you created the eigenvalues in the first place.”

Conversely, the only constraint that was remarked on by students was that the operations performed to calculate eigenvalues were concealed, for example the above excerpts from S8 which communicate that the student felt limited in their ability to engage with eigenvalues and eigenvectors as they have no ability to compute and manipulate eigenvalues outside of the figures.

However, no student remarked upon other elements of the tight boundedness of the figures’ functionality such as not being able to edit matrices entry-wise, perform calculations other than those given, or change dimensions or parameters beyond the set range given. While these constraints were nonetheless present, it is unclear whether the students did feel limited by this structure and did not remark upon it, or they were sufficiently engaged by the afforded freedoms that those constraints did not impede their investigation. Further work investigating students’ thoughts while using the interactive figures could help make this distinction.

Trouche (2020) defined instrumentation as "The action by which a subject acquires an artifact, and the effect of this action on the subject, who develops, from this artifact, an instrument for performing a task." (p. 407).

From the above student excerpts, S3's statement indicates that the student felt they were in control of manipulating the matrices, even though none of the interactive figures allowed for a direct entry-wise manipulation of the matrices, while S9's comment uses embodied language of performing actions by hand. Both of these we interpret as the students actively manipulating the interactive figures in order to pursue a goal, in this case to make observations of the algebraic and geometric objects, and thus the students have, to some degree, instrumentalized the interactive figures for the purpose of engaging in Observation-Conjecture-Proof-Theorem activity.

Concluding Remarks

This study sought to investigate the types of activity in an Observation-Conjecture- Proof-Theorem perspective of doing mathematics that students engaged in while working with the interactive figures. We saw that students were able to effectively make reasonable and coherent mathematical statements relating algebraic properties of eigenvalues based upon their observations in the interactive figures, and that we believe this activity to have helped prime the students for further conceptual and computational development of eigen-theory. Additionally, the theoretical framework of instrumental genesis was useful and operationalized to examine how students experienced and engaged with the interactive figures in the action of making observations and conjectures.

In conjunction with these interactive figures focused entirely on properties of eigenvalues, other figures have been made that also display eigenvector information. Furthermore, the second author has designed several other sets of interactive figures on the topics of linear combination and span, linear transformations, matrix multiplication, and determinants, to be used across introductory and second courses in linear algebra.

Since these interactive figures are solely intended to scaffold and elicit observation and the potential for conjecturing activity, the first and second authors are in the process of integrating these interactive figures more intentionally into an introductory linear algebra curriculum by supplementing them with explicit conjecturing and proving assignments. From this pilot investigation, we believe that students are able to instrumentalize these interactive figures for the task of investigating algebraic relationships, and thus we hope that students can further utilize those observations and conjectures in the mathematical process of Observation-Conjecture-Proof-Theorem by subsequently supporting their conjectures via proof.

Furthermore, we were not able to follow up with students to make any assessment of retention or long-term effects of this interactive figure worksheet in their learning of linear algebra. Furthermore, the reflection prompt was left purposefully open-ended so that students could direct their writing towards whatever they found notable about the worksheet, meaning only 7 of the 13 participants attempted to quantify the algebraic relationships present. In future iterations of this research, we plan to pair investigations of these interactive figures in introductory linear algebra courses with subsequent proof activities that structure and draw from the observational affordances of the interactive figures. In doing so, we wish to better understand how these interactive figures can be operationalized and instrumentalized by students to accomplish a task, in this case observing and conjecturing quantifiable algebraic relationships in order to further prove them.

Multi-Team Embodied Activity and Semiotic Games to Develop and Tune Meanings for Abstract Algebra Concepts

Jessi Lajos
Utah State University

Brian P Katz (BK)
California State University Long Beach

As students advance in undergraduate mathematics courses, the formal (e.g., textbook definitions and proofs) and informal (e.g., metaphorical) language they encounter becomes increasingly loaded. Additional work is needed to unpack how learners can engage in semiosis "meaning making" processes beyond surface marks, symbols, and verbiage. In this paper, we conduct semiotic bundle analyses to explore the potential of a full range of embodiments in meaning making. Our results show how embodiments can be leveraged in a more advanced abstract algebra setting to mediate semiotic conflicts between students' and institutional/communal signs and expand meaning-structures. We present more specific meaning tuning and elaboration strategies that utilized embodiments and were identified during our analyses.

Keywords: Embodied Instruction, Semiotic Bundle, Semiotic Games, Abstract Algebra

Introduction and Background

Much of the existing work on semiotics in abstract algebra settings is centered on (a) spoken language with puddle diagrams that instructors' produce and use to teach abstract algebra (e.g., Rupnow, 2021; Rupnow & Randazzo, 2024a) and (b) conflicts between students' signs and institutional meanings in separate interview settings (e.g., Melhuish, Ellis, et al. 2020; Melhuish, Lew, et al., 2020; Melhuish et al., 2023). Students can be proficient with formal language and symbols without being able to leverage this language to create new signs (Duval, 2017, 2006a; Sandoval & Possani, 2016). In an abstract algebra context, students can use metaphors for operation-preserving in ways that conflict institutional meanings (Rupnow & Randazzo, 2024b), experience conflict when translating a line in a proof to diagrams (Guajardo et al., 2021), and they can tear or erase parts of Cayley graphs when trying to create structure-preserving maps (Lajos, 2021). However, the interpretations that students attach to instructional language, and how they could be tuned towards appropriate interpretations in real-time, remains unclear. Melhuish et al. (2023) noted that "semiotic conflicts and resolutions are informed by contexts beyond the scope of our task-based interview study" and suggested that "additional research into the students' broader learning ecology" is needed (p. 515-516).

In research at the intersection of semiotics and embodiment in early algebra, "Gestures are highlighted as one of the ways in which mathematical cognition is embodied and they are elevated as a potentially important semiotic device in the teaching of mathematics" (Stylianou et al., 2024, p. 259). While attention to speech and inscriptions is prominent, the inclusion of a full range of embodiments (e.g., gesture, multi-body movements, etc.) and activities in which learners are free to collectively move in the classroom, is just beginning in abstract algebra settings (Gandell, 2024; Soto et al., 2024).

Such gaps along with findings on the semiotic affordances of gestures motivated this present work. We sought to devise and pilot an in-progress embodied instructional lesson for group theory topics (e.g., group properties, homomorphisms, quotient groups) to make students' interpretations for instructional language salient and to examine how students' and their instructor might leverage embodiments (e.g., gestures, multi-party enactments, verbiage,

diagrammatic inscriptions, materials such as necklaces, markers, etc.) to develop meanings and signs for abstract algebra concepts.

In this paper, we conduct *semiotic bundle analyses* (Arzarello & Robutti, 2010) on learners' evolving sign productions, that occurred during the embodied lesson. In addition, we explicate *semiotic games* (Arzarello et al., 2009) consisting of a sequence of intervention strategies that the instructor uses to tune and enrich students' meaning structures. Thus, we address the following two research questions.

1. In what ways do learners use embodied resources to construct meanings and signs related to algebraic concepts during multi-team embodied activity?
2. How does the instructor leverage embodiments in the classroom to tune and facilitate the enrichment of students' meanings and signs in real-time?

Embodiments Serving as Semiotic "Meaning-Making" Resources

We now turn to the literature to examine gestures (Alibali et al., 2019; Stylianou et al., 2024) and how other forms of embodiments (e.g., verbiage, inscriptions, whole body performances) (Nemirovsky & Ferrara, 2009) can be used by instructors and built into the classroom ecology to support meaning-making. Drawing from Vygotsky's (1978) work, Mariotti (2018) describes semiotic mediation as a "process" that "consists in the evolution from the emergence of personal meanings related to the accomplishment of a task and in the collective development/construction of shared signs related to both the artefact's use and the mathematics to be learnt." She highlights the instructor's role in integrating a variety of different tools into classroom lessons which engender different signs and personal meanings. One can also consider embodiments (Nemirovsky & Ferrara, 2009) as semiotic mediation tools (Alibali et al., 2019; Arzarello et al., 2009; Stylianou et al., 2024). From our review of the literature, we found that semiotic mediation via embodiments can be categorized into meaning-tuning and meaning-elaboration processes.

By *tuning processes*, we mean any *mediating* action that attempts to resolve a *semiotic-conflict* defined as, "any disparity or difference of interpretation between the meanings ascribed to an expression by two subjects (persons or institutions)" (Godino et al., 2007, p. 133) or any disparity among triadic signs for the same object (Duval, 2006). Alibali and Goldin-Meadow (1993) found that children who had evoked mismatches between spoken procedures and gestures, improved their performance after instructional interventions in which their incorrect interpretations were revoiced and pushed up against the meaning of the equal sign 'is the same as'. Thus, such mismatches should be viewed as a cue to the instructor that learners are at the "threshold of learning a concept" and that a learning opportunity is immediate (Alibali & Goldin-Meadow, 1993, p. 470).

By *semiotic elaboration*, we mean any mediating action in which a set of partial yet harmonious signs from subjects (persons or institutions) are preserved and pieced together rather than replaced. Alibali et al. (2019) describes cases in which instructors' regesture a learner's gesture and use speech to attach discipline specific language. In such cases, the instructor is using the learner's gesture as a semiotic resource to carry meaning associated with the gesture and attach it to disciplinary language. In addition, to the more prominent use of a gesture, speech, and inscriptions sets, multi-party formations/movements and material interactions can also serve as resources in the process of semiosis (Kelton et al., 2018; Kelton & Ma 2020). For instance, Kelton et al. (2018) found that families ambulatory movements of walking around a double torus together prompted verbiage from the children such as "Donut!" and a spatial sense for curves (p. 550). The natural embodied impulses of a child sliding, touching, feeling, and running freely without hesitation led to sense making moments that adult family members acting according to

proper normative rules (e.g., walking slowly and stopping to read exhibit signs) did not experience.

Theoretical Framework: Action Process Communication Space (APC)

The APC Space is a theoretical framework that brings together embodied cognition, communicative discourse, and semiotic meaning-making perspectives (Arzarello & Robutti, 2008). Drawing from an embodied perspective, this framework asserts that mathematical meanings stem from sensorimotor activity which is multimodal. Over time, metaphors which represent relational linkages between an abstract mathematical concept, such as adding, and physical activity, walking forward along a path, are created as new signs for already familiar concepts (Lakoff & Núñez, 2013). The communicative perspective emphasizes that becoming an "effective" communicator through mastery of written or speech "genres" (e.g., common patterns of communication) and their "meta-discursive rules" goes hand in hand with becoming an effective thinker (Sierpinska, 2005, p. 207-210). A semiotic perspective (Duval, 2017; Peirce 1931), emphasizes that meaning-making occurs in the process of creating a sign. Meaning is developed by and revealed through interpreting agents and their interactions as they modify previous signs to create new ones. The semiotic bundle is a "living" construct and analysis tool that integrates the three aforementioned approaches to mathematics education.

Semiotic Bundle and Semiotic Games

According to Peirce's triadic conception, a sign consists of the surface *representamen*, the *object* being signified, and the *interpretant* defined to be the underlying meaning structure attached to the *representamen-object*. *Representamens* are physical in that they can be observed through human senses. For any object, multiple signs can be produced, and each sign can be associated with multiple interpretants (Kehle & Lester, 2003, Figure 5.4, p. 103; Peirce 1931). *Semiotic system/register* refers to a set of signs, a set of rules for how to produce and transform signs, and relationships between signs and interpretive meanings (Arzarello & Robutti, 2010; Duval, 2017; Ernest, 2006). Signs can be transformed in at least two ways. A *treatment* refers to how a learner manipulates signs withing a single representational register, such as symbolic manipulations of an equation. A *conversion* is a mental mapping that converts *a sign* produced in an initial register to a *sign* for the same object in another target register. Additional *interpretants* may be afforded by converting across or *coordinating* various registers simultaneously (Duval, 2006; Sandoval & Possani, 2016). Meaning-making activities can also involve metacognition in which a previous interpretant, sign, object that has been consolidated, is then taken as the object of study for which a new sign and interpretant is produced (Kehle & Lester, 2003).

A *semiotic bundle* (Arzarello et al., 2009; Arzarello & Robutti, 2010) is defined as a complex adaptive structure that consists of all triadic signs produced by individual and collective bodies of meaning-makers, transformations of signs within and across production modalities (e.g., inscription, gestures, verbiage, etc.), and their relationships both temporal (e.g., co-occurrence of gesture and verbiage) and semantic. The semiotic bundle can provide information to the instructor regarding a peak learning opportunity and offers visibility into students' multimodal resources as they become available (Arzarello et al., 2009; Arzarello & Robutti, 2010; Vygotsky, 1978). In a semiotic game, students take a move by creating signs (e.g., representamen, object, and interpretant) and instructors take a move acting as mediators between student generated signs and institutional or classroom communal signs. Mariotti (2018) describes cases in which physical artefacts are used by an instructor as *semiotic mediation tools* to bridge semantic gaps between personal and communal signs. Similarly in thinking about the role of embodiment, we

seek to understand how students' embodiments performed during multi-team enactments can be used as a mediating tool in an abstract algebra classroom.

Participants and Settings

The researcher (second author) and teacher-researcher (first author) unpacked loaded instructional language to inform the design of an embodied unit consisting of four lesson days. We reflected on past teaching experiences, training in group theory, and the literature. We asked ourselves: what semiotic ingredients or resources could be leveraged to generate and tune meanings attached to metaphorical and formal language? We began to theorize possible viable paths that learners could take to develop personal meanings and signs. During Day 1 students were asked to enact a directed Cayley graph and were asked to consider how this representation encoded algebraic structures (e.g., closure, commutativity, connectivity). Tasks for Day 2 were designed to support students in embodying properties of elements within groups and embodying homomorphisms across groups. The students worked in three teams, associated with the groups D_4, $Z_4 \times Z_2$, and with mappings/homomorphisms. The eight students in each of the D_4 and $Z_4 \times Z_2$ groups were asked to develop an enactment for binary operations within these groups. Then the students were asked to consider how their embodied representation encoded algebraic structures (e.g., identity, inverses, associativity). Meanwhile, the mapping team was asked to develop a plan for testing if a candidate mapping was a homomorphism and lead the full-class congress in analyzing their potential homomorphisms.

Methodology

We audio-video recorded a total of four classroom periods that comprised the multi-team embodied unit as well as debriefing sessions. We prepared the audio-video classroom data that included agents, verbiage, gestures, inscriptions, glances (Arzarello et al., 2009; Sabena, 2008) collective body configurations and multi-party enactments (Nemirovsky & Ferrara, 2009; Kelton et al., 2018; Kelton & Ma, 2020) other socio-material interactions (e.g., with markers, Cayley table handouts, necklaces, and technology), whole body formations/movements and eye gaze (Soto et al., 2024). Agents included individual students moving as separate entities, pairs of students, and groups of students moving together as a single entity. We conducted two semiotic analyses, *synchronic* and *diachronic* (Arzarello et al., 2009).

We began the *synchronic analysis* by looking across modes of language production invoked simultaneously (e.g., verbiage, gesture, inscription, whole body movement, etc.). A column was added to code each time-stamp as either containing or not containing a semiotic conflict. Semiotic conflicts resulting from a mismatch in triadic sign components were highlighted by both the instructor and instructor-researcher. We discussed moments coded as conflict until we came to an agreement and provided a column in the coding book to take additional notes on the mediation strategies "games" and embodiments that the instructor invoked in anticipation or in response to semiotic conflicts. Following the synchronic analysis, we considered meaning-making across time and conducted a diachronic analysis.

During *the diachronic analysis* "the evolution of signs activated by the subjects in successive moments" is examined (Arzarello et al., 2009, p. 100). We kept track of any salient semiotic elaboration strategies that occurred across time such as representational *conversions*, *coordination* (Duval, 2006; 2017) defined as the linking-up of signs across time, and *embedding* (Kehle & Lester, 2003), in which the bundle at a previous time-stamp was taken as an object of study for which new *interpretants* and *representamens* are produced. We noted the time-span stamp and a description of the elaboration strategy towards enriched interpretations and signs.

Results: Day 2 Congress and Semiotic Games that Ensued

We focus our results to whole-class discussions during Day 2 [49:36.000-1:15:51.093] for this short paper. The instructor used the term "Congress" to refer to these discussion periods because these full-class discussions allowed the group to act like a legislative body that evaluates the evidence for claims and decides collectively if they are accepted. The instructor encouraged the sets of students to share their ideas and representations with a focus on the moments of friction in their work. To make progress on research question 1, we provide evidence of students' meaning-making through embodiments. To address part of research question 2, we present selected vignettes for "semiotic games" that clarify the instructor's tuning and elaboration interventions. For each vignette, we present findings on a) how the instructor engineered or responded to semiotic conflicts, b) embodiments that agents utilized as tools to tune or elaborate meanings, and c) the effects of such interventions on the living bundle.

Vignette 1 [49:36.000-54:06.520]: Engineered conflict between personal and institutional interpretants of homomorphism definition

This vignette showcases how the instructor leveraged the mapping team's inscriptions for injective mappings from D_4 to $Z_4 \times Z_2$ and embodied enactions to engineer and bring attention to a conflict between personal and institutional interpretations for a homomorphism. Namely that, it is necessary to check that a pair of elements satisfies the inscribed property equation, but it is not sufficient. The instructor opened congress with "Alright, I think we're ready to start acting. Are we ready to start commanding teams [wiggles fingers towards mapping team]. Cierra began brewing the engineered conflict as she led her classmates to physically act out the homomorphism property for a pair that would work. Mapping first and combining first led to the same embodied result, Taylor received the marker. Following this, Cierra exclaimed "It works and why is that?!" Seth grins and Cierra remarked, "That's because rotations are commutative!" The class collectively cheered "Yaaaaaaay!"

Next, Nico led the class to test the homomorphism property for a different pair, which the mapping team had planned and knew would fail the test. The choice of two rotations again is a counter to the "commutative" conflict. Nico began by pointing at the symbolic inscription of the homomorphism property on the board to direct classmates to **combine first then map**. He stated, "okay so the first group we're going to do R-ninety acting on R-ninety" and the instructor rephrased using the language "R-ninety with R-ninety". Four different signs emerged for this **combining first** computation. First, Max verbalized "double". Second, Sean gestured [makes fist with hands, half-circular motion, bumps left fist on top of right fist, and points to classmate]. Third, Nico gestured [points to domain bubble in puddle diagram inscription]. Fourth, Jez stacked two markers and handed the stack to Jacob. This fourth sign has the potential to carry the meaning that binary operations are mappings in themselves.

After combining signs were created, additional signs emerged for **mapping** R-180 to (1,0) which consisted of pointing gestures and maker passes. First, Cierra exclaimed "Jacob" [points to inscription (1,0) in range bubble]. Second, Nico followed with "and then R-180 is mapped to (0,1). Third, Jacob and Violet leveraged the previous two markers stacked sign invoked by X and chained it with a passing sign. Jacob, R-180, walked over to Violet [raises hands] playing the role of **(1,0)** and handed her the stacked markers which completed the combining first then mapping enaction. While nearing resolution of the engineered conflict a secondary conflict that the instructor had not anticipated occurred. The next vignette highlights the role of a collective body in mediating this unanticipated conflict.

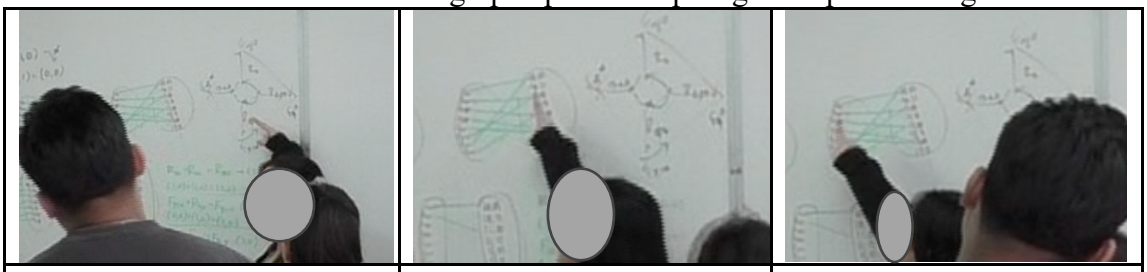
Vignette 2 [54:06.520-55:16.993]: Utilizing an explosion of embodiments to tune Julia's unanticipated conflict

Nico continued the semiotic game and directed his classmates to **map first then combine.** Nico said, "Cool. Now, we're going to **map first**". Vivian pulled the stacked markers apart clearing the previous material sign. Nick leveraged board inscriptions and stated, "we mapped R-90 [point to puddle diagram inscription on board] to (0,1)." Next, Julia R-90 attempted to make a conversion from Noah's verbiage-inscription representation to a collective body representation. Julia walked towards Noah playing the role of (0,1). She extended her arm out and handed the marker to Noah. The instructor intervened with explicit verbiage, "Julia you need both of them" referring to the markers which were needed to make the more involved conversion from Nick's verbiage "we're going to map first". Julia paused her enactions with the marker and Noah. She then turned towards the instructor and asked, "Oh because I map to myself?", clipped the two markers together and looked back to the instructor. It is at this moment that the unanticipated conflict in the form of a verbiage-classroom sign mismatch had occurred. Julia verbiage "map to myself" and the classroom sign for combining (clipping markers together) were at odds. At this point it became apparent that the meanings Julia had attached to classroom signs and instructional verbiage needed further tuning.

Immediately following this conflict, a reactive explosion of arm movements and verbiage occurred spontaneously [54:26.860-54.31.440]. The instructor remarked "No, not together you're mapping both". At the same time Cierra said "you just keep holding them separately" [grips both fists, extends arms out in front of her torso, and holds fists in air] (Fig 1, left-right). Sean straightened his bent elbows and extended his arms in parallel as if holding two markers (Fig. 1, left). The effects of collective efforts to mediate Julia's mismatch follow. Julia responded "Oh" [holds both markers side by side]. Next, she passed the left marker to Noah then passed the right marker to Noah (Fig. 1 left-middle). It is at this moment that Julia re-attempted the conversion by replacing her enacted representation with the intended target representation. Following this, June extended her pointer and middle finger in parallel. This could be evidence that June converted the previous **mapping first** signs into her fingers [54:33.300-54.34.930] (Fig. 1, right).

Figure 1. Explosion of embodiments linked temporally to mediate Julia's mismatch

Noah then enacted the classroom sign for **combine** [stacked both markers together] and passed them to Erica-**(0,0)**. Cierra exclaimed "It's not the same person! That didn't work". The instructor remarked "Didn't work? Yes, curses". The instructor explained that "no bijection between them could be a homomorphism, because then they would be isomorphic so then both would be abelian or both would be non-abelian so it's good that you found a counterexample".



Vignette 3 [55:16.910-55:45.767]: Utilizing gesture to self-tune verbiage and convert signs

In this vignette, we first showcase how a student utilized gesture to self-tune her own verbiage. Cierra walked to the board and opened her body towards her classmates to share a more "promising" mapping. She explained, "This one we thought was a little bit more promising

[points to directed graph on the board] because we have the [pauses with gaze on board] generators make two inner circ uh [traces outer circle with right index finger into the inner circle]. Following her tracing gesture, Cierra automatically restarted her verbiage "uh an inner circle and outer circle [pinches inner circle with between thumb and index finger] with her gaze still fixed on the board. She spoke, "then some partnerships" [traces right index finger up and down over line segment connecting outer and inner circle of inscribed D4 Cayley graph]. This evidence suggests that Cierra's tracing and pinching gesture provided a mediating function. Namely, an awareness that her verbiage was incorrect. Her gesture was enough to help her self-correct and re-start her verbiage given that her gaze remained fixed on the board.

Cierra also created a compounded sign by coordinating the verbiage "partnerships", which emerged during Cayley graph enactions on Day 1, and the line segment tracing gesture over diagrammatic representations. Cierra then mapped meaning from her compounded "partnership" sign into the puddle diagram as she explained, "So we thought that the partnerships" [repeats tracing gesture] "would be mapping to the same" [traces finger across map line, points to (0,0) inscription in puddle range, and traces finger backwards] "coordinate on the other side, if that makes sense" [traces finger back to (0,0) in domain puddle] (Figure 2). Upon further enacted testing the class concluded that the "promising" mapping also failed.

Figure 2. Student coordinated directed graph "partnership" sign and puddle diagram

Repeats line-segment tracing for partnerships	Points at (0,0) in range of puddle diagram	Traces backwards to domain

Discussion

A primary contribution of this work is that it identifies the semiotic functions of an entire classroom ecology, in real-time during instruction. A secondary contribution is that this work attends to a broad scope of embodiments, in addition to those (e.g., speech and inscriptions) that are typically used to teach and conduct semiotic studies in abstract algebra settings. In this embodied lesson on homomorphisms, students and their instructor used a full range of embodiments to engage in meaning-making processes such as mediating conflicts between signs, making conversions between initial and target representations, and coordinating signs. Vignette 2 highlights how a collective body can mediate conflicts between a student and classroom sign. That is, both instructors and students together can successfully take on the role of a tuning mediator. In Vignette 2, the use of mapping leaders directing conversions between board inscription and multi-team enactions served as tool for drawing out an unknown semiotic conflict. In Vignette 3, Cierra created a compounded sign for "partnerships" which emerged during Day 1 to hypothesize and test a more "promising" mapping. Thus, a sequence of multi-team embodied activities can facilitate the compounding of signs and their respective meanings giving rise to a richer more meaning dense bundle. Thus, additional work that investigates the semiotic potential of multi-team embodied instructional units in advanced undergraduate settings is warranted.

In the last 20 years, mathematics education research has taken a more critical lens (Gutiérrez, 2013), in which researchers focus on salient features of students' identities (e.g., race, ethnicity, gender) to analyze the structures within mathematics and schools to motivate change to power structures and systems that oppress such groups. In recent years, there has been a notable change in the types of submissions to the RUME community. This paper details a meta-analysis of the RUME proceedings from 2019 to 2024. Using 60 keywords related to racial identity, we sorted papers based on how they discussed race and its centrality in their work. A total of 33 papers were identified as directly engaging work that focuses on race. We draw conclusions of what may be missing in current research, and the ways we may more meaningfully engage in race-conscious research in mathematics education.

Keywords: Race, Ethnicity, Meta-Analysis

In 1995, Ladson Billings and Tate introduced Critical Race Theory (CRT) into the education field, beginning a new era of research of race in education. Tate (1995) engaged CRT within mathematics education through the development of culturally relevant pedagogy, offering an alternative pedagogy that is founded on that idea mathematics should "implement a pedagogy of social change" (p. 171). Contemporary scholars have integrated CRT within mathematics education research. Martin (2009) focused on race, (re)conceptualizing the goals of mathematics education for racially marginalized groups. Gutiérrez (2009) developed an equity framework which argues that equity is achieved along a Dominant axis and Critical axis, keeping at the forefront racially minoritized students. The Dominant axis represents access and achievement within an existing system (e.g., test scores, passing rates, economic success) for racially marginalized students. The Critical axis indicates that students' racial identities are acknowledged, and that students are empowered to become agents of change in a racially unjust mathematics system. Jett (2012) and Davis (2022) have called for mathematics educators to embrace the intersectionality of CRT and mathematics disciplinary knowledge to continue to advance racial justice in mathematics education. In response to the endemic nature of racism, scholars must continue the work of pushing for social justice within mathematics education.

In recent years, we have noticed that the topic of race has become more prevalent within RUME proceedings. Due to the increased interest in issues of diversity, equity, and inclusion (DEI), and because DEI has become a ubiquitous term to capture many different student populations, we wanted to focus specifically on race to capture how our research community engages with the topic, that is: How has the RUME community engaged with race within the paper submissions for the RUME conference from 2019 – 2024? We present here a meta-analysis of the last six years of RUME proceedings related to race. This meta-analysis is guided by two tenets of CRT: 1) the centrality and intersectionality of race and racism and 2) there must be a commitment to social justice within education (Solórzano, 1998).

Identifying Papers that Discuss Race or Ethnicity

Our research team collected six years of the RUME proceedings from 2019 to 2024. These proceedings included all finalized submissions that were labeled as contributed reports (seven pages), preliminary reports (five pages), theoretical reports (seven pages), and posters (one page). Data used for this paper included only contributed, preliminary, and theoretical reports. We excluded posters because, due to limitation of length, we could not easily discern the intention of some papers in the same way as we could for longer reports.

We utilized 60 keywords to search each set of proceedings. Keywords included words that related to (a) the topic of race (e.g., multiracial, ethnicity, of color), (b) specific racial groups (e.g., Asian, Black, Latin*), (c) minority-serving institutions (e.g., HSI, HBCU), and (d) phrases related to a critical theoretical lens (e.g., critical race theory, antiracist, whiteness). After a lengthy discussion, we did not include phrases that were not specific to race or ethnicity, such as social justice, marginalized, or equity. We came to this decision as we recognized that using phrases like this groups together many identity characteristics under one umbrella and does not distinguish the focus of the research. For example, a paper can claim that it focuses on equity, yet only specifically discusses gender disparities without mentioning the race or ethnicity of the participants or impact of findings on racial groups. Similarly, papers that focus on social justice could discuss themes related to global warming or broader human rights. Essentially, a paper needed to directly discuss race in some capacity to be captured by our keyword search.

After completing the search using the list of keywords, we identified 207 papers that had at least one mention of any of the words. The highest number of words found in one paper was 26 and the least number of words present was one. Table 1 shows the distribution of papers with keywords by year. The *N* values for each year reflect the number of contributed, preliminary, or theoretical reports that were present in the set of proceedings. Notice that the number of papers containing keywords increases over the timeframe, with the 2021 proceedings containing fewer papers due to the COVID-19 pandemic. We see that about a quarter of all six sets of proceedings analyzed here contained a keyword.

Table 1: Distribution of Papers that Contained Keywords by Focus of Race in the Paper

Year	**Papers with Keywords**		**Core**		**Peripheral**		**Unrelated**	
2019 (*N*=133)	21	(15.8%)	1	(0.8%)	16	(12%)	4	(3%)
2020 (*N*=148)	30	(20.3%)	4	(2.7%)	21	(14.2%)	5	(3.4%)
2021 (*N*=49)	12	(24.5%)	1	(2%)	9	(18.4%)	2	(4.1%)
2022 (*N*=145)	40	(27.6%)	12	(8.3%)	20	(13.8%)	8	(5.5%)
2023 (*N*=151)	47	(31.1%)	7	(4.6%)	35	(23.2%)	5	(3.3%)
2024 (*N*=154)	57	(37%)	8	(5.2%)	39	(25.3%)	10	(6.5%)
Total (*N*=780)	**207**	**(26.5%)**	**33**	**(4.2%)**	**140**	**(18.0%)**	**34**	**(4.4%)**

Once we compiled the list of papers that referenced at least one keyword, we began to determine the degree to which the paper focused on race or ethnicity. We adapted three codes to capture this: *Core*, *Peripheral*, or *Unrelated* (Boeck et al., 2024). A paper was considered *Core* if it meaningfully engaged with race. This meant that the paper had race as a focal component of the theoretical framing, data analysis, or findings. A paper was not considered *Core* if the paper engaged in quantitative analysis and only used race as a control variable. If we were not sure that

the paper meaningfully engaged with race, we then turned to counting the keywords such that if the keywords appeared throughout the paper, and at least one keyword appeared at least three times in the body of the paper, then the paper would be considered *Core*. A paper was considered *Peripheral* if the keywords were used to describe only demographic information, were used only once, had limited mention, or were secondary to a larger focus of the paper. A paper was considered *Unrelated* if the keyword was only present in the references, used in a list of protected categories, or used in a citation from another scholar.

Whenever a researcher could not determine if a paper was considered *Core* or *Peripheral*, it was labeled as *Ambiguous*. The research team met to discuss these papers and determine their category. We also struggled with how to determine studies that focused on language or multi-lingual learners, and whether language not only connected to culture, but also possibly to racial identity. We drew from LatCrit (Chávez-Moreno, 2024) to support the argument that differential treatment of multilingual students is the racialization of these students.

Table 1 shows the distribution of the focus of race by year across the papers. A total of 33 papers were identified as *Core*, representing 4.2% of all proceedings (N=780), and 15.9% of reports analyzed (N=207). 140 papers were identified as *Peripheral*, representing 18.0% of all proceedings (N=780), and 67.6% of reports analyzed (N=207) papers. This group was rather large due to the wide variety of purposes for using these keywords. On one hand, some papers only had a singular keyword to describe an institution or demographic of participant. On the other hand, we had papers that had race as a secondary focus of the paper.

After identifying *Core* papers, the research team categorized the papers using the following: (a) Population of interest (e.g., students, faculty, pre-service teachers), (b) Focus (e.g., curriculum, social interactions/instruction, student supports, beliefs/attitudes), (c) Mathematics course, (d) Theoretical Framing (e.g., critical race theory, positionality), (e) Methods (e.g., qualitative, quantitative, mixed methods), (f) Dominant or Critical focus (Gutiérrez, 2009). We selected these categories to highlight the density of key components of the research studies, with the goal to inform the RUME community of areas for continued study. *Population of Interest* and *Math Course* were categories to help understand which populations are the focus of this work. The *Focus* category highlights the topic of interest for the study. For example, *Social Interactions and Instruction* include classroom instruction or group work, where *Beliefs or Attitudes* represents work that attempts to measure or reshape people's beliefs about issues around race. To understand the nature of race-conscious studies, we coded *Theoretical Frameworks* to broadly understand how researchers framed their studies. We also captured the methods that authors used to analyze studies related to race. Finally, we adapted Gutiérrez's (2009) framework of equity along *Dominant* and *Critical* axes to account for specific dimensions studied within the papers.

Findings

We discuss key findings related to the papers that contained keywords. First, we will look at overall trends of keywords over time from 2019-2024. Then, we will discuss what we found related to the Core papers related to the categories listed in the previous section. Finally, because the Peripheral paper group covered a broad spectrum of engagement with race, we discuss the different types of papers based on keyword use.

Overall Trends

As illustrated by Figure 1, the proportion of papers including at least one keyword from our list has increased each year since 2019. Specifically, 37% of the reports in the 2024 proceedings

contained at least one keyword compared to the 15.8% seen in the 2019 proceedings. However, we note that this has occurred largely through an increase in Peripheral papers using keywords. From the figure, notice that the rate at which the proportion of Peripheral papers has increased—from 12.0% to 25.3% over six years—surpasses the rate at which the proportion of Core papers has increased—from 0.8% to 5.2% over six years. This suggests that the RUME community has incorporated race more frequently into its reports, but in a way that more often accounts for demographics than providing a focused and substantive discussion of race. The 2022 proceedings had the highest proportion of Core papers seen across the six years (8.3%), about 11 times greater than the lowest proportion seen in 2019 (0.8%). The 2024 proceedings had the highest proportion of Peripheral papers (25.3%) which was about double the lowest proportion (12.03%) seen in 2019. That is, the relative increase between the highest and lowest proportions of Core papers was notably larger than that seen in the Peripheral papers.

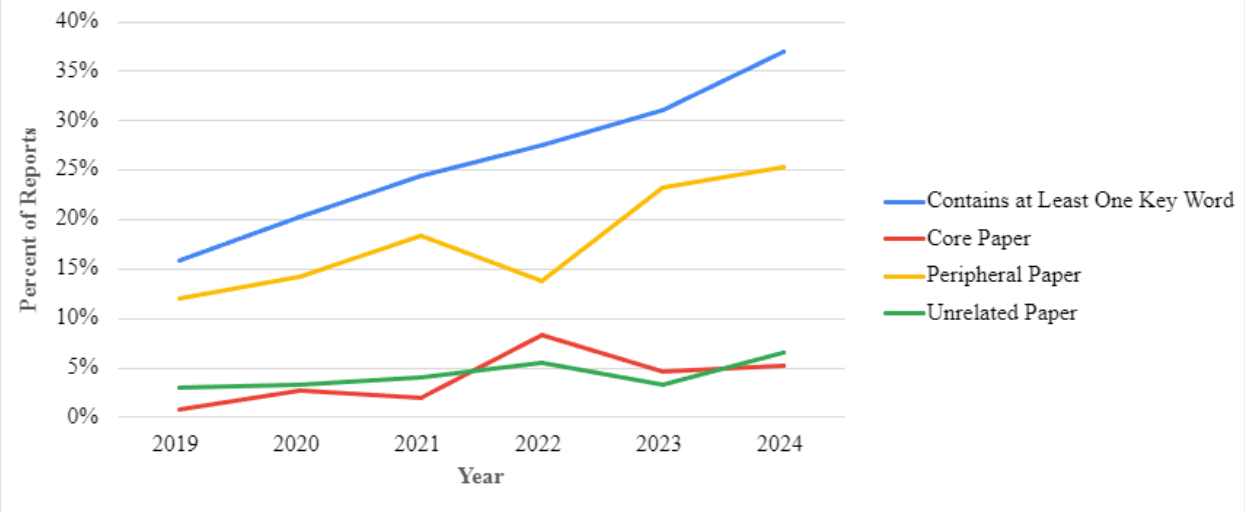

Figure 1: Line Graph of Papers Including Keywords by Focus on Race

Keywords varied by paper type, with some common keywords showing up as the most frequent among Core and Peripheral papers. Table 2 shows the top five most frequent keywords for Core and Peripheral papers. For the Core papers, seven total keywords represented the top five most frequently used; the words *race* and *racial* were present in 81.8% of papers each while *Hispanic* and *White* were present in 66.6% of papers each. You will notice that there are some common words, such as *White*, *Hispanic*, and *Black*, and that these words appeared at different frequencies. For example, in the Core papers, *Black* was the most frequently used keyword, whereas in the Peripheral papers, *White* was the most frequently used keyword. When considering the same keywords, 84.9% of Core papers used the keyword *Black* whereas only 29.8% of Peripheral papers used the same keyword. Notice that the most used keyword for the Peripheral papers is still less used than the fifth grouping of the Core papers. It is expected that the frequencies would be higher in a Core paper given our list of keywords and our selection criteria for how a paper was labeled as Core. It is interesting to note that the Core papers utilize more keywords related to the topic of race (e.g., race, racial, racialized, and of color). In fact, we found that keywords one could identify as more aligned with critical work were more highly captured in Core papers. These words include *racialized* (C: 63.6%; P: 8.51%), *racism* (C: 48.8%; P: 5.67%), *Critical Race Theory* (C: 39.4%; P: 2.84%), *racist* (C: 24.2%; P: 1.42%), and *Whiteness* (C: 21.2%; P: 2.1%), where these percentages represent relative frequency (N=33 Core, N=140 Peripheral).

Table 2: Top Five Most Frequent Words Found in Core and Peripheral Papers.

Core		**Peripheral**	
Keyword	% of Papers with Keyword	Keyword	% of Papers with Keyword
Black	84.9%	White	49.7%
Race	81.8%	Race	32.6%
Racial		Hispanic	31.9%
Of color	72.7%	Ethnic	30.5%
Hispanic	66.7%	Black	29.8%
White			
Racialized	63.6%		

Core Papers

The Core papers differed in their chosen focus. We found that 13 of the papers (39.4%) focused on the social interactions occurring in classrooms and other spaces; 13 papers (39.4%) primarily focused on the beliefs and attitudes of students and/or instructors. One paper (3.0%) focused on curriculum, two papers (6.1%) focused on student supports, and the remaining four papers looked at other issues including assessments and institutional change. Regarding population of interest, 20 Core papers (60.6%) were centered on students while 13 papers (39.4%) focused on instructors; one of these papers focused on both students and instructors. Most instructor-centered papers (64.6%) looked at beliefs/attitudes while the majority of student-centered papers (65%) investigated issues on social interactions such as instruction.

We found that 22 Core papers (66.7%) included research studies designed around a particular math course or set of courses. These 22 papers were primarily concerned with lower-division mathematics, with 13 papers (59.0%) focused on any level of Calculus and 6 papers (27.3%) focused on Precalculus. Only 3 papers (13.6%) were conducted in upper division mathematics courses, namely Abstract Algebra (2 papers) and Introduction to Proofs (1 paper).

Table 2 shows the theoretical framing found in the Core papers. 29 of the 33 Core papers (87.9%) structured their research around a theoretical framework, whereas four papers did not clearly state a theoretical framework. We found that eight papers (24.2%) utilized critical or

Table 2: Distribution of Core papers by Theoretical Framing Categories

Categories	**Example(s)**	**Frequency**
Critical and Cultural Theories	Critical Race Theory, Culturally Relevant Pedagogy, QuantCrit, LatCrit, Community Cultural Wealth	8
Identity	Emerging Mathematical and Racial Identity	6
N/A	No theoretical framing was explicitly stated	4
Other	Theory of Practical Rationality, Servingness	4
Intersectionality	Crenshaw (1991)	3
Institutional	White Institutional Space, DEI Institutional Activism	3
Sociopolitical	Sociopolitical Perspective, Social Capital Theory	3
Microaggressions	Mathematical, Racial, Gendered	2
Equity	Gutiérrez (2009) Four Dimensions of Equity	2

cultural theories (e.g., Critical Race Theory, Culturally Relevant Pedagogy, QuantCrit). The remaining papers implemented a variety of theoretical framings, which can be seen in Table 3.

Twenty-five (75.8%) of the 33 Core papers were coded as using qualitative methods, six (18.2%) used quantitative methods, and one (3.0%) was mixed methods. Twenty-three (69.7%) of the Core papers addressed race in ways characteristic of the Critical axis in Gutiérrez's (2009) framework while 10 (30.3%) papers addressed race in ways characteristic of the Dominant axis, indicating that more papers focused on issues of identity and power, rather than access and achievement. Only one quantitative paper was categorized as critical, where five studies showed characteristics of the Dominant axis. The five papers were coded as dominant because they measured levels of participation/access, graduation rates, and grades which are variables of achievement. The critical quantitative paper drew connections between intersections of students' identities (e.g., race, math) and instructional practices.

Peripheral Papers

Because the Peripheral category was so large, we noticed that there was a broad range of ways that papers focused on race. Table 3 shows the distribution of the focus of race across the Peripheral papers, listed from least to most significant. Notice that most of the Peripheral papers (58.6%) only discussed race/ethnicity in relation to the demographics of the institution, participants, or researchers—a required component of RUME proposals. We do want to note that the highest level, Secondary Focus, contains papers that were on the verge of being labeled Core papers, but because the papers had race as a secondary focus or did not clearly specify race as a focus, they were not grouped as Core.

Table 3: Distribution of Peripheral Papers by Focus of Race in the Paper (N=140)

Focus of Race	Definition	Frequency
Singular Mention	The paper had one or more keywords mentioned in one line of the paper	18 (12.9%)
Demographics	Race/ethnicity only appeared in the demographics of the institution, participants, or researchers	82 (58.6%)
Limited Mention	Mentions of race/ethnicity only appeared in the background, motivation, or future work section	25 (17.9%)
Secondary Focus	Race/ethnicity appeared throughout the paper but was not the central focus	15 (10.7%)

Discussion

The goal of this study was to provide a snapshot of the trends in the race-conscious research in the RUME community. A notable finding was the combination of population of interest and study focus. When the study investigated instructors, it was overwhelmingly to investigate their beliefs and attitudes of a racial topic. While it is important to focus on faculty beliefs and attitudes because beliefs and attitudes impact teaching practices in racialized ways (Park et al., 2024), it has also been shown that an instructors' beliefs may not immediately impact practice in the way one would expect, even if their beliefs align with best practice (Thompson, 1984). Future work could investigate instructors' teaching or assessment practices. When the studies investigated students, the focus was more on classroom instruction, group work, or other ways that we interact within learning. While these are very important areas to research, we suggest also looking into other structures in education, such as placement, course progressions, or

assessment. Other research foci in this analysis were clearly underrepresented within the Core studies. We argue that the learning process is complex and racial bias could manifest itself in localities other than social interactions and teachers' beliefs.

The student populations that were most sampled were students in lower-division courses. Most studies focused on gateway math courses, with a specific emphasis on precalculus and calculus courses. This focus on lower-division STEM mathematics courses is likely due to growing concerns about the retention of underrepresented students in STEM and introductory mathematics classes as gatekeepers in higher education (Brainard & Carlin, 1998; Bressoud, 2014; NASEM, 2016; PCAST 2012). We argue that more work should be done to include other course types. Courses like developmental mathematics, trigonometry, and college algebra also merit attention, as they have been noted as segments of the "leaky pipeline" (Larnell, 2016). Black and Brown students are placed into developmental mathematics courses at higher rates than their peers (Bahr, 2010). While developmental mathematics has been eliminated in states such as California, introductory courses have been replaced with co-requisite models that serve the same group of students (Hernandez & Cawley, 2022), and co-requisite courses merit similar attention to racial inequities. We also notice that upper-division math students are absent from race-conscious studies in the proceedings. We contend that alienation, marginalization, and attrition do not stop once racially minoritized students start taking proof-based courses.

We recognized a substantial divide between the language and terms being used within Core and Peripheral papers. In particular, the use of terms more aligned with critical work like *racist* and *whiteness* point to a substantial critique of norms and structures within mathematics education. While the overall number of studies using keywords increased over time, most of these words appeared more often in Peripheral papers. Through our investigation of Peripheral papers, the increased use of keywords seems to point to an overall increase of including participant or institutional demographic information without engaging with how the demographics inform the research topic at hand. We are unsure if this increase is due to the RUME conference call for submissions requesting that participant/institutional demographic information be included; if so, then the growing number of Peripheral papers indicates some success of this request in motivating contributors to directly name race in their work. However, our analysis here reveals the potential for the RUME community to engage in more substantive engagement with race.

We were inspired to see that a majority of Core papers engaged in research that supported identity and power (Critical axis). Unsurprisingly, we found that qualitative methods were more prominent than quantitative methods among the Critical papers in the Core category, and that quantitative papers focused mainly on issues of access and achievement (Dominant axis). While a focus on access and achievement is still important for racial equity, an overabundance of papers that measure achievement–usually a lack of achievement among racially marginalized students–can lead to a limited view of equity and a deficit view of students. Critical race scholars have argued that quantitative tools can serve social justice purposes when the questions reframe issues to highlight injustice rather than a deficit of students (Crawford et al., 2019).

In all, we found that the RUME community is making great strides to increase focus and awareness of how race exists and is experienced within post-secondary mathematics education. The findings of this meta-analysis identify where we can continue to develop our research such that we contribute more critical work that focuses on issues of race—both in ways that are obvious and others that are more historically engrained within education.

At the Crossroads of Inquiry and Equity: Synergies and Tensions in Instructor Decision-Making

Grace Morrell
Texas State University

Cody Patterson
Texas State University

Although some contemporary definitions of inquiry learning in college mathematics include instructor attention to equity as a core precept, evidence suggests the practice of inquiry-based instruction in proof-based undergraduate mathematics courses entails many decisions whose implications for inquiry and implications for equity and access may not be mutually reinforcing. We present the results of our analysis of over 40 design and facilitation decisions made by the second author as he taught an undergraduate-level number theory course for high school students in a summer residential mathematics program. In our analysis we identify some categories of instructional decisions that have both inquiry and equity implications. We also discuss in detail a scenario in which the instructor was able to choose a course of action that simultaneously supported inquiry and equity goals of the class, and one in which the goals of inquiry and equity appeared to be in tension.

Keywords: Inquiry, Equity, Instructional Practices, Proof-Based Mathematics

In 2019, Laursen and Rasmussen defined a set of four "pillars" for *inquiry-based mathematics education* (IBME). Of these, the fourth pillar called for instructors to "foster equity in their design and facilitation choices" (p. 138). However, Laursen and Rasmussen acknowledged that it was not yet known how the other pillars of inquiry – student engagement with rich mathematical tasks, collaborative discovery and discussion of mathematical ideas, instructor inquiry into student thinking – might best be brought into alignment with equity goals in college mathematics teaching. Indeed, several contemporaneous studies (Andrews-Larson et al., 2018; Johnson et al., 2020) have suggested, at a minimum, that an inquiry-based instructional approach is not a guarantor of equitable outcomes in conceptual learning or in public ownership of mathematical ideas. This raises a broad question: what are the mechanisms by which inquiry-based instruction supports or hinders equitable outcomes in student learning and mathematics identity development? In this report, we broach a narrower question: how does the relationship between inquiry goals and equity goals appear through the eyes of an instructor with an explicit commitment to both?

We argue that this question has significance for addressing Laursen and Rasmussen's (2019) call for equity research in IBME. Research has begun to explore theoretical perspectives that, if translated into practice and college mathematics instructor professional development, can help instructors set the stage for students' mathematical inquiry and take an asset-based approach in interpreting and responding to student thinking (Adiredja & Zandieh, 2020; Ellis, 2022; Louie et al., 2021). However, teaching in ways that center student inquiry while attending to access and opportunity for all students still presents some technical challenges for instructors. For example, stereotypes about traditionally marginalized groups may emerge in group discussion in ways in which they might not occur in whole-class discussion (Ernest et al., 2019). The skills that might help an instructor address such threats to the status and participation of minoritized students (Cohen & Lotan, 2014) are not the same as the skills required for delivering smooth, technically competent lecture-based instruction. Additionally, the process of orchestrating discussion of students' mathematical thinking, and weaving this thinking into a shared narrative that addresses the mathematical goals of a lesson, raises questions that have both inquiry and equity

implications: Whose thinking gets shared, and in what order? How to address thinking that contains reasoning errors, or that is logically sound but not communicated with the targeted level of formality or generality? How can we help students make sense of and appreciate their peers' thinking without immediately shifting to an evaluative frame of mind?

In this paper, we report on a retrospective analysis of the second author's teaching of an advanced undergraduate-level number theory course in a summer mathematics program. In this analysis we seek to address the research question: *In what ways do goals of student mathematical inquiry and equitable learning intersect in an instructor's design and facilitation decisions when teaching a proof-based undergraduate-level mathematics course?* We anticipate that findings from this analysis may inform the design of future studies of how instructors simultaneously address goals of inquiry and equity in proof-based mathematics courses and suggest possible ways for professional development to prepare instructors to manage classroom situations and decision points that have implications for both inquiry and equity.

Inquiry and Equity in The Context of Undergraduate Mathematics

To discuss synergies and tensions between inquiry-promoting teaching practices and equity-promoting teaching practices, we need to establish what we mean by both. The following sections review existing literature regarding inquiry and equity as constructs and conclude with definitions of each which we use to classify the teaching moments analyzed later in this paper.

Inquiry

There are two predominant characterizations of inquiry-centered instruction in the contemporary literature in the U.S., Inquiry Oriented Instruction (IOI) and Inquiry Based Learning (IBL). The two share many characteristics and philosophies (Kuster et al., 2018), but differ in some of their nuance and origins. Both offer valuable contributions to our conceptualization of inquiry. The tradition of IOI is deeply rooted in Realistic Mathematics Education (RME) (Freudenthal, 2005). Lockwood and Purdy elaborate on their use of RME, "Ultimately, a goal of leveraging guided reinvention (and RME more generally) is to infuse mathematics with meaning for students" (Lockwood & Purdy, 2019, p.227) illustrating that creating powerful and meaningful mathematical experiences is central to IOI.

On the other hand, IBL was borne out of work done by practitioners rather than from educational theory (Laursen & Rasmussen, 2019). Hence, IBL courses center student ideas as the main content of the course. In an IBL class, "Following a carefully designed sequence of tasks rather than a textbook, students construct, analyze, and critique mathematical arguments. Their ideas and explanations define and drive progress through the curriculum." (Laursen et al., 2014, p. 407). Both this aspect of IBL and IOI's emphasis on constructing mathematical meaning were central to both the large-scale design and day-to-day pedagogy of the number theory class.

Laursen and Rasmussen characterize IBME, a term meant to encompass both IOI and IBL, as a branch of active learning, where students do things, think about what they are doing, and talk to others about what they are thinking and doing (Laursen & Rasmussen, 2019). This take on inquiry positions students as practitioners of mathematics, something that Artigue and Blomhøj also do in their description of inquiry-based pedagogy. Artigue and Blomhøj say that inquiry-based mathematics education (IBME) "aims to offer students the opportunity to experience how mathematical knowledge can meaningfully develop." (Artigue & Blomhøj, 2013), which, like IOI, places meaningful mathematics at the center of inquiry.

Artigue and Blomhøj claim that Inquiry Based Education (IBE) historically aims to support "emancipation and democracy" (p.808) and use their analysis of IBME to set forth "ten

concerns", the last of which is "the critical and democratic dimensions of IBME" (p.809). We thus imagine that these authors might align with Laursen and Rasmussen's equity pillar for inquiry, though possibly for different reasons. Laursen and Rasmussen support their claim with seven "Equitable Teaching Practices" identified by Boaler in 2006, which they recognize as overlapping with the other three pillars. Hence, they suggest that equitable instructional practices are an essential fourth pillar of IBME. On the other hand, Artigue and Blomhøj examine the origins of inquiry, specifically the research and philosophies of Johnathan Dewey, who was a proponent of education as a tool to support democracy by producing students with both technical knowledge, but everyday skills (Dewey, 1916). To better illustrate this as an aspect of equity, we now turn to a brief review of literature in this area.

Equity

Gutiérrez (2011) characterized equity in mathematics as having two axes: the dominant and the critical. She describes dominant mathematics as, "the components students will need to be able to show mastery of in the discipline as it is currently defined and to participate economically in society." (Gutiérrez, 2011). Meanwhile, the critical axis "builds upon the idea that mathematics is a human practice that reflects the agenda, priorities and framings that participants bring to it." (p. 21). She associates the dominant axis with Access and Achievement, and the critical axis with Identity and Power, and argues that students ought to gain both dominant and critical mathematics identities. In the conceptualization of equity we adopt for the purposes of our analysis, we focus on the identity dimension of the critical axis.

Rubel (2017) identifies specific equity-directed instructional practices, two which she claims fall on the dominant axis and two on the critical. These teaching practices are: teaching for understanding, connecting mathematics content to students' experiences, fostering multidimensional participation, and connecting mathematics content to students experiences. Rubel uses these instructional practices to study teacher professional growth, and proposes that, "Indeed the practices on the dominant axis are practices that lend themselves to daily instruction, whereas the critical practices arguably could be seen as practices that teachers engage with less regularly" (p. 91) Therefore, when we later identify teaching practices and classify the extent to which they promote equitable learning experiences, we keep in mind that Access and Achievement may be more common than Identity and Power.

Our Definitions

We define inquiry-promoting teaching practices to be those which make the primary mathematical ideas of a class legitimately stem from the flow of students' thinking, thus making the content and progression of the course meaningful for the students. We define equity-promoting teaching practices to be those which give all students the opportunity to see themselves as central participants within the community and legitimate doers of mathematics.

Context And Method of Inquiry

The following analysis is based on teaching decisions made during a course on number theory taught at an informal summer mathematics program for high school students. In the program, students learn to prove foundational theorems in elementary number theory; the course is approximately equivalent to a semester-long advanced undergraduate course. The class was comprised of 36 students, all rising tenth or eleventh graders. The class met for an hour and fifteen minutes on Monday through Friday for six weeks. In addition to the class meetings, students also attended daily hour-long problem sessions with eight to twelve students facilitated

by undergraduate student mentors. The problem sessions reviewed major proofs from class and addressed students' questions about the material. The students also participated in nightly four-hour study sessions in groups of four, each led by a mentor. During these sessions, students worked on problem sets designed to foreshadow ideas in future lessons and build intuition behind major concepts in the course.

The class was taught by the second author and observed by the first. During the six weeks, both authors kept journals detailing events in class and instructional decisions made by the second author including small, in-the-moment interactions as well as larger pre-planned curricular design decisions. After the completion of the program, we used our journals to compile a list of over 40 instructional and design decisions. Separately, we utilized open coding to identify themes across the decisions then compared our codes. Ultimately, we identified six categories of decisions. We discussed possible implications of each decision for inquiry and for equity, as defined in the preceding section. We selected several decisions that we identified as having both inquiry and equity implications and performed an in-depth retrospective analysis of each. We present two of these cases below.

Analysis

In this section we provide an in-depth look at our thinking on two specific cases that illustrate distinct ways in which inquiry and equity goals can interact. We also present the six categories identified from our list of instructional decisions.

Illustrative Case 1: Building an Activity From Student Work

In the second week of the number theory course, students proved the theorem that if a divides bc and a and b are relatively prime, then a divides c. Students were asked to complete this proof in small groups during their nightly study session. The following day after class, one group presented their proof to the second author. Their approach was one that to our knowledge no students in the program had devised previously; however, there was a gap in their argument. Recognizing this gap, but seeing a way for the group to complete the proof, the second author decided that the afternoon's problem session should focus the attention of each group on completing the proof. That afternoon, mentors presented the incomplete proof and gave credit to the original authors, highlighting their creativity. The students were not told what the gap in the argument was, rather they were asked to identify a gap and attempt to fix it.

As a result of this decision, the proof became a central idea in the students' mathematical work that day. The instructor later attested to having chosen this course of action because it offered the group that authored the proof greater ownership of the class's mathematical ideas – a cornerstone of inquiry. Furthermore, the four students who originally brought forth the proof had not yet received public recognition of their ideas in class, particularly the female students who had had relatively few opportunities to share ideas publicly in class. Making the group's inventive proof an object of inquiry for the class highlighted these four students' ingenuity and the value of their ideas, consistent with our conceptualization of equity.

The instructor could have addressed these students' contribution in different ways. For example, he could have chosen to present an activity in problem session in which part of a more typical proof was given, and students were asked to critique or complete it. In this case, the students would still have had the opportunity to engage with a proof, look for gaps, and attempt to complete the argument. However, this would have focused more of the students' work on an artifact of mathematical thinking external to the class, rather than their classmates' own thinking, and would not have done as much to highlight the mathematical work of students who had not

received much prior recognition in class. In this sense the instructor had a choice available to him – using the group's proof – that advanced both his inquiry goals and his equity goals simultaneously. Thus we see this decision as an example of synergy between the two constructs, with the whole greater than the sum of the parts: greater inquiry-related goals were achieved by attending to equity, and vice versa.

Illustrative Case 2: Selecting a Class Activity on Quadratic Reciprocity

The number theory course culminated with an exploration of Gauss' law of quadratic reciprocity, which establishes a surprising relationship between the question of whether p is a perfect square modulo q and that of whether q is a perfect square modulo p, where p and q are distinct odd primes. The second author knew that the proof of this theorem is notoriously difficult for students to understand, so he wanted to provide multiple opportunities for students to engage with the ideas of the proof and try proving some of the foundational lemmas before seeing a full proof of the theorem in class.

This created a quandary for the instructor, especially given that this exploration took place during the last two days of the course: any class activity would need to run efficiently to allow sufficient time for the instructor to complete the proof of the theorem during class. He considered two possible in-class activities: either (1) have students get into groups and write up proofs of some of the lemmas that had been assigned for the previous nights' study sessions, or (2) have students do an exploratory activity in which they divide multiples of p by q, record quotients and remainders, and notice a relationship between the quotients and the remainders that serves as a foundation for one of the lemmas. Of these two options – we do not claim that there might not have been other possible options available – the instructor considered (1) more supportive of the inquiry goals of the course, because this activity would give more students the opportunity to anticipate more of the reasoning of the proof of quadratic reciprocity. On the other hand, he considered (2) more supportive of equity goals: he knew that only a few students had worked in prior study sessions on the lemmas he would assign in class, and he observed that many students were struggling with the level of abstraction of the parts of the argument the class had developed so far. In option (2) he saw an opportunity to roll some of this abstraction back and have students engage in a data collection activity (performing calculations for different pairs of primes p and q) that would generate strong evidence of a relationship that would later prove instrumental in the proof. While the reasoning available to students in this activity would not be the same quality as in option (1), the instructor knew that option (2) would be accessible to most students in class and would provide more concrete reference points for the reasoning in the proof.

We view this as an instance in which the instructor faced a decision in which he had to choose whether to prioritize maximizing opportunities for student inquiry or prioritize maximizing students' access to the proof he would ultimately present at the end of the course. This is not to say that inquiry and equity are inherently in tension with each other: this binary choice was forced by a number of factors, including the limited time remaining, missed opportunities to better engage all students in thinking about the lemmas during preceding study sessions, and the instructor's sense that completing the proof of the theorem was a non-negotiable requirement of any course of action. However, subject to local constraints, the instructor was forced to choose, in a certain sense, between inquiry goals and equity goals.

Categories of Decisions

Based on our compiled list of instructional decisions, we identified six categories of decisions that may have bearing on the inquiry culture of a class, equitable learning opportunities, or both: *defining class culture*, *exposition of content*, *facilitation structures*, *tasks and activities*, *eliciting and selecting student thinking*, and *responding to student thinking*. Given that our list is based on observations of one instructor and filtered in part by that instructor's perspective on his own practice, we do not anticipate that this list is complete. However, each instructional decision we identified fits well into at least one of these categories; some decisions fit into multiple categories. We speculate there may be categories of decisions that are overall more likely to create synergy for inquiry and equity, while other categories might generate more instances of tension, or a need to prioritize, between the two.

Discussion and Implications

We wish to acknowledge some limitations of this analysis. By taking the second author's teaching as an object of inquiry, we are able to account for insights, values, and obligations behind instructor decisions in ways that can be difficult to match in studies in which the instructors are third parties. However, the second author's perspectives on inquiry and equity are likely not perfectly representative of those of the inquiry teaching community or the wider community of undergraduate mathematics instructors. To build upon our preliminary results, a study with more instructors, in which researchers regularly check in with instructors for insight about key decisions while instructors' memories of those decisions are still fresh, would likely generate a more representative body of evidence of how instructors weigh inquiry and equity considerations in teaching.

Additionally, we acknowledge that what we identify as a tension between inquiry and equity may not be a tension if viewed from a different perspective, or with a more comprehensive set of design and facilitation options. We have both found anecdotally that as we gain more experience in inquiry-based teaching, we gain tools that help us renegotiate false choices (*e.g.*, between inquiry and content coverage) and false dichotomies. Therefore, we do not present any of the analysis in this paper as proof of any inherent incompatibility between inquiry and equity as guiding perspectives for college mathematics instruction. Rather, we present the experience of the second author as evidence that college mathematics instructors, even if experienced with both inquiry and equity, might at times perceive a tension between the two. If such a tension is perceived, then it is reasonable to infer that it could at times influence decision-making.

Based on our analysis, we see that instructional decisions arise in which the decision maker must simultaneously consider equity and inquiry related instructional goals. Our first case exhibits one way in which inquiry and equity goals synergize to create a learning experience for students in which they engage in legitimate inquiry and in which students are positioned as valued and capable practitioners of mathematics. Our second case exhibits one way in which the decision to prioritize a more equitable learning experience perhaps decreased some students' opportunity for deeper inquiry, placing the two goals in tension with each other.

The primary contribution of our analysis is considerations for future research and practice in inquiry teaching in proof-based courses. Our list of categories of decisions that impact inquiry and equity, while possibly incomplete, suggests some areas in which researchers might ask instructors using inquiry about design and facilitation decisions. If a further investigation revealed that some categories of decisions regularly generate perceived tension between inquiry goals and equity goals, professional development and professional learning communities could

equip instructors to navigate these tensions in ways that preserve the best of both constructs. For example, the [blinded] project (supported by [blinded award]) is helping college mathematics instructors address a common tension in inquiry-oriented proof-based courses: the fact that some students enter these courses with extensive background in mathematical proof, and as a result have disproportionate opportunities to drive the work of the class. One way the project is helping ease this tension is by developing group-worthy activities that offer all students high-quality, structured engagement with proof in forms other than proof construction. By pursuing such opportunities to broaden the range of activity and facilitation options available to instructors, the undergraduate mathematics education community can continue to work toward the fulfillment of the vision articulated by Laursen and Rasmussen (2019): a journey of mathematical inquiry that leaves no student behind.

Logical Reasoning in Probability: Further Investigation Into Students' Beliefs About the Relationship Between Covariance and Independence

Megan Ryals
University of Virginia

Brian Rickard
University of Arkansas

Morgan Sellers
Colorado Mesa University

In many undergraduate math courses, students are expected to interpret and use conditional statements without prior training in logical inference. In this paper we report on a portion of the third phase of a project exploring students' interpretations of a conditional statement in Probability relating covariance and independence. Specifically, we discuss the coding and analyzing of student written work in class and on assessments. We explain how this work was influenced by prior phases of the study. Quantitative results show no statistical difference between responses of students with and without prior training in logic. We do, however, see differences in students' responses overall as the semester progresses.

Keywords: Conditional Statements, Logical Reasoning, Probability, Covariance, Independence

Many theorems and definitions in undergraduate mathematics are stated as conditional statements. Consequentially, several researchers have begun to investigate how undergraduate mathematics students treat concepts from logic before they have taken a formal logic course (Case, 2015; Durst & Kaschner, 2020; Sellers et al., 2021). These studies have focused on students' meanings for conditional statements in calculus courses. In this paper, we report on an ongoing investigation into student interpretations of the following theorem from an undergraduate Probability course: "If X and Y are independent random variables, then Cov(X,Y)=0" (Casella & Berger, 2002, p. 171). Specifically, *we ask how students interpret variants of this theorem and how prior logic training impacts their interpretations.*

Literature Review

In this study, we focus on a conditional statement found in a theoretical probability course. Consequentially, we relied on literature related to both what is known about students' meanings for conditional statements as well as what is known about common hurdles that teachers might encounter when teaching an undergraduate probability course.

Students' Interpretations of Conditional Statements

A robust amount of previous literature suggests that students often interpret conditional statements as biconditionals (Hoyles & Küchemann, 2002; O'Brien et. al, 1971; Wason, 1968). Ryals et al. (2023, 2024) found that students in probability courses do often interpret the given theorem as a converse. Even if students have taken (or are currently taking) a logic course, students may not transfer principles of logic across different mathematical contexts; instead, their inferences depend on the context, particularly when it is a familiar one. (Dawkins & Cook, 2017; Durand-Guerrier, 2003; Sellers, 2020). In our study, we focus on whether students rely on rules of logic, their meanings for independence and covariance, or both in their interpretation of the theorem relating independence and covariance.

Students' Meanings for Probability Concepts

Some studies in undergraduate mathematics and statistics education investigate students' understandings of probabilistic ideas within statistics courses (Batanero, et al., 2004, 2016;

Pfannkuch & Constance, 2017). Kolmogorov's (1950) derived axiomatic theory of probability is a primary focus in undergraduate courses in probability. However, many of these studies relate to statistics education specifically and/or K-12 related domains, and little is known about how these undergraduate students think about many of the theorems like the one in our study. We do know from the mathematics and statistics education literature that many words in statistics and probability have "lexical ambiguities" (Barwell, 2005). These words may have different meanings in colloquial language than they do in mathematics and statistics classrooms (Sellers, 2020, 2024). Our study both draws from undergraduate mathematics education research in logic and what is known about lexical ambiguities to explore how undergraduate mathematics students might conceive of concepts in a theoretical probability course.

Theoretical Perspective

In this paper, we utilize a constructivist perspective (von Glasersfeld, 1995). We posit that each individual is constructing their own meanings for conditional statements as a whole, as well as constructing meanings for mathematical terms such as independence and covariance found within these definitions. We use the term meaning in the sense of Thompson et al. (2014), where a meaning is a scheme (Piaget, 1977). In light of this perspective, we focus on individual student responses related to independence and covariance first before categorizing commonalities in meanings across different students. In this phase of the study, we focus on our quantitative findings related to students' written work for the theorem. At this stage, we want to classify the characteristics of their argumentation (their justification for whether two variables are independent) in order that we might later use these characteristics as a basis for analyzing our qualitative (i.e., interview) data for students' meanings for independence and covariance.

Methods

Data Collection

Student participants were enrolled in an undergraduate Probability course for engineering and computer science majors in Spring 2024. For each participant we collected previous GPA and whether they had previously taken or were currently enrolled in Discrete Mathematics. We also gave students a survey asking about their exposure to logic instruction. We were prompted to do this by an interview participant in Phase 2; she had studied logic for LSAT preparation. The survey asked about other courses students had taken and other non-course related activities they had experienced. Through discussions with course instructors, we determined Discrete Math would be the only course used as an indicator for prior logic training, but students with select non-course experiences would be considered as having formal logic training.

The first author taught a 50-minute lecture to 7 sections of this course. This was a modification from our data collection in Phase 1, when only 4 sections were included in the study and were taught by two different instructors (Ryals et al., 2023). Moreover, in this phase of our study, all 7 sections were taught with the same lesson plan, similar to the standard treatment used in the prior phase. Student written work from this class meeting as well as responses to one midterm and one final exam problem were collected for all students present. There were 137 students who granted consent to participate, of whom 91 had received prior training in logic.

During the lecture, the instructor presented the theorem and discussed the possibility of the converse being true. Due to results obtained from interviews in Spring 2023 (Ryals et al., 2024), the instructor asked students for counterexamples of the converse. That is, she asked students how two variables could have a covariance of 0 but be dependent. In each of the 7 sections, at

least one example was presented and discussed and this was used to clarify that the theorem is not biconditional. The instructor then worked two examples that asked first whether two variables were independent and then asked for their covariance. In one example, the variables were independent and therefore the theorem could be used to conclude the covariance was 0. In the other example, the variables were dependent, so covariance had to be calculated. Students were then presented with two problems. They worked these two problems individually and their work was collected. In both problems, the students were first asked to compute the covariance of two random variables and then were asked to find whether the variables were independent. In the first, which we refer to as the "converse problem," the covariance was 0, so students were then expected to use the definition of independence. In the second, which we refer to as the "contrapositive problem," the covariance was not 0, so students had the option of using the theorem to conclude the variables were not independent. We also collected student responses to one problem on a midterm assessment and one problem from the final exam. The midterm problem was very similar to the converse problem and the final exam problem was very similar to the contrapositive problem. Responses collected are characterized in Table 1 below.

Table 1: Sample Characteristics

	No Prior Logic Training	Prior Logic Training	Overall
Average Previous GPA	3.5	3.7	3.6
Number of Post-Class Work Responses	46	91	137
Number of Midterm Responses	35	61	96
Number of Final Responses	37	62	99

Analysis

We began by coding the responses from the in-class problems. Each of the three authors individually coded each participant's response to each of the two problems, primarily using the codes established in Phase 1 of the study (Ryals et al., 2023). We met to discuss and resolve the codes we applied individually. The modification of codes was guided by analysis from the interviews completed in Phase 2 of the study and from disagreements in codes selected by the different authors. For example, on the converse problem where covariance was 0, multiple students stated "X and Y are independent because E[XY]=E[X]E[Y]." In phase 1, we had coded this response as "Assumes the converse is true." However, analysis of one interview revealed that one student believed that the expectations being equal, as in the equation above, was the definition of independence. (She was not referencing the theorem.) Therefore, we created the code, "Used expectation or variance equations." After completing the coding for the in-class problems, two authors coded each student response to the midterm problem and two authors coded each response to the final exam problem. We again met to discuss and resolve any disagreements.

Statistical analyses were conducted to investigate the relationship between prior logic training and response type as well as to examine how student responses changed over time. Multinomial logistic regression was used to study the relationship between prior logic training and response type with prior GPA and prior logic training as covariates and response

code as the dependent variable. McNemar-Bowker tests (Bowker, 1948) were conducted to study how student responses changed over time by comparing responses in the post-class problems to the corresponding problems on the midterm and final. Planned analyses included McNemar-Bowker tests, by logic training status, on the change in response from one converse problem, post-class problem 1, to the next, the midterm problem, as well as on the change in response from one contrapositive problem, post-class problem 2, to the next, the final problem.

Results

Types of Responses

We begin by presenting and summarizing the codes developed in Phase 3 which were modified from analysis in Phase 1 (Ryals et al., 2023). We will explain how these were condensed to quantitatively detect differences in how students interpret the variants of the theorem. Response rates for codes for each two types of problems are presented. Then we discuss inferential statistics assessing whether prior logic training impacted student responses and whether those responses changed over time.

Student responses closely resembled those in Phase 1 of the study. Each codes indicates how students responded to the question about independence and most often can be categorized as used the definition, used the value of covariance, used multiple arguments, or did not answer or provide justification.

Table 2: Phase 3 Codes Developed for Written Student Responses

Converse Problem	Contrapositive Problem
assumed converse was true	bypassed theorem (used definition)
claims independence can't be determined from covariance of 0	claims covariance not equal to 0 is not sufficient evidence to determine independence
used expectation or variance equations	used expectation or variance equations
no answer	no answer
incorrect or incomplete argument	incorrect or incomplete argument
no justification provided	no justification provided
used definition	used theorem
used conditional definition/argument	used theorem and also referenced definition
used informal definition argument	used definition and also referenced theorem
used or stated definition incorrectly	used informal definition/argument
wrong covariance calculation	Wrong covariance calculation
	bypassed theorem incorrectly

Prior to conducting analyses, the response codes listed in Table 2 were condensed into similar response types. For example, “used informal definition argument” and “used conditional definition/argument were combined with “used definition.” These condensed response types for each type of problem (converse, contrapositive) and their relative frequencies are listed below in Tables 3 and 4, respectively.

For the converse problems, relative frequencies stayed similar between the post-class problems and the midterm, though fewer students made the mistake of claiming that

independence could not be determined from a covariance of 0. On the contrapositive problems, however, a large portion of students who used the theorem on the post-class problem reverted to using the definition of independence on the final. Both methods can be used to correctly answer the question, though using the theorem is more efficient.

Table 3: Relative Frequencies of Condensed Codes for Converse Problems

Code Number		Post-Class #1	Midterm
1	Used the definition or meaning of independence	59.1%	58.1%
2	Claimed independence cannot be determined from a covariance of 0	10.9%	3.2%
3	Used covariance of 0 or expectation or variance equations	26.3%	32.3%
4	No complete argument given	3.6%	6.5%

Table 4

Relative Frequencies of Condensed Codes for Contrapositive Problems

Code Number		Post-Class #2	Final
1	Used the definition or meaning of independence	13.1%	41.9%
2	Used theorem	81.0%	53.8%
3	No complete argument given	5.8%	4.3%

Multinomial logistic regression analyses were conducted on the student response codes for each question controlling for prior logic training and previous GPA. The results for post-class Question 1 are found below in Table 5.

Table 5: Coefficients for Multinomial Logistic Regression for Post-Class Question 1

Code Number	Intercept	Prior Logic Training	Previous GPA
2	2.71	0.89	0.49
	p = 0.709	p = 0.838	p = 0.34
3	104.44	1.71	0.20
	p = 0.013	p = 0.254	p = 0.002
4	35.97	3.61	0.13
	p = 0.207	p = 0.292	p = 0.015

The intercept coefficients represent the odds of each student response code occurring compared to the reference code (1) when prior logic training and previous GPA are 0. As a previous GPA of 0 is not a reasonable possibility, these values are not interpreted. These results do suggest that prior logic training is not a significant indicator of any student response code at the 0.05 level. The results do, however, suggest that previous GPA is a significant predictor of student response code. The odds for student response code 3, compared to student response code 1, decrease by 80% for a one unit increase in previous GPA while the odds for student response code 4, compared to student response code 1, decrease by 87% for a one unit increase in previous GPA.

Multinomial logistic regressions were also conducted for post-class question 2 and the midterm and final questions. The results mirror those of the test for post-class question 1 with no statistically significant results at the 0.05 level for prior logic training. The smallest *p*-value found for prior logic training was 0.19. For the midterm question, which was a converse problem similar to post-class question 1, GPA was again a significant predictor of student response code. For this analysis, the odds for student response code 3, compared to student response code 1, decrease by 96% for a one unit increase in previous GPA while the odds for student response code 4, compared to student response code 1, decrease by 99% for a one unit increase in previous GPA.

To examine how student responses changed over time, McNemar-Bowker tests were conducted between post-class question 1 and the midterm question and between post-class question 2 and the final exam question. This test examines if there's a pattern in how students changed their answers from one question to the next. For example, imagine comparing two sets of answers from the same students. If about the same number of students changed their answers in each direction, the test would say there's no significant pattern. But if more students changed their answers in one direction than the other, the test would say there's a significant pattern.

Initially, tests by logic training status were planned, however, due to a smaller than expected number of students without prior logic training, conducting these tests by logic training status was not possible due to many missing response combinations. As a result, the McNemar-Bowker tests were conducted without regard to logic training status. For the comparison of post-class question 1 student response codes and the midterm question student response codes, the global test of symmetry has a *p*-value of 1, indicating that there is no pattern of movement from one student response code to another response code. For the comparison of post-class question 2 student response codes and the final question student response codes, the global test of symmetry has a *p*-value of 0.002, which is significant at the 0.05 level. This indicates a pattern of movement from one response code to another. To discover which pair or pairs of response codes have this pattern of moment, additional tests were conducted between each pair of response codes. The comparison of response codes 1 and 2 has a *p*-value of 0.007, when adjusted for the multiple comparisons. This indicates that there is a significant pattern of movement from the student response code of "Used theorem" on post-class question 2 to "Used the definition or meaning of independence" on the final. The comparison of response codes 1 and 3 has an adjusted *p*-value of 0.201 and the comparison of response codes 2 and 3 has an adjusted *p*-value of 0.617, indicating that there is no significant pattern of movement between codes 1 and 3 or codes 2 and 3.

Conclusion & Discussion

In this study we report on the third phase of a study investigating how students interpret variants of a theorem in probability relating covariance and independence of random variables. Using results from prior phases, we modified and applied an existing coding scheme and classified student written responses to two types of problems for 137 participants.

Upwards of 25% of students conclude that variables must be dependent when covariance is 0, immediately after instruction as well as weeks later on the final exam. This is despite an intended improvement to instruction in Phase 3, specifically presenting and illustrating a counterexample to the converse. These results support prior work showing students' tendencies to interpret conditional statements as biconditional and their approaches are not necessarily influenced by counterexamples (Sierpińska, 1987).

A large majority of students used the contrapositive of the theorem correctly in class when presented with two variables whose covariance is not 0. However, fewer students used the theorem on a similar problem on the final exam and this difference was significantly significant. We note that there was also an increase in the number of students correctly using the definition of independence on the converse problem on the midterm, in comparison to in class. Therefore, overall, it seems students become more comfortable using the definition of independence over time for both types of problems.

Consistent with results in Phase 1 (Ryals et al., 2023) and prior studies outside Probability (Attridge et. al, 2016; Cheng et. al, 1986; Inglis & Simpson, 2008), the differences in categories of responses for students with logic training and those without are not statistically significant. This is despite the fact that we more carefully considered how to classify a student's logic background in Phase 3.

We know from the quantitative results from this study that students' logic training may not be the only important factor to consider when discussing students' interpretations of this theorem. While logic training did not have statistically significant differences, GPA was a predictor for student success with this particular theorem. This has significant teaching implications because one might expect that some students with an overall lower GPA might have more difficulty interpreting the theorem as a conditional, one-directional statement. The quantitative data also led us to believe that there may be lexical ambiguities with i*ndependence*, *correlation*, and *covariance*, which might also be important factors to consider as we enter the next phase of this study. We further suspect that lexical ambiguities might be of concern because as we coded this data, we noticed that multiple students claimed that since Cov(X,Y)=0, X and Y are *uncorrelated*, and therefore are independent. We hypothesize that students' experience with colloquial uses of the words uncorrelated and independent have led them to view these words as synonyms. However, this needs to be further explored with student interviews that we recently conducted with this same pool of students for our next phase of the study. Future interviews may also be helpful in determining why some students provided multiple justifications, and why some used expectation or variance equations in lieu of covariance values.

Direct and Indirect Influence of Active Learning on Women's Sense of Belonging in Calculus

Casey Griffin
University of La Verne

Fewer women than men choose to major in STEM, and women leave STEM majors at a higher rate than men – especially after taking Calculus. Prior research identifies low sense of belonging (i.e., feeling like an accepted member of an academic community) as a key reason why women decide to leave STEM majors. Scholars have identified factors that contribute to one's sense of belonging, including students' perceived competence and social connectedness. This study explores ways in which engaging in active learning opportunities might support women's perceived competence and social connectedness, and in turn, their sense of belonging. Women's survey responses suggest that active learning supported their sense of belonging indirectly via their perceived competence and social connectedness, as well as directly.

Keywords: active learning, calculus, gender, sense of belonging

Women continue to be underrepresented in STEM fields (Bressoud, 2023; Seymour & Hunter, 2019), and this gender gap is due in part to women's decisions to (not) major in STEM (Carmichael, 2017; Chamberlain, 2017). Fewer women than men choose to major in STEM early in their college education (Eagan et al., 2016), and women leave STEM majors at a higher rate than men (Chen, 2013; Seymour & Hunter, 2019). Prior work has identified Calculus as a common exit point for women (Ellis et al., 2016; Rasmussen et al., 2019; Seymour & Hunter, 2019). Two key reasons women leave STEM majors are that they feel a low sense of belonging to the field and they perceive the instruction in their introductory STEM courses as "poor quality" (Ellis et al., 2013; Rasmussen & Ellis, 2013; Seymour & Hunter, 2019; Shapiro & Sax, 2011). This report aims to explore women's perspectives on the connections between their sense of belonging and the learning opportunities they experienced in their year-long active learning Calculus course.

Literature Review & Theoretical Foundations

Broadly, feeling a sense of belonging involves feeling connected to or accepted within a particular environment (Rosenberg & McCullough, 1981), rather than isolated or lonely (Hagerty, 2002; Solomon & Croft, 2016). Good et al. (2012) studied students' sense of belonging to an academic domain, which they define as "one's personal belief that one is an accepted member of an academic community whose presence and contributions are valued" (p. 701). This definition of sense of belonging (SB) is most relevant to the current study.

Researchers have found that students with a stronger SB in STEM are more likely to persist in STEM (Seymour & Hunter, 2019; Shapiro & Sax, 2011). However, research shows that women are less likely than men to develop a strong SB in STEM (Good et al., 2012; Rainey et al., 2018; Seymour & Hunter, 2019; Shapiro & Sax, 2011). Good et al. (2012) found that women's SB significantly predicted their intent to pursue math in the future, and that the presence of negative stereotypes about women's mathematical abilities hindered women's ability to develop a SB.

Components of and Contributors to Sense of Belonging

Good et al. (2012) developed the Mathematical Sense of Belonging scale, which measures students' SB specifically in the domain of mathematics. In their study, a factor analysis revealed five distinct components that comprise students' SB: *acceptance, affect, desire to fade, trust*, and *membership. Acceptance* refers to whether students feel included, valued, and respected in the community. *Affect* refers to whether students feel comfortable and calm or nervous and tense within the community. *Desire to fade* is the extent to which students feel like they want to be active participants or fade into the background and not be noticed. *Trust* refers to trusting the instructor to help them learn and believe in their potential, as well as trusting that they do not have to prove their worth. Finally, *membership* refers more generally to whether they feel like members of the community and like they belong.

Researchers have identified several factors that contribute to one's SB (Lahdenperä & Nieminen, 2020; Rainey et al., 2018; Rainey et al., 2019). For this study, I focus on students' social connectedness and their perceived competence.

Social connectedness refers to the extent to which one feels like they have made connections or relationships with the people in their class. Interacting with classmates and/or the instructor allows students to develop social connections (Hoffman et al., 2003). While both SB and social connectedness involve feelings of trust and acceptance among others, SB involves feeling that one is accepted into a larger community, whereas social connectedness can be felt with just a single person. Researchers have found that social connectedness is an important contributor to students' SB (Hoffman et al., 2003; Johnson, 2012; Lewis & Hodges, 2015; Rainey et al., 2018; Thacker et al., 2022; Tinto, 1975). For example, Thacker et al. (2022) found that opportunities to interact impacted students' social connectedness, which in turn influenced their feelings of belonging. And Rainey et al. (2018) found that women in particular were most likely to attribute their SB to feeling socially connected. Further, STEM leavers attributed their low SB to lacking social connections.

One's SB to a domain can also be influenced by their perceived competence in that domain. Perceived competence refers to students' perceptions of their performance and understanding of course-related material (Rainey et al., 2018), and is not necessarily correlated to their performance in that course (Cribbs et al., 2015; Carlone & Johnson, 2007). For example, one might feel competent but perform poorly on an exam due to other factors such as testing anxiety. Research indicates that students' perceived competence can impact their SB (Lewis & Hodges, 2015; Rainey et al., 2018). In Rainey et al.'s (2018) study, students reported feeling like they belonged in their major because they felt like they understood the major-related content. Further, many STEM leavers explained that their low SB stemmed from their low perceived competence. Lewis & Hodges (2015) found that ability uncertainty, or a lack of perceived competence, was associated with low SB. They suggested that perceived competence is tied to social comparison with peers. For example, if students notice that their peers have a better grasp on the material than they do, then they might feel like they are not "good enough" or do not belong in that class.

The Role of Active Learning

One aspect of students' experiences that might influence their SB is the instructor's pedagogical approach. In their follow-up study on why undergraduate students leave STEM, Seymour & Hunter (2019) report that students are less tolerant of "poor quality" instruction than they were 20 years prior. By "poor" they mean instruction that is boring and lacking engagement. More recently, there have been efforts toward supporting student engagement, performance, and retention by incorporating opportunities for students to engage in *active*

learning (Freeman et al., 2014; PCAST, 2012; Smith et al., 2020). While there are many definitions of active learning in the literature, there seems to be consensus on the students' role in the learning process – talking about or doing mathematics. One way we can characterize types of active learning opportunities is in terms of the extent to which the opportunity encourages interaction with others (Griffin, 2023), as shown in Figure 1. In this continuum, learning opportunities like individually working on problems and responding to clicker polls would be located near the individual end of the continuum, while opportunities like group work and whole-class discussion would be located near the interactive end.

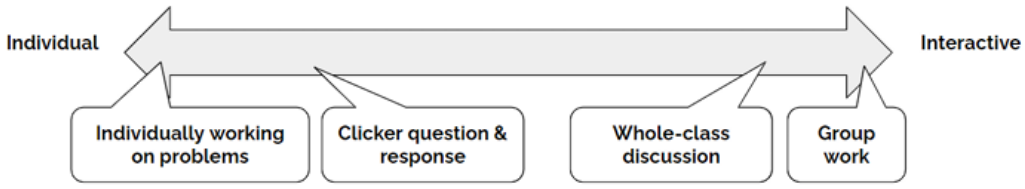

Figure 1. Active learning continuum.

I hypothesize that engaging students in active learning opportunities, especially more interactive learning opportunities, has the potential to strengthen women's SB in Calculus. First, the very nature of interactive learning opportunities enables students to form social connections with their classmates and instructor (Hoffman et al., 2003; MacMahon et al., 2020). Second, research indicates that active learning can support student achievement outcomes like performance, self-efficacy, engagement, and persistence (Freeman et al., 2014; Kogan & Laursen, 2014; Seymour & Hunter, 2019). Participating in group work or whole-class discussions presents opportunities for students to explain their thinking, which can reinforce and enhance their understanding of content, and also to form connections with their classmates. Therefore, active learning opportunities, particularly interactive learning opportunities offer promise as a way for instructors to support women's SB indirectly via their social connectedness and perceived competence.

Research Questions & Methods

The purpose of this report is to explore women's perspectives on the impact particular active learning opportunities had on their SB via their social connectedness and perceived competence. Specifically, I investigate: For women enrolled in a year-long active learning Calculus course, in what ways do they describe the impact of particular learning opportunities on their SB?

I employed a transformative (feminist) mixed methods research design (Creswell & Plano Clark, 2011) to conduct this study. I focus on women's experiences without comparing them to men's experiences because women's experiences are worthy of study in their own right (Du Bois, 1983; Kitzinger & Wilkinson, 1997), and I wanted to avoid comparisons that implicitly position the masculine perspective as "norm" and the feminine experience as "less than" (Gilligan, 1982). I administered surveys to collect data on women's perceptions of the impact of four main types of learning opportunities they experienced on their SB. The qualitative strand of this study aims to elevate women's perspectives, providing context and explanations for quantitative data.

Setting and Participants

This study was conducted at a midsized, mid-Atlantic R1 public university during the 2022-2023 academic year. The university offers a two-semester Integrated Calculus course as an

alternative to the university's standard one-semester Calculus course for STEM majors. The course and sample have been described in detail in prior work (Griffin, 2023; Griffin & Berk, 2023). Students enrolled in the course are typically first-year students who have declared or are considering a STEM major (i.e., as classified by the NSF ADVANCE Program; NSF, n.d.).

The course was designed to incorporate frequent opportunities for students to engage in active learning. During the time of the study, two sections of the course were offered, taught by two different instructors, both committed to active learning. There were 63 and 64 students enrolled in each section. The course is highly coordinated in that instructors teach from collaboratively developed lesson plans, which include recommended active learning opportunities. Specifically, instructors follow an instructional cycle of brief lecture, followed by students working on problems in groups or individually, followed by whole-class discussion. While the course was designed to incorporate opportunities for active learning, students do not know that upon enrolling in the course.

Students enrolled in the course were invited to complete a survey via email. The survey was distributed at Weeks 7, 14, and 21 of the year-long course (i.e., middle and end of fall and middle of spring). Response rates (and total number of enrolled students, N) were as follows: 90% (N=118) at Week 7, 85% (N=118) at Week 14, and 94% (N=108) at Week 21. For analysis, I include students who were first-year students and self-identified as women, which resulted in N=46 at Week 7, N=44 at Week 14, and N=39 at Week 21.

Data Collection & Analysis

To investigate my research question, I used Qualtrics, a web-based survey tool, to design and distribute an electronic survey. I administered the survey at Weeks 7, 14, and 21 of the semester. Within the survey was an item asking participants to select one of the four main learning opportunities they experienced during class (i.e., traditional lecture, interactive lecture, group work, and individual work) and describe how or why that activity has or has not impacted their SB in math. Note that the language "interactive lecture" was used in place of "whole-class discussions" because cognitive interviews with students enrolled in the course suggested that students were unclear on what was meant by "whole-class discussions" and would instead call that "interactive lecture."

At each time point, I calculated the frequencies and percentages of women's choices of activity. I analyzed their open-ended descriptions using theory-guided content analysis, anticipating the use of *social connectedness* and *perceived competence* as codes to identify times when active learning opportunities impacted women's SB indirectly via their social connectedness or perceived competence, though I also allowed for other themes to emerge. For example, I anticipated that the components of SB (i.e., *acceptance, affect, desire to fade, trust, membership*; Good et al., 2012) might emerge from women's responses, indicating more of a direct impact on their SB, so these were considered in the coding process as well. I first clustered responses by learning opportunity so that I could explore all the ways that, say, group work impacted women's SB throughout the year. Responses were not compared across time points; rather, I wanted to capture the scope of the ways in which women viewed the active learning opportunities as impactful toward their SB throughout the year.

Results

At Weeks 7, 14, and 21, participants were asked to select a learning opportunity from a list of four (i.e., traditional lecture, interactive lecture, group work, and individual work) and describe its impact on their SB. In their responses to this item, participants tended to do one of two things.

They either (1) described how the activity impacted their SB indirectly via their social connectedness or perceived competence, or (2) described how the activity they chose impacted their SB directly by invoking one of the components of SB (i.e., *acceptance, affect, desire to fade, trust, membership*; Good et al., 2012). Table 1 presents the percentages of women who chose each activity to describe its impact on their SB. Women were most likely to choose activities that fall more toward the interactive end of the active learning continuum (Figure 1). I present their responses by activity, beginning with the indirect impact it had on their SB via their social connectedness and/or perceived competence, followed by the direct impact it had on components of their SB. Given that so many women chose to discuss the impact of group work and interactive lecture on their SB, I will focus on these two activities after providing a brief synopsis of their perspectives on the impact of traditional lecture and individual work on their SB.

Table 1. Percentages of Women Who Chose Each Activity to Describe its Impact on their Sense of Belonging.

Activity	Week 7	Week 14	Week 21
Group Work	46%	52%	69%
Interactive Lecture	46%	32%	21%
Individual Work	4%	5%	5%
Traditional Work	4%	11%	5%

Note. At Week 7, N=46. At Week 14, N=44. At Week 21, N=39.

Not many women chose to discuss the impact of traditional lecture or individual work on their SB, though those who did commented on ways these activities positively impacted their SB. Those who chose traditional lecture (N=7), either discussed ways that traditional lecture impacted their SB indirectly via their perceived competence (e.g., "Traditional lecture affects how well I know the material and am able to apply it. If I feel I do not know the material well, I feel less of a sense of belonging."), or their response was vague. For those who chose individual work (N=6), responses reflected an indirect impact on their SB via their perceived competence. They either reported that they preferred to work alone or that they appreciated the opportunity to test their understanding.

Interactive Lecture

Across time, N=27 women chose to describe the impact of interactive lecture on their SB. Women's responses suggested both an indirect impact of interactive lecture on their SB via their perceived competence, as well as a direct impact on two components of SB – their feelings of acceptance and desire to fade.

Indirect impact via perceived competence. Some women (N=12, 44%) described interactive lecture as impacting their perceived competence, which in turn impacted their SB. In many cases, women explained that interactive lecture helped them understand the material. For example, one woman described, "When we have interactive lecture, we are able to discuss out all of the problems and share our ideas which helps me learn best." Others mentioned interactive lecture provided an opportunity for social comparison, which allowed them to compare their own level of understanding with that of their classmates. For example, one woman reported, "I would say interactive lecture is the most helpful because I get to hear what other people say and if they are struggling on the same things as me."

Direct impact on sense of belonging. Other women described interactive lecture as impacting one of the components of SB directly. Some women described ways it impacted their

feelings of *acceptance* (N=8, 30%). Some women described times they felt included and like they matter during interactive lecture. For example, one woman reported, "It allows my teacher to talk with us and engage us, so I feel like we are all included and listened to." Another said, "[Interactive lecture] makes me and other students feel like they matter and have a say in the class because it's encouraged for them to participate."

Many women (N=16, 59%) described how feeling involved, in contrast to fading into the background, contributed to their SB. These comments align with the *desire to fade* component of SB, though they reflect a positive view toward engagement. For example, one woman reported, "[Interactive lecture] helps with engagement and allows me to make sure I am learning which increases my sense of belonging." Others (N=2) reported that interactive lecture helped them pay attention during class, which made them feel engaged.

Group Work

Across time, N=39 women chose to describe the impact of group work on their SB. Women's responses suggested both an indirect impact of group work on their SB via their social connectedness and their perceived competence, as well as a direct impact on three components of SB – their feelings of acceptance, their desire to fade, and their affect (i.e., feeling comfortable versus anxious).

Indirect impact via social connectedness. When describing how group work impacted their SB, some women discussed how group work impacted their feelings of social connectedness, one of the contributors to SB. At times, women described group work as a means for them to feel socially connected to their classmates (N=23, 59%), which in turn supported their SB. In many cases, these were generic responses about being able to form relationships, make friends, and get to know their classmates. For example, one woman noted, "I get to know other classmates and create connections in the classroom. In a more specific example, one woman wrote:

> [Group work] has had the most positive impact on my sense of belonging in math because going over how we get an answer with my groupmates makes me feel like we're all in the same boat and I'm able to get to know my group a little better.

Indirect impact via perceived competence. Other women (N=17, 43%) reported ways that group work supported their perceived competence, which in turn supported their SB. Some simply reported that helping each other during group work supported their understanding of the material. Others were more specific and described how hearing multiple perspectives during group work supported their learning. One woman wrote, "It is helpful to get the perspectives of other students in your group and talk the problems through with them." Another wrote:

> I think talking the problems out helps me to understand the concept rather than copy answers form the professor or be confused on my own. I can also see new ways of explaining the concepts that are tricky by talking with peers.

Hearing others' perspectives also allowed students to see how well they understood the material compared to their classmates. For example, one woman wrote, "Group work is a chance for everyone to get together and share their ideas. This will allow one to get a sense of their and everyone else's understandings." Gauging others' levels of understanding made some participants feel less alone when they were struggling to understand something. One participant shared that group work allowed her to "realize that other people may also be struggling with some concepts," suggesting that she felt on-level with her classmates, which supported her SB.

Direct impact on sense of belonging. When describing the impact of group work on their SB, some women (N=9, 23%) described the ways group work impacted their feelings of *acceptance*. Some mentioned feeling valued and included. For example, one woman noted, "I

have a higher sense of belonging when working with others because it feels like I'm needed and not just there to be there." Others reported feeling like they were not alone. One said, "Group work helps with your sense of belonging because at times it's hard if you feel like you are the only one struggling. However, if you know that others are struggling too… it's a lot easier to feel like you belong,"

Other women (N=19, 49%) described group work impacting their engagement, which aligns with the *desire to fade* component of SB. Women mostly reported that engaging by getting to work together and help each other during group work supported their SB. Many women made generic statements connecting their engagement in group work with feeling like they belong. In more specific responses, women associated their level of engagement with their *affect* (e.g., feeling comfortable, calm, nervous, or anxious; N=6, 15%). In fact, all but one of the responses about affect also referenced engagement. One woman explained

> Group work makes me feel comfortable participating because I get anxious about answering questions in front of the whole class. I can share ideas with people I've grown to be comfortable and friendly with without having a fear of rejection.

Others echoed this idea that it was easier to engage when they felt comfortable. Another woman noted, "It is less intimidating to ask questions because asking in front of the whole class can be uncomfortable." Thus, participating in group work supported women's feelings of acceptance, as well as their engagement and their affect, all of which are components of their SB.

Discussion

The goal of this report was to explore women's perspectives about the impact of specific learning opportunities on their SB. The findings presented here build upon findings from Griffin (2023) by examining the impact of four learning opportunities rather than only two and providing women with a platform to describe ways their SB were impacted by these learning opportunities. When asked to select a learning opportunity and describe its impact on their SB, women were overwhelmingly likely to select group work and interactive lecture. This finding supports my hypothesis that *inter*active learning opportunities may offer more promise than solo-based active learning opportunities in supporting women's sense of belonging. In their descriptions, as hypothesized, women noted ways in which group work and interactive lecture supported their SB indirectly via their social connectedness and perceived competence. These activities supported women's ability to understand the material, as well as their ability to form relationships with their classmates, which in turn, supported their SB. In addition, women noted ways in which their SB was impacted directly as well, by invoking particular components of SB, namely, *acceptance*, *desire to fade*, and *affect,* in their responses. For example, both group work and interactive lecture supported women in feeling engaged and like their voices were valued. This is not to say that instructors should *only* employ group work and interactive lecture as women did report positive impacts of both traditional lecture and individual work on their SB. Specifically, they noted that these learning opportunities supported their perceived competence, which in turn supported their SB. However, this report provides support for employing at least some interactive learning opportunities as a way to support women's SB, which could in turn support their retention in STEM. Additionally, while other reports (Johnson et al., 2020; Reinholz et al., 2022) have noted negative impacts of active learning on women, interestingly the qualitative data in this study showed no indications of negative impacts of group work and interactive lecture on women's SB. These differences in findings could be due to several factors such as the sample, the instructors, or the enactment of the learning opportunities. More work is needed to explore aspects of enactment that are particularly important for women's SB.

This mixed-methods study evaluates the mathematical autobiographies (MABs) of STEM students to evaluate their relationship with mathematics and influential actors in their math life stories. 135 MABs were collected from students enrolled in Calculus 1, Abstract Algebra, and Topology, taught by the same instructor. Analysis revealed that students mostly had consistently positive experiences with mathematics (PME). Hypothesis testing showed that students enrolled in upper division courses and math majors had a higher likelihood of describing PMEs and that Asian students described PMEs at a lesser rate than their peers. Instructors and family members were most frequently named as influential actors, with K-12 instructors appearing more often than college instructors. These results indicate that STEM students have had primarily positive mathematical experiences, which aligns with their desire to pursue STEM degrees.

Keywords: mathematics autobiography, students' experiences in math, influential actors

Undergraduate mathematics courses have historically been considered gatekeepers to higher education (Van Dyken, 2016). As a result, researchers have focused on the equitable implementation of instructional activities that engage students in active learning and promote higher order thinking (Freeman et al., 2014; Saxe & Braddy, 2015). Instructional improvements are amiss without also attending to students' experiences in mathematics, as mathematics perception and self-efficacy have been reported as determinants of achievement (Shone et al., 2023). This study is framed by Voigt's (2020) conception of mathematics identity, which are the "dispositions and deeply-held beliefs that individuals develop…about their ability to participate and perform effectively in mathematical contexts" (p. 32). He includes three ways that a student's math identity can be shaped: 1) their perceptions of mathematical participation and ability, 2) their connection to mathematical communities, and 3) the influence of identity resources. A student's mathematics identity is the product of formative educational experiences (Silva & Roddick, 2001), and understanding students' lived experiences is an important platform on which to continue to build positive student identity (Gutiérrez, 2009). One way to understand a student's lived experience is through mathematical autobiographies (MABs) to identify and examine critical points in a student's life story with math.

Student MABs (Cook, 1995) have been essential to gain insight into students' success and struggle in math classes (Moldavan & Mullis, 1998; Williams, 2017). The benefits of MABs are twofold: math educators gain a deeper understanding of students' backgrounds and students engage in an important reflective practice. Prior work with MABs has supported the development of stronger classroom communities (Westrich, 2016) while students have also reported experiencing increased self-awareness regarding their mathematical abilities and a deeper understanding of their own math learning journey (Hauk, 2005).

The current study is focused on overall student experience with mathematics, while looking at differences by student type and influential people in their stories. Our first research question seeks to understand overall math experiences: *How do mathematics students describe their*

relationship with mathematics? We also wondered if MABs from students with different demographics (e.g., race, gender, course enrolled) differ from their peers, leading us to our second research question: *How do mathematics students' relationship with mathematics vary based on their demographics?* One aspect of identity is connection to mathematical communities (Voigt, 2020), yet little work has examined the influential actors present during these formative experiences. Our third research question asks: *How do mathematics students acknowledge influential actors in their math life stories?*

Methods

This study took place at a large public university on the West Coast of the U.S., designated as a Hispanic-Serving Institution and an Asian American, Native American, and Pacific Islander-Serving Institution. Data for this paper were a convenience sample (Creswell & Guetterman, 2019) collected between Spring 2019 and Spring 2022, totaling 133 participants enrolled in calculus 1, abstract algebra or topology taught by the same instructor. Table 1 shows the institutional student demographics. Student majors were mathematics (65%), engineering (17%), science (14%), and non-STEM (5%).

Table 1: Student Demographics (N=133)

Race	**Total**	**%**	**Gender**	**Total**	**%**	**Course**	**Total**	**%**
Latine	61	45.9	Female	56	42.1	Calculus	33	24.8
Black	9	6.8	Male	75	56.4	Abstract Algebra	86	64.6
Asian	25	18.8	Non-Binary	2	1.5	Topology	16	12
White	22	16.5						
Mixed Race	5	3.8						
Unknown	11	8.3						

Throughout the course, students were asked to submit reflection assignments, one of which students were asked to write their math autobiography. Sample prompts included to reflect on their earliest math memory, past math experiences, how they see themselves as math learners, or to reflect on meaningful mentors that impacted them. The prompts were meant to inspire, and students were encouraged to write their narratives however they wanted. 135 math autobiographies form the data set for this study. Note that the total number of MABs is larger than the total number of students as two students had enrolled in two different courses in the data collection time frame and submitted unique assignments.

The data were first analyzed using deductive coding (Creswell & Poth, 2018). Researchers coded for *overall experience with math*, *focal positive/negative moments,* and *influential actors*. Overall experience with math was categorized into five distinct codes, adapted from John et al. (2020): (a) consistently positive, (b) consistently negative, (c) consistently neutral, (d) redemption, and (e) contamination. We marked an MAB as *consistently positive*, *consistently negative*, or *consistently neutral* if their life story with math started and ended as both positive, negative, or neutral (accordingly). Even though an MAB could be coded as consistent, we also recognized that students' stories could contain ups and downs. We define a *speed bump* as a difficult or challenging moment within a student's story labeled as consistently positive/neutral. Similarly, we define a *booster* as a positive or supportive moment within a student's story labeled as consistently negative/neutral. An MAB was marked as *redemption* if their story started out negative and they had an experience that transformed their relationship with math to end

positively while an MAB was marked as *contamination* if their story started out positive and they had an experience that transformed their relationship with math to end negatively. While John et al. (2020) did not provide guidance on what was considered positive or negative in the five codes, as a team, we defined p*ositive, negative,* and *neutral* by the emotions students used to describe their experiences (e.g., "I was really curious and excited by math") as well as their self-evaluation (e.g., "I am really not great at math").

Within each MAB we also coded for any *focal positive* or *negative moment* a student wrote about that stood out as a singularly poignant experience. Within these focal moments, we coded any *influential actors* mentioned (e.g., a specific person or institution), coding whether that actor had a *positive*, *negative*, or *neutral* impact on the student. People were categorized as best as possible, and if they were a professor or mentor, we captured the course or institution type when specified (e.g., 8th grade teacher, community college Calculus 1 professor). Usually, if a student mentioned a person, they would describe a story related to that person (e.g., "Cooking with my grandma helped me count").

The entire research team deductively coded 31 MABs together, discussing coding applications and reaching agreements whenever there was disagreement. Then, three researchers coded the remaining 105 MABs, with double coding of 12 MABs (~11%), producing a reliability of 83%. In instances where there was disagreement or uncertainty, the fourth researcher reviewed and determined the appropriate coding.

Once the data were deductively coded, we utilized mixed methods to analyze the data. Thematic analysis (Braun & Clarke, 2012) was used to summarize themes within *overall experience with math* and *specific actor mentione*d. We also performed one-tailed hypothesis testing for difference of proportions for students' *overall experience with math*. We wanted to know if the difference in proportions of positive math experiences for two similarly related identities was statistically significant. To simplify the calculations, we defined two groups: *positive math experience* (PME) and *negative math experience* (non-PME). Any MAB coded as Consistently Positive or Redemption was coded as a PME, as both experiences result in current positive experience with math. Conversely, any MAB coded as Consistently Neutral, Consistently Negative, or Contamination was defined as a non-PME. We compared specific demographics (course enrolled, gender, race, and major) to determine which identities were reporting PMEs at a higher/lower rate. Our goal was to determine if there was a statistically significant difference in the proportion of PMEs for one identity compared to PMEs of all other respondents without that identity.

Findings

Table 2 shows the breakdown of overall experience with math and key events from students' math life stories. We can see that most students have a consistently positive experience with math. However, of the 87 students coded as consistently positive, we see that 86.2% were coded as having had speed bumps along their journeys. This is important to observe, as it shows the resilience of students who face adversity in their stories yet continue to push through with a positive relationship with mathematics. We also notice that students who are consistently negative or neutral also experience positive focal moments, even though their overall experience with math is negative or neutral. Most all students' MABs that were coded as consistently negative were also coded as containing a booster during their math life story (87.5%).

We wanted to compare proportions of positive math experiences (PME) by different student demographics. First, we wanted to compare lower division students and upper division students. Then we wanted to compare by gender. Because we only had two non-binary students, we

grouped non-binary and female students together as they are the non-majority gender identities in comparison to male students. We also wanted to test by race doing so for Latine, White and Asian students. We were unable to test for Black students, as our population had less than 10 Black students. Finally, we compared students by major.

Table 2: Distribution of Autobiographies as Positive Math Experience and Non-Positive Math Experience by Event

Experience with Math	**Speed Bumps and Boosters**		**Positive Focal Moments**		**Negative Focal Moments**	
Positive Math Exp (PME)						
Consistently Positive ($N = 87$)	75	(86.2%)	79	(90.8%)	59	(67.8%)
Redemption ($N = 21$)	-	-	19	(90.5%)	18	(85.7%)
Non-Positive Math Exp (Non-PME)						
Consistently Negative ($N = 8$)	7	(87.5%)	7	(87.5%)	7	(87.5%)
Consistently Neutral ($N = 15$)	11	(73.3%)	12	(80.0%)	10	(66.7%)
Contamination ($N = 4$)	-	-	4	(100.0%)	4	(100.0%)
Total ($N = 135$)	**93**	**(68.9%)**	**121**	**(89.6%)**	**98**	**(72.6%)**

Table 3 shows the eight different hypothesis tests we ran for difference of proportions. When comparing the rates of PMEs for students enrolled in different math classes, we found that students enrolled in more advanced mathematics courses were more likely to have a positive math experience ($p<0.01$). Similarly, students pursuing a degree in math or engineering were more likely to report having a PME more often than other majors ($p<0.01$). We observed that female and non-binary students had a larger proportion of PMEs but found no statistical evidence to support the idea that either gender experienced PMEs at a greater rate. Next when looking at racial identities, we were unable to find strong evidence to support the idea that Latine and White students experienced PMEs at a different rate than when compared to other races. However, with significant evidence to support, we saw that Asian students experienced PMEs at a lesser rate when compared to other races ($p<0.05$).

Table 3: One-sided Hypothesis Test for the Difference of Proportions for Positive Math Experiences

Demographic	**Test Performed**	**Test Statistic**
Class Enrolled	(Abstract Algebra & Topology) vs. (Calculus)	4.71***
Gender Identity	(Female & NB) vs. (Male)	0.87
Racial Identity	Latine vs. Other Races	1.47*
	Other Races vs. Asian	2.22**
	White vs. Other Races	1.49*
Major	Math vs. Engineering	2.11**
	Math vs. Non-Mathematics	3.99***
	(Math & Eng) vs. (Non-Math & Non-Eng)	4.05***

*p<0.1, ** p<0.05, *** p<0.01

Because so many students were coded as having consistently positive MABs (N=87), we wanted to categorize the ways students were describing their positive experience with math. Seven major themes emerged from the analysis of student responses. Table 4 shows each theme, a description of the theme, and their frequencies. MABs could be coded with multiple themes.

Easy and Fun (43.6%) and *Appreciation of Math* (34.4%) were the most common themes. For example, a female Latina math major reflected on a previous experience in middle school,

> I was doing simple algebra but I think this specific day was when I had an epiphany and really was so happy about doing math and in my 7th grade mind I was thinking wow I really love this is so easy and fun to do I can do 20 of these problems.

Many students' positive relationships with mathematics were also affected by good performance, community and support, and its perceived utility.

Table 4: Themes found in Consistently Positive Math Autobiographies N=87

Theme	Description	Count
Easy and Fun	Referenced an overall enjoyment of mathematics	38
Appreciation of Math	Found material "beautiful" or "fascinating"	30
Good Performance	Performed well on exams, assignments, or overall course grade	28
Community and Support	Received support and encouragement from teachers, peers, etc.	25
Utility	Found math useful and practical.	10
Personal Growth and Intellect	Found that mathematics helped them grow intellectually.	9
Appreciation of Difficulty and Challenge	Enjoyed solving challenging problems.	6

Of the 87 consistently positive autobiographies, 75 (86.2%) of the MABs were coded as having speed bumps. Table 5 shows the seven themes that emerged from the analysis of the speed bumps including their frequency. *Difficulty with Material* (50.6%) and *Poor Teacher Experiences* (29.3%) were the most common themes; there were times when both overlapped, meaning that sometimes if students had negative experiences with teachers and instructors, they also expressed that they found the material difficult or got low scores on exams. A Latino male math major recounted his experience entering middle school: "I struggled a lot when it came to math. Things that were considered to be easy were very complicated and I lost a lot of my confidence." A Black female engineering major in calculus wrote about when she took precalculus with the hardest teacher at her school:

> I did struggle a bit in the class and did not have the motivation to ask my teacher for help because she seemed to not want to help me when I approached her the first few times. I failed her class because one, I did not seek for help else[where] and because I lost motivation and felt as if my teacher saw me as an individual who has no skills in math and could not be successful in that field.

It was common to see that students struggled because they were unable to receive support from their teachers, or that students' confidence decreased because a teacher made them feel less than capable of doing mathematics.

Table 5: Themes found in Speed Bumps from Consistently Positive Math Autobiographies (N=75)

Theme	Description	Count

Difficulty with Material	Struggled in the course and got low scores	38
Poor Teacher Experiences	Had a negative interaction with teachers	22
Poor Study Habits	Had poor study habits that affected performance	15
Personal Reasons	Faced personal life issues or complications	12
Failing Classes	Failed their courses	10
Uncertainty of Major/ Career Choices	Uncertain about their career choices, causing stress	5
Virtual Classes	Struggled with online classes resulting from COVID	4

122 MABs (85.9%) mentioned an influential actor. We grouped these mentions into five distinct categories: (a) K-12 instructor, (b) college instructor, (c) family, (d) other support, and (e) peers. The *college instructor* category accounts for all mentions of a post-secondary instructor, regardless of the institution type. The *other support* category captured infrequently mentioned actors (e.g., mentors, college advisors, tutoring centers, clubs). Table 6 shows the distribution of mentions by positive, negative, and neutral. These counts exceed our total number of MABs because a student may have mentioned more than one actor in more than one context (e.g., a positive, negative, or neutral experience). We found that the mentions of influential actors were overwhelmingly positive (70.3%) and primarily discussed K-12 or college instructors.

Table 6: Distribution of Mentions of Actors by Positive, Negative, and Neutral

Actors	**Positive**		**Negative**		**Neutral**	
K-12 Instructor ($N = 97$)	57	(58.8%)	32	(33.0%)	8	(8.3%)
College Instructor ($N = 65$)	48	(73.8%)	14	(21.5%)	3	(4.6%)
Family ($N = 48$)	36	(75.0%)	4	(8.3%)	8	(16.7%)
Other Support ($N = 36$)	31	(86.1%)	0	(0.0%)	5	(13.9%)
Peers ($N = 13$)	10	(76.9%)	3	(23.1%)	0	(0.0%)
Total ($N = 259$)	**182**	**(70.3%)**	**53**	**(20.5%)**	**24**	**(9.3%)**

Table 7 shows the distribution of positive and negative mentions of K-12 teachers, college instructors, and family members across students experiencing PMEs and non-PMEs. We found that the frequency of positive narratives of K-12 instructors was similar among students who experienced PMEs (42.6%) and non-PMEs (40.7%). The relative frequency of positive narratives of college instructors was higher for students who experienced PMEs (38.9%) than those who experienced non-PMEs (22.0%). The relative frequency of negative narratives also differed by instructor type. We found that students experiencing PMEs and non-PMEs spoke about negative experiences with college instructors at similar rates, however more students with PMEs talked about negative experiences with K-12 teachers than non-PMEs. Interestingly, students with non-PMEs did not have more negative experiences as compared to students with PMEs. We found that students experiencing non-PMEs only mentioned one positive experience with family (3.7%), while students experiencing PMEs had 35 positive mentions (32.4%).

Table 7: Distribution of Instructor and Family Mentions by Positive and Non-Positive Math Experience in MABs

Actor	**Positive Math Experience ($N = 108$)**		**Non-Positive Math Experience ($N = 27$)**	
	Positive	**Negative**	**Positive**	**Negative**

K-12 Instructor	46	(42.6%)	27	(25.0%)	11	(40.7%)	5	(18.5%)
College Instructor	42	(38.9%)	11	(10.2%)	6	(22.2%)	3	(11.1%)

Discussion

Our study showed that a majority of students had consistently positive experiences in their math autobiographies. Our analysis showed that this was more likely to take place with math and engineering majors and for students enrolled in upper division math courses. While seemingly sensical, it is important that our analysis verified this, as in other papers, the same students have shared traumatic experiences during their academic journeys (Cawley & Wilson, 2024). We acknowledge that due to the convenience sample, participants in this study were students who already "made it" to courses like calculus and upper division math. This is known as survivorship bias (Elston, 2021), which can overshadow the narratives of students who may have been filtered out of such courses. Future work will investigate MABs from other courses that support non-STEM majors. Interestingly, we also saw that Asian students described positive math experiences at a lesser rate than their peers, which we would like to investigate further.

Students in this study with consistently positive autobiographies often shared that they enjoyed and appreciated the subject or performed well in it. In contrast, most of the speed bumps were caused by moments in their stories where they faced difficulty with material, self-expressed poor teacher experience, and poor study habits. It is important to share with our students that even those who have a positive relationship with math face challenges, highlighting the notion of productive struggle (Baker et al., 2020) and a growth mindset (Boaler et al., 2021).

Students overwhelmingly acknowledged instructors as positive influential actors in their math life stories. Prior research suggests that students' relationship with mathematics is a direct product of the learning environment created by their instructor (Moldavan & Mullis, 1998). Our study found that MABs labeled as an overall positive mathematics experience cited their college instructors at a higher rate than the MABs labeled as non-PME. The trends in our data show that STEM-focused students' early experiences with math may not appear to shape their overall relationship with mathematics, as a high proportion of positive K-12 instructor experiences was present for both students with positive relationships with math and those with negative relationships. While these rates were similar, we did notice that students with negative relationships with math simply did not write as often about specific people or institutions in their narratives. This may indicate that those with more positive experiences have stronger memories tied to those people who impacted them. This may be evidenced by the result that students with PMEs wrote more about their interactions with family members – both positive and negative experiences. Studies have shown that family members can help shape students' math identities in meaningful ways (Cunningham, 2021). We argue that more work should be done to evaluate the out-of-classroom experiences that impact students' relationship with math.

Overall, our data demonstrate snapshots of positive and negative math identities as supported by the nature of the math experiences evidenced in the students' math autobiographies.

Rethinking Single Variable Calculus for Life Sciences for Advancing Equity

Nandini Bhattacharya
University of California, Santa Cruz

Anna Sher
University of California, Santa Cruz

Calculus with Applications in the Life Sciences (Biocalculus) is an impactful and required course for all STEM majors at our institution, a large public university. A disproportionately high percentage of Latinx and students from low-income households (EOP) earn failing grades in this course. This study examines student learning outcomes and experiences based on project assessment (N=152) and student survey (N=130) to answer the following questions: (a) Did changing a course structure based on working within a teaching team change students' agency? (b) Did minoritized students achieve similar levels of conceptual understanding as their counterparts in the course, when the curriculum was designed with project-based learning situated within the teaching team? We found that the inclusive course structure provided minoritized students with a supportive environment and positively impacted their learning. We believe our specific implementation can be helpful to many large public universities with diverse student populations and relatively limited resources.

Keywords: Biocalculus, Teaching Team, Equity, Project-based Learning

Given the rise in the number of Hispanic Serving Institutions (HSIs) nationally, studying the impact of how we improve teaching calculus courses is of high priority. Equitable outcomes can be obtained by increasing the number of successful STEM majors among Latinx students and students from low-income households (broadly referred to as minoritized students). This course redesign project was implemented at a large research university, an HSI. As part of redesigning of the Biocalculus series, faculty worked closely with graduate student researchers (GSRs) in the summers of 2021-2024. We benefited from using their expertise to design eight authentic applied projects in the areas spanning from chemical reaction kinetics (for chemistry) to the Alee effect model (ecology and evolutionary biology) to delve deep into studying modeling (logistic and exponential models) and analyzing observations with conclusions. The GSRs also developed authentic section worksheets, aligned with the lectures and the projects' mathematical learning goals. The creativity of this approach accessed the elements of equity-focused design that helped undergraduate students showcase their strength in diverse forms of assessment where learners' agency was high because of the immediate cross-disciplinary applications (O'Brien & Reale, 2021) and alignment of students' motivations to learn the mathematics behind the science (Lee et al., 2014). It also impacted the graduate students' training as future faculty/team leaders, where they received close mentorship on aligning learning outcomes of concept(s) with authentic assessment and teaching material for better transparency and access within a learning community.

Theoretical Frameworks

Our course redesign project relied on two theoretical frameworks, Significant Learning by Fink (2013) and Backward Design (Wiggins & McTighe, 1998), both focused on achieving better transparency and equitable outcomes.

Fink's Significant Learning framework purposely engages students in six domains that are more likely to produce learning that endures well beyond the end of a course (Figure 1). The

domains relevant for our project are Foundational Knowledge - representing information and ideas; Application - developing skills, critical and creative thinking; Integration - connecting ideas (and people) using skills and content; Human Dimension - addressing learning about oneself and others; Caring - developing new feelings, interests, and values; and Learning How to Learn - promoting self-direction and metacognition. The Significant Learning framework was explicitly chosen to establish enduring learning in the calculus series as a motivator for long-lasting knowledge in the downstream science classes using the student's agency to learn the material as a dominant motivator.

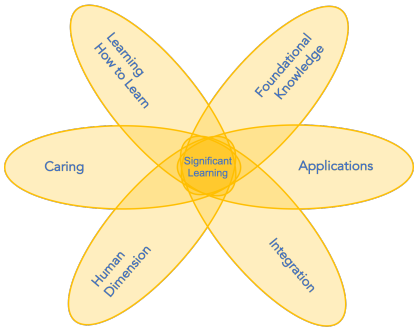

Figure 1. Significant Learning (adapted from Fink, 2013)

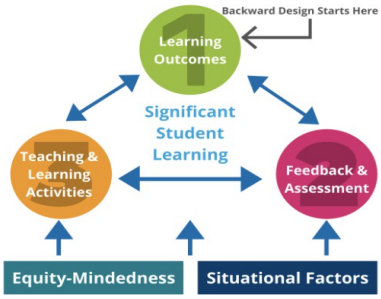

Figure 2. Backward Design (adapted from Wiggins & McTighe, 1998)

Wiggins & McTighe's Backward Design Model for equity-mindedness encompasses teaching with transparency and goal orientation (Figure 2). Since enrollment for these courses is very large (~200-500 students), establishing an alignment with teaching goals, diverse assessment types, and teaching and learning practices is imperative to achieve equitable outcomes (Garcia, 2019; Yosso, 2005). The extensive teaching team, consisting of the instructor of record, graduate teaching assistants, undergraduate tutors, and supplemental instructional team, can share a guideline for how each week progresses. Consistent instruction and messaging become more seamless once we approach the task as a team (Kerr & Samuels, 2019). Creating a sense of belonging for the students is inherent to the value held by the community, which is collaborative and reflective of the instructor's values, with the hope of changing the perception of the courses from a weeder course to a course that launches STEM students into their majors (Bhattacharya et al., 2020).

Course structure in Biocalculus for Equity

The core value of the course design was based on collaborative norms and practices.The design elements promoted a teaching team approach that integrates learning in a discussion section with large lecture experience. The course curricula aimed to develop a coherent conceptual understanding of calculus that is authentically contextualized in sciences and used metacognitive activities using reflections and other similar tools for frequent formative assessments (Cizek, 2010; Ruiz-Primo, et al., 2010) that help students become better STEM learners (so that students cultivate a sense of belonging and STEM identity). The course redesign structure is described next.

Standardized delivery of the course content (ADA compliant) includes articulating learning goals and aligning them with diverse assessments across various topics to provide all students with similar experiences in learning calculus using Canvas and Gradescope as the primary technology tools. The course learning cycle is structured by giving primary material using videos

or otherwise (Modules) to create collaborative problem-solving opportunities during lectures to develop an active learning setting. After the lecture, students worked with their TAs and tutors on worksheets relevant to the mathematical concept (calculus content) contextualized in real-world applications (precursor to the project questions). An online question bank was created using open-stack resources organized by topics (and learning outcomes), using the weekly learning outcomes of the course to better align with the lecture (and also cut costs drastically for students) and provide essential metacognitive questions/activities (reflection questions) to help students become self-regulated learners (Ambrose et al., 2010). We provided students with various formative assessment tools to develop themselves as STEM learners and to promote equitable outcomes for different types of learners.

Above all, before the beginning of the academic year, every teaching team member (graduate TAs, undergraduate tutors, supplemental instructors, and instructors of record) received professional development to work in this new framework of an inclusive teaching model, prioritizing equitable outcomes. The professional development space opened a purposeful dialogue (Alexander, 2008) to help create alignment across all teaching and learning platforms, where teaching team members with different positions and knowledge of the curriculum helped make a scaffolded learning space. The teaching team met weekly to plan and address all emerging issues to address every student's success. We hypothesized that a team-based course structure that helps create a community allowed minoritized students to ask questions. The culture of problem-solving that is dialogic is the key to promoting a sense of belonging in STEM. Achieving equitable outcomes in the Biocalculus series courses will help retain a diverse student body in STEM majors, ultimately one of our institution's (and the nation's) primary goals for this decade. An institutional culture of commitment grounded in inclusivity rather than selectivity (obstruction) promotes success among URM STEM students (Chang et al., 2014).

Methods

This study included students in the Biocalculus course taught in Spring 2024, the third quarter of the academic year. A relatively large class (N=152) was diverse in academic and demographic backgrounds. Specifically, just over a third (36%) of the class were students from low-income family backgrounds (referred as EOP students). Hispanic/Latinx students constituted a third of the class, as did White, non-Hispanic students. Of note, Hispanic/Latinx students were significantly more likely to be from low-income households than their White, non-Hispanic peers: 64% of Hispanic/Latinx and 11% of White, non-Hispanic students in this course were EOP students (X^2 (df=1, N = 110) = 32.9, p < .001).

Most students (84%) were in their first year of college, and 60% intended to major in Biology-related fields. There were statistically significant differences in students' academic achievement in the first two quarters (before taking this course): Hispanic/Latinx and EOP students had significantly lower cumulative GPAs than White, non-Hispanic students and non-EOP students, respectively (Table 1).

Table 1. Cumulative GPA at the enrolled institution by socioeconomic background (EOP) and race/ethnicity

	EOP (n=58)	non-EOP (n=105)	Hispanic/ Latinx (n=56)	White, non-Hispanic (n=54)
Mean	2.88	3.09	2.79	3.26
Std. Dev.	0.55	0.66	0.55	0.62
t-test	t(161)=-2.07, p<.05		t(108)=-4.19, p<.001	

To address the first research question, *Did changing a course structure based on working within a teaching team change students' agency?,* we used a student survey developed by the University of California Santa Cruz Assessment for Learning Excellence and Equity Center (ALEEC). The survey measures students' learning experiences in a collaborative course setting, including series of questions about student attendance and engagement during the section, reflections on the helpfulness of the section, and a sense of belonging to a community of peers. These questions were developed based on multiple studies of course- and program-learning outcomes and student focus groups. Distributed by ALEEC as a confidential, online survey at the end of the course, the survey yielded an 80% response rate and a representative sample. Survey data was merged with the demographic information, deidentified, and analyzed to examine group differences based on demographic backgrounds. We strive to provide actionable results and conduct equity analyses by focusing on specific, conceptually important points of difference (Sher & Sung, 2020). For example, students' responses about the helpfulness of attending section were collected on a 5-point scale and then dichotomized to focus on the distinction between students who indicated a moderate to high level of helpfulness (*somewhat helpful, helpful or very helpful*) vs. a low level (*a little* or *not at all helpful*). This approach allows us to report group-specific results in percentages and compare groups using Chi-square analyses. In addition, we developed an overall measure or construct for a sense of belonging to a community of peers and used t-test for examining group differences.

A rubric-based assessment was conducted to address the second research question, Did minoritized students achieve similar levels of conceptual understanding as their counterparts in the course when the curriculum was designed with project-based learning situated within the teaching team? After students uploaded their projects into Canvas, TAs used a criteria-based rubric developed by the faculty to evaluate students' skills as part of grading in Gradescope. Each specific skill was measured with four defined levels of proficiency, ranging from full proficiency (fully and correctly answered), general proficiency (minor mistakes), partial proficiency (major mistakes or omissions), to limited/no proficiency (completely incorrect or not attempted). Similarly to our work with the survey data, the rubric assessment data was extracted and merged with the demographic information, deidentified, and analyzed to measure skill-specific levels of achievement and examine significant group differences using Chi-square analyses (Sher & Sung, 2020).

Results

The survey allowed us to examine several measures of students' agency and belonging to a community. Students' attendance was very high for both lectures and discussion section. The majority (74-75%) attended most (at least 70%) lectures and section meetings. This high attendance reflects the team-based course structure and is atypical in such large courses. Most importantly, there were no differences in attendance between minoritized students and their counterparts.

Because the course redesign gave special attention to improving students' experience in the discussion section, the survey asked students about section's helpfulness for their learning. For most students, experience in section was moderately to very helpful. Notably, 80% of Hispanic/ Latinx students reported that a TA-led section helped them complete homework assignments, compared to 70% of White, non-Hispanic students (this difference did not reach statistical significance). Nearly three-fourths of Hispanic/Latinx students reported that their participation in section helped them prepare for exams; in this aspect, the activities in section were somewhat more helpful for Hispanic/Latinx students than their White, non-Hispanic peers (X^2 (df=1, N =

86) = 3.35, p = .067). Another important finding is that nearly 70% of Hispanic/Latinx students found their experiences in section helpful for feeling more comfortable in this class, and they were similar in this regard to their classmates. See Figure 3.

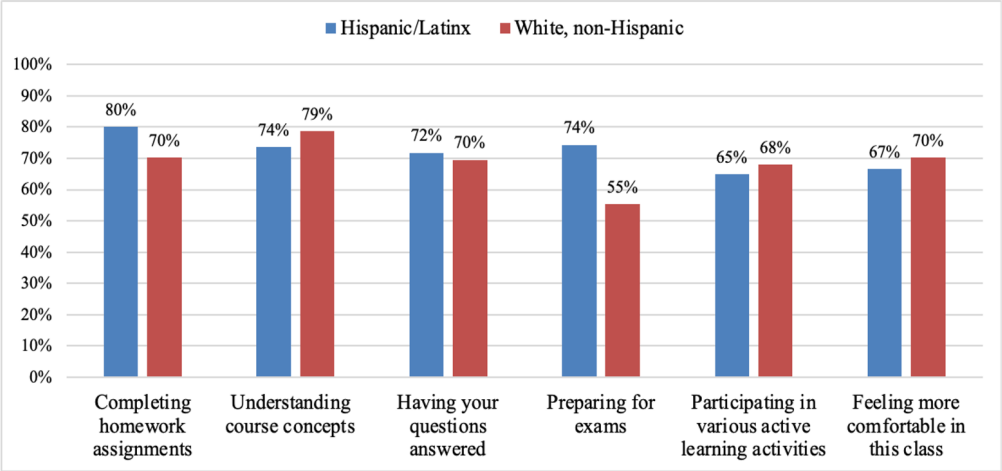

Figure 3. Equity analyses of section's impact on learning by race/ethnicity (percent of somewhat helpful to very helpful)

In addition, 65-71% of students from low-income backgrounds reported positive experiences in the section that helped them complete homework, understand course concepts, and have their questions answered. Of note, just over half (57%) of EOP students thought that their participation in the section helped them prepare for exams and for active learning activities in class (as a group, they were not significantly different from their peers). Also, just over half of EOP students indicated that section was at least somewhat helpful for feeling more comfortable in the class, which was significantly lower than 73% of non-EOP students (X^2 (df=1, N = 128) = 4.22, p < .05). See Figure 4.

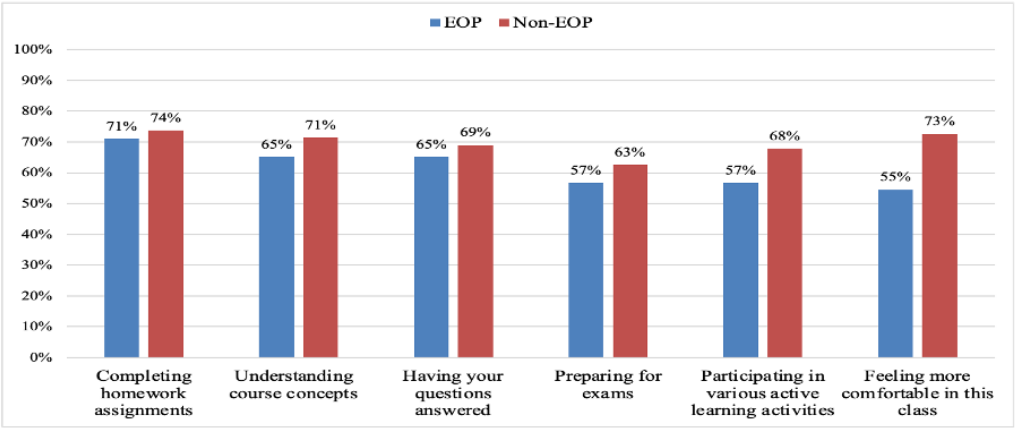

Figure 4. Equity analyses of section's impact on learning by socioeconomic background (percent of somewhat helpful to very helpful)

Such a multifaceted positive impact of the discussion section on student learning was likely possible thanks to the positive and inclusive environment created by trained graduate student TAs. When asked directly about feeling welcome and supported in section, most (89-90%)

students, including minoritized students, somewhat to strongly agreed that they felt welcome and supported, without any statistically significant differences between groups.

Another series of questions focused on students' relationships with other students in their class, designed to measure their feeling of belonging to the community of peers. In this class, most students reported high levels of connectedness to peers: the vast majority (80-86%) said that they *probably* or *definitely* had a student they could talk to, reach out for help, and share if they struggled academically. Most (87%) felt that students in this class could ask questions or give wrong answers without feeling judged by other students. As many as 70% of students reported having *probably* or *definitely* made meaningful connections with other students in this class. See Figure 5.

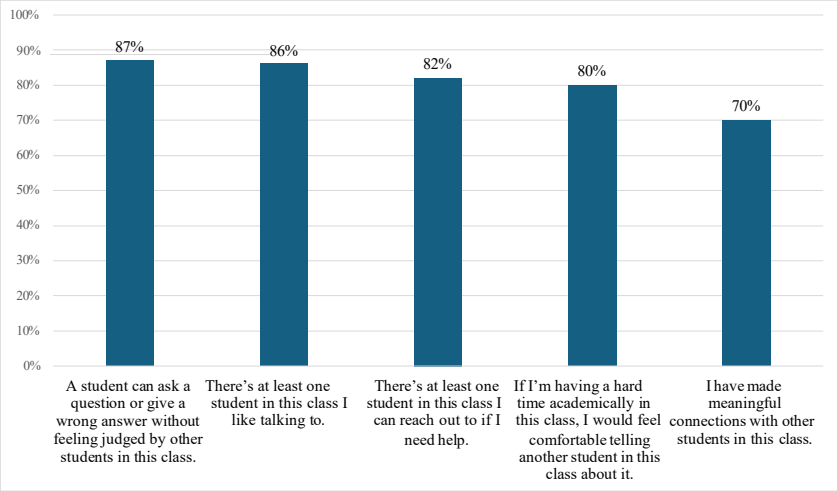

Figure 5. Students reporting belonging to the community of peers (percent of probably yes to definitely yes, based on the entire class)

We found that minoritized students experienced similarly strong belonging within the community of peers using two approaches to compare groups: (1) an overall measure or a construct based on the average across the five items on a Likert-like scale[1] (Cronbach's alpha=0.91), and (2) item-specific responses, analyzed with a focus on the more definitive responses (*yes* or *definitely yes* vs. other responses). Table 4 shows the overall measure of belonging for minoritized groups of students and their peers based on socioeconomic status and race/ethnicity.

Table 4. Equity analyses of the overall belonging to the community of peers by socio-economic background (EOP) and race/ethnicity

	EOP (n=43)	non-EOP (n=77)	Hispanic/ Latinx (n=38)	White, non-Hispanic (n=45)
Mean	4.33	4.45	4.37	4.63
Std. Dev.	1.20	1.12	1.08	0.99
t-test	$t(118)=-0.58$, $p=.56$		$t(81)=-1.15$, $p=.25$	

[1] Survey question: "Based on your interactions with other students in this course, how true are the following statements?" Responses are on a 6-point scale: 1=Definitely not, 2=No, 3=Probably not, 4=Probably yes, 5=Yes, 6=Definitely yes.

One of the major learning assessments was a project designed for students to demonstrate their conceptual understanding of rate of change in the biological context. We evaluated students' proficiencies in four related skills/concepts using a criteria-based rubric with four levels of proficiency, ranging from *full* to *limited or no* proficiency. Our faculty consider that expected proficiency in a specific skill is achieved by the whole class or specific group when close to 75% or higher percentage of students demonstrate *general* or *full* proficiency. In this class, most students (91-98%) demonstrated *general* or *full* proficiency in each of the measured skills (Table 5). Equity analyses showed that both minoritized students and their peers demonstrated high levels of proficiencies in each skill. Moreover, about 70% of minoritized students demonstrated *full* proficiency in estimating the instantaneous rate of change using the dataset (Skill 3), and in explaining the differences in the estimations and interpreting observed change using calculus in context (Skill 4).

Table 5. Results of project-based assessment of students' conceptual understanding of rate of change (N=152).

Skills and concepts:	Full proficiency	General proficiency	Partial proficiency	Limited or no proficiency
1. Interpret the average rate of change using an experimental dataset	82%	9%	1%	8%
2. Interpret reaction rate in the context of the problem	84%	12%	3%	1%
3. Estimate the instantaneous rate of change using the dataset	69%	29%	1%	1%
4. Explain the difference in the estimations and interpret observed change using calculus context	77%	18%	1%	4%

Discussion

Our study evaluated the impact of a redesigned course on student agency and conceptual understanding in the first course of the Calculus series for Life Sciences. We used direct assessment of project-based learning and a student survey to measure how minoritized students responded to a teaching team structure and frequent formative assessments aligned with learning goals. We found that all students, including Hispanic/Latinx and EOP students, demonstrated high levels of engagement and learning in an inclusive community of peers supported by a teaching team. While many minoritized students found discussion sections taught by trained graduate student TAs helpful for various aspects of their learning and social experiences, some students from low-income backgrounds still need more support to feel comfortable in a calculus class. Ultimately, our work hopes to add value to the national efforts to achieve equity in student math preparation for pursuing STEM fields by reimagining the role of the teaching team within a learning community, fore-fronted with equity-minded assessment structure using projects. We believe our specific implementation can be helpful to many large public universities (such as ours) with diverse student populations and relatively limited resources.

Undergraduate Students' Models of Subtraction and its Significance for Calculus

Erika David Parr
Rhodes College

Parth Sinojia
Rhodes College

Jude Shive
Rhodes College

Catherine Althoff
Rhodes College

Sam Lippe
Rhodes College

Anna Robicheaux
Rhodes College

The operation of subtraction, though emphasized at the elementary level, has a central role in expressing key ideas in Calculus. In graphical representations of Calculus concepts, a magnitude interpretation of a difference, that b–a gives the distance between a and b, often supports students in making sense of the representation. A magnitude interpretation uses a determine the difference model of subtraction, in which subtraction find how much a differs from b. Using exploratory teaching interviews, we investigated the models of subtraction that nine undergraduate students used on tasks designed to support them in using a magnitude interpretation. We found four distinct models of subtraction that students employed in these tasks. We describe these models and associated observable behavior. We discuss implications of these findings for the teaching and learning of Calculus and future research directions.

Keywords: subtraction, graphical representations, Calculus, difference expressions, number lines

One way to conceive of the subject of Calculus is as the study of change. As such, the operation of subtraction, which can be used to express the change in values of a variable, figures prominently in Calculus. Difference expressions form the backbone of expressions in the limit definition of the derivative ($f(x+h)–f(x)$), the Mean Value Theorem ($f(b)–f(a)$), and the Fundamental Theorem of Calculus ($F(b)–F(a)$), among others. The operation of subtraction may be conceptualized in numerous ways, including: the takeaway model, the determine the difference (comparison) model, the part-whole model, and adding up. In particular, the determine the difference model, in which subtraction is used to find how much one amount differs from another, plays a central role in Calculus, to find the change in two values of a given variable. Researchers have highlighted the role of the determine the difference model in Calculus, and some have also argued that introducing Calculus concepts, such as displacement and net change, may motivate and necessitate this model of subtraction, especially involving negative values (Stroup, 2005). When considering graphical representations in Calculus, changes in quantities or values of a variable are often represented by horizontal and vertical segments. When students can associate a difference with the distance between two positions, they can express the length of the segment as a difference and connect such expressions with segments in a graph, what Parr (2023) refers to as a magnitude interpretation of a difference.

As part of a larger study, we conducted exploratory teaching interviews (Steffe & Thompson, 2000) with nine undergraduate students using an activity designed to support students in expressing distances between two functions in the Cartesian plane using differences (Parr & Lippe, 2024). Expressing such distances are necessary for setting up integrals to evaluate areas and volumes in Integral Calculus. In this study, we ask: *What models of subtraction did undergraduate students use on an activity designed to promote a magnitude interpretation of difference expressions?*

Empirical & Theoretical Background

We begin by describing two models of subtraction commonly introduced at the elementary level, the takeaway model and the determine the difference model (van den Heuvel-Panhuizen &Treffers, 2009; Selter et al., 2012), also called the comparison model (Usiskin, 2008). The takeaway model of subtraction involves conceiving of subtraction as beginning with one amount of a quantity, *b*, taking away some amount of that quantity, *a*, which results in a final amount of the quantity. In this model, the result of subtraction finds this remaining amount. The determine the difference model involves conceiving of two amounts, *a* and *b* simultaneously, and then comparing how much larger *b* is than *a*, to find how much *b* differs from *a*. Research has shown that students struggle with such comparison operations compared to other types of subtraction problems (e.g., Stern, 1993). Further, students often default to using a takeaway model for subtraction, even when a determine the difference model provided more computational efficiency. (e.g., Baroody, 1999; Stern 1993).

To consider how a determine the difference model for subtraction may be used to represent distances graphically, we use Parr and Lippe's (2024) description of the components of a magnitude interpretation. In this description, a magnitude interpretation (Parr, 2023), involves combining the determine the difference model with a conception of distance as a quantity in space. The magnitude interpretation combines these such that a difference expresses the distance between two positions in one-dimension. To illustrate why the difference $x_2–x_1$ gives the distance between these two positions, Figure 1 shows x_1 and x_2 themselves represented as magnitudes, or distances from zero. The expression $x_2–x_1$ may then be considered to be composed of magnitudes (Parr et al., 2021; Parr & Lippe, 2024).

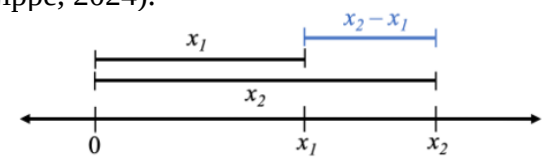

Figure 1. Composed magnitude interpretation of the expression $x_2 – x_1$ (Parr & Lippe, 2024, p. 507)

In the activity that students worked through in this study, students were encouraged to use a magnitude interpretation of differences in several ways, including drawing segments from zero to represent a given value, as in Figure 1. The magnitude interpretation of a difference expression, which aligns with a determine the difference model of subtraction stands in contrast to a cardinal interpretation (Parr, 2023) of a difference, which aligns with a takeaway model. When students use a cardinal interpretation, they often count units, such as tick marks, to show what a difference represents graphically. Even at the undergraduate level, students may favor a cardinal interpretation (Parr, 2023), perhaps because a takeaway model of subtraction is favored in their experience in elementary mathematics and daily life (Selter et al., 2012). In a previous study, we found that less than 40% of undergraduate Calculus students could correctly express a horizontal segment between a function and the vertical line x=2 using a difference expression in terms of x (Parr & Lippe, 2024). These findings motivated the development of the activity with a goal to better understand how to support students in using differences to express distances in graphs of functions in the Cartesian plane for their work in Calculus.

Methods

We conducted exploratory teaching interviews (Steffe & Thompson, 2000) with nine undergraduate math or science students at a small private college in 2023. In the interviews, students were asked to work through tasks in the Interpreting Graphs for Calculus Activity (Parr

& Lippe, 2024). The first task asked students to measure with a ruler, various lengths on a number line a certain distance to the left or right of zero, to support students in conceptualizing distances as measurable quantities within number lines. The second task, shown in Figure 2, asked students to draw a segment with a length of 5 on the *x*-axis starting at zero, a segment with a length of 3, and then a segment to represent the difference.

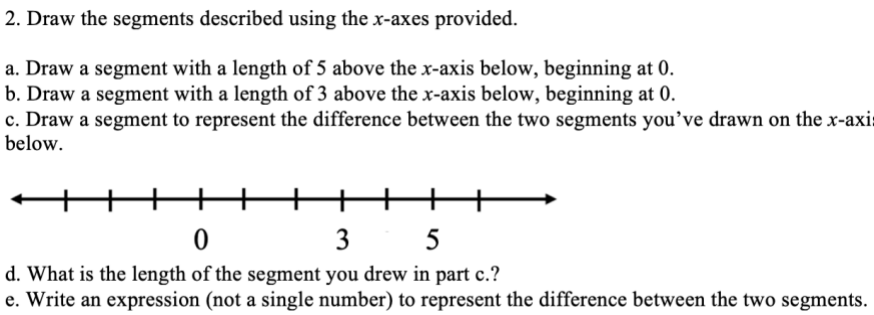

Figure 2. Task 2a-e in the Interpreting Graphs for Calculus Activity promoting a magnitude interpretation

The subsequent tasks 3-7 asked students to represent difference expressions using segments on horizontal and vertical number lines, or to write a difference expression for a segment shown. These difference expressions began with two positive integers, then included negative integers, non-integer values, and finally variables. A member of the research team served as the interviewer, with the first author serving as a witness if not the interviewer themselves. In each interview, the interviewer asked the student to further explain their thinking and may have posed additional questions to probe and test the boundaries of the students' current understanding of the task (Steffe & Thompson, 2000). The tasks were designed to promote a magnitude interpretation of a difference expression, but the interviewers refrained from expressly telling students to use this type of interpretation, unless it seemed like the student was unable to overcome a perceived obstacle without such intervention. We video recorded the interviews, as well as the iPad screen of students' work on the activity to capture their written work in real-time. The data for the study included students' words, gestures, diagrams, and written work on the activity.

We analyzed the data, with students' reasoning in the moment as our unit of analysis. That is, we considered students' models of subtraction as subject to change within their work on a given task and did not limit our description of students' work on a task to a single model. At the beginning of the data analysis process, we were attuned to the two distinct models of subtraction described above: a takeaway model and a determine the difference model. The research team used a grounded approach (Corbin & Strauss, 2014) to analyze the interviews, beginning with describing their model of how a student was reasoning in each task of the interview. At this stage, some details in students' activity became apparent, including activity using segments in distinct ways, such as moving segments and comparing segments visually. Through open and axial coding (Corbin & Strauss, 2014) we identified four distinct models of subtraction.

Results

In this study, we report four distinct ways in which the students we interviewed modeled subtraction on tasks designed to promote a magnitude interpretation of difference expressions on horizontal or vertical number lines (axes). We refer to these four models as: (a) magnitude, (b) takeaway values, (c) a takeaway segments, and (d) translation. We describe each model and the observable behaviors we used to categorize the students' activity as the given model.

Magnitude Model

We observed several students model differences as composed magnitudes, which aligned with the interpretation we sought to promote in the activity and teaching interview. Due to space, we only describe the model and observable behavior in Table 1 at the end of the section.

Takeaway Values Model

Several students modeled differences as taking away values on the number line. In these instances, students began at a position *b* on the number line, went back (or down) *a* units, and arrived at position *b*–*a*. This takeaway values model aligns with conceiving of subtraction as takeaway, more broadly, and with a cardinal interpretation of differences. We found that students used this model even after using what appeared to be a magnitude model on prior tasks.

We provide the example of the case of Ellie. Ellie had used a magnitude interpretation on previous tasks in the activity. However, on Task 5a, Ellie used what we infer as a takeaway values model. Ellie was asked to draw a segment representing *x*–2 on a horizontal number line. On this number line, *x* was represented as a point near 4.5 and labeled "*x*" (see Figure 3). These episodes show her figuring out how she would represent the result as a line. She knows the result of subtraction is a single number, so she decides that the final line she draws will be from *x* to the final product of subtraction, which in this case would be about 2.5. Here, she is using her line to represent the numerical value 2 being taken away from the starting point *x*.

Ellie: (*pauses, draws a dot near 2.5 in blue*) And by segment you really want the line?
Int: Yes.
Ellie: Okay. (*Pauses, draws line from dot at 2.5 to dot at x*)
Int: Can I ask why you were hesitant?
Ellie: Because to me *x*–2 is just a point. Like I would just take this *x*, which is…like, three, four, four and a half, and then subtract two and I would go down to two and a half. So like to me I wouldn't draw like a line segment to represent that value….I want my leftmost endpoint to represent what *x*–2 would actually be in terms of numbers…
Int: Okay so your segment is…representing, what, the answer to *x* minus 2?
Ellie: Kind of? Because I'm like literally going 2 down from *x* is what I feel like my segment is representing. Because I don't know really how else to express a single point, or at least what I'm interpreting as a single point, as a segment.

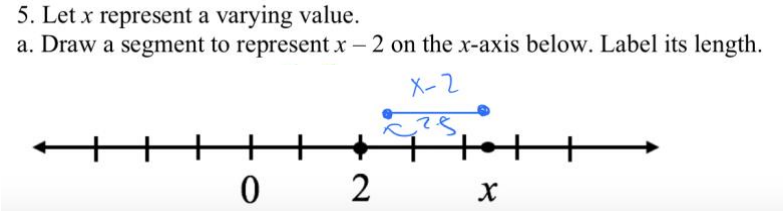

Figure 3. Ellie's work on task 5a, in which she modeled x–2 as the result of beginning at x and moving left 2 units.

In this episode, Ellie was reluctant to represent the difference as a segment, when in her mind it was "a single point." She does decide to draw a segment when she clarified the directions of the task and explained that she was going "down to two and a half." Notably, she used 4.5 as an approximation for the value of *x*, which was intended to be a generic varying value as stated in the task. Ellie's final line was a representation of the numerical value removed from *x*. By using 2 as the length of her final segment instead of one of the segment's endpoints, she suggests that she sees it as a value taken away from *x*. Therefore, we infer that she is using a takeaway values model here. For the students using a takeaway values model who were asked to draw segments,

the segments were a record of the movement from one value to another, rather than a distance whose value was the resulting difference.

Takeaway Segments Model

Distinct from the takeaway values model described above, in which students represented taking away values as counting back some amount, we found some students use a takeaway model of subtraction, but represent this through operating on the segments themselves. That is, they modeled subtraction as taking away part of a segment from another segment, leaving a segment as a result. We provide an instance with a student, Chloe. The interviewer asks Chole to explain her thinking for task 6a. She begins to explain this using the number line provided in the task, but then, she switches to thinking about how this could relate to an example about eating a chocolate bar.

Int: How would you explain for [part] a why the segment represents 3.5 minus 2?

Chloe: If you have a bigger number and you take away a smaller number, the smaller number is going to be canceled out completely, but a little bit of the big number will be left. You view almost… 3.5 as a whole, and you're taking a part out of it, and the part would be 2. So, then the remainder left would be just this tiny segment between 3.5 and 2.

Int: Is there a way you could represent what you were envisioning with a whole and a part using segments on the graph?

Chloe: Yeah. So, if I have 3.5 (*draws a rectangle next to the number line from 0 to 3.5*), and this would be 2 right here (*draws a line inside the rectangle in line with the 2 on the number line*). Okay. I'm gonna pretend that it's an object, like a candy bar. And let's say, if I only eat 2 segments out of the 3.5 candy bar, all of this will be erased right here (*scratches out the part of the rectangle under the line at 2*), and then I'm left with a segment, this red segment (*colors the remaining part of the rectangle red*)…since there's a larger number subtracted by a smaller number, I'm kind of, I'm viewing it as the larger number will stay more intact, the little number will get eaten up completely.

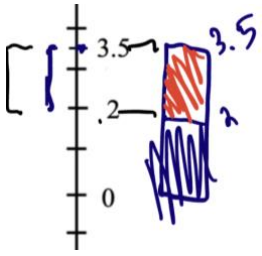

Figure 4. Chloe's work on task 6a

In this episode, we infer that Chloe was using a takeaway segments model of subtraction. Chole viewed the segment between 3.5 and 2 as what is remaining when you take away the segment from 0 to 2 from the segment from 0 to 3.5. She referred to 3.5 as "the whole" and the 2 as the "part" that is taken out. Chloe further emphasized that she was operating on these segments when she introduced the idea of a physical object, a candy bar. Although Chloe still appeared to envision a process of taking away, we note that the activity associated with this model is distinct from the takeaway values model, in which a student may begin at 3.5 and count back 2 units. We note that this model broke down for Chloe when she tries to apply it in task 6b, which asks her to represent 6 – (–2). She could not figure out how to apply the takeaway segments model and remove a negative segment from a positive segment because there was no overlap between the two segments.

Translation Model

Finally, we observed students using what we refer to as a translation model of subtraction. In these instances, students found a numerical result, and then represented that result as a length from zero. We give the example of Yasmine on task 4c. Yasmine drew a segment labeled "a" for –1, a segment labeled "b" for –5 (we note that she drew this to the right of zero rather than to the left) and then drew a segment from 0 to 4 which she labeled c, in response to task c, which asked her to draw a segment to represent –1–(–5). In this way, Yasmine translated the distance between –5 and –1 and shifted this to the right, to another segment with a length of four. Although Yasmine did not attend to the distance between –5 and –1, we refer to this as a translation model, as the drawn segment has the length of the difference, yet the endpoints of the segment have shifted. When asked to explain her reasoning, she shared that she knew the numerical result of the difference was four and that she was "more focused on getting the length right" rather than thinking about the relationships between segments a, b, and c on the *x*-axis.

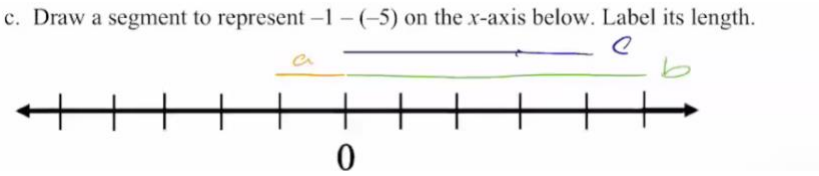

Figure 5. Yasmine's work on task 4c, an example of a translation model of subtraction

In Table 1, we summarize our description of the four models we identified and the observable evidence we used to help classify student's reasoning as such.

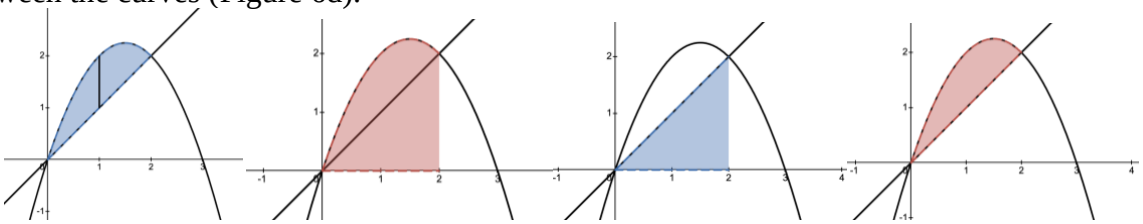

Table 1. Four Models of Subtraction

	Models *b*–*a* as	Observable Evidence
Magnitude	The distance between positions *a* and *b*	• Language: "length," "distance," "from *a* to *b*" • Draws a segment from *a* to *b* and labels it *b*–*a* • Attends to the endpoints when referencing segment
Takeaway Values	The resulting position starting at position *b* and moving left (down) *a* units	• Language: "takeaway *a*," "go *a* back" or "down from *b*" • Starts at position *b*, counts *a* units back, labels final position as *b*–*a* • Segments, if drawn, record movement from one position to another (length of segment may be associated with *a*). • Counts discrete units, uses counting language
Takeaway Segments	The resulting segment from removing a segment of length *a* from a segment of length *b*	• Language: "the segment *b*–*a*," "remove," "piece" •Considers segment from 0 to *b*, removes segment from 0 to *a*, remaining segment is result • Emphasizes remaining segment as result, may not attend to length of segment, or endpoints of the segment
Translation	The distance between *b*–*a* and 0	• Language: "length" • Finds result, draws segment of that length from 0 to *b*–*a* • Does not require end points of the segment to be *a* and *b*.

Discussion

In our study, we identified four distinct ways in which undergraduate students modeled a difference expression of the form $b–a$ in a single-dimension. These four distinct models emerged during tasks designed to promote a magnitude interpretation of $b–a$ as the distance between positions a and b. We noticed trends in the ways in which students used their models to explain their reasoning, and the extent to which students could see past their models. We theorize there may be a connection between the distinctions in figurative and operative imagery (Moore, 2016; Thompson et al., 2024) and the ways in which students were constrained or empowered by their models for modeling a range of differences, including those with negative integers, non-integer values, and variables. For instance, the takeaway segments model appeared to be tied closely to the models themselves, with students operating on an object within the model. For Chloe, these models were not able to be adapted to account for a difference between a positive and negative value. We plan further research in this direction, as well as understanding when and how students adapted their models throughout the activity.

Although three other models of subtraction emerged in a context where we were attempting to promote a magnitude model, we see ways in which some of these models can be leveraged in the teaching and learning of Calculus. We conclude by commenting on the role of various models of difference expressions in one example from Integral Calculus, area between curves. The area between graphs of functions f and g in the Cartesian plane can be found using integrals of the difference of two functions. The justification for why the difference of the functions finds the area between the curves can be conceived in several distinct ways. For example, consider the functions $f(x) = x$ and $g(x) = –x(x–3)$. Locally, the difference of the two outputs of the functions for a value of x, $f(x) – g(x)$, gives the height of a generic rectangle in the area between f and g (Figure 6a). Another way to conceive the area between the curves is as the global difference between the area under f (Figure 6b) and the area under g (Figure 6c) resulting in the area between the curves (Figure 6d).

(a) (b) (c) (d)

Figure 6. Pointwise difference gives height of any rectangle between f and g (a) vs. Global difference of area between functions gives difference between area under individual functions (b), (c), (d).

We note similarities between this global difference of the area under two functions and the takeaway segments model we observed in our study. The global difference of the area under two functions, and the area between two curves considered pointwise may each be used to conceive of the area between functions. If a student can readily perceive of these illustrations as related to the integral expression, these visuals together can serve as a proof of the difference property of integrals, that the integral of the difference of two functions is equal to the difference of the integral of each function. Still, a third way to conceive of why an integral of a difference of two functions gives the area between the curves is to conceive of a difference of two functions as translating the area to be between one singular function and the horizontal axis. In our example, the equivalent area would be under the function $h(x)=(3x–x^2)–x$. We anticipate connections between the translation model we observed in this study and this third way of conceiving of how integrals of differences of functions find areas between curves.

Undergraduate Students' Conceptualization of Repeating Decimals

Gleb Glebov
Simon Fraser University

Niusha Modabbernia
Simon Fraser University

The mathematics education community has examined how students conceptualize repeating decimals. Yet, there is potential for further investigation of how undergraduate students conceptualize the addition of repeating decimals. This paper explores pre-service teachers' conceptualization of repeating decimals. Each participant answered three open-ended questions, and our data consisted of these written responses. Our analysis highlighted that the school conventions hindered many participants from seeing how to add repeating decimals without truncating them. Initially, most participants viewed repeating decimals as processes that approximate rational numbers. Many participants came close to considering repeating decimals as mental objects rather than processes. Our data indicates that asking participants how they would check if they had correctly added repeating decimals enabled them to overcome epistemological obstacles that hindered them from seeing repeating decimals as numbers.

Keywords: APOS theory, Geometric series, Infinite processes, Infinite series, Repeating decimals

Infinite processes are vital in mathematics education, especially in undergraduate mathematics courses. Common topics that involve the notion of infinity are sets, sequences, and limits. Most students first encounter infinite series in calculus courses but rarely explicitly in school mathematics. Hence, mathematics education researchers know much more about how students think about sets, sequences, and limits (Dubinsky et al., 2005a; Dubinsky et al., 2005b) but have yet to study how students conceptualize series extensively. According to Kung and Speer (2013), the mathematics education community still needs to amass "an extensive research base that provides insights into student understanding of this topic [of infinite series]" (p. 420) because we know very little about "how students think about this topic" (p. 420).

Repeating decimals exhibit a duality between potential and actual infinity that may appear paradoxical. On the one hand, a repeating decimal exemplifies potential infinity when one views it as a continuous process of forming digits to express a rational number through long division. On the other hand, a repeating decimal is an instance of actual infinity because it represents a fixed number. This paradoxical duality between potential and actual infinity baffles many students. Some authors (see, for example, Dubinsky et al. (2013), Edwards and Ward (2004), Sierpińska (1987), Sinclair et al. (2006), Weller et al. (2009, 2011), and Yopp et al. (2011)) have investigated how students think about repeating decimals and their relationship to infinity and limits. However, researchers have yet to examine how students conceptualize arithmetic with repeating decimals. Weller et al. (2009, 2011), Yopp et al. (2011), and Dubinsky et al. (2013) have found that many pre-service teachers struggled with repeating decimals and did not believe that $0.\overline{9} = 1$. Sinclair et al. (2006) developed an instructional treatment that "draws attention away from the procedure of conversion" to allow learners to view representations of fractions in decimal form "as objects rather than processes" (p. 184). They hypothesize that pre-service teachers view the standard conversion of decimal numbers into fractions as a process "that allows them to turn decimal numbers into fractions rather than as a general relationship between fractions and repeating decimals" (p. 189). Sierpińska (1987) has also discovered that 17-year-old humanities students found the equality $0.\overline{9} = 1$ perplexing. One of her students said the left-

hand side would not equal one "no matter how many nines you put" and that it could not equal one unless "it goes to the very infinity" (Sierpińska, 1987, p. 379). Even some undergraduate analysis students who were aware of the definition of the repeating decimal "disregarded the definition" and argued that the left-hand side "was not equal to one" (Edwards & Ward, 2004, p. 417). Given these findings, our study investigates how pre-service teachers conceptualize adding two repeating decimals. In particular, we examine how adding two repeating decimals affects their understanding of the equality between repeating decimals and their rational counterparts. To frame this investigation, we turn to APOS theory because it offers one possible explanation for difficulties with repeating decimals, and we use it to analyze data from post-instructional assessments and describe the mental constructions involved in an individual's conceptualization of the addition of two repeating decimals. Our study aims to answer the following research questions: *What do pre-service teachers attend to when adding two repeating decimals? How effectively does adding repeating decimals help pre-service teachers regard repeating decimals as objects rather than processes?*

Literature Review and Contextual Insights

Repeating decimals are geometric series in disguise, and some authors have investigated how students think about infinite series and their relationship to conceptions of infinity and limits. We situate our work within this literature, focusing on endless addition, series convergence, and other obstacles in understanding series.

On Endless Addition

Sierpińska (1987) found that students generally viewed infinity as an unending and uncompleted process while studying how students face epistemological obstacles involving limits. She explored erroneous uses of the geometric series and prompted students to look for errors in her reasoning. Likewise, Martínez-Planell et al. (2012) found that students view series as an endless addition process. They observed that students continued thinking of series as infinite summations after training. Their study shows that the rigorous definition of a series may only sometimes replace the conception of series as infinite additions in most students' minds. Barahmand (2021) found that students resisted changing their intuitive use of equality and inequality signs despite facing series-related cognitive conflicts.

On Series Convergence

Alcock and Simpson (2004) suggest that some students go through a process similar to proofs and refutations because they conceive of a range of objects that satisfy the definition of convergence and debate which properties hold for all of them. They found that visual learners overestimated their understanding of the convergence of sequences and series, and they could not produce a written argument that a mathematician would consider appropriate and rate highly. However, Lindaman and Gay (2012) found that visualizing series convergence enables students to develop a longer-lasting mental image of convergence when they combine visualization with different calculus reform strategies. Fischbein et al. (1981) and Sierpińska (1987) found that some students developed implicit conceptions of convergence, but the students argued that the partial sums would never reach the limit but only get closer to it. Sierpińska (1987) also found that students could not conceive of infinite series equaling the limit of its partial sums, but some students began developing implicit conceptions of convergence. Likewise, Oehrtman et al. (2014) found that the guided reinvention approach allows students to construct a coherent definition of a sequence's limit and define the pointwise convergence of an infinite series.

On Other Obstacles

Mamolo and Zazkis (2008) and Wijeratne and Zazkis (2016) found that students perceived infinity as an ongoing process even when they indirectly dealt with convergent geometric series. Martínez-Planell et al. (2012) also show that students conceive infinite series as an unending process of addition or as limits of partial sums, but some simultaneously hold both conceptions. Martin (2013) found that experts favour the formal definition of series convergence, while students rarely do. Alcock and Simpson (2005) found that some non-visual learners can manipulate symbols correctly but are prone to errors when they restate definitions, so they shallowly consider the meaning of their manipulations. However, Movshovitz-Hadar and Hadass (1991) and Sierpińska (1987) observed that students found that algebraicly manipulating geometric series could be perplexing and paradoxical. Although Barahmand (2021) found that students resisted changing their intuitive use of equality when dealing with infinite series, Oehrtman et al. (2014) found that guided reinvention helps students construct coherent definitions of pointwise convergence of series despite notational obstacles.

Theoretical Framework

Mathematics education researchers (see, for example, Alcock and Simpson (2004, 2005), Barahmand (2021), Fischbein et al. (1981), Lindaman and Gay (2012), Mamolo and Zazkis (2008), Martin (2013), Martínez-Planell et al. (2012), Movshovitz-Hadar and Hadass (1991), Oehrtman et al. (2014), Sierpińska (1987), and Wijeratne and Zazkis (2016)) have used various theoretical frameworks and methodologies to investigate students' conceptualization of the convergence of series and their limits, but APOS theory (Dubinsky et al., 2005a, 2005b), with the Totality stage, guided our investigation.

Dubinsky et al. (2013) explain that one possible way to describe a participant's ability "to see or to imagine all of the 9s [or other repeating digits] present at once" (p. 240) without seeing repeating decimals as objects is the existence of a new stage that they call totality, between the Process and Object stages. It refers to a student's ability to view all the repeating digits as present at once and simultaneously view this process as ongoing and completed. The fraction 1/3 illustrates this more explicitly because one divided by three is 1/3, whereas using long division yields the decimal representation of 1/3. Thus, this process is simultaneously ongoing and completed. In addition, participants' evidence of both progress toward and away from a stage suggested that there might be intermediate levels in the development from one stage to another. They note that their data indicates that seeing all of the nines present at once does not give this process the status of an object. According to the genetic decomposition related to repeating decimals Dubinsky et al. (2013) provide, repeating decimals become objects when participants can think of repeating decimals as numbers, perform arithmetic operations on them, substitute them for their rational counterparts, or conclude that they approach and reach their rational representations. Dubinsky et al. (2013) also revise the genetic decomposition related to repeating decimals by including three intermediate stages from the Process stage to the Totality stage: Start toward Totality (ST), Progress toward Totality (PT), and Emerging Totality (ET). They also propose three intermediate stages from the Process stage to the Object stage: Start toward Object (SO), Progress toward Object (PO), and Emerging Object (EO). Dubinsky et al. (2013) discuss the possibility of a mental mechanism existing "by which an individual moves from thinking of a process as a sequence of continuing steps to being able to imagine these steps all at once" (p. 251). APOS theory with the Totality stage postulates that the primary mental mechanisms for building action, process, object, and schema mental structures are interiorization for progress

from action to process, de-temporalization from process to totality, and encapsulation for progress from totality to object (Dubinsky et al., 2013).

Method

Thirty pre-service secondary mathematics teachers from a mathematical methods course for teaching secondary mathematics participated in this study. At the time of data collection, our participants were in a professional development program in mathematics education. Their mathematics backgrounds and experiences varied significantly, but all held degrees in mathematics or science.

While exploring the topic of rational and irrational numbers, the participants used the definitions of rational and irrational numbers to relate them to terminating decimals, repeating decimals, and the decimal expansions of irrational numbers. The participants revisited various examples of repeating and non-repeating decimals and discussed converting a fraction to a decimal number. One student recalled the algorithm for converting a repeating decimal to a fraction by setting it equal to a variable, multiplying it by an appropriate power of ten, subtracting the former quantity from the latter, and solving for the variable. This suggestion led to a discussion about the meaning of digits and their positions, mainly focusing on repeating decimals. The students engaged in a lively debate, with differing opinions, while the instructors chose not to intervene to allow the discussion to unfold organically. Afterward, students worked in groups of two or three to discuss and respond to the following three questions:

Group Task: How would you add two repeating decimals? How would you check if your answer is correct? How would you respond to someone who says the sum of two repeating decimals is always a repeating decimal?

After that, we gave the participants a similar individual task.

Individual Task: A) How would you add two repeating decimals? How would you check if your answer is correct? How would you respond to someone who says the sum of two repeating decimals is always a repeating decimal? B) Now, add the following repeating decimals (without technology) before revising your initial responses. Please show all your work for each example: 0.252525... + 0.373737..., 0.434343... + 0.787878..., 0.858585... + 0.273273273..., 0.656565... + 0.587587587... C) After working on the above examples, please share your revised response to the three questions you answered earlier: How would you add two repeating decimals? How would you check if your answer is correct? How would you respond to someone who says the sum of two repeating decimals is always a repeating decimal?

The data for this study consisted of the participants' written group and individual responses. We categorized them by the participants' views on repeating decimals, focusing on their understanding of the underlying concepts. We analyzed their responses according to APOS's framework, focusing on intermediate stages from Process to Totality and Totality to Object.

Results

Some participants found handling infinitely many digits, converting repeating decimals to fractions, and doing column addition with repeating decimals challenging, and these particular challenges enabled us to categorize student responses.

Participants Face Challenges Handling Infinitely Many Digits

Many participants faced obstacles while checking if they had correctly added two repeating decimals in groups and their individual tasks. Many of our students viewed infinity as an unending and uncompleted process. Below, we discuss how this perception influenced their

approaches. We hoped our students would see that decimal expansions contradict the notion of potential infinity because they are approximations that consecutively grow in time while representing a completed process. Still, only some of our students observed that. We will now explain how this perception influenced their approaches.

Initial responses. Many participants argued that when adding repeating decimals, using more repeating digits would allow them to get closer to the answer. They viewed the addition as an infinite process that continuously improves the final answer as the number of digits increases.

Starting points. In class, our participants could not immediately add repeating decimals as they would terminating decimals. Hence, they used truncated versions of repeating decimals or rational equivalents because they viewed both as numbers. Since repeating decimals did not have last digits, our participants initially resorted to operating on exact rational counterparts or rational approximations instead because they had last digits. Only one participant added two repeating decimals using the left-to-right addition by claiming that "3.777... + 4.666... = 7.000... + 1.300... + 0.130... + 0.013... + ... = 8 + 0.4 + 0.04 + 0.04 + ... = 8.444... = 8 4/9."

Participants Truncate Repeating Decimals to Verify the Conversion to Fractions

We found that many participants initially viewed the sum as an endless addition process, and they could not apply mental actions to the sum (or imagine applying them). Our data indicated that all the participants could easily convert repeating decimals into fractions using algebra. However, when we asked them how they would check if their final results were correct, most did not argue for the validity of algebraic conversion. Instead, they resorted to truncating repeating decimals, approximating the sum, and using calculators. Only a few students argued that the algebraic method was valid and that they only had to check if they added the corresponding fractions correctly. We now showcase some responses exemplifying the intermediate stages between Process and Totality.

Totality stage. Some participants built on their initial responses and displayed the PT conception as they were trying to imagine all the digits present at once by physically seeing many digits. One group first "added 3.99999 to 2.22222 and got 6.22221." Then they tried "adding 3.9999999999 to 2.2222222222 and got 6.2222222221." They concluded by saying, "There is a pattern here; the sum of our repeating decimals is also repeating; the more you extend them to add, the longer the decimal of the sum will be." Another group suggested adding two repeating decimals "using regular addition," but "the answer was inaccurate." They noted that adding more digits gave "a more accurate answer" and allowed them to "see what decimals would repeat." They concluded that the more digits we use, "the closer we get to the true answer." Another group suggested using a calculator and "increasing the number of repeating digits." They started with "0.333 + 0.666 = 0.999" and then suggested using "0.3333333333 + 0.6666666666 = 0.999999999" because they wanted "to show that the answer gets closer and closer to 1 (like a limit)." Another group said we could check our work by "doing the long addition with several decimal places for the best estimation." Another group wrote that "1/3 + 1/11 = 11/33 + 3/33 = 14/33 = 0.424242…" and added that "0.33333 + 0.09090 = 0.42423" confirms their answer. Another group said, "We can check the answer by adding the decimals to several decimal points." For example, "3.333333333… + 0.7142857… = 4.0476190… = 85/21." The group added that "this shows that our approximation using fractions works except when the fraction would produce a whole number" and that "this stresses that decimals are only approximations for fractions." Another group said, "Using the rounded version of the original numbers truncated to an appropriate number of decimal places, we could find an approximate solution to compare with our exact answer." Another group said that "using the rounded version

of the original numbers" allows us to use "an approximate solution to compare with our exact answer." On their individual task, most participants abandoned the notion that adding two repeating decimals is a continuous process that improves the accuracy of the final result when more and more repeating digits are involved. We categorized some responses as the ST conception because these participants suggested truncating to estimate the sum without saying that using more digits improves the accuracy of the result. One of these participants suggested checking the addition "by manually typing out several decimal places." Another proposed to "truncate to an appropriate amount of decimals" and "add them up to check." Another suggested estimating "the approximate result of adding two decimals by manually adding the decimals up digit by digit to a certain amount." Another participant proposed "manually doing the long addition with several decimal places." Another suggested "ensuring that the sum makes sense based on an estimate."

Object conception. During the group exploration, our participants generally believed that repeating decimals were not complete numbers. They often asserted that they were approximations or approached rational numbers. We now showcase some responses exemplifying the intermediate stages between Totality and Object. Only two groups exemplified the Object conception by explicitly stating that repeating decimals are numbers. One group said that "recurring decimals are rational numbers" and "operations like adding apply and are valid when trying to add the repeating decimals together." Some individual responses exemplified the transition toward the Object conception. One participant demonstrated the EO conception by suggesting adding repeating decimals "as if they were not infinite, as the addition causes a repetitive pattern." This participant recognizes that one may add two repeating decimals, but only as if they were terminating decimals, so the participant has yet to reach the Object stage. Another proposed that "it is best to round each decimal to a certain large number of digits (12, for example) and try to add them to look for a recursion pattern." This response is similar to the previous one, but because rounding aims to identify the repetend in the final answer, this participant operates on repeating decimals as objects. Ten participants mentioned performing addition or "long addition," but we categorize these responses as the PO conception due to the lack of elaboration.

Participants Encounter Cognitive Obstacles Doing Column Addition

Our participants initially viewed the sum of repeating decimals as a process and the sum of their rational counterparts as objects. To them, the addition of repeating decimals is a dynamic process, while the sum of two corresponding fractions is a static object. Such a conceptualization involves viewing one side as an approximation to the other rather than strict equality. The standard right-to-left addition convention has prevented most of our participants from reaching the totality stage immediately. In contrast, some participants reached the Totality stage using pattern recognition but did not reach the Object conception. We now exemplify both cases.

School conventions (Totality stage). On the individual task, only one participant added using left-to-right addition, but everyone else relied on the standard right-to-left addition. This participant said, "Since repeating decimals have no last digit, we must start adding from the left to do column addition until we recognize the pattern in the new number." The same participant wrote that "$3.777... + 4.666... = 7.000... + 1.300... + 0.130... + 0.013... + ... = 8 + 0.4 + 0.04 + 0.04 + ... = 8.444... = 8\ 4/9$." This participant imagined and acted on all the digits to add from the left, reaching the Totality stage and immediately progressing toward the Object conception because the participant identified the sum as "the new number."

Pattern recognition (Object conception). Some exemplified the EO conception in their individual responses. One participant suggested "writing out the first several digits (enough to have the recurring part repeat at least three times) of each decimal and then adding them." The same participant said, "After seeing some repetition in my answer, I would assume that is the part that repeats and write the answer as a repeating decimal." This elaboration demonstrates the EO conception. The participant does not refer to the sum as a number, so we cannot conclude that this participant has reached the Object stage, but this conception is emerging. Another participant proposed to "ignore the final digit and determine the answer from the repeating portion since as the number of decimal places approaches infinity, the error tends to 0 and becomes negligible." The participant exemplifies the EO conception because the participant truncates to "determine the answer from the repeating portion" and recognizes the possibility of the sum being a number "as the number of decimal places approaches infinity." During the group exploration, only one group suggested checking "if adding the digits involves carrying ones." If it does not, "add some of the digits and look for a pattern." For example, "0.121212… + 0.656565… = 0.777… = 7/9." They added that if it does, add some digits and "look for a pattern but ignore the last digit." Since it is unclear whether this group recognizes the sum as a number or procedurally converts a repeating decimal to a fraction, we also classify this response as EO conception.

Conclusion and Discussion

Our paper aimed to investigate what pre-service teachers attend to when adding two repeating decimals and how effectively adding them helps them regard repeating decimals as objects rather than processes. Our participants demonstrated proficiency in converting repeating decimals to rational numbers and adding them that way. However, when the group and individual tasks asked them how they would verify their calculations, the majority predominantly truncated or approximated repeating decimals.

Unsurprisingly, the written group responses indicate that our participants initially viewed repeating decimals as processes that only approximated the corresponding rational numbers. The absence of the last digit and the reliance on the right-to-left addition posed the major obstacle.

Using the left-to-right addition, recognizing the sum's repetend, and stating that the final answer is a number rather than an approximation was a way of conceptualizing repeating decimals as numbers. More research could uncover the role of left-to-right addition. Most surprisingly, our data indicates that almost all the students have reached the Totality stage. A few reached the Object stage, and many came close to viewing repeating decimals and their sums as objects. Asking participants to think about how they would check that they had added two repeating decimals correctly inadvertently helped them reach the Totality stage and even the Object stage, and herein lies our main contribution to the research on repeating decimals. The data suggest that the unusual task we designed helped most participants reach the totality stage. Moreover, our study indicates the existence of the mental mechanism of de-temporalization for transitioning from process to totality, as almost all of our participants have reached it. Prompting participants for ways to check if they had correctly added repeating decimals led them to think about how to perform column addition with repeating decimals. Our participants seem to have reached the Totality stage because they eventually realized that they had to see and act on all the digits as they would when doing column addition with terminating decimals. Future research would help the mathematics education community ascertain if this is the determining factor.

Navigating Belonging, Competence, and Career Aspirations in Mathematics: Experiences of First-Generation, Low SES Women

Seyda Uysal
The University of Southern Mississippi

This study investigates the academic journeys of first-generation, low socioeconomic status (SES) women in mathematics, focusing on their sense of belonging, perceptions of competence, and career aspirations. Using narrative inquiry, the research draws on interviews and reflections to illuminate how isolation, identification as "rule followers," and a lack of mentorship shape their experiences. The study adopts Wenger's (1998) mode of belonging framework—engagement, alignment, and imagination—to analyze how these students interact with their mathematics community and envision their roles within it. Findings highlight the urgent need for mentorship and career guidance tailored to underrepresented students in STEM. This research provides insight into institutional strategies for supporting the success of first-generation, low SES women in mathematics.

Keywords: belonging, career guidance and mentorship, competence, first-generation

The underrepresentation of women and racially/ethnically minoritized students in Science, Technology, Engineering, and Mathematics (STEM), particularly in mathematics, is a persistent issue in higher education (Beasley & Fisher, 2012; Master & Meltzoff, 2020). For first-generation, economically disadvantaged students, these challenges are further compounded by a lack of institutional knowledge, resources, and mentorship (Kim & Sax, 2018; Mishra, 2020). These students often navigate the academic landscape without the familial or social networks that their more privileged peers rely on, facing significant barriers in accessing the support necessary for academic success and career development (Choy, 2001; Mishra, 2020). As a result, many of these students experience feelings of isolation and uncertainty, particularly within the competitive and exclusive environments of STEM fields (Good et al., 2012).

Mentorship plays a crucial role in fostering student success, providing both academic and emotional support, yet first-generation, low-income students often find themselves without this vital resource (Piatek-Jimenez, 2008). The absence of consistent mentorship can limit students' career aspirations, leading them to pursue more practical, though uninspired, options that do not fully align with their academic strengths or passions (Piatek-Jimenez, 2015). Furthermore, implicit biases and stereotypes can exacerbate these issues, reinforcing feelings of non-belonging and limiting opportunities for underrepresented students in STEM (McGee & Martin, 2011; Good et al., 2012; Rainey et al., 2018).

Through Wenger's (1998) framework of modes of belonging—engagement, alignment, and imagination—this study explores how gender, race, first-generation status, and socioeconomic disadvantage intersect to shape the academic experiences of women in mathematics. Thus, the study aims to answer the following research question: How do women of low socioeconomic status experience their mathematics major, particularly in relation to their sense of belonging within their mathematics community? The study highlights the role of mentorship, the challenges of belonging, and the importance of career guidance in supporting the academic and professional development of these students.

Theoretical Framework

The theoretical framework guiding this study is based on Wenger's (1998) concept of "modes of belonging," which include engagement, alignment, and imagination. These modes provide a lens for understanding how individuals negotiate their identities and find belonging within a community of practice, such as an academic or professional field. Each mode offers a distinct yet interrelated perspective on the processes through which individuals experience inclusion or exclusion, and how these experiences impact their participation and development of mathematical competence.

Engagement refers to the active participation in a community through the ongoing negotiation of meaning, where individuals interact with others and the environment to co-construct knowledge and develop their sense of belonging. Engagement is key to identity formation as it integrates doing, thinking, feeling, and belonging (Wenger, 1998). However, engagement is not always guaranteed; individuals may face barriers to full participation due to social dynamics, unequal power relations, or institutional structures. When engagement is limited, it can lead to feelings of marginalization and prevent individuals from fully developing their competence within the community.

Alignment involves coordinating one's actions and efforts with the broader structures, goals, and expectations of the community. It requires individuals to adapt to the norms, values, and practices that define what is considered competent or valuable within the community. Alignment, however, can also be disempowering if it involves blind adherence to prescriptive norms without room for individual agency. For individuals who have historically been excluded from dominant communities, alignment may be particularly challenging, as their identities and experiences may not fit neatly within the established culture of the institution. This tension can result in a disconnection between personal goals and the broader expectations of the community.

Imagination is the ability to envision future possibilities and create new ways of being within the community. It allows individuals to transcend immediate circumstances, think creatively, and imagine their potential trajectory within the community. Imagination plays a crucial role in helping individuals see themselves as capable of growth and achievement. However, when access to role models, mentors, or opportunities for exploration is limited, imagination can be stifled, restricting an individual's ability to envision a broad range of future possibilities. This limitation can hinder one's long-term engagement and commitment to the field.

Together, these three modes of belonging—engagement, alignment, and imagination—offer a comprehensive framework for examining how individuals navigate their participation in academic or professional communities. They highlight the dynamic and often complex nature of belonging, showing how barriers in any one mode can impact an individual's overall sense of identity, competence, and future aspirations within a community of practice.

Method

Background and Participants

This study employs a narrative inquiry approach to explore the academic journeys of two first-generation, low socioeconomic status women pursuing mathematics degrees at a research-intensive large university (Clandinin, 2006). Nia, a biracial (Black and White) student, and Bethany, a White student, were selected due to their shared characteristics as first-generation students and double majors in Pure Mathematics and Secondary Mathematics Teaching (SMT). Nia had switched majors twice—first in Chemistry and then Psychology—before finding satisfaction in mathematics. Bethany, on the other hand, identified more strongly with the SMT

community and managed her studies alongside work to maintain financial independence. Both participants faced challenges related to belonging, competence, and mentorship, which shaped their academic paths and career aspirations.

Data Collection

Data were collected during the spring 2022 semester through semi-structured, in-depth interviews and weekly video reflections. Three interviews were conducted with each participant via Zoom, focusing on their sense of belonging, competence, and their future in mathematics. In addition, weekly video reflections collected throughout the semester, which allowed the participants to share real-time updates on their academic and social experiences. Throughout the process, field notes were taken to document key observations and reflections, helping the researcher triangulating the data and capturing a fuller picture of the participants' experiences.

Data Analysis

The narrative inquiry approach was used to examine the participants' experiences in depth, with Wenger's (1998) mode of belonging framework serving as a lens for data analysis. In this study, narrative is defined as a way of understanding and representing the participants' lived experiences as storied phenomena that unfold over time and within specific social and cultural contexts. Drawing on Clandinin and Connelly's (2000) perspective, narratives are conceptualized as both the means of inquiry and the objects of study, reflecting how individuals make sense of their identities and experiences through the stories they tell. By centering on the interviews and weekly video reflections as the primary sources of narrative data, the study captures authentic evidence of the participants' everyday experiences—experiences that are often overlooked or devalued by institutions, instructors, and peers within the mathematics community. These narratives provide a lens into how the participants navigate the intersecting challenges of belonging, competence, and career aspirations, revealing the subtle and overt ways in which systemic barriers shape their journeys.

Open, axial, and selective coding processes were followed to systematically analyze these narratives while remaining grounded in Wenger's (1998) framework. First, open coding was employed to identify initial categories from the interview and reflection transcripts, focusing on broader patterns related to the modes of belonging, conceptualized through *engagement*, *alignment*, and *imagination* components. Next, axial coding was used to connect related themes, integrating these patterns with Wenger's (1998) framework to explore how the participants' sense of belonging within the mathematics community was shaped and negotiated. Finally, selective coding was applied to distill the core themes reflecting the participants' evolving modes of belonging, specifically in relation to participatory actions, mathematical competence, career aspirations, and the influence of mentorship (or the lack thereof).

Wenger's (1998) framework provided a theoretical anchor, enabling the analysis to explore the dynamic interplay between the participants' identities as first-generation, low SES women and their experiences within the mathematics community. This iterative approach ensured that the findings honored the richness of the participants' narratives while being theoretically informed by the mode of belonging framework, ultimately illuminating how their identities and experiences were shaped by their interactions within their academic and social contexts.

Findings

The findings from the narratives of Bethany and Nia reveal key insights into how first-generation, low SES women navigate the mathematics community. This section explores three

central themes that emerged from their stories: (a) their sense of belonging and feelings of isolation in academic spaces, (b) their perceptions of competence and identity as learners of mathematics, and (c) the role of mentorship and guidance in shaping their career aspirations. While both women share common struggles tied to their socioeconomic and gender identities, Nia's biracial identity adds an additional layer of complexity to her experiences, creating both shared and distinct challenges in how they perceive and engage with their academic environment. Nia and Bethany's experiences reveal the interconnectedness of belonging, competence, and mentorship in their mathematics journeys, each influencing the others in profound ways. Through Wenger's (1998) modes of belonging—engagement, alignment, and imagination—both participants grappled with feelings of isolation and uncertainty about their place in the mathematics community, compounded by perceptions of competence and the absence of mentorship.

Belonging and Isolation in the Mathematics Community

Both Nia and Bethany struggled with a sense of belonging within their academic community, particularly in group settings where they often felt marginalized by more confident or prepared peers. Bethany's feelings of exclusion were exacerbated by her perception that others were more capable, leading her to disengage from group work. She reflected, "I just assume people like Troy[1] know more than me, so they must be doing it right, even if it doesn't make sense to me" (Bethany, Reflection 2). This assumption hindered her ability to fully engage, aligning herself only passively within the group, which deepened her isolation.

Similarly, Nia's experience of exclusion was tied to her peers' faster pace and greater mathematical background. She remarked, "Sometimes, especially in group work, I'm just the person watching others solve problems. It's hard when others move faster, and I can't keep up" (Nia, Reflection 4). The sense of being sidelined diminished her engagement and made her feel like an outsider in a space where she struggled to align her academic identity with the expectations of the mathematics community. For both participants, their first-generation status may have contributed to their challenges, as they lacked access to social and familial networks that could have supported them in navigating college.

Perceptions of Competence: Rule-Following vs. Rule-Making

Both Bethany and Nia saw themselves as "rule followers," a mindset that limited their perception of competence and ownership over mathematical knowledge. This tendency to follow prescribed methods without feeling a deep connection to the material undercuts their confidence. Bethany reflected on this in saying, "I'm just a rule follower, really. I do what the professors tell me to do, and that's how I know I've done it right" (Bethany, Reflection 7). For her, mathematical success was defined by adherence to the rules set by her instructors, rather than by personal exploration or critical thinking.

Nia echoed this sentiment, expressing frustration that her learning experience was mechanical and devoid of intellectual autonomy. "I don't feel like I have ownership over the math I'm doing. It's just a bunch of methods I follow, and it feels like I'm not really the one making decisions" (Nia, Interview 1). This rule-following approach led both women to feel disconnected from the deeper, creative aspects of mathematics, reinforcing their position on the

[1] Troy was one of Bethany's peers who often dismissed her contributions during group work, reinforcing her feelings of inadequacy and furthering her sense of isolation. Bethany frequently referred to him in her reflections, highlighting the impact of his actions on her confidence and participation.

periphery of the mathematics community. The shift from rule-following to rule-making—an essential transition in higher-level mathematics—remained out of reach for them, thus further impacting their engagement and alignment.

Mentorship and Career Guidance

The absence of mentorship played a crucial role in shaping both participants' academic trajectories and their ability to imagine broader career possibilities. Without a mentor to help her explore the landscape of opportunities, Bethany felt confined to practical career choices, such as teaching. While she saw it as a viable and straightforward path, she expressed uncertainty about whether it was the most fulfilling option available to her. "I really wish I had someone to guide me more. I don't think I've explored all the possibilities with a math degree, but there's no one really pointing me in a different direction" (Bethany, Interview 2). This lack of guidance diminished her alignment with the larger goals of the mathematics community and limited her ability to imagine herself in a more diverse array of mathematical roles.

For Nia, the mentorship she received in high school did not continue into her university life, leaving her to independently navigate her academic and career goals. She reflected: "My high school teacher pushed me toward math, but in college, it feels more like I'm on my own" (Nia, Interview 1). This lack of consistent support left her uncertain about pursuing more ambitious career paths like data analytics, reinforcing feelings of isolation and non-belonging.

Nia also revealed that her academic advising lacked direction, particularly in relation to STEM fields. She explained: "When I was looking for different careers, there wasn't much suggestion for the STEM field... I wasn't looking at STEM. I was looking at everything but STEM" (Nia, Interview 2). This gap in guidance may reflect systemic implicit biases that can affect the opportunities and support available to students from underrepresented groups, including Black women, in STEM fields, potentially reinforcing stereotypes about who is deemed capable of pursuing scientific careers. Without tailored mentorship to counter these biases and explore broader career options beyond teaching, Nia may have experienced a sense of disconnection from the academic community. This might hinder her confidence in pursuing other fields, such as data analytics, which she saw as a more challenging and fulfilling path, but one she did not feel equipped to follow due to the lack of encouragement and support.

Discussion

The experiences of Nia and Bethany reveal the profound impact of gaps in engagement, alignment, and imagination on their academic trajectories, career choices, and perceptions of competence. These themes highlight how the absence of meaningful support structures can hinder the success and persistence of women and racially/ethnically minoritized students in mathematics.

Belonging and isolation emerged as critical issues, directly linked to the students' engagement with their mathematics community. Both participants felt sidelined in group settings, a dynamic that undermined their engagement and reinforced their sense of isolation (Wenger, 1998). For Bethany, group work often left her feeling less competent compared to her peers: "I just assume people like Troy know more than me" (Bethany, Reflection 2), highlighting how perceived disparities in competence contribute to disengagement (Good et al., 2012). Nia faced similar challenges, remarking that she often felt like "the person watching others solve problems" in group settings, further underscoring the exclusion she felt within the mathematics community (Nia, Reflection 4). These feelings of isolation were magnified by their first-

generation status, as both lacked the social capital necessary to navigate academic spaces more effectively (Choy, 2001; Mishra, 2020).

Rule-following vs. rule-making also played a significant role in the participants' academic journeys related to their perceived competence. Both Nia and Bethany saw themselves as "rule followers," a perspective that limited their sense of ownership over mathematical knowledge and stifled their ability to engage in creative problem-solving (Di Martino & Zan, 2010). Bethany reflected on this in saying, "I'm just a rule follower" (Bethany, Reflection 7), while Nia described her frustration at being unable to make decisions independently in her mathematical work (Nia, Interview 1). This internalization of prescriptive learning models prevented them from fully aligning with the broader goals of their academic community, diminishing their confidence and reinforcing their feelings of being outsiders (Wenger, 1998).

The absence of mentorship and career guidance was particularly detrimental to the students' ability to imagine broader career possibilities in mathematics. Bethany expressed regret over not having someone to guide her career exploration, stating that she wished she had more opportunities to learn about the "possibilities with a math degree" (Bethany, Interview 2). Nia echoed this sentiment, noting that while her high school teacher encouraged her toward mathematics, she felt isolated and unsupported at the university level (Nia, Interview 1). McGee and Martin (2011) argued that marginalized students may navigate academic spaces while managing or rejecting imposed stereotypes, which could explain why Nia did not initially seek support. This lack of mentorship, coupled with implicit biases that may have shaped the career advice they received, further limited their ability to align their academic goals with ambitious career paths (Beasley & Fisher, 2012; Cribbs et al., 2021; Piatek-Jimenez, 2008, 2015).

These findings suggest that the combined effects of disengagement, misalignment, and limited imagination create a cycle of self-doubt and marginalization for first-generation, low SES women in mathematics. Addressing these issues requires a comprehensive support system that fosters engagement through meaningful participation, aligns personal goals with community expectations, and encourages the imagination of broader career possibilities through targeted mentorship that is free of stereotypes and biases (Wenger, 1998; McGee & Martin, 2011; Piatek-Jimenez, 2008b).

Concluding Remarks

An exploration of Nia and Bethany's experiences revealed critical gaps in institutional support for first-generation, low SES women in mathematics. These students struggled to fully integrate into their mathematics communities, often feeling isolated and unable to align their personal goals with the academic expectations placed upon them. Their perception of themselves as rule-followers, rather than independent thinkers, compounded their lack of confidence and diminished their potential for success. Furthermore, the absence of mentorship played a crucial role in shaping their career aspirations, which were more influenced by financial necessity than by a true exploration of the field's possibilities. Importantly, this study also highlights the need to further investigate how racial identity intersects with first-generation and low SES status to impact students' experiences in STEM, particularly regarding access to support and mentorship. This study emphasizes the urgent need for targeted institutional interventions, including mentorship, career counseling, and exploratory learning opportunities, that foster a sense of belonging and competence among underrepresented students in STEM. Addressing these barriers is essential for enhancing their academic outcomes, and future research should explore how mentorship and peer networks can be effectively leveraged to support their success.

At-Success Students' Affordance and Barriers to Help-Seeking in an Active Learning College Algebra Course

Colby A. Lamb
University of Nebraska-Lincoln

Despite reforms, some College Algebra students are still "at-success": they can be identified early in the semester as having a higher likelihood of not passing or completing the course (Wakefield et al., 2018). This interview study of 3 at-success College Algebra students explores the hypothesis that there are pedagogical and environmental factors to whether at-success students engage in help-seeking behaviors that could increase their chance at success. I examine: What affordances and barriers to help-seeking do at-success students describe when talking about performance in a college algebra class? Karabenick and Berger's (2013) process of help-seeking was used as a framework for the themes found using interpretative phenomenological analysis. I propose an adaptation and extension of Karabenick and Berger's framework as a result of this study.

Keywords: help-seeking, college algebra, active learning, mathematical microaggressions

Undergraduate drop, fail, and withdrawal (DFW) rates in college algebra can be as high as 50% and even over 50% (Gordon, 2008; Herriot & Dunbar, 2009). Efforts to improve student outcomes have largely focused on active learning (Freeman et al., 2014; Theobald et al., 2020), including professional development for the Graduate Student Instructors (GSIs; Deshler et al., 2015; Rasmussen et al., 2019) who may teach courses with high DFW rates, and course coordination (Rasmussen & Ellis, 2015; Rasmussen et al., 2021). Despite these reforms at the University where this study was conducted, we can still identify college algebra mathematics students early in the semester with a higher likelihood than their peers of not passing (Wakefield et al., 2018).

This study explores the hypothesis that help-seeking (e.g., Karabenick & Berger, 2013) can mitigate the likelihood of not passing the course. It aimed to examine students' perceptions of in-classroom and out-of-classroom learning supports, systems, and experiences for at-success students. In particular, it explored the phenomenon of help-seeking in an active learning college algebra course with a population of students who were at a higher risk of dropping, failing, or withdrawing from the course.

The research question addressed is: *What affordances and barriers to help-seeking do at-success students describe when talking about performance in a college algebra class?*

Study Context: College Algebra and the "MRA"

At the research site, students are asked to review and master a set of prerequisite skills needed for college algebra and demonstrate mastery by scoring 80% on a "Mastery Review Activity" (MRA; for the validity of cutoff score as predictive of course performance, see Wakefield et al., 2018). Students are allowed to attempt this activity every day over the first two weeks of the semester.

Literature Review and Theoretical Perspective

In this section, I will present a small argument for using the term "at-success" to replace the usual term "at-risk" for the population of students I am exploring. The rest of the literature review will examine what is currently known about help-seeking and the gaps this study hopes to

address.

The Term "At-Success" in Place of "At-Risk"

For higher education professionals and staff to provide services to students who have a higher likelihood of not meeting their educational objectives, the term "at-risk" has often applied to these students (Dix et al., 2020; Horton, 2015; Quinnan, 1997). When higher education professionals who are providing these services were asked to give an operational definition of "at-risk" the answers were diverse (Dix et al., 2020). The various operational definitions for at-risk students have included both academic and non-academic characteristics: academic past academic performance, social background, and both internal and environmental characteristics (Bulger & Watson, 2006; Castro, 2014; Connolly et al., 2017; Dix et al., 2020; Horton, 2015).

The label "at-risk" was initially used within K-12 educational settings (Quinnan, 1997). Unfortunately, the term "at-risk" tends to operational definitions that blame the individual and do not address needed system changes (Quinnan, 1997). Deficit language and thinking displaces all the blame for school failure on the individual. This is victim blaming. Valencia (2010) describes victim blaming as one of the six characteristics of deficit thinking in an educational setting. This type of thinking "absolves institutional structures and inequitable schooling arrangements that exclude students from optimal learning" (Valencia, 2010, p. 18).

For this study, I do not want to view students as being deficient. By examining the phenomena of help-seeking, we can learn what fosters a supportive educational environment and empowers students to navigate barriers they may encounter and move them from being "at-risk" to being "at-success". This study aims to identify possible factors that can be changed in both course structure and institutional practices to ensure students are "at-success". The operational definition of "at-success" for this study is given to students who either failed the MRA at the beginning of the course, repeating college algebra, or did not place into college algebra or higher at enrollment into college.

Help-seeking as an Analytic Framework

Help-seeking is considered a form of agency over one's learning in a particular environment (Nelson-Le Gall, 1981; Nelson-Le Gall, 1985; Karabenick & Berger, 2013). Karabenick and Berger (2013) proposed a model of help-seeking that reflected "stages" (p. 239) where decisions were made that impacted whether a learner pursued help and what type of help they pursued. Each of these "stages" occurs in a "phase" (Zimmerman, 2008, as quoted in Karabenick & Berger, p. 254). These authors emphasized that a particular learner may not experience all stages in a particular environment, and the stages do not occur in any universal order. For most individuals, a combination of these stages may occur at any point in the decision process of whether to seek help (Karabenick & Berger, 2013).

As a starting analytic framework, I used the stages and phases proposed by Karabenick and Berger (2013). I used this framework to describe and characterize help-seeking processes college students use to engage in various assignments and activities in college algebra. Since this phenomenological study uses student interview transcripts as the data source, this framework was only used after interviews with students were first analyzed using Interpretative Phenomenological Analysis (IPA) to find various themes (Smith et al., 2009). The framework was used to explain students' affordances and barriers to help-seeking; I leave open the possibility of confirming, disconfirming, or revising this model concerning at-success college algebra students' help-seeking process.

Table 1. Stages of Help-Seeking Process and Three-Phase Model of Self-Regulated Learning

	Stages of Help-Seeking Process	Phase
1	Determine whether there is a problem	Forethought
2	Determine whether help is needed/wanted	
3	Decide whether to seek help (goal)	
4	Decide the type of help	
5	Decide who to ask	
6	Solicit help	Performance
7	Obtain help	
8a	Process the help received- judge or evaluate	Self-Reflection
8b	Process the help received - react to it	

Note. From "Help seeking as a self-regulated strategy" by S.A. Karabenick, and J. L. Berger, 2013, In H. Bembenutty, T. J. Cleary, & A. Kitsantas (Eds.), *Applications of self-regulated learning across diverse disciplines: A tribute to Barry J. Zimmerman,* pp. 237–261.

Methods

Phenomenology

This study was a phenomenological study of help-seeking processes of at-success college students within the context of an active learning college algebra course. To better understand the students' process of seeking help, it is necessary to hear from the students themselves. Since the goal of this study was to give voice to the participants, understand a phenomenon, and describe the essence of engagement with class activities, this study was well suited for a qualitative design (Creswell & Poth, 2018; Merriam & Tisdell, 2016). Creswell & Poth (2018) describe two types of phenomenology studies, hermeneutic phenomenology and transcendental phenomenology. The sub-approach chosen was hermeneutic phenomenology, which aims to interpret the meaning of a lived experience.

Participants and Data Collection

To interview the targeted audience of students who did not complete the MRA activity or repeating college algebra, or did not originally test into college algebra, about their experiences with help-seeking in completing the MRA and other course activities, students were recruited through two different methods. In the Fall of 2023 and Spring of 2024, students who did not complete the MRA activity at the beginning of the semester were sent an email inviting them to participate in an interview about their experiences in college algebra and taking the MRA. Also during both the Fall of 2023 and Spring of 2024 college algebra students were invited to participate in a survey about their experiences in college algebra. In the survey, students were asked if they would be willing to participate in a follow-up interview about their experiences in college algebra. Students who indicated that they were willing to be interviewed and were from the targeted audience were sent an email to participate in an interview about taking the MRA and their experiences in college algebra. To aid in recruiting, students were paid $20 for participating in a 30-45-minute semi-structured interview. When using IPA, it is recommended that the number of participants be between three and six due to the intensity of the interviews' analysis. Three participants were recruited.

Table 2. Description of Interview Participants

Name	Gender	Race	Year	Pass MRA	Previous college math course
Amy	Female	White	Sophomore	No	Intermediate Algebra
Jacob	Male	White	Freshman	No	College Algebra
Carmen	Female	White/Mixed	Sophomore	Yes	Intermediate Algebra

Note: Pseudonyms were used to protect the privacy and confidentiality of research participants.

Participants were interviewed individually. A semi-structured interview protocol was used to guide the interviews (Merriam & Tisdell, 2016). The interviews were done over Zoom and recorded and transcribed. Before the recording began, the participants removed their names to protect their anonymity. The transcript was then checked for accuracy. After each interview and cleaning of transcripts, memoing was done to record initial impressions from each interview. The transcripts were then used for analysis using IPA.

Data Analysis

I analyzed interviews in multiple phases. After several readings of an interview, I engaged in three rounds of "noting" (Smith et al., 2009, p. 83). First, I analyzed the transcript for descriptive comments focused on the content of what the participant said. Second, I made linguistic comments focused on exploring the language and specific words used by the participant. Third, I made conceptual, interpretive comments, drawing from my "own experiential and/or professional knowledge" (Smith et al., 2009, p. 89).

After completing all the initial notations and coding, I organized data from each participant's transcript into a table. Next, I compared all participant tables to identify common patterns. From this, I constructed a merged table of cross-cutting themes. Table 3 includes an excerpt for one cross-cutting theme across all the cases.

After this was done, a summary of recurrent themes was made. These themes and others were then analyzed with respect to the phases of help-seeking (Karabenick & Berger, 2013) as each participant relayed their individual stories.

Results

Several recurrent themes emerged. These themes related to at least one participant's process of help-seeking. I now discuss the themes.

Table 3. Table of Master Theme MRA Purpose as an Assessment or Placement Test

Assessment:	
Jacob:	*Isn't that like a course readiness assessment*
Carmen:	*I personally think it [MRA] was just busy work, but I could see how it was meant to gauge where we were.*
Amy:	*I felt like it [MRA] was just to give my instructor a baseline of where everyone was at.*
Placement Exam:	

Carmen:	*The reasoning they gave us was that it was to make sure that we're actually supposed to be in college algebra. And if we're struggling with anything on the MRA to the point were it showed that we weren't ready for college algebra. They were gonna move us down a class. Move you down to 100A. Which I thought was kind of odd because of the placement exam that we have to take to come into college placed us in college algebra.*
Jacob:	*Don't you have to like test into every math class you take? So I think it's [MRA] kind of redundant. Cause like you already have to like test into the class.*

Determine Whether There is a Problem.

All three participants did not see the MRA as an activity designed for their benefit. They each framed the activity as an assessment or placement exam. See quotes in Table 3. Amy attempted to pass the MRA. She quickly became overwhelmed with the pace of the course and felt she needed to concentrate on completing her homework. The MRA was not perceived as being equal to her homework even though it had more point value. This perception of the MRA being less important than her homework was conveyed when she responded to a question about any resources she used to prepare for retaking the MRA. Amy said, "I don't think so, because I had already been into the semester. I remember at the very beginning of the semester, I was struggling a lot with math. So I was more focused on that than the MRA." Since the MRA was not perceived for her benefit, she did not prioritize learning the material on the MRA.

Determine Whether Help is Needed/Wanted

Carmen originally did not test in remedial intermediate algebra. Her advisor contacted the mathematics department to arrange for her to retake the placement exam after she reviewed the prerequisite material independently. She then had a sufficient score to enroll in intermediate algebra. She shared that she quickly learned in intermediate algebra that material she thought she knew well from high school, but she had learned incorrectly.

> *Carmen*: I was taught the rules of exponents incorrectly in like high school. Or something like that. So I got to [intermediate algebra] and we were going over the rules of exponents. And I raised my hand. I was called on. I was like 'Are you sure that's how it is? Cause I was taught this in high school, and this isn't how they taught it to me. What's going on here?' And my instructor was like, 'Oh, yeah, no they taught it to you wrong.

She also shared a story in intermediate algebra when she learned she had previously learned the order of operations incorrectly. Both of these stories had the potential of Carmen feeling threatened about asking for help, but it produced the opposite effect. She was willing to ask questions in class. She would ask questions of both her instructor and peers. She knew from positive engagement with instructors that she may have previously mislearned a topic, and immediate help was needed to correct any potential misunderstandings.

Decide Whom to Ask

The role of identity. An important component of active learning is students engaging with their peers. During this engagement, there is both help-giving and help-seeking. Each of the participants' mathematical identities with their peers impacted their decision on whether to ask

their peers for help. Jacob had previously taken college algebra. He felt confident that he knew the material better than his peers.

> *Jacob:* I know how to do most things because I've already taken this class. But if I didn't know what I was doing, I feel like I'd be really lost. Cause he [his instructor] only does a few problems, and he just kinda lets us on our own. And if no one at your table knew how to do it, you [would] kinda just be completely lost.

He also felt that his role was to help his peers. Jacob stated, "When we finish [individually] the workbook, he [instructor] wants us to [make sure] everyone else in our group [knows] how to do it."

For Amy, she did not pass the MRA. Not passing the MRA impacted her perception of her mathematical abilities in relation to her peers' abilities. Amy stated, "It made me feel so stupid. Because almost, I mean, from what I know, the people I sit with, like most people, passed it … I should be on the same level." Comments made in class by her instructor and peers also made her feel unconfident enough to let others know she needed help. Amy stated, "When everyone is going around and saying: 'This is so easy, you should know this. This is stuff you've already learned.' It kind of creates an environment that is, you know, questionable." She also stated, "My instructor had said, like, 'this is stuff you had learned [it] in the past, people have taken it, this is so easy.' And then [my] instructor [said] 'It shouldn't be too hard. Like you've already learned this." Amy experienced mathematical microaggressions (Su, 2015). These contributed to the identity she formed within the classroom context.

As stated earlier, Carmen learned in intermediate algebra that she had mislearned several mathematical procedures, but she saw her abilities as being the same as her peers'. She stated, "I'm assuming all of my classmates passed it. … [I] didn't have any problems with it." She was comfortable asking both her instructor and her peers at her table.

> *Carmen*: [I] also talk with like [my table] group. I mainly get to like a problem. I'd be like, I don't know what this problem's asking. And then my classmates would be like, 'Oh, it's either asking this.' And I'd be like, 'Oh, great! Let's you know, do it together.' And we like do it.

She was hesitant about asking questions of her instructor in front of the whole class.

> *Carmen:* I'm not a student that likes [to] ask tons of questions with the whole class. Because I don't know what pertains to just me or what pertains to the whole class. … I don't wanna raise my had and like stop the whole class.

But during independent group work time, she stated, "I'll ask questions from my instructors."

I will discuss the results related to the steps of the help-seeking process (Karabenick & Berger, 2013): deciding whether to seek help, deciding on the type of help (goal), soliciting help, obtaining help, and processing the help received in the presentation, but not here due to space constraints.

Discussion and Implications

Lack of perception of need was a barrier in the process of help-seeking. All the participants did not see the MRA activity as an activity that was for their benefit. They all framed the activity as either a placement exam or an assessment for their instructor to know the class's current ability. Amy struggled with the MRA and tried to take it twice. She did worse on the second attempt. She did not see the purpose of the MRA and saw it as an assignment not related to her coursework. To have students fully engage with assignments, students need to understand their relevance to their success in learning the course material.

Identity was both an affordance and a barrier in the process of help-seeking (Bergey, 2023). It produced a tension that had the potential of keeping a student from seeking help from their peers. For Amy, it was very clear how her identity kept her from asking questions of both her peers and instructor during class time. For Carmen, she perceived her performance as being parallel with her peers. As a result, she was willing to ask both her peers and instructor for help during class time.

In an active learning course, identity played a significant role in help-seeking during class group work. This result suggests that a student's identity may play a significant role in the help-seeking process within the classroom environment (Gardee & Brodie, 2023). Active learning requires students to engage with each other. For "at-success" students, the role of identity has a greater potential to inhibit help-seeking. Instructors must be aware of the environment that they create in the classroom and how that can help all students be successful.

The data from this study suggest that the process of help-seeking (Karabenick & Berger, 2013) should be expanded to include the role of identity. Students may or may not be cognizant of an evaluation they make about how they may be perceived by their peers before engaging in help-seeking (Bergey, 2023). The classroom norms of discourse also played a role in help-seeking. Amy experienced mathematical microaggressions, which shut down her help-seeking within the active learning environment. She lost all the advantages of active learning.

Further research should observe help-seeking within the group dynamics in an active learning classroom. There is a need to understand what type of norms aid the group dynamics to encourage help-seeking among peers. Group work has been seen as a way to afford students opportunities to seek help. Group cohesion also impacts help-seeking in K-12 settings (Kempler & Linnebink, 2006). This may also be true with college algebra students.

Adopting a Holistic Conception of Student Success in Undergraduate Mathematics: Investigating Student Experiences With a Calculus Support Course

Colin Thomas McGrane
San Diego State University

This study investigates student experiences in undergraduate mathematics education, highlighting the importance of addressing inequities related to race and gender in student success rates. Focusing on support courses for Precalculus and Calculus I, where students participate in regular Supplemental Instruction sessions and an online course led by the university Math Equity Coordinator, I examine how these interventions influence student success beyond traditional measures such as grades and persistence to include the impact on students' confidence, sense of belonging and the perception of instructional practices. Results from this mixed-methods analysis show that students enrolled in the support course report higher levels of confidence and a stronger sense of belonging in mathematics. Interviews further emphasize the critical role of instructional practices have in fostering these positive outcomes. These findings suggest that to investigate the success of at-risk students effectively, researchers ought to broaden the scope of success indicators to include identity-related aspects of student experience.

Keywords: identity, confidence, belonging, calculus, student success

Introductory undergraduate mathematics, particularly Precalculus and Calculus courses, have long functioned as an access-controlling mechanism for STEM fields, often filtering students out and limiting progression through their majors (PCAST, 2012; Weston et al., 2019). National data highlights troubling trends, such as Koch and Drake's (2018) finding that 34.3% of students at 36 higher education institutions received a D, F, Withdraw, or Incomplete (DFWI) in Calculus. The barriers are even higher for Black or African American students and Hispanic or Latinx students, who experience DFWI rates of 47.8% and 47.9%, respectively. Moreover, women are 1.5 times more likely to exit STEM pathways compared to men (Ellis et al., 2016). Addressing these persistent disparities requires mathematics educators to invest in listening to student experiences and enacting meaningful, equity-driven reforms in instructional practices.

In response to these challenges, this study focuses on a large Southwestern University (SWU) that has faced similar racial and gender disparities in Calculus success rates. Over a two-year period, the institution has employed a holistic approach aimed at closing equity gaps in its Precalculus through Calculus courses. A central component of this effort is the introduction of support courses for Precalculus and Calculus I. These courses offer students an opt-in 1-unit program that incorporates regular attendance at Supplemental Instruction (SI) sessions and engagement with an online Canvas hub, overseen by the university's Math Equity Initiative coordinator. These courses represent a hybrid model of student support, occupying a middle ground between fully integrated corequisite courses and traditional SI programs.

This paper builds upon the findings presented in last year's preliminary report, moving beyond initial observations to provide a more comprehensive analysis of the impact of these support structures. Using a mixed-methods framework that integrates survey data and semi-structured interviews conducted in the Spring 2023, Fall 2023, and Spring 2024 semesters, I examine how students enrolled in Precalculus and Calculus I perceive the inclusivity of instructional practices and the effect of these support courses on their confidence and sense of belonging in mathematics. Our findings underscore that, while academic outcomes such as

grades and course completion are important, student success must also be understood through broader lenses—particularly the cultivation of confidence and a sense of belonging within the mathematical community. These results advance the argument that holistic support, including mentorship and equitable instructional practices, plays a critical role in addressing long-standing inequities in undergraduate mathematics education.

Relevant Literature and Theoretical Perspective

Investigating the experiences of students in mathematics courses requires careful attention to the unique and evolving identities they bring to the classroom. Student identities are not static but are continually reshaped by interactions with their peers, instructors, and the broader learning environment (Collinson, 2006). Within a mathematics context, these identities take on additional dimensions. Martin (2012) describes mathematical identity as the ways in which students see themselves as "doers" and "learners" of mathematics. This concept extends beyond mere participation, encompassing students' perceptions of their interest, enjoyment, and confidence in the subject. In this research, mathematical identity is explored as a multidimensional construct that intertwines with students' broader self-concepts and is closely tied to their sense of belonging within mathematics. By focusing on identity and belonging, the results in this paper illuminate some of the complex factors contributing to the persistence challenges observed in STEM fields, where nearly half of all students in the U.S. who begin a STEM degree do not complete it (National Center for Education Statistics, 2018).

Confidence plays a crucial role in shaping students' experiences and success in mathematics. Research shows that students' confidence in their mathematical abilities significantly impacts their willingness to engage in mathematical tasks and persevere through challenges (Nunez-Pena, Suarez-Pellicioni, & Bono, 2013). In the context of undergraduate mathematics, studies have indicated that students with higher levels of self-confidence are more likely to persist in STEM-related courses (Ellis, Fosdick, & Rasmussen, 2016). Conversely, low confidence has been shown to correlate with higher dropout rates and disengagement, particularly among women and underrepresented minorities (Boaler, 2016). As students navigate the often-intimidating terrain of calculus and precalculus, building and maintaining their confidence is essential not only for their academic performance but also for their long-term persistence in STEM fields. Therefore, fostering environments that actively promote confidence in mathematics can play a key role in reducing attrition and supporting a more equitable learning experience.

Closely tied to confidence is the sense of belonging, which is increasingly recognized as a critical factor in students' success in mathematics. A robust sense of belonging has been associated with improved academic outcomes, increased motivation, and greater persistence in mathematics courses (Good, Rattan, & Dweck, 2012). Particularly in the context of underrepresented students, feelings of exclusion or marginalization can undermine academic performance and lead to disengagement from the subject (Walton & Cohen, 2011). In undergraduate mathematics, where large lecture formats and competitive environments are often the norm, fostering a sense of belonging can help mitigate the alienation that many students feel, especially in fields traditionally dominated by white male students. As such, promoting inclusive instructional practices and creating supportive peer interactions in settings like Supplemental Instruction have the potential to significantly enhance students' sense of belonging and, in turn, improve their mathematical engagement and persistence.

These considerations necessitate a shift in how student success is conceptualized in mathematics education, moving beyond traditional metrics like grades and course persistence. A critically informed theoretical perspective, such as Critical Race Feminism (Crenshaw, 1989),

calls for an evolution in research approaches that view aspects of the student experience, such as student success, more holistically. Rather than focusing solely on academic outcomes, this perspective emphasizes the importance of examining how systemic inequities shape students' experiences in mathematics classrooms by listening to and believing their lived experience. By integrating insights from identity, confidence, and belonging, mathematics education research can advocate for changes that recognize the socio-cultural dynamics of learning and strive to dismantle structures that perpetuate exclusion and marginalization. A critically informed approach to systemic change in mathematics education thus positions identity and belonging as central components of student success, urging departments to reframe their strategies for fostering equitable, inclusive learning environments.

Methods

SWU is a large, public 4-year HSI research university. Administration of a survey resulted in 807 responses across two semesters of students enrolled in Precalculus and Calculus. The focus of this study are 60 total students (gender and race/ethnicity shown in Table 1) who opted-in to enroll in the newly developed Precalculus or Calculus I SI-based support course that also responded to a survey sent at the end of spring 2023 and fall 2023 semesters. While the survey collected demographic data beyond two genders, there are only two present in this subset of the sample population. Of these 60 students, 41 were enrolled in Precalculus and 19 were enrolled in Calculus and their respective support courses. The remaining data of 747 students were not enrolled in the support course with 367 enrolled in Precalculus and 380 enrolled in Calculus.

Table 1. Students self-reported identity. This table shows a count of each gender present by race/ethnicity.

Support Course Student Demographics									
	Alaskan Native or Native American	Black or African American	Hispanic/ Latinx	Middle Eastern or North African	East Asian	White	Native Hawaiian or Pacific Islander	South Asian	Southeast Asian
Man	1	1	14	1	3	11	1	0	6
Woman	0	2	5	0	1	13	0	1	4

Ten of these sixty students participated in a one-hour long, semi-structured individual interview that focused on a variety of topics related to their experiences in their current mathematics courses as well as their own histories of experiences with mathematics in general. Topics that were discussed included how their identity has impacted their learning of mathematics, how their confidence in their mathematics ability has changed, and the extent to which they have utilized university-offered support structures such as SI.

In order to develop a broader sense of experiences across all precalculus and calculus courses, the administered survey was an amalgamation of items built from subsets of two existing surveys. One of these surveys is the student postsecondary instructional practice survey (SPIPS-M), which specifically focuses on students' interpretations of instructional practices, changes in attitudes towards learning and doing mathematics, and their perceptions of the climate in the classroom (Apkarian et al., 2019). Supplemental to the focus of this survey, the second

survey developed by Brown and colleagues at Penn State University called the Inclusive Instructor Behaviors (IIB) survey was included to leverage student experience to determine various aspects of the perceived inclusivity of teaching behaviors and sense of belonging in mathematics.

Qualitative analysis of the interviews as well as free-response items from the survey was performed using MaxQDA, through multiple cycles of open coding, axial coding, and constant comparison. Quantitative analysis of the survey was performed using SPSS and R, utilizing methods appropriate for the large amount of ordinal data from the dataset and the large population size difference across support course enrollment. These methods include two-sample proportions tests, chi-squared tests, Wilcoxon Signed-Rank tests, and Mann-Whitney U tests.

Results

The results of this analysis are a subset of a larger study, my dissertation that is in publication. This paper contains selected results with an attempt to deliver important aspects of student experiences while still capturing the larger scope of the dissertation. I first present select quotes from student interviews specifically focusing on instructional practices that improved confidence and mediated aspects of their identity they found to be a barrier to their success in undergraduate mathematics. Following these qualitative results, I present select quantitative results that focus on shifts in confidence towards mathematics and sense of belonging compared across students who enrolled in the support course and those who did not.

Qualitative Results

Interviewed students shared their experiences with their perception of instructional practices that they perceived to have helped them due to their self-reported intersectional identities of women in STEM, English Language Learners (ELL), or first-generation college students. While the scope of these quotes reaches themes beyond their interactions with solely the support course and the SI leader, the comfort students found in engagements with all of their instructors (Lecturers / Professors, TA's, and SI leaders) indicates a broader effect of availability, approachability, and words of encouragement on students' confidence and sense of belonging.

Amy, a first-generation Asian American woman in STEM, shared about her experience with her TA for the recitation course for Calculus I. When prompted about instructional practices that assisted the barriers they found to succeeding in undergraduate mathematics, Amy said,

> One of the things that really helped me was my TA. He was always there during office hours, and he explained things in a way that made sense to me. He never made me feel stupid for asking questions, and he encouraged me to keep trying even when I was struggling. It was a huge boost to my confidence.

The encouraging interactions and support from Amy's TA indicate the significant role of personalized interactions in fostering a positive learning environment. She also spoke about impactful instructional practices of the professor for the lecture section:

> In one of my classes, the professor always made sure everyone had a chance to speak. He would go around the room and ask each person for their input. It made me feel valued and like my opinion mattered. It was a stark contrast to some of my other experiences, and it really changed how I viewed myself in the classroom.

Facilitating an inclusive classroom environment where the instructor actively seeks input from all students helped Amy combat feelings of marginalization. For her, this practice validated her contributions and fostered a sense of belonging, positively influencing her identity by changing her self-perception and her place in the math classroom.

Belinda, a first-generation Latina in STEM, spoke about group work and the positive experiences she had from attending SI due to her enrollment in the support course. When asked about instructional practices that mediated aspects of her identity and alleviated barriers she faced, she said,

> College group work is still a challenge, but having more support from SI sessions helps. It makes collaboration more effective. In SI, we often work in small groups to solve problems together, and the leader encourages us to explain our thinking, which helps me practice my English and math skills at the same time … the supportive environment in SI sessions makes me feel more comfortable asking questions and participating… and this has made a huge difference in my overall confidence and willingness to engage in class.

Belinda's experiences underscore the profound impact that specific instructional practices within SI sessions can have on a student's identity and confidence in math. The step-by-step problem breakdowns, small group dynamics, encouragement of peer explanations, and supportive, interactive environment provided in SI sessions have transformed Belinda's relationship with math in the classroom. These practices have helped her overcome language barriers, reduce feelings of isolation, and build her confidence and competence in both math and English.

Collectively, the instructional practices identified to help mediate identity-related barriers to engagement and increased self-confidence in women and first-generation students enrolled in the support course should appear familiar to an educator focused on equitable experiences for their students, as noted by multiple pedagogical frameworks in the field of mathematics education. For example, inquiry-based mathematics education promotes instruction that emphasize a focus on equity and engagement in one of its four pillars of implementation.

Quantitative Results

This section focuses on comparing aspects of student success across support course enrollment. First, I present the results from typical metrics such as grades and math course persistence. Then, I present results from a broader conceptualization of student success that includes shifts in student confidence as well as sense of belonging.

One metric that universities and math departments typically investigate is the DFW rate, which is the percentage of students who received a D, F, or WU in the course. For students enrolled in the support course and not enrolled in the support course, the DFW rates are 17.24% and 19.36%, respectively. A two-sample proportions Z-test was conducted to determine if there is a significant difference between these two DFW rates and the results indicate there is no statistically significant difference between them ($Z = -.401$, $p = 0.688$). A chi-square test of independence was conducted to statistically compare the distributions of all grades across both groups. The results revealed a significant difference in the grade distributions between the two groups, $\chi^2\ (5) = 14.102$, $p = 0.015$. This indicates that the distribution of grades for students enrolled in the support course differs significantly from those not enrolled, suggesting an association between support course enrollment and student grades. Further investigation revealed that this difference favored students in the support course slightly, with students in the support course more likely to receive a B and less likely to receive a D compared to their peers.

Next, I present three categories of persistence in students' math course plan: students who plan to take the next logical course, students who plan to take the same course, and students who do not plan to enroll in another math course. I conducted a series of chi-square tests of independence to compare the persistence rates between students enrolled in the support course and those not enrolled, across the three categories of interest. The results showed no statistically significant differences in the rates of students planning to enroll in the next logical course (χ^2 =

0.026, $p = 0.871$), retake the same course ($\chi^2 = 2.010$, $p = 0.156$), or not enroll in another math course ($\chi^2 = 0.029$, $p = 0.864$). Although some of the observed differences in percentages were notable, with 55.93% of support course students and 39.10% of non-support course students planning to enroll in the next logical course, the chi-squared tests indicate that these differences could be due to chance. Similarly, the rates for retaking the same course (13.56% vs. 2.06%) and not enrolling in another math course (1.69% vs. 1.51%) did not show significant differences, suggesting that the variations in observed counts are not statistically significant.

Moving beyond grades and course persistence, students were also asked survey questions regarding their shifting confidence in mathematics from the beginning of the semester versus near the end of the semester, as well as a group of items that targeted sense of belonging in mathematics spaces.

First, I ran a Wilcoxon Signed-Rank test to compare the paired ordinal data to determine if there is a significant difference in the median of the differences in confidence reported by students. This test considers the magnitude and direction of the changes in confidence levels for each individual student, providing an overall look at how positive and negative shifts in each group are distributed. This test revealed that while the shifts in confidence levels overall for students not enrolled in the support course were statistically significant ($W = 36103.0$, $p < 0.0001$), the difference in confidence levels overall for students enrolled in the support course did not show statistical significance ($W = 362.5$, $p = 0.166$). However, there is more detail I can extract from the data. I calculated confidence shift categories to indicate how many students were in each category of a positive shift in confidence, a maintained confidence, and a negative shift in confidence.

A chi-squared test was performed across the three confidence shift categories and revealed that there is a statistically significant association between support course enrollment and the confidence shift categories ($\chi^2(2) = 11.779$, $p = 0.00277$). To investigate the detail of these differences, a series of two-sample proportions tests that compared the proportion of students in each confidence shift category across support course enrollment showed that there was no significant difference in negative shifts ($Z = -1.054$, $p = 0.292$), a significant difference in maintained confidence ($Z = -2.127$, $p = 0.033$), and a highly significant difference in positive shifts ($Z = 3.404$, $p < 0.001$).

The negative Z-score from the difference in the number of students who maintained confidence indicates that a larger proportion of students not enrolled in the support course showed maintained confidence. The positive z-statistic from the difference of the proportion of students who showed a positive shift in confidence indicates that a larger proportion of students enrolled in the support course showed a positive shift in confidence. That is, not only is there no statistical evidence that students in the support course lost confidence more than students not enrolled, but that students in the support course reported they gained confidence significantly more than students not enrolled in the support course.

I performed one final analysis to determine the effect size of these changes with 95% confidence intervals, to add a finer detail to the results from the two-sample proportions tests. For effect sizes in differences in proportion, Cohen's h was calculated for each test result. The effect size of the differences from each category across support course enrollment are a negative shift in confidence with $h = -0.147$, 95% CI [-0.263, -0.031], a maintained confidence with $h = -0.299$, 95% CI [-0.418, -0.180], and positive shift in confidence with $h = 0.434$, (95% CI [0.302, 0.565]. Interpreting these effect sizes based on the standard scale, the negative shift difference of $h = -0.147$ is approaching a small but non-trivial effect but likely not practically significant, the

maintained confidence difference of $h = -0.299$ falls between a small and medium effect size, and the positive confidence difference of $h = 0.434$ is approaching a medium effect size suggesting a moderate and practically significant effect. Each of these effect sizes are in the direction that favors students enrolled in the support course. Since none of the confidence intervals contain zero, these effect sizes are statistically significant.

To investigate sense of belonging, factor scores based on the PCA loadings for the sense of belong items group were computed. These factor scores represent each student's overall sense of belonging captured by combined items that target sense of belonging. The median factor score for students enrolled in the support course is 0.377 (IQR = 2.456), while the median factor score for students no enrolled was -0.430 (IQR = 2.467).

To investigate the nature of the differences between these two groups, I used a Mann-Whitney U test to compare the combined sense of belonging items across support course enrollment. The results indicated a significant difference in factor scores between the two groups ($U = 36933.0$, $p = 0.011$), suggesting that students in the support course reported a higher sense of belonging compared to their peers. The effect size of this difference is computed to be 0.599 (95% CI: [0.524, 0.674]), which indicates a moderate effect size in favor of the students enrolled in the support course. Thus, students in the support course reported a higher sense of belonging in mathematical spaces.

Discussion

While students enrolled in the support course did not show many notable significant differences in grades and mathematics course persistence, they did report higher levels of confidence and sense of belonging in mathematics. One interpretation of the effect of the support course is that students who opted-in to a course for more support may have had a difficult time succeeding without it. That is, the experiences from being enrolled in the support course leveled the playing field to the point where there are only marginal statistical differences between their performance and success in terms of grades and course persistence.

With grades and course persistence relatively equal, with some results leaning towards a benefit for support course students, expanding the conception of student success to include affective measures such as confidence and sense of belonging illuminates the quantitative difference of experiences in mathematics between these groups. With a significantly greater positive shift in confidence and greater self-reported sense of belonging, students in the support course have "succeeded" beyond the scope of this one course. While grades and course persistence may often live in a static conception of one's mind as they navigate the myriad obstacles faced throughout the college mathematics experience, growing confidence and sense of belonging intertwine with the dynamics of identity and sense of self that endure beyond the semester or academic year context. Furthermore, the conversations I had with students about their evolving identities in mathematics were inspirational and highlight the impact humanistic and holistic experiences have on students' mathematical success.

Relating to the broader field of systemic change research, I contend researchers ought to broaden the conception of student success and listen to students' lived experience. I look forward to explaining any details or information omitted from this report and speaking with colleagues about how a support course may fit into their context.

Matthew Mauntel
University of New Hampshire

David Plaxco
University of Georgia

Elsie Davis
Arizona State University

In this paper we analyze the reasoning of five students who were playing a 3-dimensional digital video game called Vector Unknown: Echelon Seas. The intention of Stage 4 of the video game is to give students experience with Numeric and Geometric representations of linear combinations of vectors in the context of a pirate throwing a grappling hook to reach an anchor. We illustrate three types of Numeric reasoning, and four types of Geometric reasoning students used to solve these puzzles. For each reasoning example, we discuss issues related to which vectors the player should choose so that the anchor is within the span of the vectors, and which scalars the player should choose so that the grappling hook ends precisely at the anchor.

Keywords: linear algebra, digital games, linear combinations, span

Introduction

The purpose of this paper is to characterize the reasoning of students playing a digital video game, Vector Unknown: Echelon Seas (VUES), created to engage students with *Numeric* and *Geometric* instantiations of linear combinations of one or two vectors in R^3. The larger goal of this analysis is (1) to add to the body of knowledge of the reasoning that is involved in understanding linear combinations of vectors and (2) to provide foundational information for future creators of digital environments and tasks for the teaching and learning of linear algebra concepts involving linear combinations of vectors.

Literature Review

Literature on student understanding of linear combinations of vectors and related concepts such as span and linear independence has taken several different forms. Some papers focus on applied examples created by the research team to promote student learning (e.g., Trigueros & Possani, 2013; Cáracamo et al., 2017). Other papers consider student generated applied settings or everyday examples for basis and hence how linear combinations of vectors serve to generate or describe other vectors in the space (e.g., Adiredja et al., 2020; Zandieh et al., 2019). Other settings have been created by instructors to have students engage with linear combinations of vectors as a way to travel through space (e.g., Wawro et al., 2012; Trigueros, 2019) or to explore locations in space using Dynamic Geometry Systems (e.g., Dogan, 2019; Turgut et al., 2022). More recently there are a few examples of digital games created to engage students in learning aspects of linear combinations of vectors (e.g., Nishizawa et al., 2013; Mauntel et al., 2021).

This paper adds to this body of literature by characterizing specific types of reasoning that are involved in students' game play and connecting those types of reasoning explicitly to aspects understanding linear combinations – even when the students did not themselves make these connections. In this way, we are suggesting ways that a game such as this may be leveraged by an instructor to help students build a more nuanced, experiential understanding of linear combinations and related concepts such as the span of a set of vectors.

To this end, our Research Question for this paper is: What are the ways that students reason with linear combinations of vectors in the context of playing the 3-dimensional (3D) grappling hook puzzles of Vector Unknown: Echelon Seas (VUES)?

Methods and Theoretical Framework

Context of the Game

Our work follows the philosophy of Freudenthal (1983) that mathematics is a human activity. In this way we are interested in how students engage in tasks and the ways that their reasoning emerges through this engagement. The tasks for this study are solving the puzzles in the digital game VUES that involve a pirate using a grappling hook in a 3D environment. The goal of each of these puzzles is for the pirate to send the grappling hook from his location to the anchor. This corresponds to creating a linear combination that equals the numeric vector goal in the upper right corner of the screen. Figure 1 shows a screenshot of the VUES 3D grappling hook environment. For this paper, we have added to Figure 1 black boxes outlined in purple with the names that we will use to refer to various game elements.

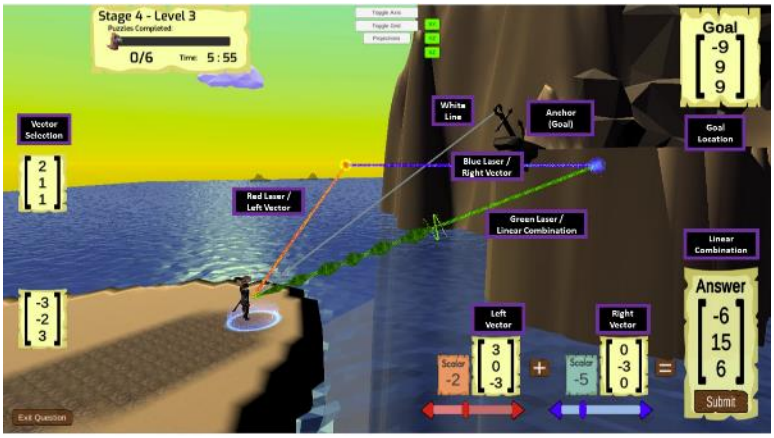

Figure 1: Illustration of Level 3 of Stage 4 (S4L3) of Vector Unknown: Echelon Seas.

As seen in Figure 1, the game provides both *Numeric* and *Geometric* information about the linear combinations of vectors. In addition, there are two main choices that the player can make in solving the Puzzle. The player can (1) select one or two vectors to move into the Left Vector and/or Right Vector slots and can (2) move the sliders underneath the Left or Right Vectors in order to change the scalar in front of the vector. Making these changes will automatically update the Answer vector and cause the Red, Blue, and/or Green Lasers to appear. We refer to these choices as *Which Vectors* and *Which Scalars*, respectively.

Data Collection and Data Analysis

To obtain information towards answering our research question, we conducted interviews with five students as they engaged in playing VUES. The fourth author interviewed each of the five students individually for at least one hour. The five students each chose their own pseudonym: Anh, Athena, Kyah, Patchy, TB. The intention of the interviews was to allow students to explore Stage 4 of VUES in which the pirate character's goal is to extend a grappling hook to connect to an anchor. For this paper we focus on the 3D level (Stage 4 Level 3, S4L3).

The video data for each student playing S4L3 was analyzed by at least two members of the author team and then discussed across team members. The S4L3 data consisted of three Puzzles

completed by Kyah and six Puzzles completed by each of the other students. An initial analysis of the data focused on *Numeric* and *Geometric* reasoning and the gameplay strategies highlighted in Mauntel et al. (2021). These strategies overlap issues of *Which Vectors* and *Which Scalars*. As pointed out by Bernier and Zandieh (2024), some of the Mauntel et al (2021) strategies focus more on the choice of vector and others focus more on the choice of scalar. For this paper we emphasize issues of *Which Vectors* and *Which Scalars* and extend these types of analyses to a 3D setting. This extension also allows us to draw out additional connections possible between digital gameplay and reasoning with linear combinations of vectors.

Conceptual Framework

Mathematically, we can interpret *Which Vectors* as referring to which vectors should be selected so that the Goal will be in the span of those two vectors, and once selected, *Which Scalars* refers to which scalars should be used as the weight of each vector in the linear combination to create the Goal vector. In this way, the questions of *Which Vectors* and *Which Scalars* point to (1) game mechanics (allowable moves a player can make in the game), (2) statements about mathematical objects and relationships (at least to an expert) and (3) in-the-moment choices a player can make in terms of their focus or attention. Our conceptual framework interprets student reasoning with linear combinations of vectors through the choices students make in the digital game (*Which Vectors* and *Which Scalars*) and their focus of attention (*Numeric* or *Geometric*) in anticipating or interpreting the results of these choices.

Results

In analyzing our data, we found multiple ways that students reasoned about linear combinations in the digital game setting. Here we highlight three *Numeric* examples and four *Geometric* examples that illustrate different ways students navigated deciding *Which Vectors* and *Which Scalars* would solve the puzzle. The examples are chosen to illuminate variety in student reasoning as well as mathematical connections across these differences.

***Numeric* Reasoning: Two 0 Entries**

We saw multiple instances of students trying to initially align one or two entries in the Answer vector (result of the linear combination) with the matching entries in the Goal vector. In this type of reasoning a student focused on initially aligning two entries and then adjusting to align the third entry as well. The more straightforward version of this reasoning occurred when the Vector Selection included a vector with two 0 entries. Each of the four students who had a puzzle including a vector with two 0 entries were able to solve such a puzzle numerically.

Anh prioritized *Numeric* aspects of the game, including leveraging 0 entries, when solving most of the puzzles of Level 2, and this continued in Puzzle 1 of Level 3 (L3P1; see Figure 2). In terms of *Which Vector*, Anh noticed that three of his vector cards had zero-valued entries saying, "Yeah, I'm thinking which one I can use because we have a lot of zeros here." To try and match the Goal vector, Anh selected <-3, -2, 3> and increased its scalar to 3 (*Which Scalar*) to match the x and z entries of the Goal vector (Figure 2(a)). After aligning these two entries, Anh used the <0, 3, 0> vector to change the y value of the Answer vector to match the y value of the Goal vector, as shown in Figure 2(b). Note that although Anh was focused on the *Numeric* features of the game, the *Geometric* effect of his gameplay was to position the tip of the Red Laser at the same height (z-value) as the Goal (Anchor) and then use the Blue laser parallel to the y-direction to reach the Goal (See Figure 2).

Figure 2: (a) Anh's use of the <-3, 2, 3> vector to match the x and z entries of the Goal. (b) Anh's use of the <0, 3, 0> vector to match the y entry of the Goal.

Numeric Reasoning: No 0 Entries

Athena's first two Puzzles of Level 3 each had a vector with two 0 entries, and she was able to solve them by reasoning in a *Numeric* way similar to Anh. However, in L3P3, Athena did not have any vectors with 0 entries. In terms of *Which Vector*, Athena initially used a single vector with a scalar of -4 (*Which Scalar*) to match two of the entries of the Goal vector (see Figure 3(a)). Eventually, she chose a second vector with $x = 2$ and $y = 3$ (*Which Vector*) which allowed her to match the x and y entries of the Goal vector, i.e., $x = -8$ and $y = -12$ (See Figure 3(b)).

Figure 3: (a) Athena's attempt to match the x and y entries with one vector. (b) Athena's initial Answer vector before she begins to incrementally decrease z by 1.

With support from the interviewer, Athena alternated between increasing the left scalar and decreasing the right scalar to decrease the z value of the Answer vector. Athena continued to alter the scalars in this manner until she finally matched the z entry of the Goal vector, decreasing the z value from 2 all the way to -10, as shown in Figure 4(a-c).

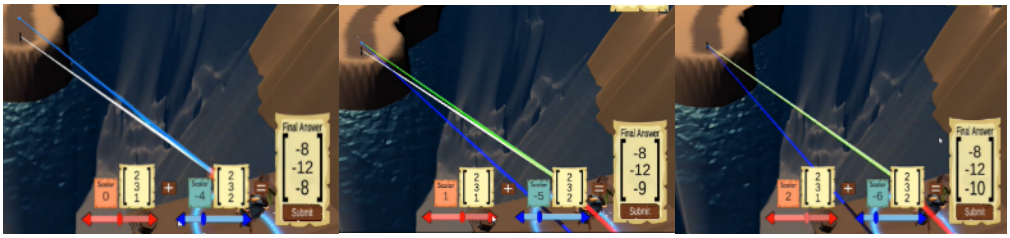

Figure 4: Examples of Athena's incrementing of the Left and Right scalars to decrease the **z***-entry.*

Athena noticed that in changing the scalars this way, "these two [x and y entries] don't change every time, but this one does." Note that in this example, Athena chose the vectors <2,3,1> and <2,3,2>, so her strategy of adding 1 to the left scalar and subtracting 1 from the right scalar is equivalent to adding (1)*<2,3,1> + (-1)<2,3,2> = <0,0,-1> to the resultant vector. This allowed her to keep the first two entries of her resultant vector -8 and -12 while she adjusted the

third entry from 2 to the *Numeric* Goal of -10. Although neither she nor the interviewer mentioned it, the *Geometric* effect of adding <0,0,-1> repeatedly was to move the endpoint of the resultant vector down vertically until it reaches the anchor (see Figure 4).

Geometric Reasoning: Green Laser onto White Line

Patchy was one of the few students who used primarily *Geometric* reasoning about the linear combination in the first two puzzles of L3. This was because a Microsoft Teams window covered Patchy's Goal vector for most of his interview. At the start of his L3 gameplay, Patchy spent about nine minutes making sense of the lasers and vector cards. Once he noticed that his Answer vector (see Figure 5(a)) resulted in the Green Laser landing on the White Line, he said "we're onto something" multiple times. Because the Green Laser landed halfway along on the White Line Patchy said, "it was like halfway there, so if like double the scaling, that should do it." Patchy increased the Left scalar to 4 and the Right scalar to 2, reaching the Anchor. Patchy answered the questions *Which Vector* and *Which Scalar* almost simultaneously. Once the Green Laser landed on the White Line, he knew he could reach the Anchor by doubling the length of the Green Laser and scaling the Answer vector <-4, 5, 3> by a factor of 2, (see Figure 5(b)).

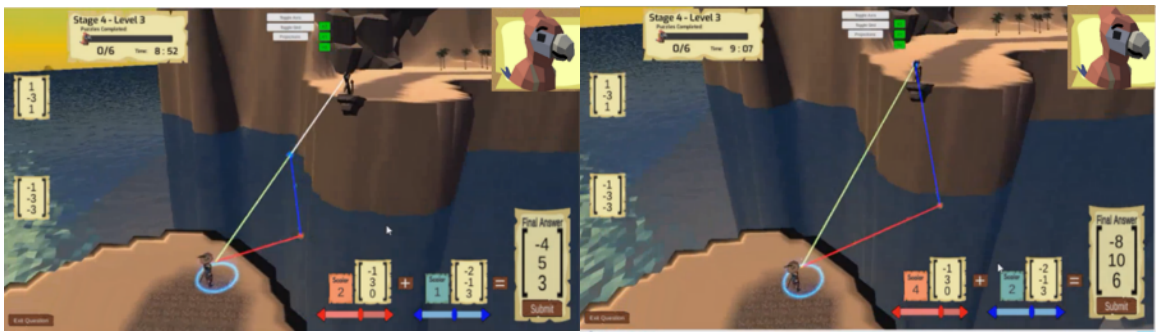

Figure 5: (a) Patchy noticed the Green Laser on the White Line, halfway to the Anchor. (b) Patchy doubled the value of each scalar to double the length of the Green Laser and reach the anchor.

Numeric Reasoning: Scalar Multiples

Previously Patchy used *Geometric* reasoning about the linear combinations because an application was covering the *Numeric* Goal vector on his computer screen. After recognizing that he could now see the *Numeric* Goal vector, he said "Oh! I haven't been seeing the Goal! This changes everything!" Patchy then said, "You can now just do it by addition." He then selected the <-1,1,-3> and <-1,-3,1> cards, and noticed that the *Numeric* Goal vector was a scalar multiple of the Answer vector, e.g., <-2, -2, -2> (see Figure 6(a)). Patchy said he wanted to "scale it up," and increased the left and right scalars each by 1 several times until he matched the Goal vector <-10, -10, -10>. Visually, Patchy was continually moving the Green Laser off and back onto the White Line each time his Answer vector resulted in a scalar multiple of <-2, -2, -2>. However, in this puzzle, Patchy was focused on making the Answer vector a scalar multiple of <-2, -2, -2> (see Figure 6(b)). Patchy's *Numeric* reasoning here can be seen as related to his earlier *Geometric* reasoning where he focused on scaling the length of the Green Laser.

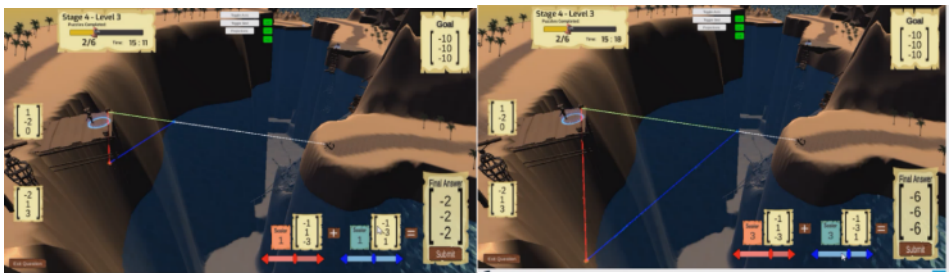

Figure 6: (a) Patchy's Answer vector <-2, -2, -2>. (b) Patchy's scalar multiple of the <-2, -2, -2> vector.

Geometric Reasoning: White Line is Not in the Span

In L3P1, Kyah moved the Green Laser onto the White Line for a fixed camera view as shown in Figure 7(a). Notice that even though she moved the Green Laser onto the White Line, her Answer vector does not match the Goal vector. After moving the camera to the view pictured in Figure 7(b), Kyah noticed that the Green Laser was not, in fact, on the White Line.

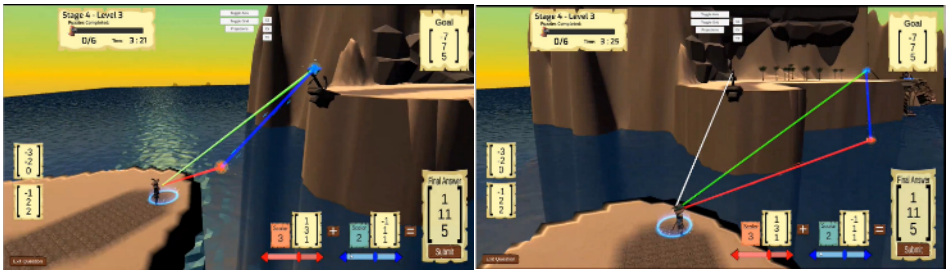

Figure 7: (a) Kyah's sees Green is on White. (b) Kyah realizes Green is not on White.

Kyah continued to leverage various camera views to determine whether the Green Laser was actually on the White Line, which helped her answer the *Which Vectors* question. From an expert point of view, this *Geometric* reasoning could be used to determine if the Anchor lies in the span of the selected vectors.

Geometric Reasoning: White Line *is* in the Span

In L3P4, TB began to answer the question *Which Vectors* using different camera views to consider the relationship between the Lasers and the White Line. As shown in Figure 8(a), TB used a top-down camera view to demonstrate how the vectors <-3, 3, -1> and <-2, 2, 2> overlapped the White Line. From an expert point of view, this *Geometric* reasoning can be seen as demonstrating that the Anchor location, as well as the White Line, lie within the span of the selected vectors. In Figure 8(a) the Green Laser appears to be on the White Line but it is actually above it. TB changed the camera view to the perspective pictured in Figure 8(b) and decreased the right scalar to move the Green Laser through the Anchor.

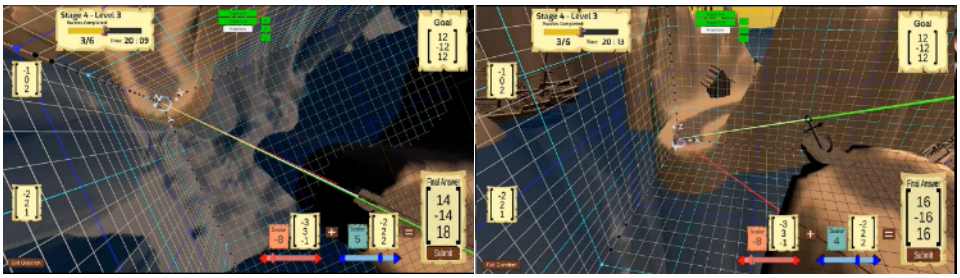

Figure 8: (a) TB's top-down view of Green above White. (b) TB's side camera view of Green through the Anchor.

Geometric Reasoning: Sweeping the Scalars

Earlier in his L3P4 gameplay, TB became convinced that the Lasers could be used to determine if a specific pair of vectors could be used to reach the Anchor. TB began L3P4 by continually increasing and decreasing the Left and Right scalars to determine possible places the Lasers could reach. He eventually turned the camera to the view pictured in Figure 9, noting that the lasers were at "a fixed angle," which would never move towards the anchor location. The narrow angle of the Lasers TB used to geometrically reason about the possible locations that could be reach by his selected pair of vectors allowed TB to consider a wedge of the plane spanned by his selected vectors. Though TB did not mention this plane, as experts, we recognize this type of *Geometric* reasoning about the linear combinations as nascent reasoning related to demonstrating that the Anchor is not in the span of TB's selected vectors, and therefore cannot be reached no matter how TB sweeps the scalars. This type of *Geometric* reasoning about the Lasers allowed TB to answer the question *Which Vectors* in the sense he recognized he needed to swap vector cards. TB summarized this by saying, "So using the line I can definitely see this combination of cards is never going to reach the right answer.

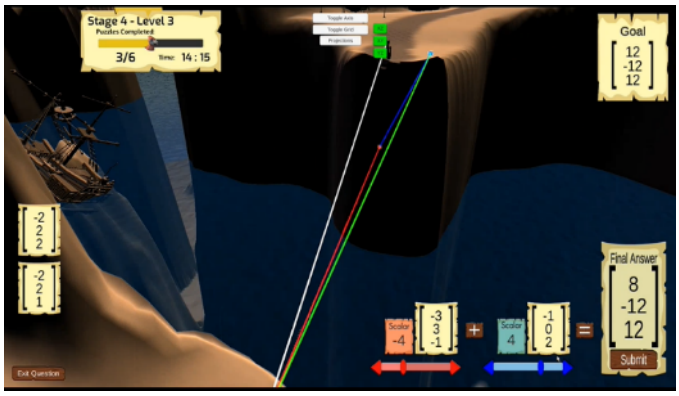

Figure 9: TB's camera view of the three Lasers to demonstrate why his selected vectors had the wrong angle and could therefore not reach the Anchor.

Discussion and Conclusion

In this paper we presented several ways (three *Numeric* and four *Geometric*) that students reasoned about linear combinations of vectors while playing S4L3 of VUES. These ways of reasoning about linear combinations were compatible with reasoning about span (*Which Vectors*) and reasoning about individual linear combinations for a specific resultant vector (*Which Scalars*) across both *Numeric* and *Geometric* conceptualizations of linear combinations.

We see this analysis as highlighting reasoning with linear combinations that adds to the body of literature in this area. In terms of *Numeric* reasoning, we see students working to coordinate three different but interconnected calculations (sum of products) to make all three numeric values align. Students must also consider issues related to orthogonal projection to consider situations in which two coordinates align and the third entry needs to be brought into alignment.

In terms of *Geometric* reasoning, we highlight the visual and experiential nature of interacting with a character that is moving in a digital 3D space and using changes in camera angles to gain deeper insight into the relationship between vectors and linear combinations in this space. We see students having a sense for what portion of R^3 is spanned by a set of linearly independent vectors and how one vector may lie within or outside of that. We also see students using both *Numeric* and *Geometric* reasoning that illustrate that if a vector v is in the span of a set of vectors (i.e., in a subspace) that a multiple of v will be in the span (subspace) as well.

Computer-Verified Linear Algebra Proofs With Programming in MATLAB

Sepideh Stewart
University of Oklahoma

Caleb Judkins
University of Oklahoma

Research on teaching and learning proofs in linear algebra is scarce. This paper used the instrumentation genesis approach to examine students' proofs and MATLAB codes. The students were studying a proof-based second course in linear algebra. The instructor included application-focused labs and a final project as part of this study. One of the labs required a proof validation using MATLAB. This lab, a proof question from the midterm exam, and an exit survey were analyzed in this paper.

Keywords: linear algebra, proof, programming, MATLAB

Literature Review

Proof is a critical component of mathematics. In light of the current technological advances, has the way mathematicians do proof changed? According to Hanna, Reid, and de Villiers (2019, p. 3):

> Proving is sometimes thought to be the aspect of mathematical activity most resistant to the influence of technological change. While computational methods are well known to have a huge importance in applied mathematics, there is a perception that mathematicians seeking to derive new results are unaffected by the digital era. The reality is quite different. Digital technologies are influencing the way mathematicians work together and the way they go about proving.

In an article by Bayer et al. (2024), ten authors from various stages of academic careers individually expressed their views on proof within eight segments of the article. The article began by stating that:

> There is a striking difference between how a proof is defined in theory and how it is used in practice. This puts the unique status of mathematics as exact science into peril. Now may be the time to reconcile theory and practice, i.e., precision and intuition, through the advent of computer proof assistants. This used to be a topic for experts in specialized communities. However mathematical proofs have become increasingly sophisticated, stretching the boundaries of what is humanly comprehensible, so that leading mathematicians have asked for formal verification of their proofs. At the same time, major theorems in mathematics have recently been computer-verified by people outside of these communities, even by beginning students (p. 79).

The article "investigates the different definitions of a proof, the gap between them, and possibilities to build bridges. It is written as a polemic or a collage by different members of the communities in mathematics and computer science at different stages of their careers, challenging well-known preconceptions and exploring new perspectives" (p. 79). As Tall (2023) mentioned, different communities have their own needs and view things (in this case, proof) differently.

Shifting our attention to pedagogy and classroom practices, Melhuish et al. (2022) synthesized 104 papers from various countries and methods to describe what is known about

proof-based learning and what is still missing. Their exploration uncovered two schools of thought for teaching proofs: lecture-based proofs and student-centered learning. While student-based learning is promising, a significant gap remains in "understanding of the theoretical mechanisms which specific instructor moves may encourage or scaffold student activity is only beginning to emerge" (Melhuish et al., 2022, p. 17). Acknowledging the wealth of studies in proof in mathematics education literature, we focus our attention on linear algebra proofs in this paper.

Linear algebra is a key topic for many mathematics majors and other fields. In the early 1990s, Steven Leon and his colleagues initiated a national project (ATLAST) to teach linear algebra with MATLAB (Leon, Herman, & Faulkenberry, 2002). Despite these national initiatives, research studies on linear algebra and using MATLAB in classrooms are lacking. The Linear Algebra Curriculum Study Group (LACSG) 2.0 recommends that mathematics departments offer a variety of second courses, including numerical linear algebra, and include wider topics (Stewart et al., 2022). The recommendations also paid significant attention to the use of technology. In a survey paper by Stewart, Andrews-Larson, and Zandieh (2019), the authors found that research on topics in second courses of linear algebra, which contain more abstract content and proof, is rare. In response to this gap, in a study by Meyer, Stewart, and Madden (2024), they employed Schoenfeld's (2010) theory of Resources, Orientations, and Goals (ROGs) to examine an instructor's (and co-author's) textbook in a second course in linear algebra. The instructor created tailored resources with many hints and pedagogical attributes to encourage students to construct their own proofs to understand and learn the materials and invited students to explore, conjecture, and prove.

Our current paper examines students' instrumentation genesis using MATLAB to verify proofs, a proof question from the midterm exam, and an exit survey.

Theoretical Framework

Our theoretical framework for this study is based on the instrumentation genesis (Vérillon & Rabardel, 1995). An illustration of the instrumental genesis is shown in Figure 1. In the instrumentation approach, an instrument starts as an artifact before the subject interacts with it and only becomes an instrument "when the subject has been able to appropriate it for himself and has integrated it." (Vérillon & Rabardel 1995, p. 84). This development into an instrument is called "instrumental genesis" (Sinclair et al., 2023, p. 398), and it incorporates more than just the subject and the artifact itself. An important aspect of an instrument includes the actions taken and the goals of the subject that led to those actions (Trouche, 2018). It is significant to note that the artifact does have an impact on the subject's experience, as the subject's actions are formed largely in response to the design and limitations of the artifact and their own comprehension. The subject must impart their own knowledge of both the goal and the artifact into the development of the instrument, an aspect of the process that shapes the resulting instrument (Balacheff, 1994). In a sense, "the artifact does not intervene in a neutral way in the teaching-learning situation. It carries its own techniques, instrumental knowledge, signs, meanings, and a technological transposition of mathematical knowledge also takes place (Sinclair et al., 2023, p. 399). According to Trouche (2018, p. 407):

> This frame leads us to clarify our initial definition: instrumentation is the action by which a subject acquires an artifact, and the effect of this action on the subject, who develops, from this artifact, an instrument for performing a task. An instrument is thus made up of

an artifact component and a cognitive component (knowledge necessary for/ from using the artifact for performing this type of task).

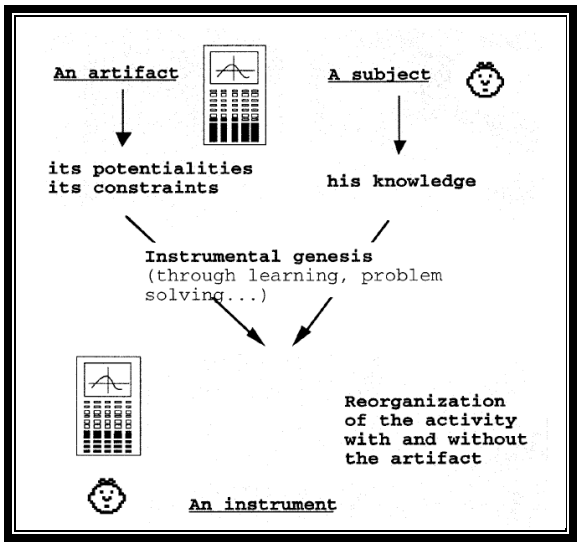

Figure 1: Instrumental genesis, from an artifact to an instrument (Guin and Trouche, 1999, p. 202).

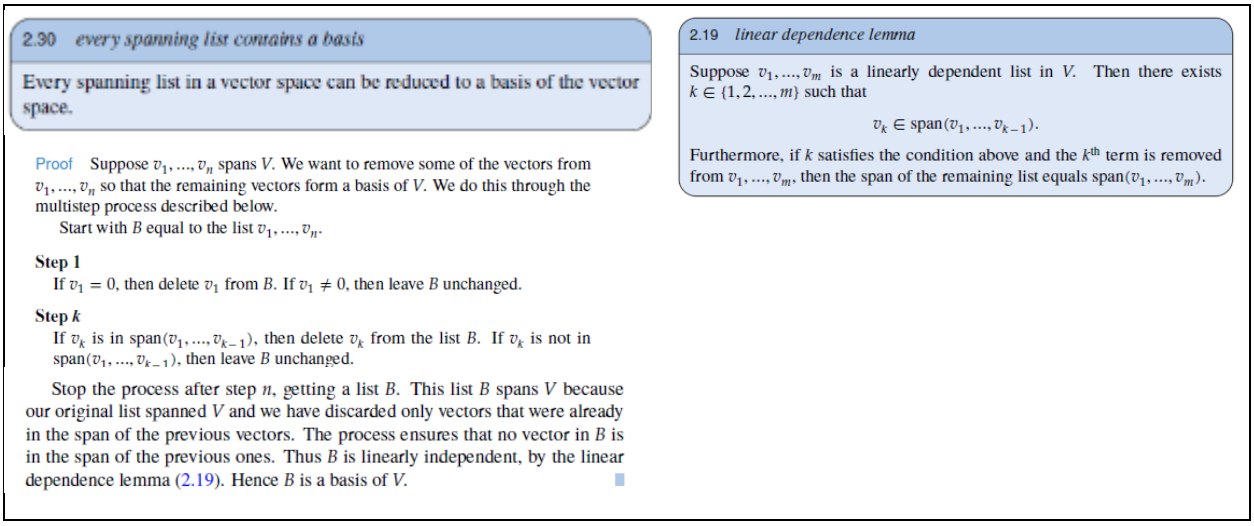
As described by Sinclair et al. (2023), the perspective of instrumentation has been employed widely in the literature, especially with graphics calculators. Notably, Gueudet et al. (2022) studied one student's ability to use programming to explore various mathematical conjectures by examining the evolving schemes surrounding his work. Their framework sought to orient the relationship between tools and students as having an impact in both directions, with the student adapting the programming process to his needs and the student adapting to the operations of the programming language.

Our research question to guide the study was the following: What was the nature of the instrumentation of programming with MATLAB in the production of linear algebra proof?

Method



This is a case study of a proof-based second course in linear algebra. There were 22 mathematics and engineering students enrolled in this course, and 15 students agreed to participate in this study. The first-named author was teaching this second course, which was highly theoretical and proof-based, and selected the textbook *Linear Algebra Done Right* by Axler (2024) for this course. The course was modified to incorporate six labs (one on proof and five on applications) and a final project using MATLAB to help students explore numerical linear algebra and its applications via programming. The instructor (first author) met weekly with a specialist and a support person from MathWorks to create the labs and provided help with MATLAB for students. The course covered the following topics: Vector spaces and their properties (including special Vector Spaces such as Isomorphic Vector Spaces and Invertibility), subspaces, span and linear independence, bases, dimension, linear maps, polynomials, eigenvalues, eigenvectors, and invariant subspaces, inner product spaces/ operators on inner product spaces (The Spectral Theorem, Self-Adjoint, and Normal Operators, etc.), and trace and determinant. The course was taught as a mixture of lectures and various group activities, such as evaluating proofs for clarity and elegance using MATLAB in class to validate results left by the

textbook as an exercise. The class participation also included unpacking proofs in their own words and sometimes coming up with different proofs and presenting them to the class.

The data for this study was collected from students' class assessments (final exam, midterm exam, and homework), the labs, the final project, and an exit survey. This paper will only show data analysis from two students' (Student 1 and Student 11) lab 2 and a midterm test question related to the proof of Theorem 2.30. Lab 2 asked students to validate the proof of Theorems 2.19 and 2.30 from the textbook (see Figure 2 for the statement of the theorem and proof).

The exit survey questions had two parts (Proof and MATLAB). A sample of proof survey questions were: What is the purpose of the proofs in linear algebra? Describe the nature of the proofs in linear algebra. How can we best teach linear algebra proofs to enhance your learning experiences? What were the best teaching techniques presented in class that helped you learn proofs? A sample of MATLAB survey questions were: Were you familiar with MATLAB before this course? Have you done any programming before this course? Did you learn coding in this course? Did your knowledge of linear algebra increase as a result of coding?

We have included the results of whole class responses to survey questions related to MATLAB, as well as the results for Students 1 and 11 on proof questions.

2.30 *every spanning list contains a basis*

Every spanning list in a vector space can be reduced to a basis of the vector space.

Proof Suppose $v_1, \ldots, v_n$ spans V. We want to remove some of the vectors from $v_1, \ldots, v_n$ so that the remaining vectors form a basis of V. We do this through the multistep process described below.

Start with B equal to the list $v_1, \ldots, v_n$.

Step 1

If $v_1 = 0$, then delete v_1 from B. If $v_1 \neq 0$, then leave B unchanged.

Step k

If v_k is in $\text{span}(v_1, \ldots, v_{k-1})$, then delete v_k from the list B. If v_k is not in $\text{span}(v_1, \ldots, v_{k-1})$, then leave B unchanged.

Stop the process after step n, getting a list B. This list B spans V because our original list spanned V and we have discarded only vectors that were already in the span of the previous vectors. The process ensures that no vector in B is in the span of the previous ones. Thus B is linearly independent, by the linear dependence lemma (2.19). Hence B is a basis of V. ∎

2.19 *linear dependence lemma*

Suppose $v_1, \ldots, v_m$ is a linearly dependent list in V. Then there exists $k \in \{1, 2, \ldots, m\}$ such that

$$v_k \in \text{span}(v_1, \ldots, v_{k-1}).$$

Furthermore, if k satisfies the condition above and the k^{th} term is removed from $v_1, \ldots, v_m$, then the span of the remaining list equals $\text{span}(v_1, \ldots, v_m)$.

Figure 2: Axler (2024, pp. 33 & 40).

Results

Case of Student 1

The portion of code not included involves the student creating random vectors using linear combinations of basic unit vectors already in a list by multiplying them with random scalars. In this code (see Figure 3), the student starts by clearing all zero vectors from the list. Next, it is worthwhile to note the last part of this code, as the student creates a function that tests if an additional vector is in the span of a given list by comparing the rank of the list with and without the vector. Student 1 used this function in the next loop to see if the ith vector is in the span of the previous vectors. If it is, then delete that vector from the list. Thus, the resulting list is a linearly independent list of vectors and forms a basis. The only shortcoming of the code is that it does not necessarily check what the spanning space is. However, this could be considered a demonstration of Student 1's understanding that for any vector space, the number of vectors in a linearly independent list gives you the dimension.

The design of Student 1's code is also significant, as the concept of checking the *i*th vector against all previous being sufficient does directly come from the dependence lemma. In this way, Student 1 seems to have made a significant connection between their use of MATLAB as an instrument and the proofs being computer-verified.

Student 1's proof of Theorem 2.30 (see Figure 3) is similar to Axler's (2024) proof (see Figure 2). They both used the linear dependence lemma to iteratively delete linearly dependent vectors from the list until they reached a list satisfying the definition of a basis. However, Student 1 also incorporates the theorem that a linearly independent list of vectors has a length less than or equal to the length of any spanning set of vectors for that space, though this statement is not necessarily being used in the proof itself. This directly connects to their code's test of comparing the rank of a list with and without a vector appended, suggesting their instrumentation of MATLAB has impacted their understanding of the proof.

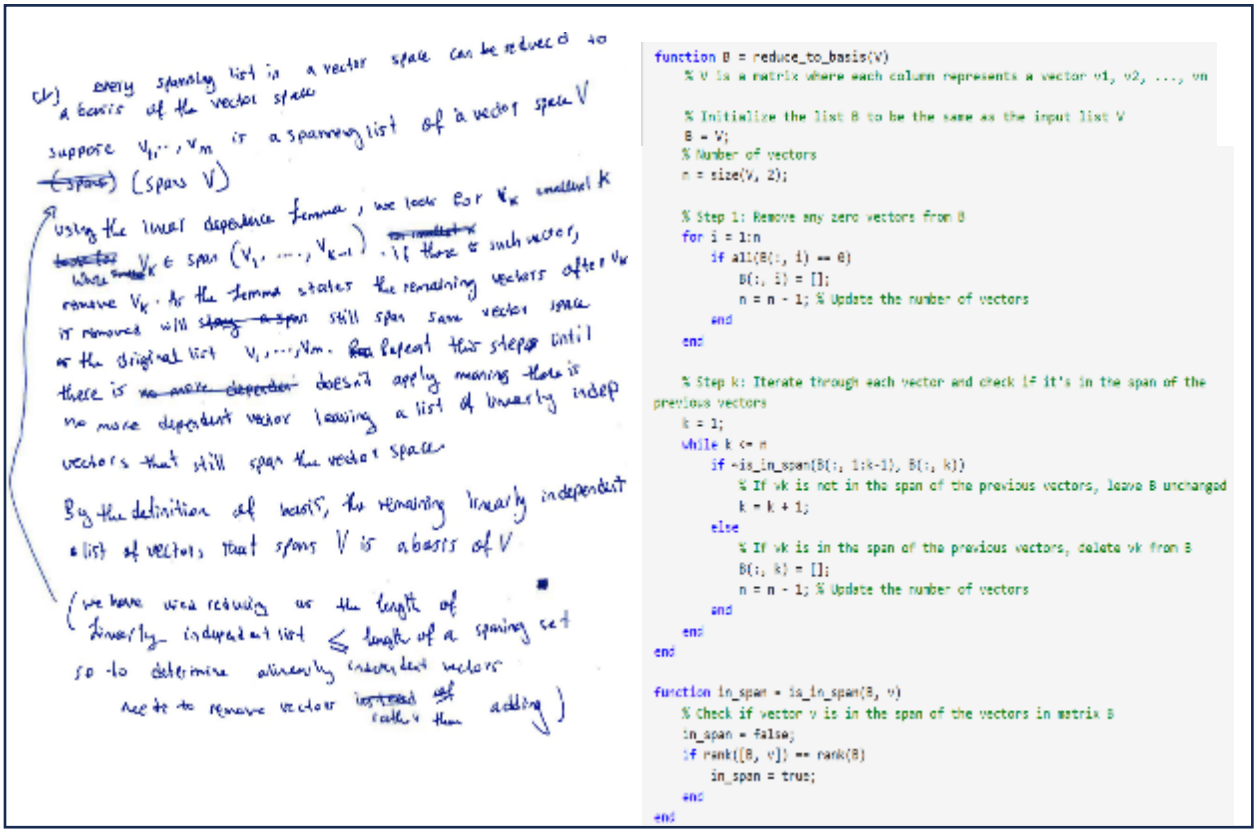


Figure 3: Student 1's proof and MATLAB code for Theorem 2.30.

Case of Student 11

While not included in this block of code (see Figure 4), Student 11 finished this exercise by verifying if the list was a basis by checking the rank against the length of the list. However, there is concern regarding the student's ability to construct vectors that meaningfully demonstrate the theorem. While generating a list of vectors, the student forced it to be linearly independent. Thus, there is not a general list of vectors being tested; there is only a list that is already going to be a basis. However, it does seem that the student has a well-developed understanding of what qualities of a list are necessary to be a basis for the space, as they verified that the length matches the rank of the list. That being said, it is not a proper test of the theorem, as they only check

whether their list has a property already built into it. It is worth pointing out that the construction of a list of vectors worth testing is an entirely distinct exercise from testing the qualities of a given list, so the student did seem to adapt the work that they had practiced and learned to MATLAB even though they were not able to properly develop a new skill in creating a sufficient list of vectors.

Student 11's proof produced in the midterm exam (see Figure 4) started with a proof of the linear dependence lemma (Theorem 2.19), which was not required as long as the result of the theorem was mentioned. In the next steps, the conditions were not set up correctly, and it is not clear what step is getting repeated and for what reason. The proof ends with the definition of linear independence without mentioning the concept of a basis.

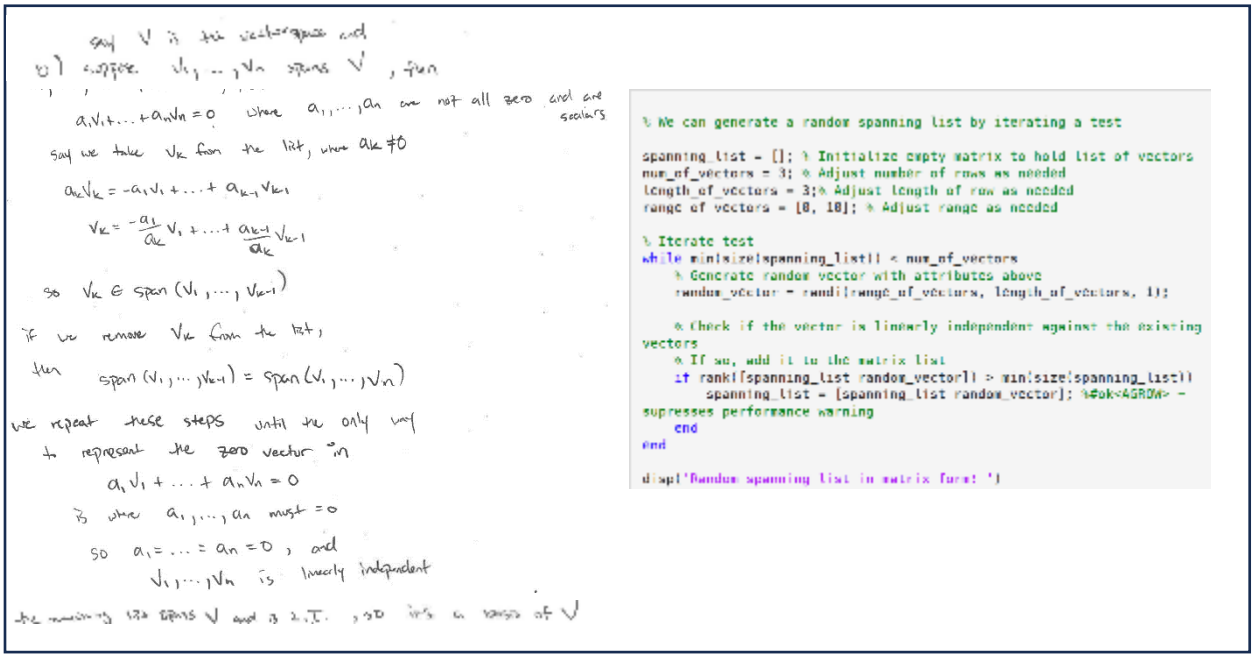

Figure 4: Student 11's proof and MATLAB code for Theorem 2.30.

Analysis of the Exit Survey

The results of the first portion of the exit survey are related to the purpose and nature of linear algebra proofs. Students 1 and 11 both referenced that proofs offer some form of verification. However, Student 11 also claimed that proofs help to understand by providing alternate ways of perceiving the concepts and equipping learners with "a skillset for applied work". Both students mentioned that proofs connect and incorporate different concepts.

Regarding teaching and how students' learning could be enhanced, Student 1 claimed that they best learned proofs by comparing different proofs. Student 11, on the other hand, suggested that they learned best by studying proofs and looking at examples of the relevant mathematics being worked out beside it.

For the best teaching techniques presented in class that helped to learn proofs, Student 1 directly referenced the labs, saying, "…the labs … showed how many of the concepts were applied. Though I enjoy theory more, I cannot deny that application further strengthens my understanding." Meanwhile, Student 11 claimed they learned best from the verbal explanations of the proofs in class.

The second section of the survey was designed to assess the students' perceptions of MATLAB and its use in the course. The results showed that four out of thirteen students were familiar with MATLAB before this course, including Students 1 and 11. Additionally, twelve students reported that they had learned coding in the course. In regards to whether or not coding helped their understanding of linear algebra, some responses were similar to one student's claim that it enabled them to "see what the theory was", as multiple students referenced some form of visualization even with labs that did not offer anything apart from symbolic results. In contrast, some students suggested it helped them learn how to apply the theorems in linear algebra. Additionally, there were a number of students claiming it helped them understand the theorems, such as Student 2's response, "Labs 2 and 6, and the final project were very important to my understanding of 2.19 [the linear dependence lemma], Gram-Schmidt, SVD, and other concepts."

Discussion and Conclusions

The results of Student 1's performance (MATLAB code and the proof of theorem) revealed that although the proof was available at the time of writing the MATLAB code, it required specific skills and expertise. For example, how to make functions, use the commands available, generate random vectors, modify lists of vectors, validate their own codes, and follow the proofs to reach a desired goal with the artifact. While the algorithmic structure of the proof made it somewhat ideal for programming, the translation of the proof into MATLAB was not trivial. As Sinclair et al. (2023) pointed out, the artifact carries its own techniques. Based on the differences between Axler's (2024) proof and Student 1's validation of it, the intervention of the artifact seems to have impacted the transposition of their proof understanding into the MATLAB environment. In the limited data analyzed here, there is an argument for some potential relationship between the quality of a student's code and their proof-writing abilities. Notably, the entire process in this particular lab was based on an abstract theorem, did not include any numerical computations, and naturally added to the complexity of the process for students. While we can conclude the results from the instrumentation process, a closer examination of students' instrumental genesis would be necessary to better understand the possible role of MATLAB in developing their understanding of the proof concept.

The results of the exit questionnaire revealed that students had a positive perception of the role MATLAB played in their learning and exposure to new experiences in an abstract course.

The authors are in the process of analyzing the remaining labs, which are primarily related to applications. Future research projects will include evaluating students' abilities to validate other linear algebra proofs with programming.

Elaboration on Lists and Listing Processes in Combinatorics

Adaline De Chenne
New Mexico State University

Lists are a foundational way to reason about and solve counting problems, yet it is unclear to what extent their role should continue for advanced learners and what that role should be. I draw on case study data of two undergraduate students who used lists repeatedly as they worked through a sequence of combinatorial tasks. I demonstrate that the students' use of lists refined over time, and their representations developed from outcome-oriented to process-oriented, thus allowing them to draw on their knowledge of lists for increasingly sophisticated problems. Further, the forms of their solutions were impacted by their use of lists. I argue that these data shed light on broader questions of the role of representations in solutions to combinatorics problems as students develop combinatorial facility.

Keywords: combinatorics, combinatorial reasoning, lists of outcomes, semiotics

Introduction and Relevant Literature

Combinatorics is the mathematics of counting and enumeration. Finding the solution to counting problems often involves reasoning about and quantifying structure in the set of outcomes being counted (Lockwood, 2014). At the same time, there are few institutional means to represent those sets of outcomes in ways that are conducive to connecting structure to expressions of cardinality (Wasserman, 2019), despite the demonstrated positive impact of using representations as tools for combinatorial reasoning (Maher & Yankelewitz, 2010; Maher et al., 2010). Listing outcomes and reasoning about how to list the outcomes has been shown to enrich student combinatorial facility across grade level (De Chenne & Lockwood, 2022; English, 1993; Halani, 2012; Lockwood & De Chenne, 2020, 2021; Lockwood & Gibson, 2016; Montenegro et al., 2021; Tillema, 2018). One drawback of listing is that it can be intractable for larger problems. Lockwood and De Chenne (2020, 2021) address this issue by having students write computer programs to list the outcomes, and then reason about their algorithm and the produced list of outcomes to find a solution to the counting problem. However, De Chenne and Lockwood (2022) showed that even when students articulated a process to list the set of outcomes in a computer program, they were sometimes unable to articulate the same structure in the produced list of outcomes. These discrepancies in student reasoning call into question the comparative roles of lists themselves (inscribed representations) and reasoning about how to list when finding solutions to counting problems.

This paper elaborates on lists and listing processes in combinatorics, and their connections to how students find solutions and what form these solutions take. I draw on case study data of a pair of undergraduate students as they worked on a sequence of counting problems intended to elicit the use of inscribed representations. I focus on these two students because they regularly engaged in listing processes across six interviews, and importantly their use of lists was often challenged by balancing tractability with providing key combinatorial insight. Thus, these data demonstrate affordances of lists and listing process while also providing insight into how they can be applied in increasingly challenging and sophisticated scenarios. I seek to answer the following research question: *what roles do lists and listing processes have as students find solutions to combinatorics problems of increasing complexity?*

Theoretical Framework

I draw from Lockwood's (2013) model of combinatorial reasoning to describe broadly how students reason about and find solutions to counting problems. I then provide a theoretical characterization of lists and listing processes in combinatorics.

Model for combinatorial reasoning, and solutions to counting problems

Lockwood's (2013) model frames combinatorial reasoning in terms of sets of outcomes, formulas and expressions, and counting processes. Sets of outcomes are the collections of objects described in counting problems, the cardinalities of which are typically the solutions. Formulas and expressions are the mathematical expressions that yield some numerical value, most frequently used to express the cardinality of the set of outcomes. Counting processes are the real or imagined processes one engages with to enumerate, or count, the outcomes. While creating this model, Lockwood observed that some students approach counting as an activity of identifying the correct problem type (e.g., arrangement with repetition or selection without repetition) for the outcomes at hand, and applying a corresponding formula/expression. When one student was unsure which problem type was correct, she would "go off [her] gut" (Lockwood, 2014). Such an approach to counting poses a challenge for continued development as it minimizes understanding of why the formula applies.

Lockwood (2014) described a set-oriented perspective on counting as one where reasoning about the set of outcomes is an intrinsic component of solving counting problems. Entailed in this perspective is that sets of outcomes can be considered to contain underlying structure, and by leveraging and quantifying this structure the counter can identify a corresponding mathematical expression that provides the cardinality of the set of outcomes. Such a solution approach may employ a combinatorial formula such as $\frac{n!}{k!(n-k)!}$, but with the understanding of how and why that formula counts the set of outcomes. Wasserman (2019) reinforces this perspective, and he additionally argues that counting experts also have a complementary perspective where a mathematical expression represents a specific counting process. That is, the form of the solution represents what outcomes were counted and how they were counted. Drawing on this perspective, I characterize finding solutions to counting problems as determining a mathematical expression with two roles: yielding an integer value of the cardinality of the set of outcomes, and representing the structure of the outcomes used to determine this value. Hence, when examining the role of lists and listing processes in student solutions I will be examining the form of the solution as a way of understanding how students leveraged structure to find a mathematical expression of cardinality.

Lists and listing processes

Drawing from De Chenne and Lockwood (2022), I define a *listing process* to be a counting process in which one imagines how a set of outcomes can be enumerated, producing an ordered sequence. A *list* of outcomes is the artifact produced by enacting a listing process. Listing processes need not be able to produce a complete and totally ordered sequence of the outcomes, and I use the term *resolution* to describe the extent of the order in the resulting list. A listing process that demonstrates complete resolution is one where every outcome is created in a pre-defined order, whereas low resolution articulates a broad structure in a set but not substructures. For example, a low-resolution listing process might state how a set can be partitioned, but not how the outcomes in each part are ordered. I make no attempt to quantify resolution here, and I only use resolution as a means of comparing differences across the course of multiple interviews.

Methods

Participants and Data Collection

The data in this paper come from a larger study conducted at a large R1 university in the Northwest United States that investigated how undergraduate students use representations in their solutions to combinatorics problems. Hallie and Leah (pseudonyms) were two participants who worked as pair on a sequence of combinatorial tasks. The students completed six task-based interviews (9 hours total) over the course of one semester, and the data reported in this paper span the first five interviews. I chose to pair Hallie and Leah based on their similar educational background and their responses to the combinatorics problems presented in selection interviews. Both students were biological data science majors (Hallie was a senior and Leah was a sophomore), and neither student successfully used combinatorial formulas to solve the problems. Hallie had previously taken a discrete mathematics course with a section on combinatorics, but her responses in the selection interview indicated that she did not use formulas from that course to answer combinatorial tasks. Leah was currently enrolled a discrete mathematics course, but at the time of the interviews she had not completed the section on combinatorics.

I chose to present these data as a case study because Hallie and Leah repeatedly used lists and listing processes as foundational aspects of their solution. That is, lists and listing processes were fundamental to how they found solutions and were not used merely to communicate a solution found through other means. Additionally, over the course of the interviews Hallie and Leah adapted their lists and listing processes to increasingly complex problems with growing cardinalities. In doing so, they leveraged lists and listing processes with other structural information such as symmetry and recursion, which provides insight into how lists might be used as one tool used in conjunction with others. These data thus provide insight into how lists might be used specifically, and how external representations might be used more generally in combinatorics.

Tasks and Data Analysis

The task sequence presented to students in the interviews consisted of combinatorics problems that could be solved using arrangements with and without repetition, and selection without repetition. These problem types are consistent with other combinatorics education literature (see Lockwood & De Chenne (2020) for a broader discussion of problem types). However, I selected tasks to elicit the use of representations, and thus while the problems could be framed as arrangements and selections the literal outcomes described did not always match this framing. For example, the outcomes in the Three Cards Problem (described in the Results section) can be framed as a selection without repetition problem even if the literal outcomes described are ordered arrangements. Parts of tasks also explicitly asked students to describe how they would represent the outcomes.

The interviews were conducted in a private office and video and audio recorded. I provided students with writing materials, and their work was collected and scanned after each interview. From these scans I created a catalogue of representations, and in conjunction with the recordings of the interviews I used thematic analysis (Braun & Clarke, 2022) to identify what types of representations students used, categories of representations, and the roles of the representations in solutions. I focus here on Hallie's and Leah's use of lists and listing processes; however these two students used other representations across the six interviews.

Results

I describe three themes that emerged in Hallie and Leah's use of lists and listing processes. First is the balance between the resolution of a counting process and the affordance of a list for providing a means of reflecting on a counting process. The second the application of lists to solve part but not all of a problem by allowing for flexibility in what is being listed. The third is moving from representations of outcomes in lists to representations of listing processes more directly, and how those listing processes are reflected in the solution.

Resolution and Reflection

Hallie's and Leah's work on early tasks demonstrates how low-resolution listing processes could be used because the act of listing allowed them to reflect on and create lists in the moment. The first task Hallie and Leah completed was the Coin Flip Problem, which asked how they would record flipping a coin three times, how many ways there are to do so, and how their answers to these problems would change if the number of coins increased. For three coins, both Hallie and Leah created complete lists of the outcomes, although their listing strategies differed from each other. These lists are shown in Figure 1. Hallie's listing process entailed using two columns, where the second column was the mirror image of the first. This approach leveraged the symmetry of the outcomes; however, she did not have a pre-determined strategy for which outcomes would occur in which column. Rather, her approach was to write an outcome in the first column, write the mirror outcome in the second column, and then in the first column write another outcome that had not already appeared in the first or second column. Hallie concluded listing when she could not find an outcome that had not appeared in either column. She described this approach as "I kind of start where I separate at both extremes [HHH and TTT], and then get kinda to the middle."

Leah's approach was to structure the outcomes by the number of heads that occurred; that is, she listed all outcomes where three heads occurred, then all outcomes where two heads occurred, etc. While this provides a broad structure to the list of outcomes, the occurrence of each individual outcome within that structure was not predetermined, and she concluded each part of the list when she could not think of any unlisted outcomes. Hence, Hallie's and Leah's listing processes demonstrate a low-resolution strategy. Despite this, neither Hallie nor Leah appeared to have difficulty solving the problem. The low resolution of the listing processes was navigated by periods of time to reflect on the list—both Hallie and Leah were able to read which outcomes had been listed and create in-the-moment strategies.

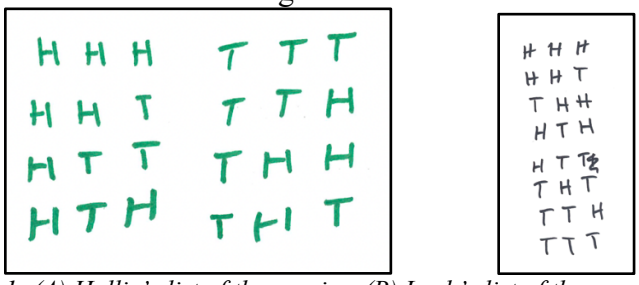

Figure 1: (A) Hallie's list of three coins, (B) Leah's list of three coins

Hallie and Leah also used lists of outcomes to determine the number of ways to flip four and five coins. Leah persevered in her original strategy of ordering the coins by the number of heads, and her list for four coins is shown in Figure 2 (A). While the broader strategy for ordering the outcomes is clear, her strategy within each of the parts appears to have been determined in the moment. She describes how she listed all outcomes with three heads as "I put all the three heads

at the start, and then I put them all at the end, and then I put one on the left, and then two on the right, two on the left and one on the right, and that got rid of... this one [crossing out HHHT] was just a repeat of what I did up here." This description shows that she produced these outcomes in an organized way (rotation around a central axis), but notably she chose a different strategy to arrange the outcomes with three tails, and this strategy was not extended for outcomes with two heads and two tails. I contend that her approach to listing the outcomes showed increasing resolution, but each part was structured using in-the-moment techniques. However, the list was a sufficient tool to enact this approach as it allowed her to keep track of her reasoning and reflect on the current state of the list to determine which outcomes had not been counted. I asked Hallie and Leah to find the number of outcomes in each part of their list, and they found that the number of outcomes was $1 + 4 + 6 + 4 + 1 = 16$.

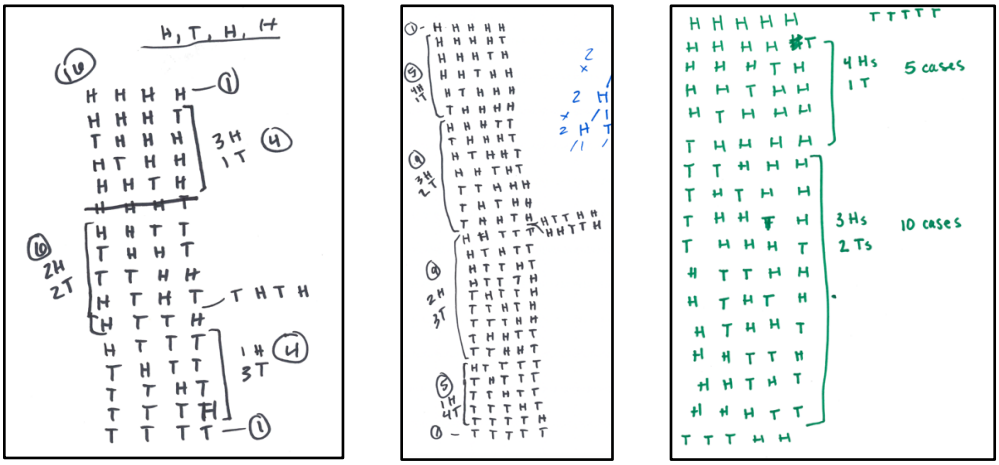

Figure 2. (A) Leah's list for 4 coins (B) Leah's list for 5 coins (C) Hallie's list for 5 coins

Both Hallie and Leah demonstrated increased resolution for five coins, as shown in Figures 2 (B) and (C). Leah's list shows repeated reasoning about ordering for outcomes with four heads and one tail, and outcomes with one head and four tails; however, her counting process for three heads and two tails, and two heads and three tails, demonstrates that the order was still determined in the moment (only after comparison with Hallie's list did she find that she missed two outcomes). Hallie relied on the symmetry of the outcomes in her list, and further she appears to use complete resolution in her listing process. Although the broad structure of her list was identical to Leah's, her organization within each part was consistent throughout. After writing half of the list, she concluded and noted "I kind of stopped writing, because of the symmetry thing we talked about." That is, Hallie reflected on her observations from prior lists and observed that by creating only half the list the remaining outcomes could be produced in the same manner. Hence, her solution reflects the mathematical expression $2(1 + 5 + 10)$. These examples demonstrate how Hallie and Leah used lists as tools for reflection, allowing them to reason about the structure of the list at hand and connecting that structure with cardinality even when using low-resolution listing processes.

Partial Lists for Part of the Problem

In the third interview Hallie and Leah worked on the License Plate Problem, which asked *A license plate consists of an arrangement of six letters and/or numbers. How many license plates consist of three numbers followed by three letters?* For this problem, Hallie and Leah were able to determine that the solution was $10^3 \cdot 26^3$ without using external representations. A subsequent part of the problem asked *How many license plates have four letters and two*

numbers? The solution to this problem is $\binom{6}{2} \cdot 10^2 \cdot 26^4$, which can be found by selecting the two positions in which the numbers occur, and then arranging the numbers and letters. At this point in the interviews Hallie and Leah appeared adept at solving problems of arrangement with repetition, but this new problem also involved selecting which of the six characters would be letters or numbers as one step in the problem. Hallie and Leah recognized that the solution was $10^2 \cdot 26^4$ multiplied by the number of ways to select two of the six characters, but they were not sure how to determine that number. Hence, they were able to solve one step of the problem but not the other. Their solution to the problem involved listing some of the ways to arrange two numbers and four letters, as shown in Figure 3. This use of listing is both partial in that it omits some ways to arrange numbers and letters, but also each inscription in the list denotes a number of outcomes rather than individual outcomes. Hence, the list was used as a tool for part of the problem, allowing them to physically outsource their reasoning for the parts of the problem they could not perform mentally. Additionally, this example demonstrates how the students began to move away from lists as outcome-oriented tools to process-oriented tools as each 'outcome' in the list stood for a collection of outcomes rather than an individual outcome. Hence, the list itself reflects one stage in the counting process.

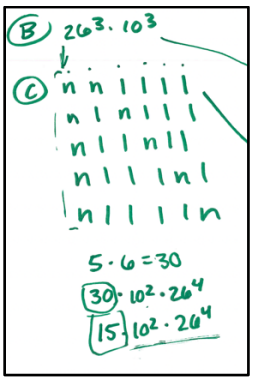

Figure 3: Partial listing of arrangements of two numbers and four letters

Representations of Listing Processes and Connections to Solutions

During the fifth interview the students solved the Three Card Problem, which states *You and your two friends, Ben and Charlene, are playing a card game that only uses spade cards (i.e., your deck consists of the Ace through King of spades). You each draw a card, and whoever has the highest card wins. How many ways are there to play this game so that you come in first, Charlene comes in second, and Ben comes in last?* The solution to this problem is $\binom{13}{3}$, which can be found by determining which three cards will be given to the players, and then giving those cards to the players in a way that preserves win order. Early in the solution Hallie stated "I could just write the cards themselves, since I know who's coming in first, who's coming in second, and who's coming in third," which indicates that she understood that finding the number of ways to select three cards would solve the problem. However, the students had not found a formula for counting selections.

Hallie and Leah employed a listing process that fixed the winning card, iterated through the second card, and then iterated through each losing card for each second card, as shown in Figure 4 (A). Hallie then created a representation of this listing process in Figure 4 (B), which demonstrates all instances where the winning card is the King. The listing process represented in these figures demonstrate complete resolution, showing how Hallie and Leah's application of listing processes was refined over the sequence of interviews. After representing this partial

listing process and observing there are $11 + 10 + \cdots + 2 + 1$ outcomes where the winning card is the King, the students then continued the process to find that there were $(11 + 10 + \cdots + 1) + (10 + \cdots + 1) + \cdots + (2 + 1) + (1)$ total outcomes, which reflects the listing process they used. To simplify this expression, Leah observed that the 11 appears in 1 of the sums, the 10 appears in 2 of the sums, and this pattern continued, as demonstrated in Figure 4 (C). I contend that he representations shown in Figure 4 (A) and (B) represent a listing process rather than simply a list of outcomes, as demonstrated by the use of arrows to signify the continuation of a process and brackets accompanied with numbers to signify the numerical value of terminating that process. Hence, it appears that the students simplified their use of notation to accommodate sets with larger cardinality by moving from notations of individual outcomes to notations for processes that generate those outcomes. In addition, their solution to the problem, $11 + 2(10) + 3(9) + \cdots + 10(1)$ reflects their use of the representations, leading to a form that differs substantially from a canonical solution of $\binom{13}{3} = \frac{13!}{3!10!}$.

Discussion

These data demonstrate how lists of outcomes and listing processes can play a role in student understanding of counting by influencing how students approach a solution, and the form of the solution they find. This was true even for counting problems where the cardinality of the set of outcomes made a complete list intractable to produce by hand. Rather than abandoning lists as a viable strategy, Hallie and Leah adapted their listing techniques by leveraging structural aspects of the set of outcomes (such as symmetry), relying on lists to answer only parts of problems, and representing listing processes rather than lists of outcomes to articulate strategy without needing to carry out that strategy in its entirety. These data inform broader questions of how students create, use, and adapt representations as they solve counting problems because they show how students can become adept at leveraging a specific type of solution approach and become successful in applying that approach to increasingly sophisticated problems.

Exploring Factors Impacting Students' Engagement in a College Precalculus Course

Aida Alibek
University of Georgia

This study aimed to gain insight into students' experiences of engagement in undergraduate Precalculus. A series of interviews were conducted with a group of 12 college students to solicit their lived experiences of engagement, using methods of hermeneutic phenomenology. The analysis uncovers that some of the key factors influencing engagement include the physical layout of the classroom, the nature of student-instructor and student-peer relationships, students' comfort level with the course material, and their interpretation of grades as formative feedback. Insights gained from these findings can provide us with important information about how students engage in college Precalculus and suggest ways to improve the teaching of the course.

Keywords: engagement, precalculus, student experiences, phenomenology.

Researchers and educators would agree that engagement is an integral part of the learning process, so engaging students in mathematics is viewed as an important goal at both the undergraduate and K-12 levels of education (Middleton et al., 2017). Efforts aiming to increase college students' success in mathematics courses emphasize the importance of student-centered instruction, providing supports for learners, and implementing pedagogies that promote students' active participation in the learning process (e.g., Apkarian et al., 2021; Rasmussen et al., 2019).

As we push for certain curricula and instructional approaches, it is important to consider not just the dehumanized numbers quantifying success and failure, but also the lived experiences of students who are on the receiving end of these reforms. Some questions we ought to consider include: Would students themselves say that they feel engaged in these classrooms? What does engagement look like for them? The study presented here aim to promote this conversation and shed light on factors that students experience as impactful on their engagement. The data and findings are part of a larger phenomenological study on students' experiences of engagement in college Precalculus.

Literature Review and Theoretical Framework

Precalculus is one of the more common gatekeepers to entering STEM majors in universities and colleges, while also ironically playing the role of a terminal mathematic course for certain majors in some universities (Bailey et al., 2008; Ganga & Mazzariello, 2018; Roksa et al., 2009; Seymour & Hewitt, 1997; Seymour & Hunter, 2019). In the last 14 years, groups of researchers in the US RUME community have conducted a number of large-scale national studies of the college-level Precalculus-Calculus sequence (Apkarian & Kirin, 2017; Bressoud et al., 2015; Rasmussen et al., 2019). The findings from these studies produced a plethora of insights into multiple aspects of teaching and learning in these mathematics courses. However, there is still a growing need for research on affective aspects (which includes engagement) of college-level mathematics instruction (Melhuish et al., 2022), and a need for more research that solicits students' perspectives on their own learning (e.g., Leyva et al., 2021).

Mathematics Engagement

Despite its importance, there is no consensus on the conceptualization of student engagement in broader education research (e.g., Appleton et al., 2008; Wong & Liem, 2022). A commonly

adopted framing in K-12 mathematics education comes from Fredricks et al. (2004) that positions engagement as a dynamic, malleable, multi-dimensional meta-construct (Middleton et al., 2017). In their Compendium chapter Middleton et al. (2017) note the complexity of the phenomenon, which makes engagement rather difficult to research, especially when it happens in the moment.

When it comes to the multiple dimensions of engagement, the three most common ones are: affect, behavior, and cognition. Affective or emotional engagement is oriented towards students' emotional reactions to aspects of schooling (e.g., interest, feeling of belonging, attitudes, relationships, etc.). Behavioral engagement is oriented towards participation in schooling (e.g., positive conduct, effort and involvement in learning, participation in school-related activities, etc.). Cognitive engagement, which is oriented towards students' investment of effort in learning (e.g., investment in learning, self-regulation, setting and working towards learning goals, etc.). When considering students in the mathematics classroom, it is easier for instructors and researchers to observe behavioral engagement and much harder to glean students' affective and cognitive engagement.

Hermeneutic Phenomenology

The method used in the proposed study is hermeneutic phenomenology, which focuses on the human experience of a phenomenon, as well as the meaning of that experience (Friesen et al., 2012). The process of interpreting meaning is valuable in education research as it allows for contextualizing both the participants' experiences within the broader socio-cultural environment where learning happens, and the individual learner's personal disposition and interaction with education. This study builds on the interpretive approach of van Manen (2014) with the influence of the reflective lifeworld approach of Dahlberg, Drew, and Nystrom (2008).

Since student engagement is a complex and dynamic phenomenon, it makes sense that by exploring students' rich descriptions of their lived experience, we can get to the dynamic essence of engagement, as opposed to capturing a static image at some point in time. In order to conduct a phenomenological study, the methods of data collection need to emphasize soliciting students' descriptions of lived experiences of the phenomenon as they happened (van Manen, 2014).

Methods

This qualitative study was conducted at a large public university in the southeast United States during the Spring semester of 2024. Data collection involved a series of four audio- and video-recorded interviews with each participant that were spread out over the course of the semester. I also conducted non-recorded classroom observations of the sections attended by the participants with field notes. To support the interview process, the participants were asked to produce engagement artifacts and an engagement graph, which allowed them to respond to the interview questions in a more nuanced way producing rich qualitative data (Alibek, 2024).

Engagement Artifact

When asking participants to describe their experiences of engagement, interpreting data can be difficult since each participant have their own interpretation of engagement. Thus, it was critical to prompt the participants to explicate their conceptualization of the phenomenon. However, due to the complexity of the term, it would have been unfair to ask participants to produce a definition on the spot. Instead during each interview they were prompted to reflect and expand on ways they believe a college student can engage in their Precalculus course with additional prompts during each subsequent interview.

During Interview 1 participants were asked to jot down on paper their response to the following prompt: What are some ways you think a college student can be engaged in their Precalculus class? The produced artifact was brought back for Interview 2 for the participants to review and edit if they wished to do so. Additionally, during the second meeting they were asked to note the specific ways they have engaged in their Precalculus course themselves within the last week. Since engagement can manifest in similar ways across different disciplines, while simultaneously being discipline-specific, it was important to contrast the participants' experiences of engagement in Precalculus with their experiences in a different university course. This was brought in during Interview 3, when participants were asked to produce an engagement artifact for another class that they are enrolled in during that semester and then to compare it to the Precalculus engagement artifact. Finally, during Interview 4 participants were asked to do a final review and edit of their engagement artifact, as well as select one item that they felt was most representative of their engagement in the Precalculus course.

Graphing Mathematics Engagement

In addition to the engagement artifact the participants were asked to sketch how their self-reported engagement has shifted throughout the semester. Graphing as an elicitation tool is not a novel approach in neither education research more broadly (Bravington, 2023) nor mathematics education (Olarte, in press; Riske et al., 2021; Satyam et al., 2022). In fact, graphing is especially useful when dealing with constructs like engagement that involve affect, are malleable, and can significantly shift and change over time.

Participants were given a blank first quadrant of the coordinate plane and during each interview participants graphed their engagement up until the moment of the interview: first few weeks during the first interview, the weeks between the first and second interview during our second meeting, etc. Thus, each graphed segment covered around 3-4 weeks of the semester. Moreover, the graphs were all done on the same sheet of paper, so participants could review their sketches from previous interviews and build on them. Participants were provided alternative color markers to show how they would revise previously sketched graphs or letting them sketch the new segment in a different color if they desired to do so (e.g., Fig. 1 and 2).

It is important to reiterate here that the graphs were not analyzed by themselves: their main purpose was to elicit rich qualitative data and thick lived experience descriptions. Participants' graphs were not compared to each other as part of the data analysis. Instead graphs together with artifacts informed the interpretation of interview transcripts.

Participants and Context

At the beginning of the semester 12 participants enrolled in the research study, with only 9 participants completing all four interviews. The other 3 participants withdrew from the course at various points in the semester and thus couldn't complete all planned interviews. The data set includes a total of 42 participant interviews.

10 out of 12 participants in the study were enrolled in the flipped classroom sections, while the other 2 were enrolled in lecture-based sections. The flipped classroom sections of Precalculus at this university were coordinated for the most part. All students had to watch a set of videos, as well as solve and submit a short assignment prior to class. Once they were in the classroom, they worked in small groups to solve the worksheet problems from a printed packet, which they bought from the university. The in-class worksheets were never turned in for grades or feedback. Additionally, students had online ALEKS homework, weekly graded quizzes, three tests taken

during class time (corresponding to the three main content units of the course), as well as a cumulative final exam at the end of the semester.

While the overall findings are based on data from all 12 participants, the comparative examples used in this proposal focus on two participants from the study: Ashley and Beth, who despite having many similarities, had vastly different experiences with engagement. They were both freshmen at the university, who have taken a year-long Precalculus course during their junior year in high school. They were both enrolled in a flipped classroom section of Precalculus, taught by different instructors. Neither participant saw herself as a math person, but both were motivated and hard-working students, who aspired to get the best grade possible. However, while Ashley ended the semester feeling positive about her involvement in the course, Beth, on the other hand, voiced strong negative sentiments towards both the course and her engagement in it.

Data Analysis

This proposal focuses on the results of an intermediate analysis question within a larger study on student experiences of mathematics engagement in college Precalculus. The research question addressed in this presentation is: *What are some factors impacting students' engagement in college Precalculus?* The process of data analysis involved rounds of phenomenological bridling (Dahlberg et al., 2008), followed by reviewing participant interviews for lived experience descriptions of engagement (van Manen, 2014), and then writings narratives of experiences. The lived experience notes, phenomenological narratives, and interview transcripts were then analyzed across participants.

As a result of the analysis, certain factors consistently appeared across narratives of engagement experiences. Two participants, Ashley and Beth, were chosen to frame the findings due to their contrasting depictions of similar factors, informed by versus coding exercises (Palacios-Díaz & Moreno-Londoño, 2023). It's noteworthy that these factors resulted from a holistic analysis of the entire data set, not just Ashley and Beth's interviews.

Findings

When contrasting Ashley and Beth's experiences in the course, on the surface it seems like their stories of engagement couldn't be more different from each other. Ashley sustained a relatively high level of engagement throughout the semester and felt overall good about the course and her own learning at the end (Fig. 1). Beth on the other hand shared many frustrations about the course and how it is taught, she would regularly say that she doesn't really feel engaged in the class (which was reflected in her graph), and by the end of the semester she admitted that she can't wait for it to be over (Fig. 2). Despite these surface differences, data analysis has shown that there are certain aspects of the Precalculus course, instruction, and classroom environment that students see as impactful for their engagement and learning.

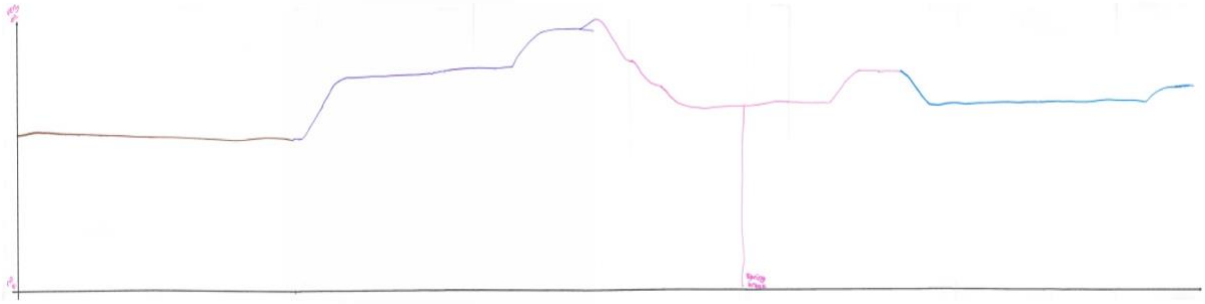

Figure 1. Ashley's final engagement graph.

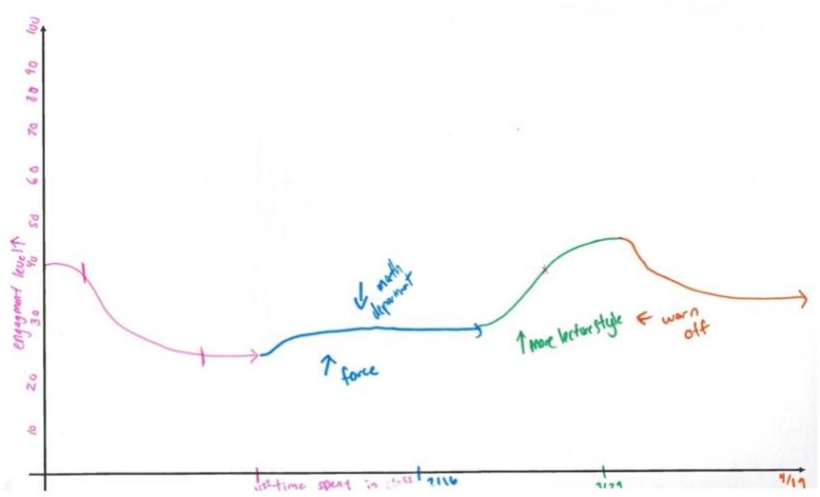

Figure 2. Beth's final engagement graph.

Physical Layout of the Classroom

Participants brought up the physical setup of their classrooms when discussing engagement, especially the way tables are set up for groupwork. When working on her engagement artifact, Beth said that one of the ways students can engage in a Precalculus course is by sitting at round tables, or at least facing each other (Fig. 3, left). However, she later noted that this is something she experienced in her high school Precalculus class, but not in her college course. Beth noted that her college Precalculus classroom had tables that were set up for a lecture-style class, where she had to move to work in a group with other students (Fig. 3, right).

Figure 3. Beth's first engagement artifact (left) and sketch of her classroom (right).

Ashley also noted that sitting together with other people and facing each other helps her feel engaged during class. She contrasted it with her experience in another lecture-based Precalculus section that she attended once during the add/drop week. She said that sitting at her desk, not looking at other people caused her to feel disengaged, which was one of the reasons she switched sections. Similarly to Beth, in her artifact Ashley noted the physical classroom setup as one of the ways to engage (Fig. 4, right) compared to the disengaging lecture setup on the left (Fig. 4).

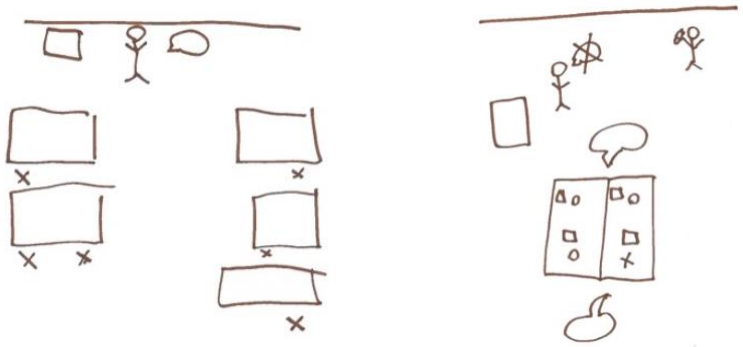

Figure 4. Ashley's first engagement artifact for the lecture class (left) and flipped class (right).

Relationality of engagement

When it comes to learning environments, it's not just the physical setup of the class that impacted participants' engagement. The students in this study noted the great role that the relationships play in the way they experience engagement.

First, classmate relationships greatly influence engagement, particularly in a flipped classroom. Initially, Ashley felt less competent in mathematics than her peers, leading to self-consciousness. However, she grew comfortable with her group and with asking questions during class, attributing her active engagement to the supportive learning environment. Conversely, Beth felt her group members knew less than her, leading to frustration as she felt her learning was hindered, describing her participation as forced and inauthentic. She would feel frustrated that she was held back by her group instead of trying to get through the in-class worksheet.

Second, the relationship with the instructor also affected their engagement. Ashley had a positive perspective of her instructor, appreciating their approachability and interactive teaching style, which significantly contributed to her active engagement. Ashley valued how her instructor structured their class time and the interactions between students. Meanwhile, Beth had less positive feedback, expressing frustration with the instructor's tendency to go on tangents and over-explain to the point of unhelpfulness, as well as perceived inefficient use of class time, leading to suboptimal engagement, despite acknowledging the instructor's care for students.

Comfort with the Mathematics Content

Something that was relevant for many participants in the study was how engagement shifted depending on the students' comfort with the topic discussed in the course. For context, the first part of the class focuses on functions in general (equations, graphs, polynomials), the second on exponential and logarithmic functions, and the third on trigonometry (angle measures, arcs, and trigonometric functions). Both Ashley and Beth shared that they struggled much more in the first part of the class but felt more comfortable with some of the latter topics. While the reasons behind their comfort levels were different, both noted that engagement would decrease a bit in level or intensity when they felt more comfortable with the content and increased when they struggled with the content.

Although Beth and Ashley experienced a similar relationship between Precalculus topics and shifts in their engagement levels, there was a clear distinction between how Beth and Ashley felt about their own conceptual understanding of the material. On one hand Ashley was thrilled that unlike her time in high school, she was finally getting the "why" behind mathematics in Precalculus at the university. She gave an example of finally understanding the unit circle and even why it was called the unit circle. Meaningful engagement in the course was paying off for

Ashley. On the other hand, Beth shared that her engagement in this class was more about studying and practicing procedures. She shared that despite her comfort with the content (especially trigonometry), she believed a lot of it was still from her time in high school. In contrast to Ashley's unit circle, Beth shared that she could solve problems involving co-terminal angles, but she still didn't know what they were.

Grades as a Factor Informing Engagement

While it is common for educators to talk about the role of formative assessment in giving feedback about student learning and their own teaching, it was interesting to see how the study participants talked about adapting their engagement using grades as feedback. This point is related to the previous idea of comfort with the content: for students their grades are an indicator of sorts whether they grasp the content or not. This informed their next steps: lower grades signaled to them that they need to do more, pay more attention; higher grades signaled that they have some level of understanding and thus can shift their energy towards engaging in other things. This was also highly related to the students' busy college schedules, when they are juggling multiple demands on their time and energy towards engagement.

One instance when grades informed students' engagement manifested for Ashley and Beth during the time leading up to Test 1. Ashley was not doing well on quizzes in the class so far. In fact, her first quiz she got a 6.5 out of 12 and the instructor told her class that anyone who got a 6 or below on the quiz should consider withdrawing from Precalculus or enrolling in a support class. Ashley's ongoing struggles with quizzes impacted how she felt about her understanding of the material. She even shared that she thought she knew the content well enough before the first quiz, but the grade proved otherwise. These struggles led Ashley to increased engagement and a lot of preparation for the first test of the semester, resulting in her getting a 90.5 out of 100 on it. One must note that the highest point in the entire engagement graph for Ashley in Figure 1 was around Test 1. Beth had quite the opposite situation compared to Ashley. She felt confident in her knowledge of the material, averaging 95% on her quizzes. She wasn't as engaged in the course leading up to Test 1, on which Beth earned a 77 out of 100.

Discussion

Many of the factors identified as impacting students' engagement in this study are in line with extant literature on mathematics engagement. In particular, the value of student-teacher interactions has been identified as having a great impact on students' engagement (e.g., Barnes, 2019; Durksen et al., 2017; Lin et al., 2018). Beth's negative experiences of engagement with her instructor's in the moment feedback have also been noted in research on flipped mathematics classrooms (Cevikbas & Kaiser, 2022). Previous research has also noted the role of the physicality of the learning environment (e.g., Imms & Byers, 2016; Waldock et al., 2017).

Simultaneously some of the findings have the potential to expand our understanding of how students experience engagement as it relates to their comfort with course content. This is especially relevant for early-college mathematics classes like Precalculus, where the material is not new for students and their engagement might shift differently compared to courses where material is mostly new (Amman, 2022). Understanding how college students use grades as formative feedback for regulating their own engagement can prompt us as a research and teaching community to think more critically about how assessment tools are used in courses like Precalculus. Moreover, this can promote highly needed conversations about further soliciting college students' descriptive experiences of mathematics gatekeeper courses as it relates to their motivation, engagement, and self-regulation.

Mathematicians Reject, Teachers Embrace: Different Perspectives on the Role and Significance of Disciplinary Obligations in Secondary Mathematics Teaching

Yocheved Mytlis
Weizmann Institute of Science

Alon Pinto
Weizmann Institute of Science

A key objective of academic mathematics courses in teacher education is to enhance teachers' awareness of disciplinary values and principles, ensuring alignment between mathematics education and the discipline. However, research indicates that this goal is often not met. A possible explanation is that mathematicians and teachers have different perspectives regarding the discipline's role in mathematics education. This study examines these perspectives in three extreme cases, where mathematicians and secondary mathematics teachers disagreed on the legitimacy of secondary mathematics activities from a disciplinary standpoint. Analysis of professional obligations that underlie the mathematicians' and teachers' reasoning reveals distinct interpretations of the obligation to the discipline and of its implications and significance in consideration of other obligations. These findings emphasize that teacher education should go beyond fostering awareness of disciplinary values and principles, and support teachers in learning how they can apply this understanding effectively in school to guide and inform their teaching.

Keywords: Teacher education, Mathematicians, Professional Obligations, Decision-Making

Introduction

One of the key roles of academic mathematics (AM) in the education and professional development of secondary mathematics (SM) teachers is to help teachers orient their teaching so that it aligns with and represents the values and principles of the discipline (Ball & Bass, 2009; CBMS, 2012; Cooper & Pinto, 2017; Hoffman & Even, 2023; Shulman, 1986). A common approach in AM courses for teachers is that mathematicians provide teachers with AM learning experiences, with the expectation that this experience will trickle down into their classroom instruction (e.g., Wu, 2011). However, current research and policy documents do not specify how this orientation is supposed to happen in practice, nor how AM learning experiences become a resource for teachers' instructional decisions. There is empirical evidence that both teachers and mathematicians do not always have a clear vision of how AM studied by teachers is brought into classroom teaching (e.g., Lai, 2019; Wasserman, 2018; Zazkis & Leikin, 2010).

Therefore, in recent years, there has been a growing interest in the subtle process by which aspects of AM may become a resource for SM teachers' instructional decision making (e.g., Biza et al., 2022; Herbst & Chazan, 2020; Pinto & Cooper, 2022, 2023; Zazkis, 2020;). One approach for delineating these processes is by exposing how the obligation to the discipline may orient teachers' decision making (Herbst & Chazan, 2020). Specifically, Herbst and Chazan (2020) propose that mathematicians will share their mathematical knowledge and practices with teachers to develop their sense of the discipline and inform their teaching. However, Herbst and Chazan also emphasize the crucial role of SM teachers in revising the initial ideas offered by mathematicians in consideration of the realities of SM education as manifested in other professional obligations. In this study, we adopt and adapt this approach by engaging mathematicians and experienced SM teachers with authentic SM instructional situations in ways that invite both sides to interpret and negotiate the role of obligation to discipline with respect to specific and concrete teaching decisions.

This paper is focused on three extreme cases where mathematicians deemed mathematical activities as inappropriate for secondary education since they breach values and principles of the discipline. The SM teachers, while acknowledging the breach, still considered using these activities in their classes. In these contexts, we investigate differences between mathematicians' and teachers' perspective regarding how obligation to the discipline should orient SM teaching. Our investigation is guided by the following research question: *How do mathematicians and SM teachers perceive the role and significance of the obligation to the discipline in relation to concrete instructional situations in SM education?*

Theoretical Framework

Teachers and mathematicians may be considered as different communities of practice. According to Akkerman and Bakker (2011), encounters between such communities, in which issues related to the practices of each community are discussed, may reveal a boundary – 'a sociocultural difference leading to discontinuity in action or interaction' (p. 133). For example, differences in professional obligations expressed by members of these communities reflect such discontinuities. The cross-community dialogue in these meetings provides a fertile ground for initially identifying these differences, and negotiating the role and significance assigned to them.

Herbst and Chazan (2020) identified four central professional obligations that guide mathematics teachers in making instructional decisions: the obligation to the discipline, the student as an individual, the class as a group, and the school. In articulating these obligations, they point out that mathematics teaching is expected to be influenced by the discipline. At the same time, they recognize that instruction takes place within a specific context, involving the student, the classroom, and the institution. These obligations reflect the tensions underlying teachers' decision-making. In extreme cases, tensions sometimes turn into an outright contradiction between obligations. Such contradictions reveal different perspectives on the role and significance of the obligation to the discipline in consideration of the context, and how this obligation may orient the teaching.

Methods

This research is part of a long-term research project – M-Cubed (Mathematicians, Mathematics teachers, Mathematics), conducted in Israel between 2019-2024 (Goor et al., 2022; Pinto & cooper, 2022, 2023). In this project, small groups of mathematicians and experienced secondary mathematics teachers watch videotaped lessons together, collaboratively exploring the mathematical and pedagogical issues they identify therein. The design and facilitation of M-Cubed is informed by the literature on boundary-encounters and boundary-crossing (Akkerman & Bakker, 2011). The videotaped lessons are carefully selected by the mathematics education researchers who lead the meetings, aiming to reveal professional dilemmas arising from the exploration of practices derived from AM, as well as the pedagogical vision of both SM teachers and mathematicians. Thus, this research setting serves as a laboratory for generating and analyzing the implications of ideas and perspectives from academic mathematics in the context of real-world instructional situations. Data for this study include video recordings of approximately 30 meetings, each with a duration of about three hours. A summary was prepared for each meeting, and selected excerpts were transcribed according to the research goals.

This study focuses on extreme cases in which mathematicians strongly opposed the teaching activities presented in videotaped SM lessons, deeming them mathematically flawed and inappropriate for secondary education. In contrast, teachers did not accept the mathematicians' critiques at face value and advocated for using these activities despite their apparent

misalignment with the discipline. These cases were selected to expose differing perspectives on the role and significance of disciplinary values and principles in the context of authentic SM teaching decisions. The contrasting views between the mathematicians and the teachers prompted both groups to articulate their tacit perspectives, facilitating the identification and characterization of various professional obligations that guide and constraint teaching decisions. To this end, we first analyzed the reasoning of both groups regarding the legitimacy of the activities, identifying how they referenced broader principles or values that extend beyond the specific cases yet impact decisions about using such activities in SM lessons. We characterized these principles and values according to Herbst and Chazan's (2020) four professional obligations, guided by descriptions and examples of these obligations in the literature. We then compared the obligations to the discipline expressed by mathematicians and teachers, and how these shaped their reasoning and conclusions. Additionally, we explored how they positioned the obligation to the discipline with respect to other professional obligations. In this paper we present an analysis of three extreme cases that illustrate how mathematicians and teachers perceive differently the role of disciplinary values in SM teaching, and how obligation to discipline may intersect with other professional obligations.

Findings

In each of the three cases we will describe, we first present the mathematical and pedagogical context under discussion. We then characterize the mathematician's obligation to the discipline as reflected in their critique of the activity. Finally, we describe the teachers' voices that emerged throughout the discussion, emphasizing the different perspectives of the teachers on the roles and significance of the obligation to the discipline in consideration of other professional obligations.

Case 1: Mathematical Statements Teachers Make Need to Be True.

This case revolves around a task from an 11th grade advance-track class that the teacher, Sergei, introduced as an example that underlines the need for intuitions in mathematics. The task is to determine whether a plane 'like' the plane illustrated in Figure 1a exit, given that EK∦AB and FG∦AB. In the lesson, Sergei argued that there cannot be a plane that contains the points E, F, G and K, as such a plane would necessarily also contain the segment AB and therefore will necessarily contain the face ABD, which 'clearly' cannot be.

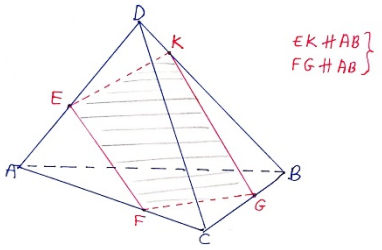

Figure 1a. Reconstruction of Sergei's board

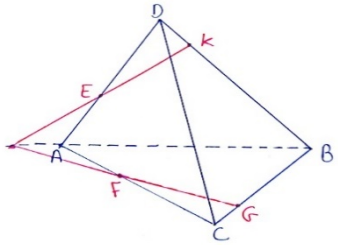

Figure 1b. Reconstruction of David's board

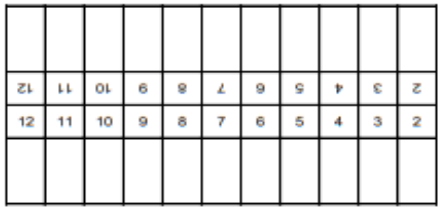
One of the Mathematicians, David, immediately recognized that in contrast to Sergei's argument, given a tetrahedron with vertices A, B, C and D, there always exists a plane that intersects BD, AD, BC and AC at points K, E, G and F respectively such that EK∦AB and FG∦AB (see Figure 1b). He further noted that this plane would not look 'like' the plane in the

drawing on the board, but that this drawing cannot be taken as data. He contended that Sergei made a very critical error and framed the lesson as a "mathematical catastrophe":

> [Sergei] gave the [students] a statement that is not well defined, with conditions whose sole purpose are to confuse the students because they are not relevant. False data, a false statement, a false proof, what could be worse in a mathematics lesson?

David's criticism of the task is clearly in disciplinary values, as he makes no reference to the individual student, to the class, or to the school. Notably, David recognized potential pedagogical value in the task. When considering teaching alternatives, he suggested that after convincing students that the proof is correct, a teacher may lead students to explore and where the argument fails, which in his words would afford students an "amazing lesson." However, David insisted that students cannot be left believing a false mathematical claim that a teacher made.

Some of the teachers disagreed with this position in ways that suggested that the teachers were oriented by additional obligations that were not outweighed by their obligation to the discipline. For example, Vera, noted that she loved what Sergei did in the videotaped lesson, and would use this task in the same way. She noted that as a teacher, the issue that David highlighted does not bother her as much:



> OK, I'm convinced [there exists a plane]. But, if from now on I will be afraid to bring [to class] something beautiful because maybe somewhere, mathematically, I'm wrong, then I will never bring anything. Because there is a difference […] between a teacher that wants to show the beauty, that wants to light up [students' faces], that wants to get them to think, and between the mathematician that must have everything precise, precise, precise.

In contrast to David's criticism of the task, Vera centralizes the students when considering the use of the task in class. She considers mathematical errors an acceptable price she is willing to pay to be able to share with her students' beautiful pieces of mathematics. She considers the difference between her positions and David's as representing a distinction between how teachers' and mathematicians' disciplinary obligation to precision.

Case 2: The Mathematics Discussed in Lesson Needs to Be Well-Defined

This case revolves around the probability game introduced by a teacher, Ari, in his 8th-grade advanced class. In the game, called 'Rive-Crossing Game' (RCG), students are given a board as described in Figure 2a, and 18 office clips, which they place on numbered squares ranging from 2 to 12. Players take turns rolling two dice, and if the sum of the dice matches a number on which a clip is placed, the player can move the clip across the "river". The objective is to be the first to transfer all clips. During the observed lesson, Ari guided the students in constructing a graph that represents the optimal clip distribution on the board (see Figure 2b).

a

b

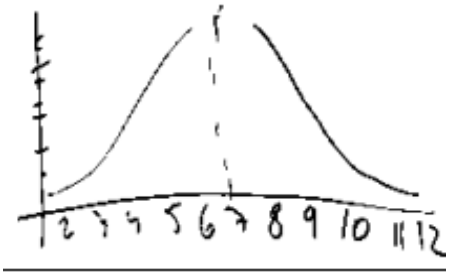


Figure 2. (a)The RCG's board and (b) A snapshot of board with the graph Alex built with his students

One of the mathematicians, John, identified the game as complex to solve, in terms of the mathematics underlying the game. He suggested the solution was likely not optimal: "I don't understand, what is the optimal strategy… I think that without a computer I don't stand a chance of calculating an optimal strategy." And then he explained: "… It's possible that there is a strategy with a slightly better expectation and slightly worse variance and another strategy that is the other way around. It's a very sensitive game."

In light of this perspective, during the continued discussion, John and another mathematician, Bill, explained they couldn't bring a mathematical problem to the classroom without being able to provide intuition for it, due to the complex mathematics behind it.

> Bill: Because I don't understand it myself. It's really hard for me to bring in something, where even on an intuitive level, I'm not entirely sure what's happening. Okay? Because I agree with John, that when the numbers are very large, it's better to approach this curve… As long as every throw moves a clip, there's no problem. The problem starts when we begin hitting zero, right? And that's something that will happen in smaller trials. It's a problem when I can't provide intuition myself.

In this case, as well, the mathematicians' critique of the task did not address the students, the class, or the school context. Again, it was grounded in disciplinary values. Specifically, the obligation to fully understand the mathematics brought to the classroom and the ability to model the problem, and well define it, to analyze it. During the discussion, John noted that without fulfilling this obligation, the RCG game loses relevance to probability learning, saying: "It is strategy thinking, game thinking. Is it related to probability? So-so".

Some of the teachers disagreed with the mathematicians' view on the activity's legitimacy. They didn't dismiss the claim that the task compromised the obligation to the discipline but gave it less weight compared to other interpretations of the disciplinary obligation the task invited, as well as other professional obligations. For instance, one of the teachers, Leah, argued that the stage of choosing how to distribute clips at the start of the game fosters initial intuition, mathematical thinking, and discussion. Unlike the mathematicians, she placed less importance on justifying optimal strategies through detailed mathematical analysis, due to time constraints that prevent students from reaching such advanced questions. Additionally, she highlighted the game's value in terms of her obligations to her students and the class, given the enjoyment it provided. She weighed her arguments against the 'damage' pointe out by the mathematician, comparing it to the 'benefits' she pointed out, as she said:

> … I don't understand what the big problem is. I see a lot of benefits. ...What's so scary … it's exactly what he was trying to say—frequency versus probability… as they said here, there's not enough time to play. They won't see the optimal strategy

And she added:

> I just want to defend the game as well. ... With all the disadvantages you listed. first of all, it's really fun. It's much less fun to flip a coin 100 times. Sorry, but that's super boring… It [RCG] really sparks a lot of interest. Kids talk about it. …usually, it works out for the ones who don't ignore the smaller tiles, who actually spread things out like a bell curve... And it's also really fun when you think you've figured out the optimal strategy, but you don't win... I think John said… opening with games. And especially with a game like this, it totally fits that purpose. In my opinion, it's a really good game.

Case 3: Motivation to learn a new mathematical idea needs to be authentic.

This case revolves around an activity from an 'introduction to function analysis' lesson in a 10th-grade high-track class. As part of the task, a student volunteer leaves the classroom while

the teacher momentarily displays on the board a graph of an unfamiliar function, such as the graph of the function $f(x) = x^2(x + 3)$. Upon the student's return, the class was asked to verbally explain how to draw the graph, without using gestures or images. One of the mathematicians, John, was highly critical of the task from the start, questioning whether it is even mathematical. He explained: "You just start with a figure and end with a figure, so [it's] more a discussion in visual communication, not in mathematics". He elaborated on what he would expect from a task designed to motivate function analysis, clarifying what he meant by "not mathematics":

> *John*: It all depends on the selection of a function, right? If you choose a function that looks like the back of a crocodile, they [students] will say it looks like the back of a crocodile, and there would be no mathematical at all
>
> *Facilitator*: …But if you wanted to use mathematical concepts to describe a crocodile's back… you could say the function has many local maxima, here it's convex…
>
> *John*: It wouldn't be natural. Anyone who would work this way would be using mathematics not for its purpose, in a way, right? We want mathematics to be used in places where it is natural… and so the function needs to invite a mathematical description.

John went as far as describing the lesson as 'terrible' and some of the other mathematicians supported his stance. In their critique, they generally did not consider the specific teaching context—the particular classroom, the specific students, or the institution. Instead, their concern indicated a strong obligation to the authentic way of things to be done in the discipline – arising naturally from a genuine need for mathematics, such as modeling in physics, rather than creating an artificial use of mathematics.

The mathematicians' utter dismissal of the task led one of the teachers, Emily, to press John to explain why he found the lesson so "terrible". Additionally, she elaborated the goals of the whole lesson and particularly the value of the activity from her perspective. In her explanation, Emily described a teaching process intended to create a need for a shared language in order to analyze functions, as another teacher explained it before John's critique:

> The goals of this lesson were different, in my view… they've spent a whole year learning about straight lines, and another whole year on parabolas. so, what now? Are we going to spend a whole year on cubic functions? … The idea is that we need tools to help us investigate functions in general... and regarding the second task, drawing something you haven't seen before. That's really... the motivation behind it is to develop a common language. Using it is part of the motivation.

Emily further elaborated: "All the words we use now, such as increasing, decreasing, positive, negative […] part of important concepts, [they] still do not have this language."

Emily and other teachers envisioned a process that achieves a pedagogical goal—creating a need for new mathematical ideas among the students. Her entire description was based on mathematics, but it is possible that her interpretation of mathematical motivation was more focused on school mathematics, whereas the mathematicians perceived it in its broader sense. Additionally, during the discussion, teachers also mentioned the students' enjoyment of the activity, which provided additional value to the activity.

Discussion

This study examined how mathematicians and SM teachers relate to breaches of disciplinary values and principles of the discipline in three extreme cases where mathematicians and teachers disagreed about whether mathematical activities are suitable for SM education. Analysis of the professional obligations that emerged in the mathematicians' and teachers' discussions of these

activities highlights differing perspectives regarding the role and significance of obligation to the discipline in SM teaching. Our findings illustrate why awareness of disciplinary values and principles that teachers are expected to develop during their academic studies does not always manifest in their teaching the way mathematicians might expect. While this phenomenon has already been discussed in the literature (Herbst and Chazan, 2020), the cases in our study stand out since they illustrate vastly different perspective on obligation to the discipline even in cases that from a disciplinary perspective could be considered as 'black and white', and even when mathematicians have the opportunity to explain their perspective and persuade the teachers.

In all three cases, mathematicians identified the activities as breaching their obligation to the discipline so fundamentally that they rejected their suitability for SM education. The teachers, however, did not dismiss these concerns; instead, they sought to refine and reconsider the issues the mathematicians had raised, weighing against other professional obligations to determine their significance from their perspective. Consequently, teachers expressed alternative interpretations of the obligation to the discipline, often taking precedence over the mathematicians' view.

Our findings underline that the role of disciplinary values and principles in knowledge for SM teaching extends well beyond mere awareness. As Herbst and Chazan (2020) have observed, teachers need to interpret and weigh the significance of these values and principles in specific situations while considering other professional obligations. Thus, our study further underlines the necessity that mathematicians and teacher educators attend to teachers' disciplinary obligations not only in theoretical settings that are detached from the realities of SM education, such as academic mathematics courses, but also within the authentic context of classroom teaching.

Moreover, our study indicates that teachers should not be passive recipients but rather active participants in the articulation of the role and significance of the discipline in SM education. Furthermore, our findings suggest that there may be merit in mathematicians and teachers collaborating rather than working separately, as proposed for example, by Herbst and Chazan (2020). In our study, the mathematicians and teachers challenged each other's perspectives and pushed them to elaborate and refine them, and eventually negotiate not only whether the activities could be used but also how the activities could be used more responsibly from a disciplinary perspective while maintaining the pedagogical productivity the teachers recognized (cf. Pinto & Cooper, 2023). Such negotiations may pave the way for the development of a clearer and shared vision about the role and significance of the discipline in SM education.

Academic mathematics studies for teachers are intended to be a vital component of their professional preparation, equipping them with tools to teach school mathematics faithfully to the discipline. However, our findings indicate that presenting disciplinary obligations in a dichotomous way, without considering the authentic teaching context, may discourage teachers from fully integrating these obligations into their teaching. If our community aims to represent the discipline productively in teaching, the challenge lies in fostering a dialogue that accounts for both disciplinary and contextual obligations. Yet, this dialogue is often missing in current teachers' education frameworks. Further research is needed to investigate how such dialogue can be integrated into teacher preparation programs to better align disciplinary perspectives and professional obligations.

Collaborative Preferences for Learning Mathematics: A Scale Validation Study

Sang Hyun Kim
University of Auckland

Tanya Evans
University of Auckland

Collaboration within mathematics has been established as being effective in providing students with crucial opportunities to develop critical thinking, effective communication, and teamwork skills. By engaging in group problem-solving and shared learning experiences, students may gain deeper insights into mathematical concepts and learn to approach challenges from multiple perspectives. However, there remains a need for a reliable instrument to capture students' preferences for collaboration. This study aims to develop and validate the Collaborative Preferences for Learning Mathematics (CPLM) scale to measure student preferences for collaboration. Exploratory factor analysis revealed a single-factor structure, and a confirmatory factor analysis conducted with a separate sample (N = 243) demonstrated a good model fit. Further testing established the scale's strong invariance, confirming its ability to reliably measure collaborative preferences over time. The CPLM offers a valid and reliable way to capture student preferences regarding collaborative learning in mathematics.

Keywords: Collaborative learning, Group learning, Team-based learning, Peer instruction, Collaborative Preferences for Learning Mathematics (CPLM) scale

Undergraduate students are offered various opportunities to engage with mathematics, including a diverse range of pedagogical approaches, assessments, and resources. It is important to acknowledge that the backgrounds, experiences, and values students bring influence their preferences for how they engage with mathematics, particularly with their peers. Understanding and accounting for these preferences enables educators to tailor their teaching strategies, create more effective group dynamics, and foster inclusive environments that accommodate diverse learner needs. However, the extent to which students prefer collaboration or individual work, especially in the context of mathematics, remains underexplored, and there is a notable lack of systematic, quantitative tools to capture these preferences on a large scale. To address this gap, this study sought to develop and validate the Collaborative Preferences for Learning Mathematics (CPLM) scale, providing a robust measure to better understand these preferences. In the following sections, We review the literature on student perceptions of collaborative practices in mathematics, outline the study's context, present the results, and discuss the implications.

Literature Review

Collaboration is widely established in the literature as an efficacious approach to learning. Grounded in social learning theories such as Bandura's social-cognitive theory (1997), collaborative settings allow students to learn vicariously, increasing self-efficacy. Collaborative learning positively affects achievement and attitudes towards learning across various disciplines (Springer et al., 1999; Tullis & Goldstone, 2020; Xu et al., 2001). Specifically in mathematics, it has been argued that collaboration positively shapes students' learning experiences and could be used as an approach to foster motivation, confidence, and achievement for some students (Cuneo, 2008; Duah et al., 2014). However, achievement is not directly predicted by the time spent studying or the proportion spent studying collaboratively (Alcock et al., 2020).

Despite these general benefits, not all students have the same inclination to work with others (Johnson & Johnson, 1995); collaborative and individual learning preferences vary significantly. For instance, gender and age have been shown to impact this, with girls showing stronger preferences for cooperative learning than boys, who tend to favour competitive and individualised learning approaches. Additionally, preferences for cooperative and competitive learning have been reported to increase with school age (Owens, 1985). Personality traits may also be a predicting factor in students' willingness to learn collaboratively. One study reported that extroversion was significantly negatively correlated with a preference for independent study, and neuroticism, a measure of emotional stability, was negatively correlated with preferences for social modes of learning (Chamorro-Premuzic et al., 2007). Furnham et al. (2008) reported that group work was preferred by younger extroverted students with low conscientiousness and low general knowledge. Furthermore, these preferences and attitudes may also vary across disciplines (Gottschall & García-Bayonas, 2008), where disciplinary norms play a significant role. In mathematics, an emphasis on individual problem-solving, commonly used teacher-centered instruction (Dietrich & Evans, 2022; Melhuish et al., 2022), and assessments that focus on procedural knowledge may limit opportunities for collaboration and reinforce a perception that mathematics is best learned independently rather than collaboratively.

Student Perspectives of Collaborative Learning

Beyond individual factors, there is considerable nuance in students' experiences that are shaped by the social context in which they operate. In broader educational contexts, students' collaboration preferences often reflect their priorities and inclinations. Some students may choose to study alone to minimize distractions, while others may prefer group study to expose themselves to diverse perspectives. Many of the key difficulties of group work identified in the broader education literature tend to highlight the importance of equal contribution from group members (Feichtner & Davis, 1984; Salomon & Globerson, 1989; Tucker & Abbasi, 2016). This issue can be especially problematic when group work is assessed and has also been reported in the mathematics education literature.

Within the context of undergraduate mathematics, one study that interviewed three cohorts of students across different universities revealed that while students generally had positive attitudes towards group work, many still expressed a preference for learning individually in mathematics (MacBean et al., 2004). Within their study, group work, which was largely experienced in informal settings outside of class, provided a sense of camaraderie between students. These casual meetings offered the time for students to discuss their collective difficulties. Additionally, the student-driven nature of these informal interactions allows students to have the freedom to use the time as they desire with peers with whom they get along. Group work done in a formal capacity, such as during lectures or for assessments, can provide similar benefits but also expose numerous drawbacks. One such drawback is the occurrence of social loafing, which refers to "the reduction in motivation and effort when individuals work collectively compared with when they work individually or coactively" (Karau & Williams, 1993, p. 681), is more salient in larger groups than in smaller groups (North et al., 2000). Working with unfamiliar group members was another issue mentioned by students who must work to establish new relationships whilst navigating mathematical challenges (MacBean et al., 2004).

D'Souza and Wood (2003) corroborated the findings of MacBean et al. (2004): students perceived group work as a valuable experience with potential cognitive benefits and saw it as an opportunity to meet new people and increase self-esteem. However, they also identified significant challenges, including the presence of less outspoken and unprepared students who

were reluctant to participate, as well as individuals who did not contribute equally. The latter aspect might be advantageous for disengaged or weaker students who benefit from others' efforts. This observation prompts a nuanced discussion about the balance between supporting weaker group members while managing unequal workloads and maintaining fairness within collaborative environments.

Further research exploring student attitudes toward group work revealed generally positive views, with most students believing that collaboration enhances the effectiveness of mathematics teaching (Sofroniou & Poutos, 2016). However, like the previous studies, Sofroniou and Poutos (2016) reported concerns about unproductive group dynamics that were salient among students. Additionally, some students even recognized that group work "can slow down the lesson" (p. 7).

While collaborating in mathematics can be difficult for students, little is known why this might be the case. One reason could be that the strong tendencies of students to compare themselves with peers may hinder their ability to collaborate effectively in mathematics (Campbell & Yeo, 2023). When reflecting on their actions during collaborative activities, students demonstrate an acute awareness of various elements of their interactions – such as how often they speak and the overall group rapport – and the underlying factors that influence these dynamics, including confidence and personality (Campbell & Yeo, 2023).

Research Aims

The aim of this study was two-fold: (1) to develop and validate the CPLM scale, an instrument intended to measure general student preferences towards learning mathematics, and (2) to establish measurement invariance of the CPLM.

Rationale

Given the challenges and potential benefits of collaborative learning in mathematics, it is essential to better understand and gauge students' preferences for learning in this context. While collaborative learning has been explored in other subjects, there remains a need for research specifically focused on mathematics education. Much empirical and theoretical research highlights the various ways that working with others in educational settings can impact student learning; researchers should maintain a keen interest in students' preferences in these educational settings.

Firstly, this exploration of student voice indicates what students, a significant stakeholder in education, are experiencing and valuing in their learning. Kouros et al. (2006) describe students' attitudes towards learning as a reflection of the quality of their experiences. Understanding their preferences for individual versus collaborative learning in mathematics can provide valuable insights into how instructional approaches can be tailored to meet their needs better and support these experiences. Secondly, in a rapidly evolving world where social interaction preferences are continually shifting, having accurate methods for evaluating students' desires and needs can be invaluable for our understanding of the nuanced views from the students' perspectives, which has the potential to enhance overall student engagement and satisfaction. Lastly, even though student views represent just one overlooked dimension of mathematical learning, it can help identify whether the practices and policies that are implemented are aligned with their wants.

This research does not aim to advocate for or against any specific instructional method or any particular attitude towards students' collaborative preferences. Instead, it offers a way to get a snapshot of undergraduate students' preferences in collaborative settings within a mathematics context. While much existing research has focused on samples from different educational levels, our study seeks to explore straightforward and accessible methods to gauge student preferences

in learning. Specifically, this work captures undergraduate student experiences in a more generalized and context-independent manner, providing a broad overview of current student preferences. Developing a validated scale to measure student preferences for collaborative learning in mathematics can provide educators with insights into how instructional strategies might be adjusted to better align with student needs and promote engagement in this traditionally individualistic discipline.

Methodology

Collaborative Preferences for Learning Mathematics (CPLM)

This short scale contains five items that prompt students to consider their preferences for collaboration in mathematics. The items gauge different contexts and settings where these preferences may vary, including when learning for high- and low-stakes assessments and in different stages of their mathematical competency (being exposed to new concepts). All items were responded to on a slider scale from 0 to 100. The prompt and items in the scale are shown below.

Prompt: "Consider yourself learning mathematics. By moving the slider, state the extent to which you prefer to do it from 0 = Individually to 100 = Collaboratively for each of the items:"

1. What is the most effective way for you to learn mathematics? (CPLM_1)
2. What is the best way for you to make sense of mathematics? (CPLM_2)
3. What is the most effective way for you to study for high-stakes maths assessments (e.g., exams)? (CPLM_3)
4. In what social setting do you prefer to be exposed to novel concepts? (CPLM_4)
5. In what social setting do you prefer to engage in problem-solving in low-stakes assessment (e.g., homework, practice exercises)? (CPLM_5)

Analysis

Exploratory Factor Analysis (EFA). To validate the CPLM, we conducted an EFA to confirm the underlying structure of the five items (observed variables) and the latent variable (CPLM). Exploratory factor analysis was performed using principal axis factoring as the extraction method, which is more appropriate for non-normal data (Costello & Osborne, 2005). We assessed the appropriateness of the data for factor analysis using the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and Bartlett's test of sphericity. A KMO value above the .50 threshold and the rejection of the null hypothesis for Bartlett's test were considered indicators that the data was appropriate for this analysis (Dziuban & Shirkey, 1974). Cronbach's alpha values greater than .70 were considered satisfactory (Taber, 2018). The EFA was conducted on SPSS (Version 29).

Confirmatory Factor Analysis (CFA). We conducted a CFA to validate and confirm the factor structure identified in the EFA. A 'good' model fit was defined by $\chi^2/df < 3.0$, TLI > .95, CFI > .95, RMSEA < .06, and SRMR < .05. An 'acceptable' fit was indicated by $\chi^2/df < 5.0$, TLI > .90, CFI > .90, RMSEA < .08, and SRMR < .08 (Hu & Bentler, 1999). We assessed convergent validity by evaluating whether the Average Variance Extracted (AVE) exceeded .50 and Composite Reliability (CR) was greater than .70. AMOS (Version 29) was used for the CFA and invariance testing.

Multi-Group Confirmatory Factor Analysis (MGCFA). We conducted an MGCFA to test the measurement invariance of the CPLM over three different time points. We compared changes in model fit indices to evaluate the invariance, focusing on the Comparative Fit Index (CFI). A

change in CFI of less than 0.01 between models was considered indicative of good measurement invariance (Cheung & Rensvold, 2002).

Data

In this study, we utilized self-report data collected as part of a larger project. Participants rated their preferences on a 0 to 100 scale using five slider-based, close-ended items. The questionnaires were distributed via Qualtrics, an online survey platform. Two data samples were collected. The first sample consisted of undergraduate students recruited through Prolific, an online participant recruitment platform. These participants were current undergraduates from the UK or USA, studying STEM or commerce-related majors. After data cleaning, 273 valid responses were used for EFA. The second dataset was collected during the second semester of 2023 from a second-year undergraduate service mathematics course at a large university in New Zealand. This sample involved repeated measures from 224 students across three time points. Data from the first time point (N = 243) was used for CFA, and the repeated measures across the three time points were used for the multi-group confirmatory factor analysis (MGCFA) to test for measurement invariance over time.

Results

Exploratory Factor Analysis. The inter-item correlations of the CPLM ranged from .209 to .619. Bartlett's Test of Sphericity was significant, $\chi^2(10) = 322.69$, $p < .001$, and the KMO measure of sampling adequacy was .759, both indicating that the data were suitable for factor analysis. The results of the EFA yielded a single factor with an eigenvalue of 2.005, accounting for 40.09% of the variance. All five items loaded adequately to strongly to the factor (.476 to .863) (Costello & Osborne, 2005) and had communalities ranging from .227 to .744 (see Table 1). The five items in the factor show an acceptable degree of internal consistency, with a Cronbach's alpha value of .744.

Table 1. Factor loadings and communalities for each item from the EFA.

CPLM		
Item	Factor Loading	Communalities
CPLM_1	.863	.744
CPLM_2	.734	.539
CPLM_3	.507	.257
CPLM_4	.488	.238
CPLM_5	.476	.227

Confirmatory Factor Analysis. The results of the CFA showed that the one-factor model demonstrated a good fit to the data: $\chi^2/df = 1.601$, TLI = .988, CFI = .994, RMSEA = .050, and SRMR = .0230 (see Figure 1). The factor loadings ranged from .59 to .87. The Cronbach's alpha for the factor was .848, indicating good internal consistency among the items. Additionally, the Average Variance Extracted (AVE) was 0.54 and the Composite Reliability (CR) was 0.85, indicating that convergent validity was achieved. This evidence provided a strong basis for proceeding with the MGCFA to test for measurement invariance.

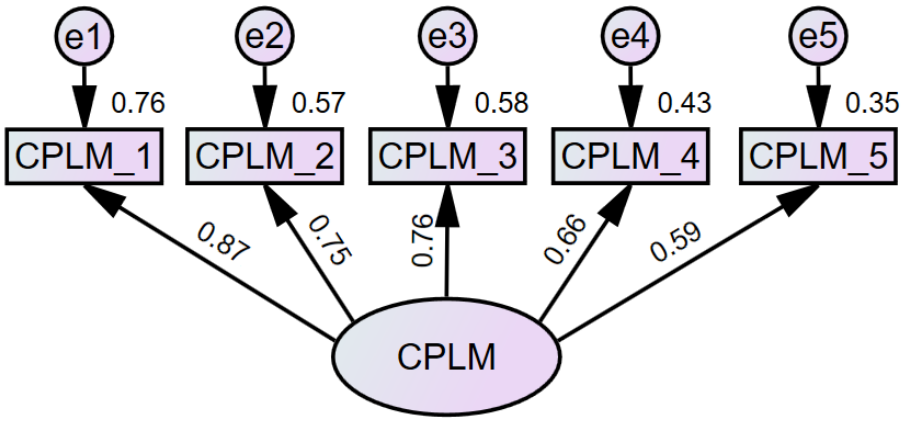

Figure 1. One-factor model for the CPLM.

Invariance Testing. The changes in CFI across the models remained within 0.01 of each model, except for the residual model, which had a change in CFI of .043 (see Table 2). From this, we can conclude that the model demonstrates strong invariance (configural, metric, scalar) but lacks strict invariance (configural, metric, scalar, and residual). Establishing strong invariance is generally regarded as adequate for determining model equivalence, allowing for valid comparisons of latent factor means across time (Meredith, 1993). Strict invariance, while rarely achieved in practice due to its stringent requirement of identical reliability across groups, is typically not considered necessary unless the research question specifically involves comparing observed variances or covariances across groups.

Table 2. Measurement invariance of the CPLM over a semester (N = 224).

Model	CFI	ΔCFI	χ^2/df	RMSEA
Configural (Unconstrained)	.993	-	1.804	0.035
Metric	.990	.003	1.803	0.035
Scalar	.991	.001	1.671	0.032
Residual	.948	.043	3.742	0.064

Discussion

This study aimed to develop and validate an instrument to measure students' general preferences for collaboration within mathematics. The results suggested that the CPLM scale is reliable and valid for measuring these preferences. EFA identified a single-factor structure, while CFA indicated the model demonstrated a good fit. Furthermore, MGCFA provided evidence of

strong invariance, confirming that the scale reliably measures the same construct across different time points.

One limitation of the CPLM is that, while it was validated in an undergraduate context, its application in other settings will necessitate further investigation and validation. Future research could expand the scale to include a broader range of collaborative experiences across different contexts, thereby enhancing its comprehensiveness and applicability.

Additionally, incorporating qualitative data, such as interviews or observations, could provide a richer and more nuanced understanding of students' collaborative preferences and the underlying factors that shape them. These insights could inform the refinement of existing tools and frameworks, ensuring they better capture the complexities of collaboration in educational settings. Such approaches would also create opportunities to explore how these preferences impact group dynamics, engagement, and overall learning experiences.

Despite the limitations, we believe this instrument offers a practical and efficient way to assess collaborative learning preferences on a large scale. Its ability to quickly gauge these preferences provides educators with valuable insight into their students' preferences towards collaboration. Such insight would enable instructors to anticipate and plan for diverse preferences within their classrooms, allowing them to better structure group activities and allocate resources. The CPLM scale is not intended to advocate for pedagogical practices that exclusively align with student preferences. Therefore, educators should use CPLM results as one of many tools to inform their teaching strategies rather than as prescriptive guidelines.

From a research perspective, the CPLM scale offers a quantitative tool to assess these preferences systematically, allowing researchers to incorporate student learning preferences into studies, which could serve as a useful variable to account for alongside other factors in future research. This integration can deepen our understanding of how collaborative dynamics influence learning outcomes and student engagement. Longitudinal studies, in particular, could shed light on how these preferences evolve over time or in response to targeted instructional interventions. In summary, the CPLM scale contributes to advancing educational research by offering a reliable tool for understanding collaborative learning preferences in mathematics.

Go-to Strategies Used by Undergraduate Developmental Mathematics Students to Support Their Fraction Understandings

Lucinda Ford
Texas State University

Difficulties with fractions are well-documented for undergraduate developmental mathematics students. As such, fractions are a known gatekeeping topic for this demographic. However, research on fraction understandings for this population is scarce. In this paper, I synthesize relevant literature regarding undergraduate developmental fraction understandings and related K–12 fraction literature. I then report findings from task-based clinical interviews to share examples of various go-to strategies these participants utilized as they worked through fraction tasks. I close with a discussion relating these findings to extant literature and propose future research directions.

Keywords: Fraction Understandings, Student Thinking, Undergraduate Developmental Mathematics

Many students experience difficulties when working with fractions, a gatekeeping topic for college-level mathematics courses (Mesa et al, 2014; Ngo, 2019). In this paper, I share examples of go-to fraction strategies that Nine, Vivian, and Sofia demonstrated as they worked with fractions in task-based clinical interviews (CI) (Ginsberg, 1997). These participants were undergraduate developmental mathematics students at a large research institution in the southern United States when they participated in their respective interviews during a spring semester between 2022 and 2024. Nine viewed fractions as division problems. Vivian considered fractions to see if they were in "the majority." Sofia simplified fractions and used known percentages as benchmarks when simplification did not help.

Literature Review and Theoretical Background

Research on the fraction understandings of undergraduate developmental mathematics students is scarce (Alexander, 2013; Mesa et al., 2014). Studies involving the mathematical thinking of undergraduate developmental mathematics students build on K–12 research since undergraduate developmental mathematics students study K–12 topics while being college students (Alexander, 2013). Fraction knowledge has been shown to function as a gatekeeper for algebra readiness, though further need for research has been suggested (Booth & Newton, 2012; Ngo, 2019; Siegler et al., 2012).

In this report, I draw on the fraction literature using three of Lamon's (2020) five fraction understandings as I examine what is productive in my participant's fraction thinking. Lamon's (2020) framework includes five fraction understandings: part-whole, operator, quotient, measure, and ratio. The part-whole understanding of fractions relates the number of equal parts of a whole to the whole (Lamon, 2020). The operator understanding views fractions as a set of instructions to be carried out (Lamon, 2020). The measure understanding is a geometric meaning for fractions and involves measures, or lengths, of intervals (Lamon, 2020). For the purposes of this study, I define fractions as numbers written in the form of a/b, where a and b are not necessarily integers, such that b is not equal to zero (Lamon, 2020; Empson & Levi, 2011). By strategy, I mean the approach the participant approached the problem when working on a task. The research

question for this study is: What go-to fraction strategies do undergraduate developmental mathematics students tend to rely on as they encounter fraction tasks?

Methods

In this paper, I present data from a larger dissertation study. The overarching goal of the dissertation study is to get a picture of the way the participant is currently understanding fractions using frameworks from Lamon (2020) and Steffe & Olive (2010) and then to examine ways to create an environment to foster the strengthening of the measure understanding of fractions (Lamon, 2020). The data for this paper comes from initial task-based clinical interviews (CI) (Ginsberg, 1997). A CI is a semi-structured interview that focuses on describing the participant's current thinking and reasoning (Ginsberg, 1997; Steffe & Thompson, 2000). The CIs were conducted as the first phase in the dissertation study, in anticipation of the participant potentially continuing into a teaching experiment (Steffe & Thompson, 2000). The clinical interview data comes from video recordings, the participant's written work, and any field notes taken (Cobb & Steffe, 1983; Steffe & Thompson, 2000; Steffe & Ulrich, 2020).

Participants, Data Collection, and Analysis

Nine, Vivian, and Sofia (all pseudonyms), were recruited from randomly selected undergraduate developmental mathematics classes at a large research university in the southern United States. Each of them participated in a CI that included 12 fraction tasks, divided among two 45-minute sessions. Data was collected during the spring semesters of 2022, 2023, and 2024. I served as the interviewer, and my witnesses came from a pool of graduate students and faculty who had experience and knowledge about the CI methodology. Witnesses served based on availability. A primary camera captured the participant's written work, while a secondary camera recorded the interaction between the participant and the interviewer. Both ongoing analysis and retrospective analysis were utilized (Steffe & Thompson, 2000). For ongoing analysis, I wrote notes following each CI session to review what had taken place. During retrospective analysis, I watched the CI, wrote a thick description of each session, then analyzed the data using grounded theory techniques in the form of open and axial coding (Corbin & Strauss, 2015) to identify the strategies, or approaches, that the participants demonstrated in their sessions.

Fraction Tasks Overview

The following list contains a subset of the tasks that were used in the CI. The interviews began with two open-ended questions that asked what $\frac{2}{3}$ and $\frac{7}{3}$, respectively, meant to the participant. These questions allowed the participants to share their fraction thinking before encountering tasks that targeted specific fraction understandings. The participants were also asked to read these questions out loud, as they may be read in multiple ways.

1. *What does 2/3 mean to you?*
2. *What does 7/3 mean to you?*
3. *This figure* (a picture of a hexagon) *represents a whole. Show me* (blank). This blank can be filled in with $\frac{15}{6}$ and/or $\frac{4}{6}$, depending on the difficulty participants experienced with the previous tasks.
4. Number line task
    a. Give the participant four index cards marked with $\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{8}$, and $\frac{7}{6}$ respectively. *Without using decimals, put these fractions in order from least to greatest.*

b. Give the participant a piece of paper with a line across it lengthwise. *If this is a number line, where would you place the fractions as accurately as you can?*

5. *Jade shared 5 candies among 3 friends. What amount of candy did each friend get?*
   Note: Alternative questions included sharing 12 candies among 5 friends and 2 candies among 3 friends.

Results

Nine, Vivian, and Sofia demonstrated varied go-to strategies as they worked on the fraction tasks in the CI. Nine viewed fractions as division problems. Vivian considered fractions to see if they were in "the majority." Sofia simplified fractions and used known percentages as benchmarks when simplification did not help. In the following I will explain each go-to strategy with a few illustrative examples.

Nine

Nine's go-to strategy was to primarily think of these tasks as division problems. Below, I will give examples from three tasks that illustrate this line of fraction thinking. When asked to explain what two thirds means to her in Task 1, Nine shared, "When I think two thirds, I just think two over three or two divided by three." Nine gave two examples for scenarios a teacher might give for two thirds. The teacher might give information about having pizza or brownies and the need to divide the food so they can be shared fairly. This lent to Nine viewing fractions as instructions for dividing the numerator by the denominator. She gave a similar response for seven thirds in Task 2, saying that seven thirds was "seven divided by three." This time she added that her "first instinct was generally to turn [seven thirds] into a mixed fraction." Then Nine talked through her process of using division to turn seven thirds into two and one third. Mixed numbers were not the only results of Nine's viewing fractions as division problems. When Nine was figuring out how she would share twelve candy bars among five friends in Task 5, Nine's immediate reaction was to divide 12 by five, this time using long division to find the decimal equivalent for 12 divided by five, shown in Figure 1. While we know that this problem refers to the fraction $\frac{12}{5}$, there is no evidence that Nine viewed this particular task as a fraction.

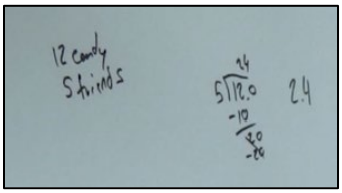

Figure 1. Nine finds how much candy each person gets when sharing 12 candies among five friends.

Vivian

Vivian's go-to strategy was to check to see how a fraction compared to "the majority," which is greater than one half. Below, I will give examples of two tasks that illustrate this comparison. In response to Task 1, two thirds meant to Vivian that "the majority of something is taken up or something has happened to it." She gave an example of three buildings in a location where two of the three buildings have people in them, shown in Figure 2. When interpreting her drawing, Vivian stated, "So, the majority of the three buildings, two thirds of the three buildings, are occupied." A second way that Vivian could describe what two thirds meant to her was to measure two thirds of a cup. As with the buildings, Vivian referred to the two thirds of a cup as "the majority of the cup."

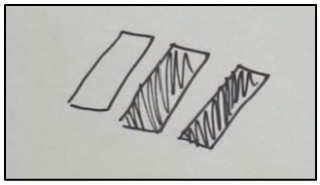

Figure 2. Vivian shared an example of what $\frac{2}{3}$ means to her.

During Task 4, Vivian decided to place the $\frac{2}{3}$ card to the right of the $\frac{1}{2}$ card, stating "Two thirds is the majority. So, that $\left(\frac{2}{3}\right)$ would probably be bigger." The $\frac{7}{6}$ card posed an issue for Vivian. To Vivian, fractions exceeding 1 did not exist. Specifically, with $\frac{7}{3}$ in Task 2, and again with $\frac{7}{6}$ in this task, she stated "seven sixths doesn't exist." Despite this issue, Vivian continued to try to analyze $\frac{7}{6}$ in this task, stating "that's (pointing to the $\frac{7}{6}$ card) more than the majority, that's more than the whole." This helped her decide to place the $\frac{7}{6}$ card to the right of the $\frac{2}{3}$ card, as two thirds is less than a whole. Vivian later described seven sixths as overflowing when she placed the fraction to the right of one on a number line. The $\frac{3}{8}$ card was placed to the left of the $\frac{1}{2}$ card because "three eighths is less than the majority." When asked about $\frac{3}{8}$ being less than the majority, Vivian elaborated that "it's less than half, so it's the smallest." This statement provides evidence that Vivian views one half as the dividing line for what is in the majority. The only time when Vivian used a benchmark other than one half was when she used one whole with seven sixths.

Sofia

Sofia's go-to strategy was to simplify a fraction and then to compare the fraction against a known percentage. Below, I will present three examples of Sofia simplifying fractions and one example of using known percentages.

Simplifying fractions. When asked what $\frac{7}{3}$ meant to her in Task 2, Sofia said that her "first thing [reaction] was to simplify" the fraction, which in this case involved working to turn $\frac{7}{3}$ into a mixed number. After determining that there were two wholes, with three in each whole, and one left over, shown in Figure 3, Sofia took out a hexagon and seven triangle pattern blocks. She arranged six triangles on the hexagon, remarking that she had one more left because she had used six of the seven triangles. She returned to her original work and interpreted her "two whole and one left" to mean that seven thirds is two and one third.

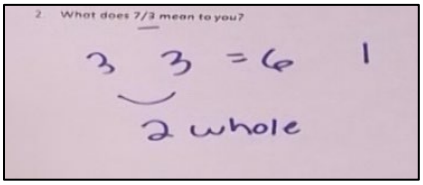

Figure 3. Sofia interprets 7/3 as two whole and one left.

Next, Sofia was presented with Task 3, where she read $\frac{15}{6}$ as "fifteen over six." Sofia's first action with this task was to simplify $\frac{15}{6}$ to $\frac{5}{2}$. Given her answer of $\frac{5}{2}$ in Figure 4a, I interpreted

Sofia's written justification to mean that she was dividing both the numerator and denominator by three in her simplification process. She reinterpreted five halves as "two wholes and one left over." Sofia initially interpreted this simplification as $2\frac{1}{6}$, but quickly changed her answer to $2\frac{1}{2}$. When she expressed that she was unsure how to continue, I asked Sofia to explain more about the "one left over." Sofia explained that since there is a two in the denominator of $\frac{5}{2}$, the one left over would indicate one half, since that is the simplified part of $\frac{15}{6}$. She still seemed to be unsure of her simplification. So, I asked Sofia to draw or represent what her answer might look like. Sofia worked to find two pattern blocks that work together to add up to the whole given in the prompt, which was the hexagon. After a bit of experimentation, Sofia chose to represent her answer with two trapezoid blocks, which she arranged on top of a hexagon block. Sofia clarified that the two trapezoids represented the two wholes as she pointed to the simplified fraction. Then she added a triangle block beside the stack, shown in Figure 4b, to represent the remainder of one sixth from the original task prompt. I interpreted Sofia's actions to mean that she was using the pattern blocks to check her fraction simplification process.

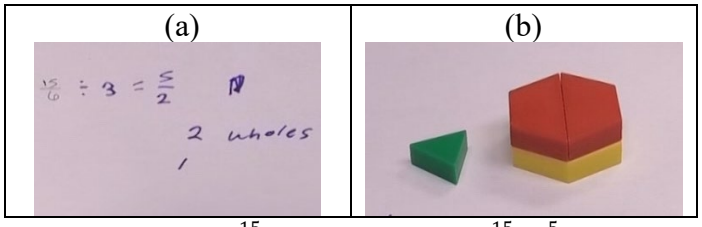

Figure 4. (a) Sofia simplifies $\frac{15}{6}$. (b) Sofia represents $\frac{15}{6} = \frac{5}{2}$ with pattern blocks.

However, Sofia seemed uneasy with her answer to Task 3, expressing that she "is so bad at fractions." To foster more confidence in Sofia, I gave her another copy of the Task 3 prompt and asked her to show me four sixths. Sofia took out a hexagon pattern block and five triangle blocks. She arranged four of the triangle pattern blocks on the hexagon block, shown in Figure 5a. Next, she took out two rhombus blocks and placed them on top of the triangle blocks, shown in Figure 5b. Sofia said that "if this (pointing to the triangles) represents four sixths, the two rhombi represent two thirds." Sofia could have left her answer in the form of the task prompt, as shown in Figure 5a. But to her, the answer was incomplete. This time, Sofia used the pattern blocks as a means of not only representing two thirds, but in finding the simplified fraction.

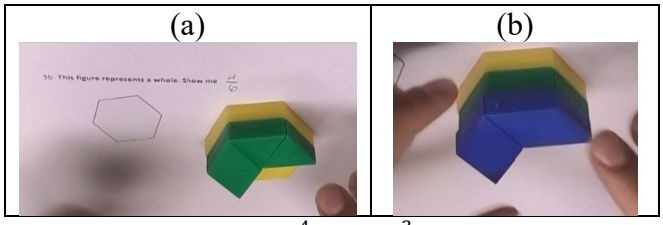

Figure 5. Sofia shows (a) $\frac{4}{6}$ and (b) $\frac{2}{3}$ using pattern blocks.

Comparing fractions to known percentages. During the number line task (Task 4), Sofia initially moved the $\frac{2}{3}$ card to the left of the $\frac{1}{2}$ card. Next, she stated that she needed to see what three and eight had in common to make sense of the fractions. I interpreted this to mean that Sofia was deciding where to place the three eighths card, and she was attempting to simplify the

fraction. After being offered scratch paper, Sofia began comparing fractions to known percentages. She wrote the fraction $\frac{2}{3}$ and set it equivalent to 66%, shown in Figure 6. I took this to mean that in that moment, Sofia's known percentage for two thirds was 66%. Next, she set $\frac{1}{2}$ equal to 50%, shown in Figure 6. Sofia is unsure about her placement of the $\frac{7}{6}$ card, so she decided to work from a percentage that she knew. She began by saying that one fifth of 100 was 20%, writing $\frac{1}{5}$ 100 = 20%, as shown in Figure 6. From there, she reasoned that $\frac{1}{6}$ as a percent was less than $\frac{1}{5}$ as a percent, adding "I'm not sure by how much, but I'm sure that it's less than 20." At this point, Sofia moved the $\frac{7}{6}$ card to the right of the $\frac{2}{3}$ card but before the $\frac{3}{8}$ card, as shown in Figure 7. She said that she was unsure she placed the $\frac{7}{6}$ card far enough to the right, but she tabled her placement of the $\frac{7}{6}$ card and moved on to considering the $\frac{3}{8}$ card. Sofia went back to her work for $\frac{7}{6}$, and noted that if she went to one eighth (writing $\frac{1}{8}$ 100 $= \downarrow$, shown in Figure 6), "then that would be even lower than from where we started from at one fifth." Sofia also noted that one fifth was "her only reference point, since she [knew] that clearly." Using this comparison to her known percentage of one fifth being 20%, one sixth being less than 20%, and one eighth being less still, she moved the $\frac{3}{8}$ card to the left of the line of fractions, indicating that three eighths was less than one half. After further contemplation, Sofia decided to leave the $\frac{7}{6}$ card at the right end of the line of cards since it was the only number that is a whole with a remainder, as shown in Figure 6 with her $1\frac{1}{6} = \frac{7}{6}$ notation.

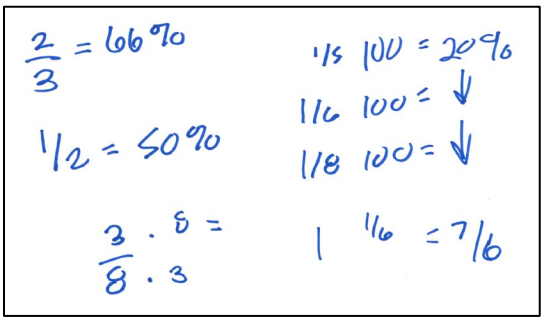

Figure 6. Sofia found known percentage equivalencies for $\frac{2}{3}$ and $\frac{1}{2}$, then reasoned to find how to order $\frac{3}{8}$.

From Figure 7, we see that the fractions have now been ordered as $\frac{3}{8}$, $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{7}{6}$. For the second part of the task, Sofia created a number line that included the fractions she had ordered. First, she marked the line with zero on the left and 100 near the right end, before adding 50 approximately halfway between them. Then she further segmented this space in increments of 10 (i.e., 10, 20, 30, 40, 50, 60, 70, 80, 90). She wrote the fractions on sticky flags and used her calibration and previously worked percent relations to place the sticky flags where she thought they should go, as seen in Figure 8. An orange flag representing $\frac{3}{8}$ was placed near the 10. A pink flag representing $\frac{1}{2}$ was placed above the 50. A green flag was used to represent $\frac{2}{3}$ and placed just to the left of the 70. At this point, Sofia added 120 at the end of the printed line then 110 halfway between the 100 and 120. A blue flag went above the 110 to represent $\frac{7}{6}$.

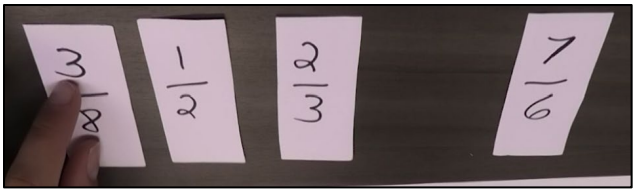

Figure 7. Sofia's final order of the fraction cards for $\frac{3}{8}$, $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{7}{6}$.

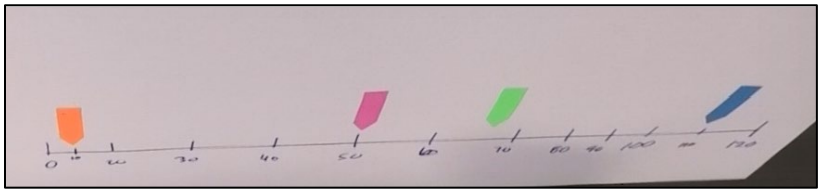

Figure 8. Sofia creates a number line with her fractions. The orange flag represents $\frac{3}{8}$. The pink flag represents $\frac{1}{2}$. The green flag represents $\frac{2}{3}$. The blue flag represents $\frac{7}{6}$.

Discussion

Nine, Vivian, and Sofia exhibited different go-to fraction strategies with both the open-ended task for what two thirds and seven thirds mean to them. These strategies also appeared when the solution path for fraction tasks were not straightforward for these participants. Their go-to strategies could be mapped onto fraction understandings and schemes from the literature. Nine tended to go to her operator understanding of fractions (Lamon, 2020), in which she viewed the fraction as a set of instructions for a division problem of numerator divided by denominator. This was carried out both to find mixed number and decimal solutions. Vivian used a benchmarking strategy. Most often, her benchmark was one half as she contemplated whether fractions were in the majority. She used a benchmark of one, or the whole, when she said that $\frac{7}{6}$ was overflowing. Sofia may have found mixed numbers, but she was doing so for a different reason than Nine did. Where Nine tended to go straight for division, Sofia wanted to find fractions she viewed as being easier to work with. Thus, Sofia's go-to strategy used commensurate fractions (Hackenberg et al., 2016; Steffe & Olive, 2010) as she sought to simplify the fractions presented to her, generally before working further with them. She also used a benchmarking strategy as she compared fractions with "known" percentages in the number line problem.

K–12 mathematics research has worked hard to provide an environment that is conducive to preparing students for college mathematics. And yet, there are students who are testing below college readiness for mathematics and being placed into developmental courses. While the K–12 curriculum often focuses on the part-whole understanding of fractions (Lamon, 2020), the go-to strategies in this paper are not within that silo. This paper provides a few examples of fraction thinking of undergraduate developmental mathematics students; it is not seeking to make a generalization of the go-to fraction understandings that are used by undergraduate developmental mathematics students. Rather, the purpose of this paper is to provide examples of what an instructor may witness as they work with students in this demographic. Sharing this information may serve to inform those working with developmental mathematics students by providing examples of the fraction understandings that developmental mathematics students hold. Future research may yield other go-to strategies used by undergraduate developmental mathematics students.

Engendering Students' Experience of Intellectual Need: Is Task Design Enough?

Michael A. Tallman
Oklahoma State University

Jason Martin
University of Central Arkansas

Aaron Weinberg
Ithaca College

The research reported in this paper examines undergraduate students' mathematical thinking while engaged with an intellectual need-provoking (IN-P) task. Our central goal is to infer design characteristics and strategies for the pedagogical implementation of IN-P tasks that orient students to confront the key idea that the task was designed to necessitate. The results of our analysis demonstrate that provoking a cognitive state of intellectual need is nuanced and complex and extends beyond thoughtful task design.

Keywords: Intellectual need, Task design, Perturbation, Student thinking

Engaging with genuine mathematical problems crucial for students' conceptual learning of mathematics. However, much of students' interactions with undergraduate mathematics is "problem-free" in the sense that the mathematical "problems" they encounter are usually solvable by applying skills and knowledge they have already constructed (Fuller, Rabin, & Harel, 2011). These routine procedural exercises do not require students to make strategic decisions or deeply engage with mathematical concepts. While completing such exercises, students often lack a clear mental image of the problem or even an awareness that they are addressing an intellectual challenge. Schoenfeld (e.g., 2016) similarly noted that college mathematics instructors frequently engage students in routine exercises rather than complex problems. In contrast, "problem-laden" activities arise from and are maintained by students' interpretation of a mathematical task that leads them to (1) recognize that their existing knowledge is inadequate to solve the problem, and (2) develop an understanding of what new knowledge they need to construct reason productively about the problem. Well-designed tasks can promote students' awareness of the limitations of their current conceptions and support the development of new mathematical insights.

The positive impact of "desirable difficulties" and "failure-driven scaffolding" on students' mathematics learning is well documented in the literature (e.g., Dewey, 1938; Kapur, 2015; Sinha et al., 2021). For instance, Brousseau (1997) highlighted that engaging with authentic problems can challenge and evolve students' initial ideas. Chevellard's Anthropological Theory of the Didactic suggests that human activities aimed at resolving difficulties are driven by a desire to address problems within institutional settings. Piaget's genetic epistemology also posits that cognitive growth occurs when individuals experience disequilibrium, such as when they encounter unexpected situations. Empirical studies have supported these theoretical claims, demonstrating that students' experience of cognitive incongruities and their engagement in genuine problem-solving prior to participating in formal instruction supports their conceptual learning and development of mathematical reasoning skills.

Consistent with this theoretical tradition of impasse-driven catalysts for cognitive development, Harel and Tall (1991) introduced the concept of *intellectual need*, a notion later formalized by Harel (1998) as the *necessity principle:* "For students to learn what we intend to teach them, they must have a need for it, where 'need' refers to intellectual need" (p. 501). The principle of intellectual need has been extensively applied in instructional and curriculum design efforts, with empirical research supporting the proposition that students' experience of intellectual need is crucial for their learning. Despite this consensus, however, there remains a

lack of practical guidance in the literature on how to assess the extent to which students experience intellectual need and what affordances this psychological state provides for students' mathematical thinking and learning.

The research reported in this paper examines students' mathematical thinking while engaged with an intellectual need-provoking (IN-P) task. We seek to understand the "problem" that students attempted to solve and to document the precise impasses they experienced. Our central goal is to infer design characteristics and strategies for the pedagogical implementation of IN-P tasks that orient students to confront the key idea that the task was designed to necessitate. The results of our analysis demonstrate that provoking a cognitive state of intellectual need is nuanced and complex and extends beyond thoughtful task design.

Theoretical Background

The concept of intellectual need is central to the *DNR-based instruction* framework in mathematics (Harel, 2008), which outlines conditions to provoke students' experience of intellectual need and ensure they internalize and retain what they learn. Harel's *DNR* framework emphasizes that knowledge construction involves experiencing cognitive conflicts or perturbations. Consistent with Piagetian theory, intellectual need arises when students experience cognitive disequilibrium, leading to curiosity that drives them to consider important mathematical ideas and relationships. Unlike mere confusion, intellectual need involves perceiving a situation as problematic and actively working to resolve it.

Intellectual need differs from psychological need and affective need. Affective need relates to a student's initial motivation to solve a problem, driven by personal interests, social obligations, or societal goals. This motivation, along with epistemic emotions like surprise and curiosity, influences students' engagement with mathematical tasks. While affective need and epistemic emotions help initiate and maintain mathematical activity, intellectual need specifically enhances the quality and depth of that activity by driving students to develop powerful mathematical meanings. Unlike other descriptions that view intellectual need primarily as a means to stimulate motivation and engagement, our perspective emphasizes the role of intellectual need in improving the nature of students' mathematical reasoning and learning.

Methods

We engaged mathematics majors and prospective secondary teachers at two public universities in the southern United States in an IN-P task that we modified from Thompson, Carlson, and Silverman (2007) to necessitate a quantitative conception of angle measure[1, 2]. Two students from one university (Group A) and three from another (Group B) collaboratively engaged in the task during class meetings of a mathematics content course for pre-service secondary teachers. The second and third authors were instructors of the same course at two different institutions and coordinated their curriculum to align. We video recorded students' activity and discussion while engaged with the task and collected and scanned and all written products of the students' work. The instructor of Group B did not allow calculators while the students were working on the IN-P task whereas the instructor of Group A did. The students in Group A collaboratively worked on the IN-P task for one 75-minute class; the students in Group B were engaged in the task for one full 50-minute class period and the first 31 minutes of the

[1] We describe what we mean by a "quantitative conception of angle measure" in the section titled, "Conceptual Analysis of the Intellectual Need-Provoking Task."

[2] See Weinberg et al. (2024) for a discussion of the theoretical principles that guided our development of IN-P tasks.

following class meeting. All students had volunteered to participate in the study. The cameras were focused on one primary pair from each class, (Anne and Tessa from Group A and Jane and Eve from Group B). Any other student interacting with the primary pair from either class will simply be referred to as "Student."

The research team collaboratively engaged in grounded theory procedures to analyze the data. We began by developing a provisional set of open codes. Each of the three authors then conducted several iterations of independent analysis of the video data, between which we negotiated our individual interpretations to inform revisions and extensions to our open coding framework. Once we established a stable set of descriptive open codes, each author reanalyzed the videos and the research team again met several times to negotiate differences in our coding and to collaboratively construct an aggregable set of analytical notes that described our justification for applying each code and documented the significance of each coded instance on the students' mathematical thinking and activity. Our subsequent elaboration and refinement of these notes, which involved frequent reengagement with the primary data, resulted in the findings we present below.

Conceptual Analysis of the Intellectual Need-Provoking Task

Students often conceive of angle measure as a quantification of an angle's "openness." Several scholars (e.g., Moore 2010, 2014; Moore et al, 2016; Tallman & Frank, 2020; Thompson, Carlson, & Silverman, 2007) have documented the affordances of understanding an angle's measure as the length of a subtended arc, measured in a unit that varies proportionally with the circumference of the circle centered at the angle's vertex containing the subtended arc. The ratio of the magnitude of the subtended arc and the magnitude of the unit is invariant for an angle with a fixed amount of "openness."

To support students' identification of subtended arc length as the attribute of a geometric object for which angle measures are quantifications, we modified a task from Thompson, Carlson, and Silverman (2007). Our IN-P task simply prompted students to sketch a graph of the function $f(\theta) = \sin(2\cos(\theta))$, with θ measured in radians. Our goal was to problematize students' understanding of the quantity (subtended arc length) represented by the argument of a trigonometric function. Students who conceptualize "$\sin(x)$" as the ratio of the side length of a right triangle opposite the interior angle labeled "x" and the length of the triangle's hypotenuse will likely struggle to interpret this the composite trigonometric function $f(\theta) = \sin(2\cos(\theta))$ in a way that enables them to sketch an accurate graph. As an IN-P task and introduction to a conceptual approach to angle measure and trigonometric functions, we did not expect students to interpret the argument $2\cos(\theta)$ as "twice the horizontal distance of the terminal point to the right of the vertical diameter of a circle centered at the vertex of an angle in standard position." But we did anticipate that students might confront the issue of how the quantity represented by "$2\cos(\theta)$" might be the kind of "thing" (i.e., measurable attribute of an object) that makes sense as the argument of the sine function. We expected that reasoning productively about the task would require understanding the input variable as a representation of the varying values of an angle's measure (as a subtended arc length measured in units of the arc's radius), the argument of f as the length of an arc subtended by a second angle, and "$\sin(2\cos(\theta))$" as the vertical distance of this second angle's terminal point above the horizontal diameter of the circle centered at the vertex of the angle, which is in standard position. See Figure 1 for an illustration of these quantities.

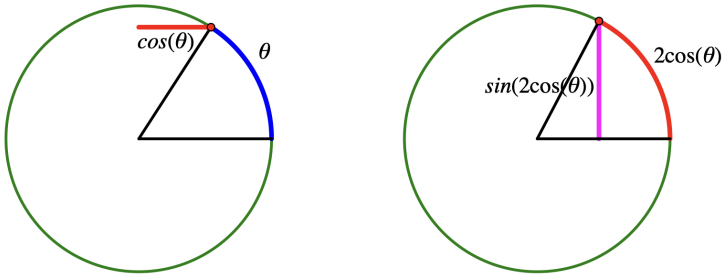

Figure 1. Quantitative interpretation of $f(\theta) = \sin(2\cos(\theta))$.

Results

We present the results of our analysis of two groups of students (Group A and Group B), respectively participating in the study from two different universities. We contrast these students' interpretations of the IN-P task, their goal orientations, and the impasses they encountered to evaluate the extent to which the students' engagement with the task necessitated the meanings we intended to promote.

Group A

The students' initial discussion focused on the graphical transformation contributed by the constant in the expression $\sin(2\cos(\theta))$. They considered whether this constant "stretched" or "compressed" the graph, or if the "2" affects the amplitude (Anne suggested that it might "make sine taller"). They then considered the graphical behavior of $y = \sin(x)$ and $y = 2\cos(x)$ separately and attempted to use sketches of these graphs to reason about the graph of their composition. Anne and Tessa quickly lost confidence in their initial strategy, and transitioned to computing values of $2\cos(\theta)$ for integer multiples of $\pi/4$ in an effort to plot points on a graph. After a long pause following the students' realization that they could not mentally compute $\sin(2\cos(\theta))$ for $\theta = 0$ and $\theta = \pi/4$, the instructor prompted the students to "try to articulate what about this task is difficult and what you are currently struggling with?" The students acknowledged that they were having difficulty with "having cosine inside of sine." Tessa suggested, "cosine and sine are like, they're obviously not inverses of each other, but they're shifted functions. … Then you also have a factor of two, so you're changing that relationship by two. There's just multiple things we have to juggle." Tessa considered how the graph of sine being a shift of $\pi/2$ units to the right of the graph of cosine might influence the graph of f. Anne followed by explaining that while their knowledge of the coordinates of terminal points corresponding to convenient angle measures on the "unit circle" was appropriate for computing values of $2\cos(\theta)$, there were several values of $\sin(\cos(\theta))$ that they were not able to compute using coordinates on the unit circle.

The instructor attempted to direct the students' activity away from their effort to plot points and instead to infer the behavior of the graph that connects these points. He suggested, "Is there a way to think about how output values are related to input values as θ varies?" Tessa was confident that the graph of f "is going to oscillate because of what we know based off sine and cosine. Um, the bounds at which it is oscillating between … that's the part that we would have to compute more." Tessa expressed the need to compute enough values of $f(\theta)$ for select values of θ to infer the graphical behavior of f between these input values. She expected that these computations might reveal "the bounds at which it is oscillating between." Anne expressed that she thought about the problem similarly to how Tessa described her reasoning.

In response to being asked to propose a question they would want answered to help them progress towards a solution, Tessa suggested, "Confirmation on basic properties and rules for layering [i.e., composing] those things." Tessa was oriented to assume that there was some algebraic property or rule for composing trigonometric functions presented in a prior course that she was currently unable to recall. In contrast, Anne expressed that she wanted an answer to the question, "When you take a radian measure and put it through a trig function, will you get a radian measure out still? That lets me reason if what I'm putting into sine makes sense."

Anne's awareness of the need to associate a quantity (i.e., measurable attribute of an object) to the expression "2cos(θ)" so that she might be able to reason about the sine value of this argument penetrates a key issue in developing a productive meaning for angle measure: How can the quantities for which sin(x) and cos(x) are respective measures be the same kind of quantity represented by the input x? Anne pursued this reflection and proposed the additional query, "The thing is when you're graphing these, I realized that the 1 and –1 that you're oscillating between, is that a radian measure? The y-value that we get out after putting in an x-value?" After considering her question, Anne concluded, "Whatever we're putting into sine doesn't make sense to put into sine." Tessa agreed and attempted to articulate a justification for Anna's conclusion:

> We were talking about when you do cos(0) and you get 1 as the output, that 1 corresponds to your length of your radius of your circle, like when you're thinking unit circle, and so you wouldn't plug a radius unit back into sine. You need to plug in radians, so you need to convert that.

Tessa's agreement with and elaboration of Anna's comment demonstrates their initial lack of association between quantities represented by sin(θ) and cos(θ) being measured in units of the "length of the *radius* of your circle" and the quantity represented by an angle's measure in *radians*. Still, that the students interpreted the task in a way that guided them to consider the quantities represented by the inputs and outputs of trigonometric functions has likely implications for their orientations towards and expectations for learning about angle measure in subsequent lessons.

Group B

After being given the prompt to sketch the graph of $f(\theta) = \sin(2\cos(\theta))$, both Jane and Eve began to evaluate the function at the angle measures for which they knew the value of cos(θ) (see Figure 2). Both Jane and Eve's scheme for graphing functions included plotting points based on evaluating functions for certain input values. This was demonstrated by both Jane and Eve as they would later add axes and plot points based on the values they computed. Their graphing of trigonometric functions additionally included selecting integer multiples of $\pi/2$ to produce readily known values for the argument of f.

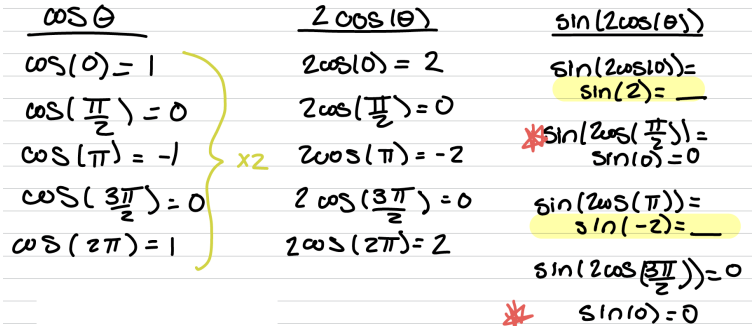

Figure 2. Eve's notes for evaluating cos(θ) *for convenient angle measures and how known values from* cos(θ) *can be used to evaluate* sin(2cos(θ)).

After about five minutes of working, Eve observed that she could evaluate $f(\theta) = \sin(2\cos(\theta))$ for $\theta = \pi/2$ and $\theta = 3\pi/2$ (see the equations marked with asterisks in Figure 2), but was unable to evaluate $f(\theta) = \sin(2\cos(\theta))$ for the input values 0, π, and 2π because she was unable to determine exact values for sin(2) and sin(–2). Since the function f is a composition of two trigonometric functions, values of $2\cos(\theta)$ are often inconvenient as the argument into $\sin(\theta)$ if a student is looking for known values from "the unit circle."

For the equations corresponding to sin(2) and sin(–2), Eve then added the blank line to the right of the equality to indicate not knowing these values, later coming back to highlight these equations to reemphasize how angles convenient for evaluating $\cos(\theta)$ did not reliably produce known values for $\sin(2\cos(\theta))$. When comparing their work, Jane described her approach and admitted that she too was unable to evaluate f for particular values of θ. "And I'm still running into that problem, where I don't know the sine of these values [pointing to her table of values that contained a column for $\sin(2\cos(\theta))$ that was empty except for when $\theta = 0$]." Jane and Eve problematized their situation as follows:

Jane: Yeah. Well not, like, sin(2).
Eve: Like, sin(2), I don't know that. [...]
Jane: [Looking at Eve's notes] So basically, all we're getting is the pi-over-twos [likely in reference to $\pi/2$ and $3\pi/2$].
Eve: Basically. But I don't know what it does in between.

At this moment, Jane and Eve had encountered an impasse that their activated cognitive structures were insufficient to resolve. This impasse included their recognized inability to produce values for the output of $y = f(\theta)$ for no more than a few select values of the input. Because of this, they acknowledged not knowing the behavior of the function between these select few values of θ. The students then proceeded to locate additional points and infer the graphical shape between the points based on contextual clues. For example, Jane indicated searching for the y-intercept. Both students confused locating the y-intercept with solving $\sin(2\cos(\theta)) = 0$ for θ to eventually get $\theta = \pi/2$. Eve noted how multiple values for the input produced identical output values, such as $\theta = \pi$ and $\theta = -\pi$, both of which correspond to an output value equivalent to sin(–2). Eve then leveraged her knowledge of the basic shapes of the graphs of $y = \sin(\theta)$ and $y = \cos(\theta)$ to produce the graph of $y = f(\theta)$ displayed in Figure 3.

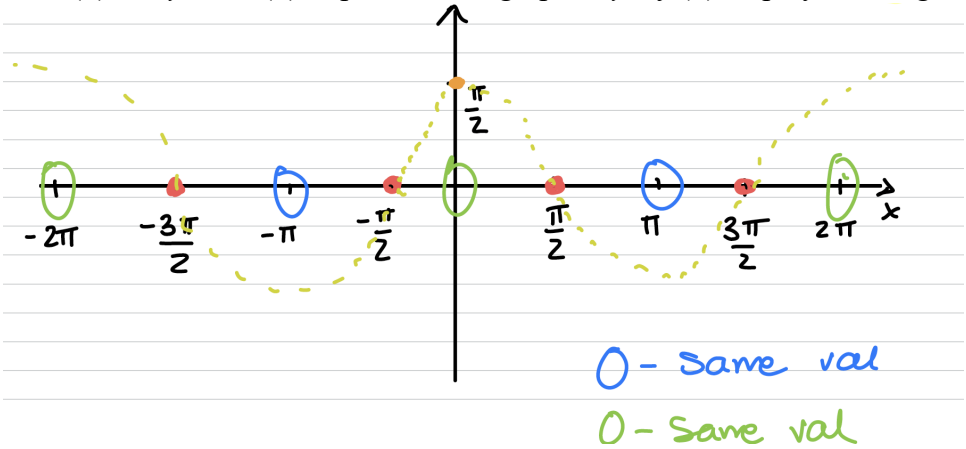

Figure 3. Eve's initial graph for $f(\theta) = \sin(2\cos(\theta))$ where she notes where particular values of input would correspond to the same value of output.

Jane momentarily proposed an alternative graph that did not include negative output values while Eve indicated thinking about "regular sine and cosine graph." They concluded that the graph of $y = f(\theta)$ must "go under" the horizontal axis because "both" graphs for $y = \sin(\theta)$ and $y = \cos(\theta)$ "go under" the horizontal axis. Other attributes of trigonometric functions were also mentioned by the pair, such as period and amplitude. Following this, Eve declared that "We have a sketch." She went on to acknowledge that she still wanted to know the value for sin(2) and indicated that if she knew this value, then she would know if her graph was accurate.

Notably absent from Eve and Jane's expressed reasoning to this moment were indications of them coordinating the quantities represented by the input, argument, and output of *f*. Although the students labeled locations on the unit circle and evaluated functions for particular values of θ, they did not indicate, for example, conceiving of $\cos(\theta)$ as a measurement of horizontal displacement of the terminal point from the vertical diameter of a circle centered at the angle's vertex. Nor did they indicate that via the function composition, the argument of the sine function $2\cos(\theta)$ could be conceived of as the directed length of a subtended arc that is twice the length of the aforementioned horizontal displacement. And, most related to the students' experience of intellectual need, neither Eve nor Jane appeared to confront the issue of how the output of one trigonometric function could be the kind of thing that can serve as the input into another trigonometric function. Although these students had encountered an impasse and eventually produced a graph for which they were confident represented the covariational relationship between θ and $\sin(2\cos(\theta))$, they had not yet confronted the central ideas rooted in quantitative reasoning about angle measure that we had designed the task to necessitate.

Discussion

Our study reveals significant variations in how individual students interpreted and engaged with the intellectual need-provoking (IN-P) task. These differences stem from students' diverse assumptions about the prior knowledge and mathematical meanings that must be applied to successfully complete the task. Our findings demonstrate that tasks alone have limited effectiveness in inducing a cognitive state of intellectual need. Instead, achieving the desired cognitive engagement requires careful pedagogical strategies and a deep understanding of the students' pre-existing conceptions and expectations. This study highlights that fostering intellectual need is more intricate and nuanced process than previously suggested in the literature.

The findings from the study suggest several important implications for educational practice. First, simply implementing intellectual need-provoking (IN-P) tasks is not sufficient. Educators need to carefully design tasks to ensure they appropriately connect with students' prior knowledge. Instructors also need to consider the pedagogical actions that might challenge students' thinking about the core mathematical ideas reflected in the IN-P task. This may involve providing in-the-moment scaffolding of tasks to orient students' attention to the central mathematical issue(s) that the task was designed to necessitate, and to do so in ways that are sensitive to the strategies a student has already employed, the operational goal the student is working to accomplish, and the mathematical facts, skills, and meanings the student brings to the task. Effective teaching requires flexibility and responsiveness. Educators should be prepared to modify their pedagogical strategies based on their ongoing assessment of students' engagement and comprehension. This may include adjusting the level of difficulty of tasks, providing additional explanations, or incorporating different teaching methods to better support students' conceptual learning of mathematics.

The Politics of Aesthetics of Mathematical Coherence: STEM Students' Aesthetic Interpretations of Cross-Curricular Stories

Brady A. Tyburski
University of Georgia

As part of a larger participatory, arts-based study, six STEM students engaged in sustained arts creation and reflection across their curricular experiences as a form of holistic, multimodal, and multisensory aesthetic critique of their cross-curricular mathematical experiences. In this contributed report, I detail instances where students' perspectives on curricular coherence (i.e., their aesthetics of coherence) deviated from privileged forms of disciplinary (logico-rational) coherence in mathematics education. In doing so, I highlight the exclusionary politics of aesthetics that result from a narrow adherence to one perspective of curricular coherence and the epistemic harm this can inflict on students in relation to how they position themselves as learners and doers of mathematics. These examples suggest a need for additional criticality concerning our often-unquestioned definitions of curricular coherence and acknowledgement that mathematical coherence seeking is governed by both aesthetic and logical forces.

Keywords: Curricular coherence, Student perspectives, Aesthetics, Arts-Based research

A common educational assumption is that curricular coherence is a pre-requisite for a "good" curriculum. Buchmann and Floden (1992), for instance, touted coherence as one of the "guardian angels of [curriculum] reform" (p. 4). In mathematics education, this perspective has persisted both nationally and internationally. For example, the recent ICMI study of mathematics curriculum reforms around the world puts coherence on a pedestal as one of the organizing themes for reform, with the final report stating matter-of-factly that "Coherence is likely to be a universal aspiration" (Morony, 2023, p. 148).

While curricular coherence is often unquestioningly accepted as desirable for student learning, some researchers have urged caution, arguing that "curricular coherence" is loosely defined with no widespread agreement over its meaning (Muller, 2022; Thompson, 2008). Canrinus (2024), for example, likened curricular coherence to a "disco ball" (p. 258) with several distinct forms and conceptualizations. Buchmann and Floden (1992) went further, referring to curricular coherence as a "rebel angel" escaping singular definition given that "coherence allows for many kinds of connectedness, encompassing logic but also associations of ideas and feeling, intimations and resemblance, conflicts and tension, previsagements and imaginative leaps" (p. 4). Indeed, the polysemous nature of "coherence" is reflected in its etymological origin, the Latin word *coharere*, meaning "to stick together" (Kolln, 1999). In other words, a "coherent whole" is one in which its parts are perceived as sticking together—or being related—in a satisfactory way. The upshot is that judgements of coherence involve a *holistic interpretation* of an object (curricular, artistic, or otherwise) formed based on one's aesthetic sensibilities and preferences for structural logics (Aschenbrenner, 1985; Repp, 2017).

For this reason, research on curricular coherence and designing coherent curricula in practice requires the consideration of multiple stakeholder interpretations of coherence (Bateman et al., 2009; Modeste et al., 2023). The perspectives of education researchers, disciplinary experts, and to a lesser degree teachers and administers have been investigated; however, outside of mathematics teacher education (Nguyen & Munter, 2024), *students'* perspectives on curricular coherence have only been peripherally considered. One result is that *disciplinary* forms of

curricular coherence have become the de facto status quo for curricular coherence in mathematics education (Cuoco & McCallum, 2018; Morony, 2023). From these perspectives, a coherent curriculum is one that consists of "a sequence of topics and performances that are logical and reflect, where appropriate, the sequential or hierarchical nature of the disciplinary content from which the subject matter derives", which requires that the particulars should evolve to "deeper structures inherent to the discipline" (Schmidt et al., 2002, p. 9).

These interpretations of curricular coherence reify a particular choice of mathematical aesthetics. As famed mathematician Henri Poincaré remarked:

> Mathematics is the art of giving the same name to different things . . . when language is well chosen, we are astonished to learn that all the proofs made for a certain object apply immediately to many new objects; there is nothing to change, not even the words, since the names have become the same. (1908/2012, p. 375)

Benis-Sinaceur (2014) called this form of generalization *idealization*, which involves "leaving aside or discarding all other aspects" thereby "extracting a *form* from sundry situations" (p. 94, emphasis in original). Disciplinary forms of coherence mirror this so-called art of idealization, privileging an aesthetic of "FUGS" (that primarily spotlights practices of Formalizing, Unifying, Generalizing, and Simplifying, see Hausberger, 2017, p. 418). Greeno (1992) has called this a "thinking-with-basic" philosophy in the sense that all concepts are seen as building hierarchically from the "basics". But what is "ideal" for some is not "ideal" for all. Not even mathematicians universally endorse such a limited form of aesthetics (Hausberger, 2017)!

Indeed, Sikorski & Hammer (2017) argued that there is a danger in a strict reliance on premeditated, expert interpretations of curricular coherence, suggesting that we must also consider students' idiosyncratic, in-the-moment coherence seeking in its many forms. Premeditated coherence, they argued, often undermines and undervalues the active role students play while seeking coherence: "sequences that attempt to guide students through a series of investigations to arrive at the canonically accepted (and 'coherent') explanation may do so at the risk of students' own epistemic agency in deciding what coherence to seek next" (p. 935).

Most importantly, there are grave ethical implications of privileging a singular, narrow view of curricular coherence. Buchmann and Floden (1991) observed that curricular coherence often has evaluative overtones which associate "coherence" with other aesthetic notions often viewed as universally positive, like "harmony" and "wholeness". They concluded that any perspective on curricular coherence required critical examination before being taken for granted as an inherent good. In other words, interpretations about what is "coherent" are fundamentally value-laden carrying with them (implicit) assumptions about the nature of learning and what "make sense" (Shemmer, 2012). As such, Richmond et al. (2019) argue that we must always question, "Coherence for whom? According to whom? To what end(s)?" (p. 188). Without such criticality, well-intentioned efforts to design curricula that is coherent from one perspective may inadvertently convey harmful messages about students who interpret these curricula as *in*coherent—i.e., that these students are *themselves* "incoherent," "bad," "not smart," "do not make sense", etc. (see e.g., Appelbaum, 2010).

In this participatory, arts-based study, I investigated the ethical implications when students' perspectives of curricular coherence and their aesthetics of coherence clashed with entrenched forms of disciplinary coherence. Six student-artists participated in sustained individual and collective arts creation and reflection across their curricular experiences with the goal of fostering "conspiratorial conversations" (Barone, 2000, 2008) on the topic of curricular coherence. An aim of these critical conversations was to destabilize privileged politics of

aesthetics underlying disciplinary coherence by drawing attention to a multiplicity of students' aesthetic sensibilities of coherence through the generation of aesthetically and emotionally impactful artistic educational critique (Barone & Eisner, 2012). In this contributed report, I focus on two research questions: (RQ1) What interpretations of coherence did these STEM students express that deviated from disciplinary forms of curricular coherence? (RQ2) What ethical implications did students' alternative aesthetics of coherence have on how they positioned themselves as learners and doers of mathematics?

Curriculum as a Storied Artform

I conceptualize curriculum as a form of art (Eisner, 2004) in the sense its content and *aesthetic form* cannot be disentangled, meaning that aesthetics cannot be ignored in curricular analysis. Specifically, I adopt the perspective that the mathematics curriculum can be metaphorically conceptualized as a *storied* artform (Dietiker, 2015b). As mathematics curricula enculturate students into the discipline of mathematics (Brown, 2022; Plut & Pesic, 2003), the stories they tell—and the *ways* these stories are told—should not be an afterthought. Indeed, the holistic form and structure of a story interpreted as a kind of narrative conveys disciplinary-cultural aesthetic, ethical, and onto-epistemological values about learning, living, and being (Stephens & McCallum, 1998). Following Dietiker's (2013, 2015a) curriculum-as-story metaphor, I take a reader-oriented perspective on narrative interpretation based on literary theory (Bal, 2017). From this point of view, meaning is not contained in the text itself but instead developed through a transactional process as the reader engages hermeneutically with the text (Rosenblatt, 1988; Weinberg & Wiesner, 2011). Through this active reading, *the plot*—a reader's aesthetic reactions to the unfolding of the story—is constructed based on their holistic interpretation of all story elements (e.g., characters, settings, themes) coordinated with their reactions to how the story events unfold. Importantly, the plot is constructed through both *logical* and *aesthetic* sense-making as a reader engages with (curricular) stories (Richman et al., 2019). From this reader-oriented point of view, curricular coherence is *not* an objective property of the curriculum itself but rather an idiosyncratic interpretation of (in)coherence a student makes while actively engaging with curricular stories.

The upshot of this theoretical framing of curriculum is that students' aesthetic sensibilities influence their curricular engagement and therefore learning of mathematics (Wong, 2007) as they construct subjective personal meanings and conclusions (Sinclair, 2005) concerning the (in)coherence of said curricular stories. In other words, one's personal aesthetics are fundamentally intertwined with how they make sense of the world and learn mathematics. By "aesthetics" I do not just mean judgements of beauty but rather "knowledge acquired through sensory perception" (Marini, 2021, p. 40), in line with its original etymological meaning where epistemology, aesthetics, emotion, and sense-making are inseparable (e.g., Dietiker et al., 2023). From this perspective, aesthetic experience (Dewey, 1934/2005) is an idiosyncratic response a person has to a particular object or event (e.g., a cross-curricular story), which could be positive (joy, wonderment, curiosity), negative (disgust, boredom, disappointment), neutral, or an eclectic mix of all these. Such aesthetic responses have been shown to play several roles in both professional mathematicians' and students' mathematical activity (Burton, 2004; Sinclair, 2004). For example, wonderment, surprise, and curiosity have been repeatedly linked to sustained engagement with mathematical inquiry (Dietiker & Richman, 2021; Gadanidis et al., 2016). Aesthetic considerations have also been shown to influence the nature of one's mathematical inquiry, including the questions one deems as (un)interesting and (not) "worthy" of further consideration (Fiori & Selling, 2016; Jasien & Horn, 2022).

Personal aesthetics are not developed within a vacuum but in relation to the *intersubjective* aesthetic sensibilities of the socio-cultural contexts individuals inhabit (Chilton et al., 2015; Conrad & Beck, 2015). Rancière (2000/2004) argued that which aesthetics become privileged within a community of practice (e.g., the discipline of mathematics) is political insofar as shared aesthetic practices result in distributions of what is considered sensible, often in ways that are covert. Consequently, aesthetic sensibilities (e.g., privileged views of curricular coherence) that are dominant within a socio-cultural context (e.g., the mathematics classroom) have a powerful influence on not only an individual's personal aesthetics but also how one's personal aesthetics are perceived (by the individual *and* others from within the socio-cultural context) (de Freitas & Sinclair, 2014). In this way, intersubjective aesthetics becomes a yardstick against which all other aesthetic sensibilities are measured and judged: privileged socio-cultural aesthetic sensibilities become a way of policing who/what is considered "aesthetic" and who/what is not.

Students' Perspectives on Curriculum in RUME

Research in undergraduate mathematics education displays many of the same general trends I detailed earlier concerning (a) a mostly unquestioned privileging of disciplinary forms of curricular coherence (e.g., Tague & Czocher, 2016) and (b) a dearth of curriculum research that centers students' holistic judgements about the holistic curriculum. There are a small number of studies that attend to the idiosyncratic ways students' engage with curricular stories at the grain size of a single course or lecture (Andrà, 2013; Krupnik et al., 2018; Weinberg et al., 2014) or, more broadly, to students' interests and what they value *across* their mathematics courses (Asada et al., in press; Leyva et al., 2022), but much less attention has been paid to students' general (aesthetic) perceptions of the undergraduate mathematics curriculum. One exception is a small handful of studies investigating mathematics *graduates'* retroactive reflections on whether their curricular experiences prepared them for their careers (King et al., 2017; Wood, 2010).

Participants and Methodology

This contributed report is based on a larger arts-based study (Tyburski, 2024) where I recruited six undergraduate STEM students from various disciplines who had just successfully completed multivariable calculus. Students were recruited from different STEM disciplines to spotlight a variety of (disciplinary) aesthetic sensibilities and promote the sharing of a multiplicity of perspectives of curricular coherence across their mathematics courses.

Student-artists came together for a series of four approximately one-hour sessions of individual and collective arts creation and reflection on their curricular experiences, with an emphasis on their interpretations of the (in)coherence of cross-curricular mathematical stories. I started by asking about their definitions of (in)coherence, beginning in familiar, everyday contexts ("a story, a TV show, or movie, a song, a conversation, etc.") and ending with the cross-curricular mathematical context. Next, students created artwork to reflect on the coherences or incoherences they had noticed or felt across their undergraduate mathematics courses. Following an arts-based research approach (Leavy, 2018), participants created and then discussed art in the form of their choosing to allow for a holistic, multimodal, and multisensory investigation of the learned mathematics curriculum (Bagnoli, 2009; Papoi, 2017). This centered opportunities for reflection on the roles that *aesthetic* as well as logical forces played in making curricular stories connect and cohere (Clark & Rossiter, 2008; Sinclair, 2009) across their everyday mathematical experiences. It also enabled student-artists to depict both positive and negative emotions related to these experiences. To allow for cross-pollination of perspectives (Leavy, 2020) on curricular coherence across artists and their artwork, private exhibitions of their art were used to elicit

richer group conversation and subsequent mathematical storytelling about their interpretations and feelings concerning the (in)coherence of their cross-curricular experiences. Interactions were spread over a period spanning three months to allow sustained space for artists to consider alternative perspectives and (co-)develop more nuanced critiques of their curricular experiences.

In line with most arts-based research, analysis went beyond reducing artwork, curricular critique, and complex discussion into a list of collectively agreed upon themes (i.e., a *similarity* analysis) (MacLure, 2006, 2013). As McNiff (2018) put it, "Of course, themes exist in life and art, but there are many other things too—characteristics, features, aspects, principles, ideas, patterns, structures, designs, compositions, similarities and differences" (pp. 29–30). In particular, analysis was conducted in two flanks: (a) a *participatory analyses* conducted by student artists across both group discussions based on each other's artwork and (2) a *collage analysis* (Butler-Kisber, 2008; Scotti & Chilton, 2018) that I used to juxtapose students' metaphors for curricular coherence with those found in the literature. Specifically, by cutting out ephemera from students' curricular critiques (i.e., visuals from photocopies of their art and transcripts from our individual and group conversations), I was able to *live and breathe* students' perspectives on coherence to further empathize with and understand the nuances of these perspectives (Margolin, 2014). I purposefully omit an image of the collage because my aim is to spotlight *students'* interpretations of curricular coherence (rather than my own). However, further methodological details and the collage can be found in Tyburski (2024).

Learning From Student Artwork

Student-artists regularly acknowledged how judgements of coherence are idiosyncratic and subjective. Fred, for example, explained how his experiences across mathematics courses felt "flowy" and coherent, but then quickly added the caveat that "Some people kind of struggle with math and, yeah, we all have our own strengths and weaknesses. I'm not really a good essay writer, so that is probably coherent to someone and that's not coherent to me". As VKN put it, "a lot of people don't experience math the same way I do . . . there are different lenses and different levels of coherence". Comments such as these foreshadowed *several* interpretations of curricular coherence that deviated from disciplinary, logico-rational forms of coherence.

Among these, I focus herein on different *emotional* forms of coherence students proposed. For example, wuyen shared that emotional investment played a leading role in interpreting whether a story (mathematical or otherwise) was coherent to her. For a story to make sense to her, it had to make her feel: "I think emotional [*sic*] is a big component for me to make things make sense because I'm a very emotionally driven person, more than logic for sure" In particular, she found Taylor Swift's discography to be coherent because of the emotional stories told in each of her songs and albums. She also expressed a similar view of mathematical coherence when I introduced the curriculum-as-story metaphor late in our first group discussion:

> The different applications of math as a story was [*sic*] very interesting because to me during our first conversation, we were talking about how stories make sense to me if it was emotionally touching in some way to me. So, applying that to the bigger idea now of the whole math experience being a story, I feel like emotions still should play a part.
>
> Well, not *should*. For me, it *does* play a part in the math journey to make it make sense.

wuyen expressed a clear aesthetic preference for stories that involved emotion and made her feel. For her, *these* stories were coherent. Meanwhile, Fred likened his love for math to his love of Disney animated movies, concluding that "I'd say math is kind of similar, *if* you care about math. I kind of care a little too much about math. Other people don't give a shit about it". In both

these cases, wuyen and Fred alluded to the inseparable relationship between aesthetic sensibilities, emotion, and preferences for particular kinds of (curricular) stories.

Emotions were not just peripheral for these student-artists: they played a leading role in their holistic aesthetic judgements of the (in)coherence of cross-curricular mathematical stories. VKN, for instance, regularly brought up a negative experience she had with unit vectors in multivariable calculus across our interactions: "I passed multivariable calculus. Got a 4.0 even. I 'understood' it. And yet, I am sitting here trying to remember what the hell unit vectors are". When I asked VKN follow-up questions, I was surprised to learn that (at least from my perspective) she understood the normative definition and uses of a unit vector, at least the recurring ones privileged most by the traditional multivariable calculus (MVC) curriculum. Rather, she was hung up primarily on how a particular unit vector was used in just *one* formula that *did not* recur throughout the MVC curriculum. From the perspective of a disciplinary expert, I perceived this formula to be largely insignificant to the overarching story of MVC, yet this local experience of extreme *emotional* incoherence colored her entire perception of the MVC curriculum as *in*coherent. This was not an isolated case: Joy similarly reflected about how she perceived her cross-curricular mathematical experiences to be largely *incoherent* for the years it took her to feel comfortable with logarithms. Just like when reading any literary story, *emotional* factors were the deciding factor between whether a cross-curricular mathematical story was enjoyable and coherent or confusing and incoherent for multiple student-artists.

Figure 1. Joy's The Smoke Trail

Joy's *The Smoke Trail* (Figure 1) is one of most evocative pieces in terms of conveying the central role that emotion played in some students' judgements about mathematical (in)coherence. In her art, Joy reflected on how she frequently *saw* the seemingly coherent "fire" of the mathematics curriculum but would often struggle to reach this fire in practice (i.e., to interpret her mathematics experiences as fully coherent), even when she had a smoke trail leading her to it. The deceptiveness of the smoke trail and how it "would come into [Joy's] lungs and choke [her] out as opposed to gently guiding [her] along" (as expressed in her artist statement) were part of why her entire painting takes place next to a frozen lake. As she shared, "I started with the color blue because that's how [mathematics] made me feel. . . . isolated. Sad." The frozen-over blue lake that dominates the foreground of Joy's art emphasizes that judgements of mathematical coherence for her are governed by a looming sense of sadness, as well as other emotionally painful memories that she likened to being choked, drowned, or burned alive. For Joy, mathematical coherence seeking was often panic-inducing and marked by negative emotion.

Discussion and Conclusion

In light of these student perspectives on curricular (in)coherence that deviate from logico-rational forms of curricular coherence, the epistemic harm (Tanswell & Rittberg, 2020) of privileging just one strict view of coherence becomes apparent. For starters, adherence to just one curricular aesthetics of coherence fails to capture the aesthetic and affective idiosyncrasies students attended to as they engaged in their coherence seeking processes. Worse, a devotion to just one set of aesthetic values can enforce an exclusionary politics of aesthetics that conveys messages about who/what is (in)coherent (Appelbaum, 2010; Buchmann & Floden, 1991). This phenomenon was on full display across Joy, wuyen's, and VKN's curricular reflections and critiques, where they often positioned themselves as struggling or incapable as they strove to interpret the cross-curricular mathematical stories they had engaged with as coherent. Recall, for example, Joy's hauntingly evocative art in which she recounted how seeking disciplinary coherence across her mathematics courses has led to her repeatedly feel as if she was being choked or even burned alive by the *supposedly* ideal "fire" of (disciplinary) coherence.

All three of these participants were highly successful mathematics students in the grand scheme of the K-16 mathematics curriculum that had successfully completed most of the undergraduate calculus sequence and all preceding pre-requisite courses. Still, I listened repeatedly as they expressed perpetual frustration about "not seeing" the (disciplinary) curricular coherence across mathematical stories expressed in other students' artwork. Though each of these students eloquently expressed highly idiosyncratic perspectives on curricular (in)coherence that deviated from disciplinary coherence, they appeared to have internalized that disciplinary forms of coherence were "more desirable" and "more correct" than their own. It was not until the final group discussion that each of these students started to challenge these deficit views they held about their own aesthetic judgements. This appeared to be a positive and perhaps even empowering outcome for these participants. But what about the other students navigating these exclusionary politics of mathematical aesthetics without sufficient space for critical reflection?

While the culture of exclusion (Louie, 2017) in mathematics classrooms is not something that will be solved overnight with just one change, there are some concrete steps that can be taken to mitigate these harms in future curricular coherence research. We can remain open to *several* perspectives on curricular (in)coherence, rather than strictly espousing just one perspective. This can be done by explicitly acknowledging the fundamentally *aesthetic* nature of making judgements about curricular coherence, clarifying that coherence seeking is *not* an objective evaluation but an idiosyncratic judgement based on one's personal aesthetic sensibilities. In other words, not everyone will find the same curricular story to be "coherent". While the definition of "coherence seeking" offered by Sikorski and Hammer (2017) does much to shift power into the hands of students to make their own judgements about what is coherent, it still positions this activity as a mostly *cognitive* act. Almost nothing is said about the *emotional* and *aesthetic* factors that influence coherence seeking (as demonstrated across students' perspectives in this study). Future research, therefore, ought to more explicitly embrace (as well as further investigate) how affective forces and other value judgements (including *aesthetics*) influence and *drive* coherence seeking. As past research in mathematics education repeatedly demonstrates, such aesthetic forces play a highly non-trivial but often overlooked role in students' mathematical activities (e.g., Fiori & Selling, 2016; Jasien & Horn, 2022). It is high time that we fully acknowledge how these personal subjectivities impact judgements of mathematical coherence and, in doing so, begin to rid our discipline of the dangerous myth that mathematics is objective, pure, or immune to exclusionary politics of aesthetics.

Covariation-in-Pieces: Covariation as a Coordination Class

Steven R. Jones
Brigham Young University

Jon-Marc G. Rodriguez
University of Wisconsin, Milwaukee

Much of the work in covariation, to date, has focused on "large-scale" themes, such as broad reasoning levels and behaviors. We propose that covariation research could be greatly enhanced by attending to the "fine-grained" cognition happening in students' covariational reasoning. We propose that covariation can be considered as a coordination class, which models knowledge as a complex cognitive structure wherein an emergent system of knowledge resources are activated in response to context and cueing. We explain what this perspective on covariation would look like, and we provide an illustrative vignette to explore the power of this perspective.

Keywords: covariation, covariational reasoning, knowledge in pieces, coordination class

Covariation and covariational reasoning have become major themes in secondary and tertiary mathematics education research (e.g., Carlson et al., 2002; Castillo-Garsow et al., 2013; Johnson, 2022; Moore et al., 2019; Thompson & Carlson, 2017). Consequently, deeply unpacking covariation as a construct, and the reasoning done in covariational situations, is critical for building this area of work. To situate this paper, we note that most of the work done to date in covariation has focused on a relatively large cognitive scale, which tends to operate under the assumption of the stability of knowledge – e.g., broad developmental levels that encompass mental actions and behaviors (Carlson et al., 2002; Thompson & Carlson, 2017). We argue these mental actions and behaviors may involve the coordination of less stable knowledge-in-use that is manifold in structure and context-dependent in emergence. Our previous work has started to add a "fine-grained" perspective on covariation (Rodriguez, Bain, & Towns, 2019), and we have highlighted the value of applying a fine-grained lens to consider students' graphical reasoning, including students associating intuitive ideas with graphical patterns (Rodriguez & Jones, 2024). These fine-grained ideas operate at a scale of analysis that affords consideration of the flexibility of a student's knowledge, as well as their knowledge structure's dependence on context and time.

In this paper, we systematize this emerging work by discussing covariational reasoning through a fine-grained constructivist lens, highlighting the affordances provided by situating covariation within coordination class theory (and knowledge-in-pieces broadly). We claim that the importance of doing so is that it provides more accurate modeling of student thinking and it better accounts for conceptual change in developing expertise in covariational reasoning.

Brief Literature Review on Covariation

Covariation consists of two quantities or variables whose values are linked, such that changes in one correspond to (possibly) changes in the other in a smooth continuous manner (Saldanha & Thompson, 1998; Thompson & Carlson, 2017). For simplicity we use the term "variable" in this paper to encompass both real-world quantities and mathematical variables. Covariational reasoning consists of mental actions related to situations involving covariation, which have generally been described through broad "behaviors" and developmental "levels." For example, Carlson et al. (2002) described covariational reasoning through coordinating variables' values, coordinating directions of change, coordinating amounts of change, and coordinating changes in the rate of change. Thompson and Carlson (2017) gave an alternate set of broad levels, including

asynchronous tracking of variables' changes, coordinating variables' values, envisioning changes in chunks, and envisioning changes smoothly (see also Castillo-Garsow, 2012).

Covariational reasoning has been a powerful framework for building coherent mathematics instruction. It has been used to reimagine key ideas such as function (Ellis et al., 2016; Oehrtman et al., 2008; Paoletti & Moore, 2018), graphs (Carlson et al., 2002; Moore & Thompson, 2016; Rodriguez, Bain, Towns, et al., 2019), coordinate systems (Moore et al., 2013), and calculus concepts (Jones, 2017, 2019; Kertil & Gülbağcı Dede, 2022; Thompson, 1994). Covariational reasoning also coheres well with quantities-based thinking and reasoning at the intersection of math and science, or with other disciplines. It has been used to describe reasoning in chemical kinetics (Rodriguez, Bain, Towns, et al., 2019), in scientific representations (Panorkou & Germia, 2021), and in modeling quantities (Panorkou & Germia, 2021).

What might be the next step in building covariation as a construct in educational research? A major theme in the literature cited here is that covariation is generally considered through "large-grained" cognitive structure, such as a student's ability to coordinate directions of changes, or a student's ability to imagine smooth variation. Accounts of "fine-grained" cognitive structure in this area are only beginning to be produced (Rodriguez, Bain, & Towns, 2019; Rodriguez, Bain, Towns, et al., 2019). The next important step is to systematize this emerging "fine-grained" work to better understand the nature of actual covariational reasoning used by students in practice.

Knowledge-in-Pieces and Coordination Class Theory

Overview

Knowledge-in-pieces (KiP) (diSessa, 1988, 2004, 2018; diSessa & Sherin, 1998) is a paradigm centered on fine-grained knowledge and conceptual change. KiP is based on a manifold view of cognitive structure, where knowledge is modeled as an emergent system of elements that are activated in concert, in response to context and perceptual cueing. Knowledge elements can be quite small, such as intuitive extractions from experience (e.g., *closer means more intense*), or a simple idea picked up from a class (e.g., *x means a variable*). These individual knowledge elements become *resources* that a person can activate in a situation (Hammer, 2000). Thus, we call them *knowledge elements* and *resources* interchangeably.

KiP and Graphing

Because much work in covariation has been done in the context of graphing (e.g., Carlson et al., 2002; Castillo-Garsow, 2012; Moore et al., 2019; Moore & Thompson, 2015), we provide here some work done on graphing using a KiP lens. Recently, Rodriguez and colleagues (Rodriguez, Bain, & Towns, 2019; Rodriguez & Jones, 2024; Rodriguez et al., 2020) have interpreted students' graphical work through a fine-grained examination of knowledge resources students might flexibly use at different times. This work resulted in a large collection of "graphical forms" students might employ such as *curved means changing rate*, *big dot as focal point, discontinuity means sudden*, and so forth (see Rodriguez & Jones, 2024 for more). As students create a graph, they might infer graphical patterns based on what they observe in the context. For example, if one is creating a graph to model the height of grass mowed once a week, they could notice the sudden change in grass height when cut. This could lead to the activation of *discontinuity means sudden* and they might draw a jump discontinuity in the graph. However, in another situation, there may be no sudden events, so no inference is made to *discontinuity means sudden*. Thus, not observing a resource in context does not imply the students does not posses it.

In addition to graphical forms, there are also more general knowledge elements regarding axes, scaling, beliefs, conventions, and quantities (Jones & Rodriguez, 2023). These can include

resources like *spacing means duration* on an axis, the belief that *the presence of π implies trig functions*, or the quantitative resource *time as a natural independent variable*. When students are asked to create graphs, they extract information from the context that traces inference to some of these resources, which are activated and in turn may trace inferences to other resources. This activated collection of resources are used in making moves toward constructing a graph. Graphical resources play an important role as elements nested within larger knowledge systems such as a coordination class, and have strong connections to covariational reasoning, as well.

Coordination Class Theory

Coordination class theory builds on knowledge-in-pieces to provide a model to describe a "concept" within a systems view of knowledge (diSessa & Sherin, 1998). Importantly, not every concept can be modeled as a coordination class, with a coordination class being a specific type that serves the function of allowing an individual to recognize or "see" the concept across contexts. To illustrate, consider the idea of "proportional reasoning." The actual cognition pertaining to proportional reasoning is complex, with basic ideas of difference, products, scaling, balancing, ratios, rates, fractions, inverse relationships, and so on, networked together in some way (Jacobson & Izsák, 2014; Sherin, 2001). Here, a sophisticated coordination class would allow an individual to recognize and apply these ideas across a variety of situations where proportional reasoning is relevant, such as in constant difference, constant growth, or exponential growth contexts. Due to context, it is not necessary to employ the entire coordination class, and only a subset of resources might be activated in a situation. For example, a constant difference situation might elicit a distinct set of knowledge resources related to proportions than an exponential growth situation. The functioning of the concept in one specific situation (subset of resources used) is called a *concept projection* (diSessa, 2004; diSessa & Wagner, 2005).

The defining structural features of a coordination class that allow an individual to see a concept involve two major components: *extractions* (previously called *readouts*) and *inferential nets* (diSessa, 2018; diSessa & Sherin, 1998; diSessa & Wagner, 2005). Extractions are the features attended to – what are seen, noticed, or observed in the context that are relevant to the target information. In the proportion example, features that may cue a student to recognize proportionality in a situation might be specific symbol templates (A/B = C/D), the presence of rates (X lbs/min), percentages (X %), and so on. Inferential nets are the set of possible inferences that lead toward the target idea. These can connect an extraction to a knowledge element, or may connect that knowledge element to yet additional knowledge elements.

Covariation as a Coordination Class

We now turn to the main purpose of this paper, which is to propose covariation as a coordination class, and covariational reasoning as the employment of a covariation concept projection into some context. In the current literature, "covariation" levels tend to be given as hierarchical progressions toward the ideal of covariation. While this lays a useful and important foundation, we posit that we can zoom in further into the concept of "covariation" by modeling it as a coordination class. Here, it would consist of a large network of resources that function differently in different situations, such as when constructing a graph, or identifying quantitative relationships in a physics equation, or imagining different types of mathematical functions. Different collections of resources pertaining to covariation might be activated in certain of these situations, but not in others, meaning each situation represents a *concept projection* of covariation into that context. For each situation, one would employ extractions to "read" the situation and begin making inferences across the knowledge elements, to determine the desired

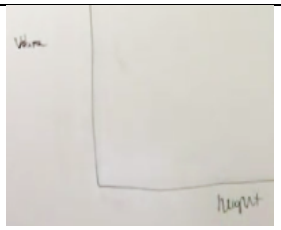
information. For example, in a graph-interpretation context, extractions might consist of observing features in the graph's shape, noticing axis scales or labels, or locating straight or curved sections of the graph. In a context considering a scientific quantitative relationships, extractions might consist of how those real-world quantities behave, or how their magnitudes change. In a math-function context, extractions might consist of noticing what type of function is present, or what symbols portray the input or output. Inferential nets connect these extractions to knowledge elements that might be relevant for reasoning covariationally. These might include resources like *straight means constant rate*, or *up-down as inverse relationship*, or *sine as periodic*. Inferences can further be made from these resources to yet other resources, in a chain that activates a certain subset of knowledge elements in that context.

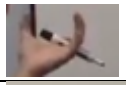
To dig deeper, let's consider a common example of a covariational situation: the well-known bottle task (Carlson et al., 2002; Johnson, 2015a, 2015b). In this task, a bottle is filled with water and students are asked to draw a graph of volume as a function of height. Analyzing this task has previously consisted of finding evidence for certain levels of covariational reasoning through students' behaviors (Carlson et al., 2002), or describing general natures of the coordination (Johnson, 2015a, 2015b). Certainly these findings have been very helpful in understanding students' thinking. To now reframe this situation using coordination class theory, we first note that students' covariational reasoning for this task reflects a single concept projection into the bottle context. Thus, we should expect that subsets of their resources might be activated, while other resources remain dormant. In this concept projection, the extractions would be those features students see or notice about the bottle that would be relevant (to them) in identifying the covariational relationship and capturing it graphically. These might include noticing a constant rate of water pouring in, the width of the bottle, or the emptiness of the bottle of at the beginning.

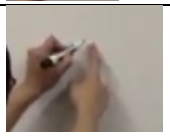
An important implication of thinking of covariation as a coordination class is that these extractions then influence what the student might do next, as inferences are made to other knowledge elements. Their extractions drive inferences for which resources get activated. It is entirely possible that seeing the constant rate of pouring might activate a resource that *straight means constant rate*, leading them to initially draw a straight line segment. In coordination class theory, this action does not reflect a misconception (Smith et al., 1994). This resource is perfectly legitimate in certain contexts; it is simply misapplied here, because that volume per time rate is not what the volume-height graph is meant to reflect.

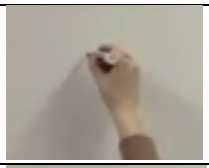
Additionally, what has been termed covariational reasoning "levels" (Carlson et al., 2002; Thompson & Carlson, 2017) may be reinterpreted as possible extraction strategies students use in their concept projection. For example, gross coordination (i.e., general increase/decrease behavior in the variables), can be a strategy for what to focus on, guiding what students may "see" in the context. Zooming in further, these extractions shape what resources get activated, and the collection of activated resources drives the actions taken. In the bottle context, a student might observe that as water comes in, height and volume both go up, leading to the activation in the inferential net of *up-right means increasing*. Consequently, the students may make a general up-right initial sketch. Increasingly sophisticated covariation levels may represent increasingly sophisticated methods for reading situations for relevant information. But if we view covariational reasoning simply as a set of levels, the in-the-moment cognition induced from that extraction strategy and the subsequent inferences might be overlooked.

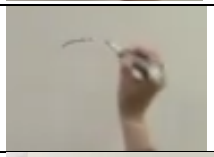
Illustrative Vignette and Discussion

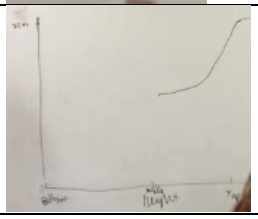




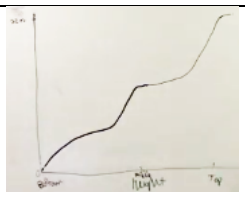








To show covariation-as-a-coordination-class in action, we provide here an illustrative example of students working in the well-known bottle context and use it to suggest the power



one can get from the coordination class perspective. Figure 1 shows an excerpt from two students working with a version of the bottle task, and includes their speech and inscriptions. We also document the knowledge resources activated on the right of the figure (see Jones & Rodriguez, 2023; Rodriguez & Jones, 2024 for more details on these specific resources).

Figure 1. Eric/Ellie's work in the bottle task, with identified extractions (E), resources (R), and other inferences (I)

Task: This bottle is being filled up with soda. Graph the volume of the soda in the bottle as a function of the height of the soda.

Name	**Utterance**	**Drawing**	**E=extraction R=activated resource I=other inference**
Eric:	I'm going to assume it fills up, like the volume.		E: Volume fills up
Ellie:	Let's start at zero. So, which axis should be volume?		E: Bottle starts empty R: Origin as natural start R: Axes need labels
Eric:	Probably this one [points to *y*-axis], 'cause the height [points to *x*-axis] is the constant increase. … I think it's a more, I'm guessing this is probably a curved function [i.e. graph], because the bottle's curved… It'd probably fill up the volume if you're going up height.		E: Height goes up R: Independent as 'marching on' R: Other on vertical axis E: Bottle's curvy shape R: Graphs preserve visual features I: graph is curvy
Ellie:	Like that, a little bit, maybe	Gestures 'up-right' arc	R: Up-right as increase
Eric:	… It would take up longer to fill up the areas where the bottle is wider.	Gestures fingers apart 	E: Bottle shape R: More takes longer
Eric:	…[later]… Like in the middle we should probably have a point [touches middle of graph space], kind of like right here [draws a dot in the middle].		E: Halfway point as significant R: Dot as focal point
Ellie:	Yeah. I feel like the closer we get to the top [draws a dot at the top-right],		E: Top of bottle I: scenario ends at top R: Dot as focal point
Ellie:	[continued] the more it'll kind of level off a little bit [draws slight curve going into a straight line segment].		R: Plateau as leveling off
Eric:	'Cause it's more constant [i.e. straight line segment]. This is like the middle of the bottle, so it's like a steady followed by a rapid increase. [Ellie agrees: "yeah"].		R: Straight means constant rate E: Middle is curvy I: Growing rate of increase R: Connection as transition R: Steepness as rate

Eric:	And then I think it's the same thing here [points to left of graph portion]. It's kind of followed by a sharp kind of, just kind of like gradual [finishes drawing curve].		R: Connection as transition R: Steepness as rate

In a "holistic cognition" analysis, we might identify that the students can perform basic coordination (e.g., labelling axes) and gross coordination (e.g., up-right graph), and can coordinate values (e.g., identifying height-volume pairs for the middle and top) and coordinate rates (e.g., less steep to more steep) (Figure 2, left). However, stating these does not help distinguish this pair of students from another pair who might use similar levels, but in a very different way. For example, in constructing their graph, Ellie and Eric did not move in an orderly "left-to-right" fashion, which is not accounted for in major covariational reasoning frameworks. They chose to start at the middle and end, but what accounts for those actions? Similarly, a holistic view might identify a difficulty in constructing the middle of the graph, and might try to identify the level at which the students struggle, such as the "changing rates" level from Carlson et al. (2002). But Ellie and Eric successfully manage changing rates in other places, so this description does not seem to provide much detail on the actual cognition being used.

By contrast, what might a coordination class interpretation entail? As mentioned before, it provides the ability to "zoom in" on each of these covariational reasoning levels to see how those extractions lead to other inferences, including graphical forms, graphical resources, or other knowledge elements (Figure 2, right). In Figure 3, we provide exactly this type of "zoom-in" in the form of a resource graph that models at a much more detailed level what these students' cognitive work consisted of. Notice that the covariation "levels" functioned more as broad strategies for extracting information from the task, leading to resources activation. This perspective allows us to see how their reasoning at each level operated in-the-moment. It could allow us to distinguish Ellie and Eric's work from other students' work using similar levels.

As they extracted information, they connected it to relevant resources and used those to build certain pieces of the graph, one at a time (Figure 3). They started by constructing axes they felt matched the task, based on resources related to the origin, labels, and what counts as an "independent" variable versus the "other" variable. After identifying the general "up-right" nature of the graph, they identified key locations in the graph, such as the mid-point and end-point, based on graphical forms related to dots, plateaus, and straight segments. They progressed to generating curves for the later and earlier portions of the graph, based on graphical forms related to slope, curves, and connecting points (Figure 3). When these two sections did not match up, they simply invoked a belief about the necessary "curviness" of the graph, and a graphical form *curve means changing rates* to try connect them. Thus, the incorrect middle portion seems less about abilities at the large-scale covariation levels, and more about which resources they invoked at that particular time to address a perceived discrepancy.

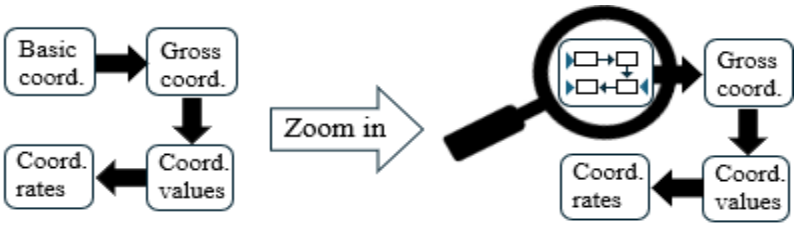


Figure 2. Coordination class theory helps with more explicit "zooming" into covariational levels (see also Figure 3)

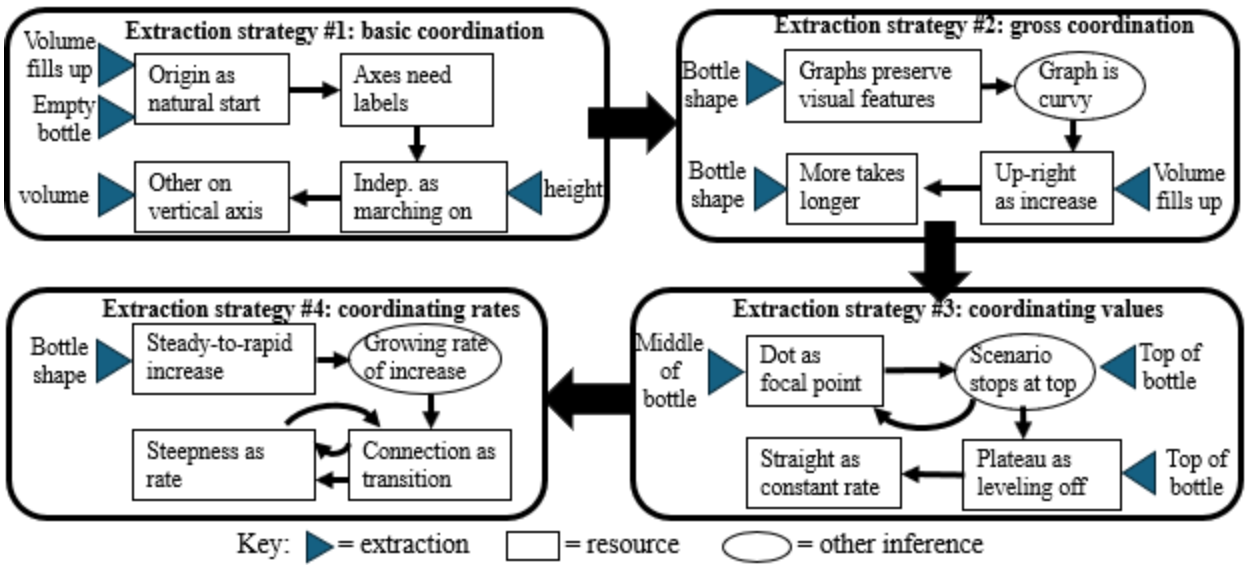

Figure 3. Resource graph as a model of the students' cognition with much greater detail

Further, consider how they determined to draw curves for a certain portions. Sometimes it was driven by an inference from the increasing rate ("it's a steady followed by a rapid increase"). Other times it was driven by the visual appearance of the curvy bottle ("probably a curved function, because the bottle's curved"). Positioning their reasoning at a certain level does not account for this subtle shift in justification. A coordination class lens helps us move away from viewing such ideas as unitary objects, toward seeing more fluid reasons and justifications.

Also, it is possible some might want to deem it "wrong" that the students appeared to use the bottle's curvy appearance at one point to infer that the graph was also curvy. But, again, the coordination class perspective helps us realize that that idea might sometimes be a legitimate inference in certain contexts, but perhaps not for others. In fact, the incorrect part in the middle is likely due to an overuse of this resource, in that they extracted the curviness of the bottle, combined it with the fact that changing rates are reflected by curves, and produced a tentative sketch of a graph they felt depicted that. This lens provides better instructional fodder, as well, because an instructor can try to highlight what resource the students drew on in that particular instance and to help the students question whether it was the right one to use. In other words, the difficulty might not be due to some larger underlying issue with one of the covariational reasoning levels. Rather, it could be as simple as the activation of the wrong resource at the wrong time. Helping the students identify their knowledge usage could help them shift from that resource to other resources, such that they could correct their incorrect portion of the graph. This constitutes, in part, the gradual shift from more novice activity to more expert activity.

Conclusion

In summary, we believe we get significant power through a coordination class interpretation in modeling these students' cognition related to covariational reasoning and to account for individual actions taken. It also provides a better narrative that follows what the students actually do. We also have better recourse for assisting the students in developing expertise, by shifting their resource usage and helping reorganize their knowledge elements. This power is important to researchers, as it improves our ability to faithfully render actual student thinking in-the-moment in real time. This power is also useful to instructors, in our ability to track what our students are thinking and doing in any given moment, in order to better scaffold and direct it.

Using Intertextuality to Study (Student) Conceptions of Proofiness

Dov Zazkis
Arizona State University

Andre Rouhani
Arizona State University

This work provides a theoretical grounding for proof education studies that utilize proof comparison tasks. We leverage the notion of intertextuality, borrowed from genre theories, to discuss mathematics education theory and methods. Intertextuality involves the implicit or explicit comparison of two or more texts with regard to a given genre. We discuss how this comparison can serve explorations of (student) conceptions of the genre of proof and argue that intertextual comparisons lead to novel insights into (student) conceptions of the genre. Specifically, we illustrate how someone's comparison of two (or more) justifications relative to the genre of proof can provide insights into how they view (a) proof as a genre, (b) which attributes of a justification are relevant to that justification's (potential) status as a (good) proof, (c) the relative importance of those attributes, and (d) the reasons for that relative importance.

Keywords: Proofiness, Justification, Intertextuality, Genre

Küchle and Dawkins (2024) argued that proof is a genre; consequently, genre theories might be helpful for mathematics education researchers as lenses for studying proof. They discussed the three major genre theory approaches, focusing on what these approaches have in common in their conceptualization of genre. We focus on one of those common threads, the notion of intertextuality. This construct has two competing definitions (Duff, 2002). The definition Küchle and Dawkins (2024) discussed involves texts referring to other texts. For instance, when the proof of a theorem references another proof/theorem or when a scientific paper references other scientific papers. Instead, we reference the other definition of *intertextuality*. That definition refers to examining genre via studying the (implicit or explicit) comparison of two or more texts. This definition has a rich history in studies of literary genres (Duff, 2002). When applied to proofs, the definition implies that conceptions of proof as a genre are explorable via comparison of two or more justifications with respect to their status in the genre of proof. This definition of intertextuality harnesses two key insights. Firstly, genre is a rhetorical category that expresses a relationship between texts. So, intertextual comparison is a relevant tool for studying it. Secondly, disagreements regarding which texts belong to which genre rarely resolve, so it is commonly more fruitful to further such debates by comparing two or more texts with respect to a genre.

For illustration, we discuss an example from film genre. Consider the 1988 action movie "Die Hard." Since the movie takes place on Christmas day, some have argued that this film belongs to the Christmas Movie genre. That interpretation of genre led to "Die Hard" being voted #7 in USA Today's list of 20 best Christmas movies (Truitt, 2023). However, most participating in the debate about its Christmas movie status would agree that, for instance, the movie "Scrooged" is comparatively more representative of the genre of Christmas Movie. Thus, two people who disagree on the genre status of Die Hard might still find fruitful common ground via comparison. Additionally, those people's comparison of the two films might lead to a discussion of which motifs and themes contribute to the Christmas movie genre, why they are relevant, and their relative importance. Thus, these comparisons can lead to more precise images of individual conceptions of the Christmas movie genre.

Some proof education studies have utilized proof comparisons (Brown, 2018; Mejía Ramos et al., 2021; Vroom & Alzaga Elizondo, 2024). However, these tend to focus on some properties a proof might have, such as explanatory value (Mejía Ramos et al., 2021) or its convincingness (Brown, 2018), rather than juxtaposing justifications with respect to the genre of proof as a whole. This work advocates for expanding this approach by considering the comparison of justifications with respect to the genre of proof. We argue that such comparisons can be particularly revealing. Specifically, intertextual comparison of justifications in relation to the genre of proof can reveal not just what students attend to but also the reasons for their attention. This attention need not be limited to the attributes that delineate the difference between proof and non-proof; it can also include attributes that contribute to the relative status of valid proofs, such as elegance or cleverness. Additionally, in cases where students attend to multiple attributes of a justification, comparison can also reveal the relative importance of the attributes they attend to, and the reasons for that relative importance. The phrase, "intertextual comparison of justifications in relation to perceived ideals and norms of the genre of proof," is quite onerous. So, it is helpful to create a construct to describe it.

Proofiness

Seife (2010) defines proofiness as manipulations of mathematical norms that "make falsehoods look like numerical fact" (p. 18). We borrow this construct's name (though not its definition) from Seife (2010). We instead use *proofiness* to refer to a person's intertextual conception of justifications in relation to perceived ideals and norms of the genre of proof. Our definition is naturalistic since it is consistent with student use of the word "proofy" in mathematics settings. For example, when participants in our studies were presented with multiple justifications simultaneously and asked to what extent they should be considered proofs, they responded with phrases like, "This one feels proofier to me" and "This one is not proofy." In doing so, they commented on proofiness via intertextual comparison (Authors, submitted).

Proofiness is intrinsically comparative. So, we discuss two kinds of intertextual comparisons. The first is to examine a person's conception of proof via their comparison of two (or more) (researcher-generated) justifications in terms of which is proofier. The second is to encourage participants to edit justifications to make them proofier. This editing allows them to (implicitly or explicitly) compare their edited version of a justification to the original and elucidate how those edits contributed to proofiness.

One crucial way the approach we describe differs from some past proof education studies is that we are treating the comparison of two valid and complete proofs with respect to the genre of proof as legitimate. In other words, one proof may be proofier than another, even when both are valid and complete. A consequence of this is that we explore not just the boundary between proof and non-proof but also what makes a justification a good/desirable proof. This approach is reminiscent of Paul Erdös' discussion of 'The Book,' where God keeps the perfect proofs for mathematical theorems (Aigner & Ziegler, 2004). That is, there is some (possibly unreachable) perfect proof for a theorem, and other proofs of that theorem are, using our terminology, less proofy.

The Utility of Proofiness

The remainder of this document discusses the utility of proofiness for exploring conceptions of proof. We begin by engaging the reader in an intertextual comparison of proofs. Later, we use excerpts from student interviews to illustrate insights about their conceptions of proof gained from this approach.

Your Conceptions of Proofiness

Imagine two people, Paul and Valentin, debating the proofiness of several proofs. Of the three proofs below, Paul states he believes that proof A is proofier than proof B. Valentin disagrees, claiming the opposite. Consider your stance on the matter. The three proofs are below:

Claim: $\sqrt{2}$ is irrational.

Proof A: Toward a contradiction, assume that $\sqrt{2}$ is rational. The definition of rational implies that there exists $a, b \in Z$ with $b \neq 0$ such that $\frac{a}{b} = \sqrt{2}$. Furthermore, we may assume that a and b share no common factors. Since $\frac{a}{b} = \sqrt{2}$ we know that $a^2 = 2b^2$, which implies that a^2 is even. Since a^2 is even, a is also even. This implies there exists a $k \in Z$, with $2k = a$. Substituting into the equation and simplifying, we get $2k^2 = b^2$. We then use a similar argument to conclude that b is even. Since we have shown that a and b are both even, they are divisible by 2. So, we have contradicted our assumption that they share no common factors. This means that $\sqrt{2}$ must be irrational.

Proof B: Suppose that $\sqrt{2}$ is rational. The definition of rational then implies that there exists $a, b \in Z$ with $b \neq 0$ such that $\frac{a}{b} = \sqrt{2}$. This means that $a^2 = 2b^2$ (*). The prime factorization of a squared integer has an even number of primes in its prime decomposition. Consequently, in equation (*), the left side has an even number of prime factors, and the right has an odd number of prime factors. This contradicts the fundamental theorem of arithmetic since prime factorizations are unique. So $\sqrt{2}$ is irrational.

Proof C: Let p be prime. Assume $\sqrt{p}$ is rational. By definition, there exists $a, b \in Z$ with $b \neq 0$ such that $\frac{a}{b} = \sqrt{p}$. This implies that $a^2 = pb^2$. Since the left side of the equation has an even number of prime factors, and the right has an odd number of prime factors, we have a contradiction. So, we conclude $\sqrt{p}$ is irrational. This implies that $\sqrt{2}$ must be irrational.

Consider the various stances that might emerge concerning Paul and Valentin's debate. Some might consider proof A proofier than proof B because of its similarity to the proof in their preferred textbook. Someone may believe proof B is proofier than proof A because its argument is more compact or makes fewer assumptions. Some might view proof C as proofier than proof A and proof B because it is more general. Alternatively, proof C leaves many warrants implicit compared to proofs A and B. So, some might base their judgment on that observation. Finally, a significant possibility is that one might avoid the debate entirely by asserting that if some justification is a proof, then it is no more (or less) a proof than any other. In that case, one considers relative proofiness as illegitimate. Regardless, the answers one gives and the reasons for them provide a lens into the values and norms they hold concerning proof. Both those who (1) believe the question is not legitimate, and (2) those who sighted some differences between the proofs to conclude some proof was proofier have sensible responses. The point we wish to highlight here is that it is reasonable for a person who answers (1) and a person who answers (2) to not attend to some of the differences in their respective conceptualizations of proof when discussing the subject (Author(s), submitted). That creates a potential mismatch, which can be especially problematic when, for instance, the former is a mathematics education researcher

interested in student conceptions of proof and the latter is a student interviewed about their conceptions.

Student Conceptions of Proofiness via Comparison

We argue that student explorations of proofiness can provide helpful insights. Below is an excerpt from an interview with a student, Redmond, who was near to completing an introduction to proof course (Author(s), year). Additional information regarding the tasks he worked on are in Author(s) (Submitted), and the two justifications he examined can be found below in Figure 1.

Claim 1: For integers $a, b,$ and c, if a divides b and b divides c, then a divides c.

Justification 1: Since a divides b, there exists an integer k, such that $ak = b$. Similarly, since b divides c, there exists some integer l, such that $bl = c$. Substituting for b in the equations yields:

$$(ak)l = c$$
$$a(kl) = c$$

Since k and l are integers, so is kl. Therefore, a divides c.

Claim 2: 5 divides 10, and 10 divides 30, so 5 divides 30.

Justification 2: Since 5 divides 10, there exists an integer—in particular, 2—such that $5 \times 2 = 10$. Similarly, since 10 divides 30, there is some integer—namely, 3—such that $10 \times 3 = 30$. Substituting for 10 in the equation yields:

$$(5 \times 2) \times 3 = 30$$
$$5 \times (2 \times 3) = 30$$
$$5 \times 6 = 30$$

Note that 6 is an integer. Therefore, 5 divides 30.

Figure 1: Justification Comparison Task

From our perspective, justification 1 is a valid, complete proof of the divisibility property of integers, and justification 2 is a corresponding *generic proof* (Leron & Zaslavsky, 2014). In other words, Justification 2 goes through the same steps as Justification 1 but does so using specific integers. Raymond was asked to read both justifications and compare them in terms of how proof-like (proofy) they were—that is, compare their relative proofiness. The excerpt begins after Raymond reads Justification 1:

Redmond: I like it because that is precisely how we would have to do it if that was on a test.
Interviewer: Tell me a little bit more about that. Why does it remind you of that?
Redmond: Because, my professor, she's very, very picky about the words that you use: let, assume, suppose, thus, therefore. This looks like a 6 out of 6 points, for sure. Yeah, without a doubt.
[Reads Justification 2]
Redmond: This would be the same exact proof as Justification 1, but they have integers. So, I would consider this a 5 out of 6. The reason for it is just... There are certain things like terminologies. For instance, this part here, "in particular 2." My professor would have

liked, "Since 5 divides 10, there is an integer 2", or "Let integer 2", you know, or "there's just an integer, such as 2", just sort of things like that.

Redmond indicates that Justification 1 is proofier than Justification 2 by assigning them grades 6/6 and 5/6, respectively. He believes this is reflective of how his professor would have graded these. Redmond notices the generic proof approach to justification 2 when he states, "This would be the same exact proof as Justification 1, but they have integers." However, that is not what he attends to when articulating the reasons for the two justifications' differing proofiness. Instead, the reasons for this difference in proofiness are the 'terminologies' used in Justification 2, specifically the phrase 'in particular 2.' From our perspective, those terminology differences are necessary when moving between proof and generic proof. However, Redmond's conception differs from ours. Redmond indicates that if Justification 2 had instead used the kinds of wording that his instructor expects it would have been proofier.

We can learn about Redmond's conceptions of proof from his excerpt. For instance, he believes that using the language normatively found in proofs is relevant to proofiness. Additionally, given comparable language usage, he believes generic proofs are just as proofy as non-generic proofs. In other words, moving between generic vs. non-generic proofs has no effect on proofiness from his perspective, but minor deviations from the word choice he expects do. Had we presented justifications 1 and 2 as separate tasks, without the juxtaposition of the two, we would have just learned that he regarded both as proofs and learned less about his conception of proofiness. That discussion of proofiness allowed us to glean his views on the relative importance of genericness vs. language to his assessments.

Student Conceptions of Proofiness via Editing

Next, consider the following excerpt from Claudette. When the excerpt begins, she has already participated in comparing justifications 1 and 2 (Figure 1). The excerpt is from the subsequent stage of the interview, editing. The transcript below begins after the interviewer encouraged her to revisit Justification 1 and edit it to make it more proof-like from her perspective. Her inscriptions are in Figure 2.

Claudette: ‘Since a divides b’. And then this [ak=b for some integer k] is just the definition of divides. Which in the words of [name of ITP instructor], 'sometimes you need to say that there's a definition. But also, it should always be assumed.' So here it looks there's more assuming that you know the definition of divides. In our class, most of the time you write it out… [Edits by adding ', by definition of divides.']

Interviewer: If you add that, does that make it feel more proof-like?

Claudette: I would say that it's very proofy, to begin with, but this gives more clarity. It's the idea, like if you are working with an 8th grader, whose never seen the definition of divides, then it's going to be like okay, by definition of divides, and if they have notes, they can look at the definition of divides and be like, Oh, if a divides b, ak=b for some integer k… definitely having the name of the definition so you can look it up makes it easier.

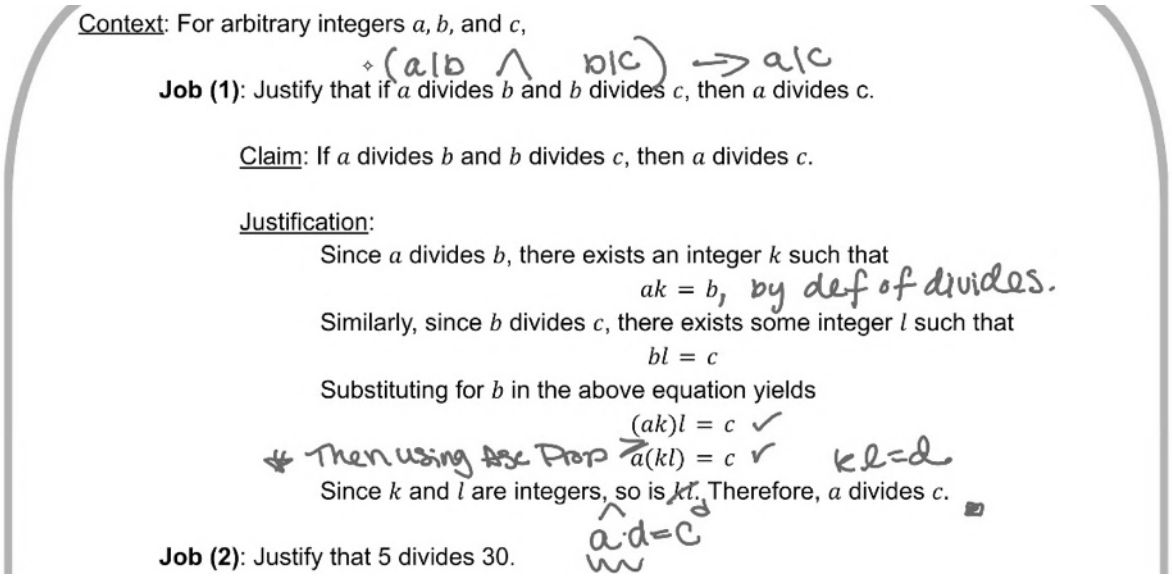

Figure 2: Claudette's inscriptions on Justification 1

Notice that Claudette indicates that her adding phrases and adjusting language is done to improve 'clarity' and 'make it easier.' So, in making these edits, she makes the justification more perspicuous from her perspective. She knows that the definition of divides implicitly warrants $ak = b$. So, that part of the justification is *transparent* to her. However, by adding 'by definition of divides' (Figure 2) she is 'making it easier' for someone else to make the same link. Additionally, she states that her intended audience is 8th graders. So, she is conscious of a potential audience for whom the justification should be clear. It is worth mentioning that proofiness facilitated our observation. By treating valid proofs as capable of being edited to be proofier, we were able to encourage Claudette to undertake such edits even though she viewed Justification 1 as initially 'very proofy.' This helped us glean what she viewed as the purpose of such edits: perspicuousness. Czocher and Weber (2020) discuss perspicuousness as one of the five properties mathematicians consider when determining whether a justification should be considered a proof. Claudette's excerpt shows that some students have similar considerations when editing proofs.

Both Claudette's and Raymond's excerpts reference their instructor. These references help illustrate that, especially in early proof courses, an instructor's discussions of proofs and how they should be communicated influence the conceptions of the genre students form. Specifically, their instructor spent significant time and effort emphasizing the importance of clarity and adherence to mathematical terminology. These themes were thus evident in their discussion of the proofiness of the justifications.

Discussion and Conclusion

Commonly, the themes studied concerning proofs are themes known to contribute to expert conceptions of proof. For instance, Czocher & Weber's (2020) expert cluster model of proof includes convincing, a priori, and sanctioned as properties mathematicians attend to when evaluating whether a justification is a proof. These three properties roughly correspond to the themes that Weber et al. (2022) argue that mathematics education researchers have historically prioritized (when studying students): 1) the psychological function of proof (Brown, 2018; Harel

& Sowder, 1998), 2) its logical or structural features (Hub & Dawkins, 2018), or 3) its social or institutional layers (e.g., Devlin, 1993). This correspondence between mathematicians' conceptions of proof and proof education researchers' priorities means that much of the current proof education research implicitly centers mathematicians' practice. The approach we described focuses on conceptions of proof as a genre. Thus, our approach leaves students open to articulate themes they believe contribute to the proofiness of a justification which may differ from themes identified by mathematicians.

Treating proof as a genre within the context of proof education points to the likely possibility that proof students and mathematicians view the genre very differently from each other. For instance some themes and motifs students view as central to the genre may be treated as surface by mathematicians (Selden & Selden, 2003) and vice versa (Chazan, 1993). Additionally, students are convinced by proofs in ways that differ from mathematicians (Healy & Hoyles, 2000; Weber, 2008). Thus, there are also differences in the role personal conviction plays in mathematicians vs. students' conceptions of the genre of proof. In this document, we have argued that intertextuality borrowed from genre theories provides one potential path for exploring student's conceptions of proofiness. This path is a potentially fruitful direction for proof education research, which does not center mathematicians' practice.

We describe two potential avenues for intertextual comparisons: comparison of researcher-generated justifications and student editing. For both, we demonstrated with brief excerpts of data that these intertextual comparisons of justifications revealed students' conceptions. The broader vision this work advocates involves using these tools to understand the themes that students view as relevant to the genre of proof, especially when those themes differ from those prioritized by mathematicians. Studying how students view the genre of proof and why can help the field better understand how students' experiences shape their conceptions of proof. Their conceptions of proofiness connect to how they approach proof construction and reading of proof. So, a better understanding of these conceptions, how and why they emerge, and their influence on reading and production of proofs can further proof education research and the design of proof-centered curricula.

New Methods for Analyzing Students' Reasoning About Definite Integrals in Introductory Physics

Olha Sus
Tufts University

Andrew Izsák
Tufts University

Over the past decade, research on students' understanding of integrals has grown significantly. While previous studies have noted students' difficulties in coordinating the "product layer" with definite integrals in applied contexts, they often overlook the diverse knowledge resources students use in their moment-to-moment reasoning. Additionally, effective methods for analyzing this complexity have been lacking. This paper introduces new methods for examining students' reasoning about the "product layer", $f(x) \cdot dx$, and definite integrals, combining a modified dynamic conceptual blending diagram and an expanded Visualization/Analysis/Physics (VAP)-model. We demonstrate these methods with an example of an integration task, illustrating their application and impact on integration research (see Sus & Izsák, 2024b for further examples). This contribution advances the literature on integration research by providing a more nuanced analysis of students' reasoning.

Keywords: Integration, Product Layer, Knowledge-in-Pieces, Expanded VAP-Model, Dynamic Conceptual Blending

Introduction and Literature Review

Integration is fundamental in modeling many applied phenomena and is a core topic in calculus. It is a complex concept, structured around the coordination of multiple quantities through various mathematical operations. A significant body of literature has explored students' understanding of integrals in applied contexts (e.g., Meredith & Marrongelle, 2008; Cui et al., 2006). Researchers have identified challenges students face when modeling quantities like distance and work using rectangular areas (e.g., Thompson et al., 2013; Nguyen & Rebello, 2011; Christensen & Thompson, 2010).

Students often interpret the definite integral in one of three ways: as the "area under the curve," as a "derivative/antiderivative" relationship, or as "adding up pieces through multiplicatively-based summation" (e.g., Jones, 2015a, 2015b; Ely & Jones, 2023; Jones & Ely, 2023). Research suggests that the third is especially useful when applying integrals to physics, engineering, and other fields. However, there is ongoing debate about the range of situations where the multiplicatively-based summation and Riemann sum interpretations are applicable. Meredith and Marrongelle (2008) argued that using the product structure $f(x) \cdot \Delta x$ in a Riemann sum is sufficient for modeling accumulation only when the integrand represents a rate of change or density. However, many contexts do not naturally conform to this quantitative structure.

Particular challenges arise when reasoning about the "product layer" in definite integrals, as highlighted by several studies (e.g., Ely, 2017; Jones, 2013; Sealey, 2014). For example, Sealey (2014) developed a framework for understanding Riemann sums and definite integrals, identifying the "product layer" as a particularly complex and challenging concept for students.

This paper builds on Oehrtman and Simmons' (2023) discussion of Emergent Quantitative Models for definite integrals, which includes three primary models: basic, local, and global. The researchers provided examples showing how student reasoning can involve varied interactions among these models, such as choosing which factor in a product to treat as infinitesimal and how to approach partitioning. However, they stopped short of exploring knowledge resources which

students applied while coordinating multiplication with definite integrals through the construction of all three models. This omission is significant in being able to analyze the complexity of students' reasoning about multiplication and definite integrals in applied situations.

In other studies (Sus & Izsák, 2024a; Izsák & Sus, 2024), researchers have examined how students coordinate multiplication with definite integrals, finding that students draw on a variety of mathematical and physics knowledge resources, their combinations, as well as related drawings. These resources fluctuate depending on the problem context, which can lead to shifts in student reasoning. Such instances reveal the complexity of students' reasoning about the "product layer," highlighting the need for a closer examination of students' moment-to-moment reasoning and the knowledge resources they employ.

In this paper, we propose new methods for analyzing the complexity of students' moment-to-moment reasoning about the "product layer" and definite integrals with a focus on the knowledge resources they use. This serves as a significant contribution to the existing literature on integration.

Theoretical Perspective

In this section, we outline the theoretical perspective we use to analyze students' complex reasoning about mathematical concepts, specifically multiplicative structures in applied integration contexts. This perspective includes three components: the knowledge-in-pieces epistemology, the dynamic conceptual blending framework (e.g., Van den Eynde et al., 2020), and visual conceptual blending (Cunha et al., 2020).

The Knowledge-in-Pieces Epistemological Perspective

The knowledge-in-pieces epistemological perspective was first developed in science education research on conceptual change (e.g., diSessa, 1993, 2006). It has since been applied to various topics in mathematics, including whole-number multiplication (Izsák, 2005), functions (e.g., Izsák, 2004; Moschkovich, 1998), the law of large numbers (Wagner, 2006), and integrals (Jones, 2013). From this perspective reasoning is supported by diverse, fine-grained knowledge resources and more novice knowledge evolves into more expert knowledge through processes such as the construction of knowledge resources that are sensitive to context for activation, refinement of contexts in which resources are applied, and reorganization that can involve forming new connections among some recourses and loosing connections among others. In the present study, we are particularly interested in knowledge resources students evidenced when coordinating multiplication with definite integrals in the introductory physics context.

Conceptual Blending

Original version of the conceptual blending perspective. Conceptual blending was originally introduced by Fauconnier and Turner (1998) to model how people create new meaning in linguistic contexts by selectively combining information from different domains of previous experience. Figure 1 shows a schematic representation of the conceptual blending diagram. In its basic form, the framework consists of four connected mental spaces: two partially matched input spaces, a generic space, and the blended space. Input spaces are small self-contained regions of conceptual ideas (knowledge resources). The generic space provides the underlying structure to the input spaces, identifying commonalities in content and structure. The blended space is constructed through the combination of selected elements from the input spaces. Fauconnier and Turner distinguished three approaches to form a blended space: composition (blending can

compose elements from the input spaces to provide relations that do not exist in the separate input spaces), completion (adding new elements based on background models that are brought into the blend unconsciously), and elaboration (treating the blend as a simulation and "running" it imaginatively, which creates new insights). Also, the blend has emergent dynamics: It can be "modified" while its connections to the other spaces remain in place.

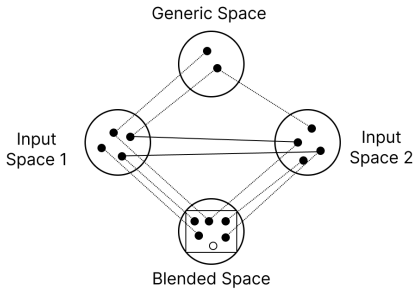

Figure 1. Schematic representation of a blending diagram (Fauconnier & Turner, 1998, p.143).

For example, Fauconnier and Turner (2002) illustrated the idea of a blend using the construct of a "computer virus" which blends meaning from the two domains of "computers" (files, software) and "viruses" (harmful, discrete, replicating) to create a new term that describes a harmful, replicating piece of software (Fauconnier & Turner, 2002, pp. 274–275).

Adapted conceptual blending perspective: Students' use of mathematics in physics. Prior research studies (e.g., Bing & Redish, 2007; Hu & Rebello, 2013; Odden, 2021; Wittmann, 2010) have investigated conceptual blending to describe students' use of mathematics in physics. For instance, Bing and Redish were the first to introduce the language of conceptual blending as a way to analyze problem solving in physics at the introductory level. Schermerhorn and Thompson (2014) used the symbolic forms framework (Sherin, 2001) and incorporated it into the conceptual blending framework to describe students' construction of differential length vectors with extensions to equation construction and interpretation generally.

Hu and Rebello (2013) adapted the conceptual blending framework from cognitive science to make sense of ways in which students combined their knowledge from calculus and physics to set up integrals. They found that many students were not able to blend their mathematics and physics knowledge in a productive way even though they had the required mathematics knowledge. An example of their blending diagram consists of three input spaces, symbolic ($\rho(x), R = \frac{\rho L}{A}$), math notion space (function, integral as a sum, '$d[\,]$' as a variable of integration), physics space (resistivity, resistance, length), and the blended space (resistivity varies along length, $\frac{\rho(x)L}{A}$ substitute resistivity, $\int_0^L \frac{\rho(x)L}{A} dx$ sum up over).

Van den Eynde et al. (2020) utilized the conceptual blending framework to study student thinking in integrating mathematics and physics within the context of the heat equation. They introduced dynamic blending, enhancing earlier diagrams by incorporating time stamps and both implicit and explicit connections to better capture the dynamics of reasoning.

Odden (2021) investigated how undergraduate physics students create conceptual connections to overcome challenges with complex and counterintuitive ideas in introductory physics. The study demonstrated how students construct and use conceptual blends to understand difficult physics concepts.

In this paper, we take a dynamic conceptual blending perspective (Van den Eynde et al., 2020) which incorporates the dynamic aspect of students' reasoning and explicitly visualizes how students switch between symbolic, mathematics, physics, and blended elements throughout their reasoning process.

Visual conceptual blending. Visual conceptual blended elements emerge from a process of visual blending grounded in conceptual understanding. Visual blending involves merging two or more visual representations (such as images) to create new ones. When visual and conceptual blending are combined, they result in what is known as visual conceptual blending (Cunha et al., 2018). This blending process plays a crucial role in students' moment-to-moment reasoning, supporting the creation of new visual elements that reflect their dynamic thought processes.

New Methods

In this paper, we use a modified version of the dynamic conceptual blending diagram from Van den Eynde et al. (2020) to explore students' reasoning about multiplicative structures and their application to integration tasks in physics. We introduce a new step for identifying activated and deactivated elements and connections and apply a different coding scheme to elements in the transcript. Our modified dynamic conceptual blending diagram (MDCBD) is illustrated in Fig. 2.

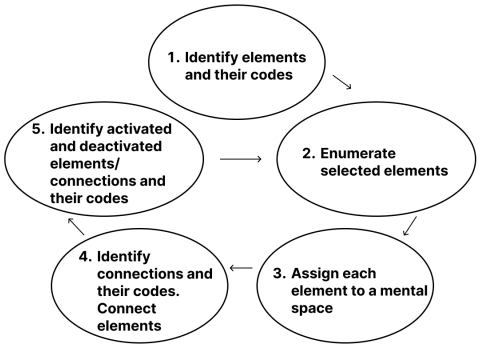

Figure 2. Schematic representation of MDCBD.

Step 1. We identify elements from verbatim transcript, which represent pieces of knowledge or resources. These elements are defined as new steps, ideas, concepts, or phrases in a student's reasoning. Unlike Van den Eynde et al. (2020), we recorded all elements from the transcript and categorized them into two groups: more confident and more tentative elements. An element is considered more confident if a student expresses confidence in introducing it, using phrases such as "I remember," "I am sure," or "I recall." Conversely, elements are classified as more tentative if the student shows hesitation, using phrases like "I guess" or "I am not sure." More confident elements are coded with solid dots, while more tentative elements are marked with empty dots. Elements introduced in the problem statement are also included in the MDCBD and can be either more confident or more tentative. Notably, we do not categorize elements as correct or incorrect within the MDCBD.

Step 2. We enumerate only those elements that capture students' reasoning about the multiplicative structure and its coordination with the concept of definite integrals. The elements are listed in the order they appeared in the transcript, allowing us to better understand the dynamics of students' reasoning throughout the interview.

Step 3. We assign each enumerated element to one of four mental spaces in the MDCBD: three input spaces (symbolic, physics, and mathematics) and one blended space. The *symbolic*

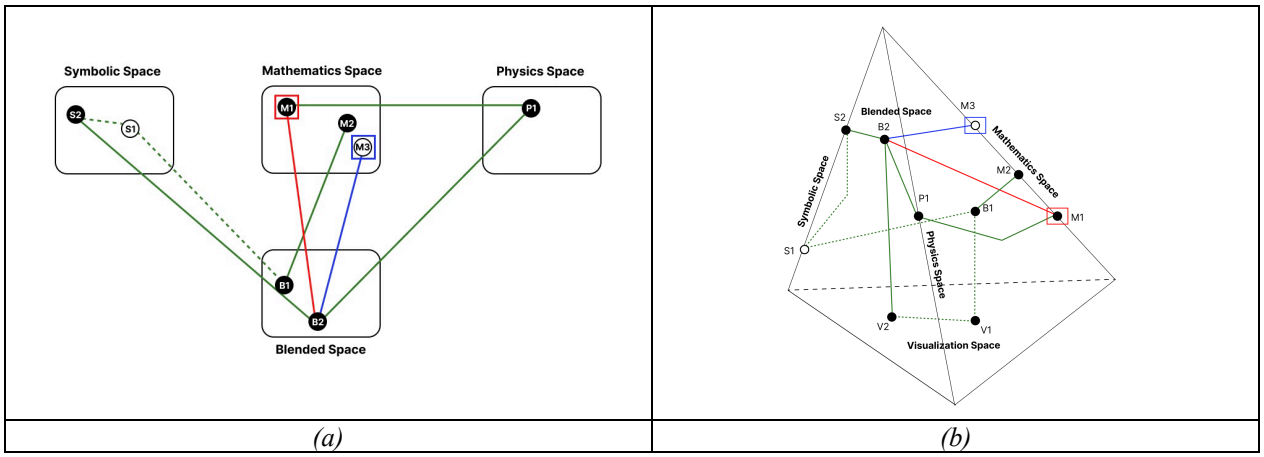
space includes mathematical and physical symbols and notations. The *physics space* encompasses elements related to physics knowledge (e.g., concepts, statements, and drawings about physics laws) without introducing new mathematical input. The *mathematics space* includes elements related to mathematical knowledge (e.g., drawings, functions, equations, derivatives, and integrals) without new physical input. The *blended space* consists of elements that integrate ideas from the symbolic, mathematics, and physics spaces, including equations and drawings. We denote enumerated elements assigned to each mental space by S1, M1, B1, P1, etc. In our study, we use the generic space to represent the overall structure based on inferred reasoning, as interpreted by the researchers. Since our analysis focuses on students' statements and reasoning, we exclude the generic space from our diagram.

Step 4. We trace students' dynamic reasoning about multiplicative structures by connecting the selected elements across all spaces and within each space. These connections are categorized into two groups: more confident and more tentative. These connections are defined similarly to the more confident and more tentative elements described in Step 1. To represent these connections visually, we use solid green lines for more confident connections and dotted green lines for more tentative connections.

Step 5. In contrast to the dynamic blending framework described by Van den Eynde et al. (2020), our approach accounts for dynamic interactions among elements and their modifications. Modifications refer to students' actions of activating or deactivating elements and connections, whether more confident or more tentative. Activation occurs when a student recognizes the relevance of an element to the current phenomena. Activated elements are represented by blue squared boxes, while deactivated elements are represented by red squared boxes. At this stage, we identify elements modified by students and repeated steps 2 to 4 for the updated set of elements. Consequently, a connection identified in Step 4 may initially be active and later become inactive. An activated connection indicates that a student has recognized the relevance of elements to the current phenomena. Activated explicit connections are represented by solid blue lines, while deactivated explicit connections are shown with solid red lines. Activated and deactivated implicit connections are denoted by dotted blue and red lines, respectively.

Figure 3a provides a schematic representation of the modified dynamic conceptual blending diagram, including all the coding conventions discussed. By elaborating on the four mental spaces, the connections among elements within those spaces, and their dynamic changes, we described students' moment-to-moment reasoning about the "product layer" when blending ideas from the symbolic, mathematical, and physical input spaces.

The Expanded VAP-Model



Zimmerman (1991) wrote that "visual thinking is so fundamental to the understanding of calculus that it is difficult to imagine a successful calculus course which does not emphasize the visual elements of the subject" (p.136). Other researchers contend that in order for students to construct a conceptual understanding of mathematical concepts, both visual and analytic reasoning must be present and integrated (Aspinwall & Shaw, 2002; Zazkis et al., 1996). There is also a literature dedicated to graph interpretation and construction outside of mathematics. For instance, Beichner (1994) developed a test to determine students' interpretations of kinematics graphs. Therefore, we consider visual representations (drawings) to be an important part of a student's moment-to-moment reasoning when connecting mathematics (calculus) to physics.

Our perspective extends the VAP-model which Zazkis (2013) developed to analyze students' visual (V), analytical (A), and physical (P) modes of reasoning, and the transitions between reasoning with graphs, functions, and physical concepts. The VAP-model diagram has a

tetrahedron shape where its edges represent three modes of reasoning. The transition between the modes is a disorderly, unpredictable path that moves upward with time and has a spiral form. The upward direction indicates that visualization and analysis become closer to each other as one moves to more advance levels.

In our extended model, we incorporate five reasoning spaces: symbolic (S), mathematics (M), physics (P), blended (B), and visualization (V). The spaces S, M, and P are represented by the vertical edges of a tetrahedron, with the blended space occupying the interior. The altitude of each element within the tetrahedron reflects its activation time, moving from bottom to top. The coding of elements and their connections in spaces S, M, P, and B follows the same scheme as the modified dynamic conceptual blending diagram (MDCBD) described earlier.

Under visualization space V we consider a visual blended space complemented by a conceptual layer developed through elaboration (e.g., Cunha et al., 2020). It is represented by elements located at the base of the tetrahedron, arranged chronologically (V1, V2, etc.). These elements, drawings, are connected to the blended elements in space B, with coding consistent across all spaces. Figure 3b provides a schematic representation of the expanded VAP-model diagram.

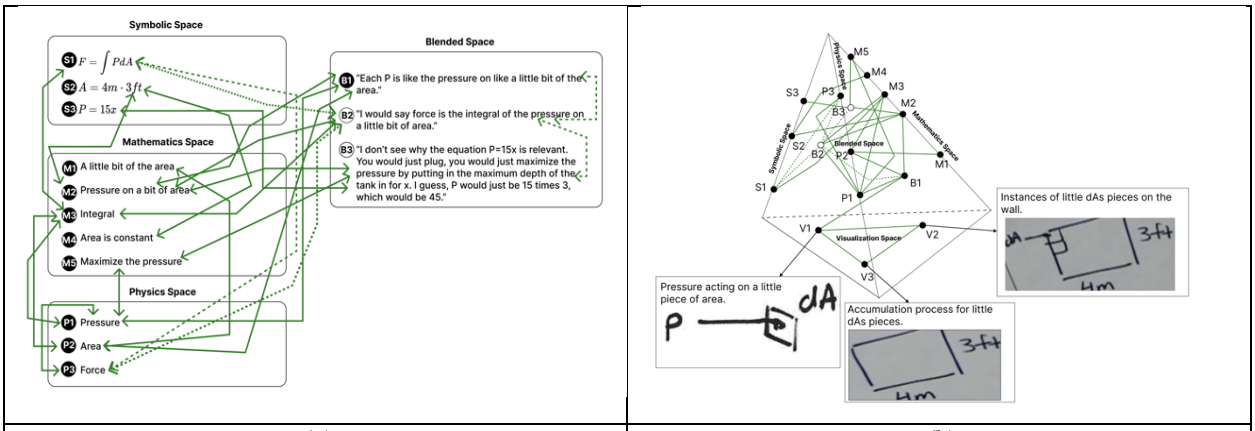
Figure 3. The MDCBD and the expanded VAP-model diagram.

Water Pressure Task: An Illustrative Example



In this section, we provide an illustrative example of how the above methods can be applied to analyze student's moment-to-moment dynamic reasoning about the "product layer" and the definite integral in an applied context.

The example comes from a college student, Matthew, enrolled in a second semester calculus-based physics course. Matthew was working on a Water Pressure Task (adapted from Sealey, 2014) during a one-to-one interview session. The task asked him to estimate the total force from the water pressure on a $4m \cdot 3ft$ vertical side wall of a tank, where the pressure was given by the function $P = 15x$ and x was the depth of the water. Here is a sample of interview data.

Matthew began by writing down the given data which led him to think that "Each P is like the pressure on like a little bit of the area." He claimed that he did not know the actual relation between the quantities in the given problem situation: "I don't know the actual relation, so I'm just guessing." Then he stated: "I would say force is the integral of the pressure on a little bit of area [$F = \int PdA$]. And umm the area is, well the area is constant essentially makes sense [$A = 4m \cdot 3ft$]." Matthew expressed some confusion about the depth of the water to be given as x,

where the tank is full of water. As a result, he stated that he did not see why the equation $P = 15x$ is relevant because "you would just plug, you would just maximize the pressure by putting in the maximum depth of the tank in for x." He continued: "So, I guess P would be 15 times 3, which would be 45." Later, Matthew added the graphical representation showing how the pressure is acting on a little bit of area (see drawings in Figure 4b).

We now illustrate (see Fig. 4) how this piece of data can be analyzed using MDCBD and the expanded VAP-model diagram given in Figure 3.

(a) *(b)*

Figure 4. The MDCBD and the expanded VAP-model diagram.

Discussion and Conclusion

Modeling Matthew's responses with the modified dynamic conceptual blending diagram (Figure 4a) and the expanded VAP-model diagram (Figure 4b) allowed us to conduct a fine-grained analysis of his reasoning in the given problem situation. We can see that Matthew applied knowledge resources coming from three input spaces to generate blending elements such as B1, B2, and B3. For instance, combing elements S1, M1, M2, M3, P1, P2 and P3, the student generated a blended element B2, which stood for the force definition via the integral representation and represented the "product layer" structured as PdA. Later, the student added a visual representation of the pressure acting on a little bit of area, which was captured by the element V1 of the visualization space and corresponded to the expression PdA. He demonstrated instances of little bits of area by V2 and blending it with the element V1 produced the accumulation process given by V3.

Overall, creating these diagrams enables researchers to move beyond analyzing word choices, gestures, or inscriptions, allowing for a deeper exploration of the meanings that students construct. For instance, the diagrams in Figure 4 helped us capture the complexity of Matthew's dynamic reasoning about the definite integral by identifying a set of knowledge resources and their interactions. Analyzing these diagrams alongside the data can help researchers refine their theories of students' mathematical understanding in applied contexts and significantly contribute to the existing literature on integration.

Although much research has made the case for the value of students' making sense of others' solutions, explanatory mechanisms for how such learning occurs are lacking. In this theoretical report, we consider how students' making sense of others' mathematical solutions may support learning from a radical constructivist perspective. We elaborate on radical constructivist constructs–social goals, cognitive perturbations, and reflective abstraction–and use these constructs to model how engagement with others' mathematical solutions may engender learning. We illustrate our model with a task we designed to promote students' meanings for spatial coordinate systems. We conclude with implications for research and teaching.

Keywords: Learning Theory; Cognition; Problem-based Learning

Students' making sense of classmates' solutions to mathematical problems (e.g., Webb et al., 2014) and with worked examples (e.g., Barbieri et al., 2023) has been positively associated with mathematics achievement. Although researchers have suggested reasons why such student activity may translate to achievement gains (Brown et al., 1992; Webb et al., 2023), they have not provided explanatory mechanisms for how such learning occurs for an individual. As a theory of learning focused on ways individuals develop knowledge, radical constructivism can provide such explanations. Broadly, radical constructivism explains how individuals build knowledge through persistent cognitive adaptation in concert with their lived experiences, and it defines learning in terms of shifts in an individual's mental structures (von Glasersfeld, 1995). In this theoretical report, we consider how students' working to make sense of others' mathematical solutions may support learning from a radical constructivist perspective (Table 1 provides colloquial descriptions of key terms).

Table 1. Colloquial descriptions of terms to orient the reader

Term	Brief colloquial description of constructs to orient the reader
Perturbation	Anything that creates a disturbance in a student's equilibrated (or settled) state. A perturbation is neutralized when the disturbance no longer exists.
Experiential Provocation	A perturbation that a student conceives as external in origin (i.e., from their interaction with their environment). Examples include other people, tasks, etc.
Social Goal	A goal a student establishes and assumes is shared with others.
Scheme	Goal-directed regularities in a student's functioning consisting of: (1) a perceived situation, (2) activity triggered by the situation, and (3) an anticipated result.
Cognitive Perturbation	A perturbation in which a student experiences discrepancies in their use of a scheme.
Affective experience	Experience in which a person's feelings, attitudes, or moods are activated.
Reflective Abstraction	A mechanism to explain an individual's modification of their schemes toward greater cohesion and generality.

Learning in Radical Constructivism and Connections to Social Interactions

In this section, we present and coordinate constructs to yield explanatory mechanisms through which a student may learn from others' solutions. First, we conceptualize that a student prompted to interpret a solution can experience a disturbance to their settled cognitive state (i.e., a perturbation). Second, as the student works to understand the solution, they can enact schemes relevant to their understanding of, and goals for, interpreting the solution. If the student experiences a cognitive perturbation, they may modify or reorganize their schemes to neutralize the disturbance. Such reorganizations can result in learning at a higher cognitive level (i.e., reflective abstraction). Below, we offer more elaboration on this process.

Schemes, Goals, and Learning

As students engage with others' solutions, we posit they would draw upon *schemes*. Drawing on von Glasersfeld (1995), Hackenberg (2014) defined schemes as "goal-directed regularities in a person's functioning that consist of three parts: a situation, an activity triggered by how the person perceives the situation, and a result of the activity that a person assimilates to her or his expectations" (p. 87). A student's schemes are activated through interactive experiences and involve their anticipation of the outcome of the interaction; thus, a student's goals are central to the schemes they enact. Any interaction prompting the student to draw on one or more schemes is a disturbance to the student's settled (equilibrated) state.

A student uses their schemes as part of their goal-directed activity. Moreover, in classrooms where sharing solutions is prioritized, the student may conceive they are working toward a *social goal* with others. Steffe and Thompson (2000) describe that an observer can identify a student working toward a social goal when the observer can infer the student (1) understands others in the group have intentions and (2) pursues a goal they assume is shared with the others. For example, a student may assume their classmates are working toward articulating solutions that are understandable to others and adopt this to inform their own goal-directed activity. We note even if other students are working toward a different goal (e.g., only intending to obtain a correct solution), a student's perception of a social goal can drive their goal-directed activity.

Experiential Provocations and Perturbations

If a student works to interpret classmates' solutions, they have experienced a disturbance to their equilibrium; von Glasersfeld (1980) broadly defines a *perturbation* as any input that creates a disturbance in a student's equilibrium. In this report, we use Steffe and Thompson's (2000) distinction between two kinds of disturbances (experiential provocation versus perturbation) based on the student's perception of the source of the disturbance (external versus internal). We refer to *experiential provocations* as disturbances that the student conceives to originate from their interaction with their environment (Steffe & Olive, 2002; Steffe & Thompson, 2000; Steffe & Tzur, 1994). We note the environment may include tasks, tools, teachers, other students, and, relevant to this report, others' solutions. Prompts that require a student to interpret a classmate's solutions can serve as experiential provocations from the student's perspective; in some cases, such an experiential provocation may lead to the student establishing a social goal with their classmates such as solving a particular problem or understanding a novel solution.

Experiential provocations are perturbations, but not all perturbations are *cognitive perturbations*. Students might be able to neutralize some perturbations using their current schemes and without experiencing any discrepancies as they activate and anticipate the results; such perturbations are *not* cognitive perturbations. Neutralizing other perturbations may involve a student experiencing discrepancies in their use of a scheme (Steffe & Olive, 2009; von

Glasersfeld, 1995). Such perturbations *are* cognitive perturbations. Cognitive perturbations can lead to a student reorganizing or modifying their existing schemes to achieve an equilibrated state (Steffe, 1991a, 1991b; Tillema & Gatza, 2024; von Glasersfeld, 1995). We conceptualize learning occurs through adjusting schemes in response to cognitive perturbations.

To illustrate, a student engaging in the goal-directed activity of interpreting a classmate's solution encounters a perturbation in the form of an experiential provocation. If they can interpret the classmate's solution without modification to their schemes (such as when the classmate's solution is nearly identical to their own), then the experiential provocation did not create a cognitive perturbation. However, if the student has difficulty making sense of a solution, then the experiential provocation could result in a cognitive perturbation. Such a cognitive perturbation could require the student to modify or reorganize their schemes to achieve an equilibrated state. We elaborate on this example and provide more details in the next section.

Types of Cognitive Perturbations and Affective Experiences

When a student experiences a cognitive perturbation, they may experience a minor or major cognitive perturbation. Many researchers have equated perturbations with major cognitive conflict or experiencing a 'problem' (e.g., Booker, 1996; Lerman, 1996; Simon et al., 2010). Although a major conflict is one type of cognitive perturbation, students can also experience minor cognitive perturbations without (consciously) experiencing a problem (Steffe, 2011; Steffe & Olive, 2002, 2009). If an individual neutralizes a perturbation, an observer's hypotheses about the steps taken can serve to differentiate major and minor cognitive perturbations. Major cognitive perturbations require more significant accommodations to a student's schemes to resolve, whereas minor cognitive perturbations may be easily resolvable with small adjustments to a student's schemes. Students may also experience non-neutralizable cognitive perturbations when they do not yet have schemes that allow them to neutralize the perturbation.

To exemplify this distinction, we again turn to a student work. A student might experience a minor cognitive perturbation when a solution has some feature or way of reasoning that is novel, and the student is able to neutralize the perturbation with minor modifications to their current schemes. If an observer infers the student undertakes a major modification or reorganization of their schemes, then the observer could characterize the perturbation as major. Finally, the student may experience a non-neutralizable cognitive perturbation if the student's current schemes do not support them in satisfactorily interpreting (from the student's perspective) the solution.

Moreover, as the above descriptions suggest, the perturbations students encounter, cognitive or otherwise, may bring forth different affective responses (Steffe & Wiegel, 1996; von Glasersfeld, 1995). For example, Steffe (2011) described, "A perturbation may be a surprise (e.g., unanticipated success, elation, or a sensation of pain)" (p. 258) and von Glasersfeld (1995) noted a perturbation may include "disappointment" (p. 65). A classmate's solution that a student finds hard to follow may lead them to experience frustration (i.e., a negative affective experience). In contrast, a solution they recognize as different from their own may result in a positive affective experience (e.g., pleasant surprise or delight). Thus, a student's affective experiences are important considerations in the design of learning environments that may engender reorganizations in students' schemes, thereby leading to learning.

Reorganization of Schemes and Reflective Abstraction

To further describe the reorganization of schemes that may occur after a perturbation, we use Piaget's (2001) notion of abstraction. Abstraction is a mechanism explaining an individual's modification of their schemes toward greater cohesion and generality. In this report, we use the

concept of *reflective abstraction*. In broad strokes, reflective abstraction entails two processes: a projection of actions or schemes to a higher level of thought and a reorganization that occurs at this higher level (Ellis et al., 2024; Piaget, 2001; Steffe, 2024; Tallman & O'Bryan, 2024; Tallman & Uscanga, 2020; von Glasersfeld, 1995). The reorganization can involve the creation of a coherent relationship or network of relationships between existing schemes as well as with new schemes (Piaget, 2001; Tallman & Uscanga, 2020). Such a reorganization involves taking prior meanings as input for further operating and thus can be considered a "higher" level. We note the cognizing subject need not be consciously aware of any reorganization.

Connecting to a students' affective experiences, a student might experience what an observer would call reflective abstraction as the student considers aspects of a solution they do and do not appreciate. This consideration could result in the student reorganizing their schemes to incorporate aspects of solutions they appreciated and avoid aspects they did not perceive as valuable (e.g., adopting steps or language from a particular solution they find useful and avoiding confusing lines of reasoning). In this way, affective experiences can work in concert with cognitive perturbations, leading to students' reorganizing their meanings at a higher level.

Other researchers have argued for the importance of supporting reflective abstraction and have provided suggestions for doing so. First, providing students repeated opportunities to develop schemes relevant to particular meanings can support their connecting their schemes and reasoning across similar (and different) contexts (Tallman & O'Bryan, 2024; Thompson, 2013). Second, providing occasions for students to compare activity across tasks can support reflective abstraction (Ellis et al., 2024; Piaget, 1976, 2001; Tallman & O'Bryan, 2024). We use these two suggestions to try to create opportunities for reflective abstraction as we describe below.

Exemplifying the Constructs: X-marks the Spot

We designed the *X-Marks the Spot Task* leveraging the above constructs to support students' work with spatial coordinate systems (described below). We included occasions for students to engage with their classmates' mathematical ideas with the intention they would set social goals. We conjectured multiple rounds of describing (to classmates) and interpreting descriptions (written by classmates) of locations in space could occasion experiential provocations for students. We hypothesized these experiential provocations could lead to major or minor cognitive perturbations along with associated affective experiences. Further, we provided deliberate opportunities for students to reflect on location descriptions at a higher level of thought. We intended these experiences to support students in engaging in reflective abstraction as they reorganize their meanings for organizing space.

Before describing the task, we first provide important background information about spatial coordinate systems. We then describe the task with the above constructs in mind. We provide examples from when we used the described tasks with elementary pre-service teachers (EPSTs) in a classroom setting to help contextualize how we view the constructs relating to the task.

Task Background: Spatial Coordinate Systems and Conventions

Researchers in mathematics education and spatial cognition have explored ways individuals conceive of and describe two-dimensional space (Lee, 2017; Piaget & Inhelder, 1967; Taylor & Tversky, 1996). In this report, we focus on a task designed to support students' developing meanings for spatial coordinate systems (Lee, 2017; Lee & Hardison, 2016; Lee et al., 2020; Paoletti et al., 2022). A spatial coordinate system is a coordinate system (CS) that entails either mentally overlaying a CS onto some perceived space or overlaying a space onto an already established CS. In either case, objects within the space can be located via coordinates. Radar on a

ship and GPS are different examples of spatial CSs (i.e., polar and Cartesian CSs, respectively).

We note there are countless ways an individual can organize space or construct a spatial CS. Cartesian and polar coordinates are two conventional spatial CSs. Conventions, including conventional coordinate systems, involve choices often developed or adopted for the purposes of efficiency and communication (Moore et al., 2019; Zazkis, 2008). Given the communicative value of such conventions, we conjectured we could support students in developing a social goal by providing them repeated opportunities to describe locations in space, with the anticipation of classmates' interpreting it, and to interpret classmates' descriptions of locations. This goal could lead to activity that supported students in reorganizing their schemes for organizing space towards more clear and efficient strategies. This conjecture is supported by Lee (2017), who found the goal of relaying instructions to others when locating an object in space supported ninth-grade students in developing viable spatial CSs much like conventional ones.

The Design of the *X Marks the Spot Task*

In the *X Marks the Spot Task*, we provide students with the map, buttons, and prompt shown in Figure 1a/b. Students can try each button and observe different overlays. Several overlays can be used to generate conventional coordinate systems: Star and Circles when coordinated can create a polar-like coordinate system; Vertical and Horizontal together can create a Cartesian-like coordinate system. Other overlays can be used to create unconventional yet viable ways to organize space (e.g., Figure 1b shows the map with the Waves and Vertical overlays). We conjecture the introduction of the task itself could serve as an experiential provocation for each student, and a student may experience minor cognitive perturbations as they develop associations between the action of clicking each button and the resulting change to the map.

After exploring the overlays, we ask students to mark an X. To support the creation of a social goal, we prompt students to use the overlays to provide a written description for their X's location that classmates will use. Thus, a student may assume their classmates have a shared goal of marking the same location. To achieve this social goal, a student may try to write a description clear enough for their classmates to mark a precise location.

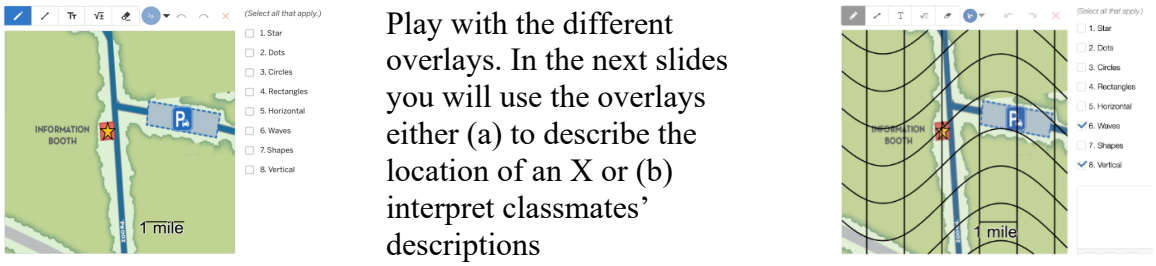

Figure 1. (a) The initial map, (b) initial prompt and (b) the map with Wave and Vertical overlays.

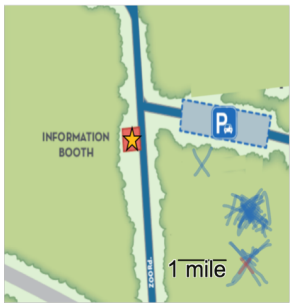
In classroom settings, we have EPSTs write their initial descriptions in groups. We share each group's description and the other EPSTs mark an X based on that description. After this, we engage in a whole class discussion using each group's description, original X, and an overlay of all the classmates' marked Xs (e.g., Figure 2). By comparing the locations of all the marked Xs, the EPSTs can determine whether they have achieved the *social goal* of marking their Xs in the same location. After several rounds of this activity, we provide numerous hypothetical classmate descriptions (Table 2) and ask students to mark an X from the description and provide feedback on the description to the hypothetical classmate. These hypothetical descriptions are intentionally

designed to (a) move from vague to more specific while (b) leading to more viable and/or conventional spatial CSs (i.e., polar and Cartesian).

Table 2. X Marks the Spot Task hypothetical descriptions and reflection opportunity

#	Description	Intention
1	Click the Star (1) and Circles (3) options. The X is on the 2nd circle on the line above the line going to the left from the star.	Polar-like CS that is intentionally vague
2	Click the Star (1) and Circles (3) options. Imagine the star is like a clock with the line going straight up being 12 o'clock and the line going straight down being 6 o'clock. The X is on the 4 o'clock line halfway between the 2nd and 3rd circle.	Polar-like CS that should provide enough information to locate an exact location that lies on a reference object in the CS.
3	Click the Star (1) and Circles (3) options. Imagine the star is like a clock with the line going straight up being 12 o'clock and the line going straight down being 6 o'clock. The X is 1.25 miles from the star halfway between 10 and 11 o'clock.	Polar-like CS that should provide enough information to locate an exact location that does not lie on a reference object in the CS.
[Reflection prompt for #1-3] Below are all the descriptions that used the Star (1) and Circles (3). Talk with your neighbor about which part of these descriptions was most helpful		
#4-6 provide similar phrasing with Cartesian-like CSs. There is also an opportunity for reflection on #4-6.		



The act of interpreting others' responses occasion *experiential provocations* which could result in a student experiencing a *cognitive perturbation*. We conjecture students would be able to interpret many descriptions using their current schemes (i.e., *without cognitive perturbation*). We also conjecture interpreting vague descriptions (e.g., Description 1 in Table 2) or observing discrepancies in the location of marked Xs for the same description (e.g., Figure 2c) could create *cognitive perturbations*. For example, consider one group's description for the marked X (Figure 2a/b). During a class conversation, the teacher presented an overlay of their classmates' marked Xs for their description (Figure 2c). Observing the variance of the marked Xs, the EPSTs had opportunities to consider ways each student interpreted "two boxes up from the bottom" (i.e., does this include the bottommost box?). In this case, an EPST may have experienced a *cognitive perturbation* as they attempted to understand their classmates' descriptions or interpretations.

"With the horizontal and vertical overlays selected, the x is in lower right hand side below the parking garage. It is one box over from the right and two boxes up from the bottom."

(a)

(b)

(c)

Figure 2. (a) A description EPSTs gave for the X marked in (b), and (c) the Xs marked by the rest of the students

We anticipate the descriptions could lead to a student having a positive affective experience in concert with a cognitive perturbation. A student might have positive affective experiences as they interpret descriptions they feel are interesting, clear, or lead to precise locations (e.g., #2-3 in Table 2). For example, when tasked to provide feedback on Description 3, one EPST stated, "No advice, very precise. I like that clock analogy." We conjecture the EPST might have experienced a minor cognitive perturbation along with a positive affective experience as they made sense of the clock analogy for the first time ("very precise. I like…").

Further, we conjecture tasking EPSTs to provide feedback to the author of each description can engender reflective abstraction as students reorganize their meanings for organizing space. For instance, we observed some EPSTs adopted phrases (and associated reasoning) that included elements from the classmate description involving the clock analogy when engaging the final prompt. This prompt asked them to describe the location of a novel X (Figure 3a). Using the visual in Figure 3b, one EPST described: "Using the idea of a clock with the top line being 12, go in between 4 and 5 o clock in the third outermost circle. The x is in the middle of this box." We note how the clock language this student incorporated aligns closely with a polar-like CS used in Descriptions #2-3 (Table 2). Thus, we conjecture reflecting across descriptions supported the student in reorganizing their meanings for organizing space to incorporate elements they found useful, lending themselves toward constructing a viable and conventional spatial CS.

(a) (b)

Figure 3. (a) the last X described by EPSTs and (b) an EPST's use of polar-like coordinates

Contribution, Implications, and Areas for Future Research

In this report, we elaborated on social goals, experiential provocations, cognitive perturbations, and reflective abstraction. Importantly, we characterize how affective experiences are intertwined with cognitive perturbations in ways that can engender learning. We are unaware of examples in which radical constructivist researchers detail ways positive or negative affective experiences interact with students' learning. Given the emphasis on collaborative group work, such learning is likely to occur in classrooms where students interpret others' responses positively and reorganize their own meanings as a result of these interpretations.

We conjecture the use of others' descriptions to potentially provoke cognitive perturbations was productive in this task due to the communicative nature of the mathematics at hand. We conjecture providing students with repeated opportunities to first generate their own descriptions and then interpret descriptions that communicate more or less effectively and efficiently increases the chances students would experience positive affective experiences and cognitive perturbations that could result in their reorganizing their meanings for organizing space. There are likely other concepts that rely heavily on communicative goals such as conventions, in which students could be supported in learning via the use of others' solutions. We call for additional research exploring this possibility. This and other research could build on prior work showing how examining others' solutions to mathematical problems can support learning (Barbieri et al., 2023; Webb et al., 2014). Further, such research could leverage the constructs outlined here to provide explanations for *how* examining others' solutions can lead to learning.

Exploring Gender Differences in Tertiary Mathematics-Intensive Fields: A Critical Review of Social Cognitive Career Theory

Huayu Gao
University of Auckland

Tanya Evans
University of Auckland

Gavin Brown
University of Auckland

Social Cognitive Career Theory (SCCT) has been extensively employed to elucidate the enduring gender differences in mathematics-intensive fields, with a particular emphasis on the complex interplay of motivational factors and extra-personal influences contributing to the underrepresentation of women. Although a plethora of empirical studies corroborate SCCT, three crucial aspects for refinement have come to the fore. First, the theory should place a more substantial emphasis on how cultural and contextual diversity influences academic choices. Second, given the dynamic nature of motivation, which evolves over time, more longitudinal analyses are imperative to capture their temporal trajectory, in contrast to the predominantly cross-sectional empirical studies. Finally, considering the intricate interplay between emotion and motivation, integrating the dimension of emotion into SCCT would significantly augment its explanatory power and provide a more comprehensive understanding of academic selection processes.

Keywords: Gender Differences; Mathematics-intensive Academic Fields; Social Cognitive Career Theory; Women in STEM

Gender disparities in tertiary mathematics-intensive fields and subsequent career trajectories remain a pervasive issue in most Western countries, with women consistently underrepresented. This persistent challenge is particularly evident in tertiary education, where women's participation in disciplines such as geoscience, engineering, economics, mathematics, computer science, and the physical sciences (chemistry and physics) is notably lower compared to their male counterparts (Ceci et al., 2014). Alarmingly, women's representation in computer science and electrical and electronic engineering has not only stagnated but has declined over time in Spain (Olmedo-Torre et al., 2018). Moreover, the gender gap transcends the boundaries of academia and permeates the workforce, with women's participation in math-intensive careers ranging from a mere 14% to 24% across various countries (Piloto, 2023), further underscoring the systemic nature of this disparity.

The persistent gender disparity in mathematics-intensive domains within tertiary education and its far-reaching implications for women's career trajectories necessitate a comprehensive exploration of the underlying factors perpetuating this inequality. Specifically, the underrepresentation of women in math-intensive fields serves as a critical antecedent to their subsequent underrepresentation in related career paths, exerting a profound influence on various aspects of society, including economic growth, wage equality, and the effective utilization of women's potential (Card & Payne, 2021). This underutilization of women's potential is particularly alarming, given that girls often outperform boys at most educational levels (OECD, 2015). To effectively address this multifaceted issue, Social Cognitive Career Theory (SCCT) has emerged as a valuable framework for elucidating the persistent gender gap, providing nuanced insights into the complex interplay of individual, social, and institutional factors that influence academic selection and career trajectories.

SCCT offers a robust framework for understanding academic choices and career development among boys and girls; however, empirical evidence indicates that further

refinement is necessary to enhance the theory's explanatory and predictive capabilities. This paper critically elucidates the limitations of SCCT, particularly its applicability across diverse cultural contexts, its reliance on cross-sectional empirical research despite the theory's dynamic nature, and its underestimation of emotional factors in academic decision-making. By identifying these limitations and proposing potential improvements, this theoretical paper aims to contribute to the ongoing evolution of SCCT, ensuring that it remains a relevant and effective tool for understanding individuals' choices and performance among boys and girls in increasingly complex and diverse environments.

Social Cognitive Career Theory: Key Concepts and Relations

Social Cognitive Career Theory, developed by Lent and Brown (1994), is a comprehensive framework that elucidates the intricate processes involved in academic selection and career development. Rooted in Bandura's (1986) social cognitive theory, SCCT emphasizes the interplay between individual agency and environmental factors in shaping academic choices and career trajectories. The theory posits three interconnected models—interest, choice, and performance, each centered around the core constructs of self-efficacy, outcome expectations, and goal representations. These constructs interact dynamically with personal factors, contextual influences, and learning experiences to shape career-related behaviors and decisions.

The Distinctive Roles of Self-Efficacy and Outcome Expectations in SCCT

Self-efficacy and outcome expectations are two key constructs in Bandura's (1986) social cognitive theory that play crucial roles in shaping individuals' selection processes. Self-efficacy refers to individuals' appraisals of their capability to organize and execute the requisite actions to attain desired performance outcomes. Crucially, self-efficacy is distinct from objectively assessed abilities. Social cognitive theory posits that human capabilities are malleable rather than fixed, asserting that successful performance in complex or demanding tasks typically necessitates not only foundational skills but also a robust sense of efficacy to effectively deploy those skills (Bandura, 1991). While self-efficacy focuses on individuals' confidence in their ability to execute actions, outcome expectations pertain to the anticipated consequences of those actions. Bandura (1986) classified outcome expectations into three categories: physical (e.g., tangible rewards), social (e.g., external validation), and self-evaluative (e.g., self-satisfaction). These expectations can exert a significant influence on career-related decisions and behaviors.

Bandura (1986) acknowledged the dual role of self-efficacy and outcome expectations, but he contended that these two forms of belief often differ in their relative potency, with self-efficacy serving as a more influential determinant of behavior. To illustrate this point, there are numerous instances in which individuals may anticipate valued outcomes resulting from a particular course of action but refrain from pursuing such action if they harbor doubts about their capabilities. However, in situations where outcomes are only tenuously linked to performance quality, outcome expectations may contribute to motivation and behavior independently (Bandura, 1989). This scenario may be especially pertinent to career development, as the intricacies of academic and career environments often yield only imperfect connections between performance quality and outcomes. For instance, an individual with a high ability for mathematics might opt to eschew mathematics-intensive career fields if they lack the support of significant family members; their anticipated outcome is far away from math.

The Structure of SCCT: Interest, Choice, and Performance Model

Interest model. Self-efficacy and outcome expectations, which incorporate values, are crucial in forming interests. Through repeated activity engagement, modeling, and feedback, children and adolescents refine skills, develop performance standards, and establish self-efficacy in specific tasks while acquiring outcome expectations (Lent & Brown, 1994). The development of self-efficacy and outcome expectations contributes to the formation of interests both directly and indirectly. These emerging interests lead to intentions for further activity exposure, increasing the likelihood of task selection and practice. Activity involvement results in performance attainments, such as successes and failures, which prompt the revision of self-efficacy and outcome expectancy estimates (Lent & Brown, 1994).

Choice model. The choice model builds upon the foundation of the basic interest model, extending it to encompass the developmental aspects of academic or career decision-making. This model conceptually divides the choice phase into several interconnected processes (Lent & Brown, 1994). Firstly, individuals express a primary choice goal, selected from their major interests. This choice goal represents the intention to pursue a specific career path or engage in a series of actions, such as aspiring to become an engineer. Secondly, individuals take concrete steps to implement their choice, which may include enrolling in relevant training programs or selecting an appropriate academic major. Finally, the model incorporates a feedback loop, wherein subsequent performance attainments, such as academic successes or failures and admission outcomes, shape future career behavior and choices.

Performance model. The performance model presented here adopts a broad definition of performance, encompassing both the level of achievement (e.g., academic grades) and indices of behavioral persistence (e.g., stability in a chosen major). This model emphasizes the significant roles played by ability, self-efficacy, outcome expectations, and performance goals while omitting interest as an intermediate mechanism. Lent & Brown (1994) posit that interest is more closely linked to selecting career or academic activities rather than setting performance goals. As the choice model suggests, choice goals contribute to determining the performance domains (e.g., work tasks) that an individual will pursue; however, the quality of performance attained may be partially contingent upon the level of one's performance goals. For instance, students who opt for an engineering major (choice goal) also establish goals pertaining to their grade performance in the requisite courses. Aspiring to achieve an A in math (performance goal) serves to regulate one's subsequent course-related behaviors (e.g., study time allocation).

Sociocultural Influences on Gender Disparities in Career Choice and Performance

The SCCT provides a robust framework for understanding how sociocultural factors contribute to gender disparities in career choice and performance from a motivational perspective. Specifically, the theory emphasizes the influence of personal factors, such as ethnicity and gender; contextual factors, including cultural norms, gender role expectations, and emotional support; and experiential factors, like personal achievements, vicarious learning, social persuasion, and physiological states, on career-related outcomes (Lent & Brown, 1994). These factors serve as antecedents of motivational variables, moderators of key relationships, or direct facilitators or barriers to career development. Furthermore, SCCT posits that gender differences in motivation are primarily influenced by social contexts. While acknowledging the role of innate aptitudes and interests, the theory suggests that these predispositions can be molded by environmental factors throughout an individual's life, highlighting the significance of the social contextual factors in shaping career-related outcomes and contributing to gender disparities.

Social Cognitive Career Theory: Empirical Evidence on Gender Perspectives

Gender Differences in Motivation

A growing body of research consistently demonstrates the predictive validity of self-efficacy and outcome expectations in relation to interests, choices, and performance, particularly in mathematics-intensive domains (Lent et al., 2017; Sheu et al., 2010). These findings underscore the central role of motivational variables in shaping individuals' math-related behaviors and outcomes. However, research also indicates that these motivational variables do not operate in a vacuum; they are influenced by broader socio-cultural factors, including gender-role identities. For instance, due to societal expectations and the internalization of gender norms, girls often exhibit lower self-efficacy and outcome expectations, as well as reduced interest in math-intensive fields compared to their male counterparts (Luo et al., 2021; Lv et al., 2022).

The Impact of Family and School on Gender-Based Motivational Differences

As essential carriers of socio-cultural influences, family and school have been widely recognized as critical determinants of choices and performance. The family, as the primary social unit, provides children with their initial exposure to gender-specific expectations and roles. This early socialization within the family context lays the foundation for the development of gender-specific beliefs and behaviors. Schools, on the other hand, provide opportunities to refine these beliefs and behaviors. Therefore, the complementary relation between family and school is crucial in the evolution of children's career aspirations.

Family factors. The family factors, including socioeconomic status (SES), parental beliefs, and parental behaviors, exert a profound influence on individuals' academic achievements and career aspirations. SES, a multidimensional construct encompassing income, education, and occupation, has been consistently linked to children's academic choices. Gao et al. (2024) demonstrated that SES accounted for a substantial 50% of the variance in adolescents' mathematics achievement in New Zealand. Mathematics achievement serves as a critical prerequisite for students' selection of math-related majors (Wang & Degol, 2013). Higher SES families tend to provide greater resources, support, and extracurricular activities that foster the development of mathematical skills (Bandura & Bussey, 2004; Wang & Degol, 2013), thereby fostering the formation of interests and influencing future choices. Conversely, low-SES families often prioritize meeting their children's fundamental daily necessities over fostering the pursuit of mathematics-related competencies, with girls' academic performance and development receiving even less attention and support.

Beyond SES, parental beliefs about gender also exert an important influence on children's confidence and career aspirations. Empirical evidence suggests that parents' perceptions of their children's abilities can have a more significant impact on their offspring's self-beliefs and career goals than actual performance (Fredricks & Eccles, 2002; Parsons et al., 1982). More specifically, parents who endorse gender stereotypes in math tend to underestimate their daughters' abilities while overestimating their sons' abilities, and they may even place less importance on their daughters' participation in tertiary math-intensive majors (Parsons et al., 1982; Nicoletti et al., 2022). Moreover, parental behaviors often vary based on gender, inadvertently reinforcing gender disparities. Research has revealed that parents are more inclined to engage in scientific discussions with their sons and provide them with related resources while unintentionally limiting opportunities for their daughters (Crowley et al., 2001; Meece et al., 2009). This differential treatment can perpetuate gender stereotypes and contribute to the underrepresentation of women in math-intensive areas (Jacobs et al., 2005).

School Factors. Alongside family influences, schools and tertiary institutions also play a crucial role in shaping gender-specific beliefs and influencing students' motivation and career aspirations. Professors, teachers and peers are key agents in this process, with their beliefs, expectations, and interactions contributing to gender disparities in math-related participation. Specifically, teachers' beliefs and expectations about gender-specific stereotypes can significantly impact students' motivation. For example, teachers may emphasize girls' efforts over abilities in mathematics, leading to lower expectations and diminished confidence among girls (Patrick et al., 2007; Meece et al., 2006). However, the effect of teacher support can vary by grade level, with elementary school environments often favoring girls, while secondary schools tend to emphasize performance goals that may disadvantage them (Wang & Degol, 2013).

Peers also play a significant role in influencing math-related achievement and participation. Girls in supportive peer groups tend to excel in mathematics and science; however, the Big-Fish-Little-Pond Effect suggests that while being surrounded by high-achieving peers can provide academic stimulation and motivation, it may also lead to a diminished self-concept. This phenomenon occurs because individuals tend to compare their performance to that of their peers, and in a group of high achievers, even objectively strong performers may perceive themselves as less competent, thus lowering their academic self-concept (Leaper et al., 2012; Marsh, 1984). In addition to the influence of teachers and peers, it is important to consider the potential impact of single-sex schooling on girls. Docherty et al. (2020) discovered a peculiar discrepancy in engineering enrolments at the University of Canterbury (New Zealand) between 2005 and 2017. The study revealed that the proportion of female enrolments in engineering from single-sex high schools was disproportionately high, accounting for 56% of all female students in engineering, despite the fact that only a small proportion of girls (15.73%) attend single-sex schools (MoE, 2023). This finding suggests that single-sex settings may play a role in shaping girls' academic choices. Moreover, Smith and Evans (2024) reported that girls attending single-sex schools perform better in mathematics and science than their co-educational counterparts in New Zealand. They suggested that single-sex environments may reduce stereotype threat for girls by providing them with a more supportive and nurturing learning context, thereby fostering their confidence and interest in traditionally male-dominated fields. However, the research on the effectiveness of single-sex schooling is complicated, with some studies suggesting that single-sex schools do not have any significant advantages for girls in pursuing math-related goals compared to co-educational settings (Gao et al., 2024).

Social Cognitive Career Theory: Limitations and Pathways for Future Development

The aforementioned studies offer considerable empirical evidence that substantiates the SCCT, especially concerning its capacity to elucidate gender disparities in mathematics-intensive domains. Nevertheless, while these studies corroborate the SCCT framework, it is imperative to acknowledge that certain research also underscores the theory's limitations. These constraints encompass the inadequate emphasis on cultural diversity, the predominant reliance on cross-sectional research, and the absence of an emotional dimension. The limitations identified through our summary provide valuable guidance for future scholarly efforts to refine and expand the SCCT framework, thereby strengthening its explanatory capacity and applicability across diverse contexts.

Placing Stronger Emphasis on Cultural Diversity to Strengthen SCCT

The SCCT underscores the crucial role of sociocultural factors in shaping gender differences, but it falls short in providing a comprehensive analysis of the social environment due to its

Western origins, which may limit its universal applicability across diverse global contexts. Despite distinguishing between the social and biological concepts of gender and ethnicity, with a primary emphasis on the former, the SCCT has not adequately addressed the influence of cultural backgrounds in different countries on individuals' motivation and career choices. Recent cross-cultural studies investigating the application of SCCT have yielded inconsistent results, underscoring the complex interplay between cultural factors and academic choices. For example, Wang et al. (2023) identified significant gender disparities in the application of SCCT within the Chinese educational system, with girls exhibiting lower interest and requiring greater confidence in mathematics compared to boys. Conversely, Gao et al. (2024) found no such gender discrepancies in New Zealand. Moreover, Michaelides et al. (2019) observed that in some Eastern European and Islamic countries, girls outnumbered boys in math-intensive fields and demonstrated higher confidence in mathematics. These divergent findings highlight the need for a more nuanced understanding of the cultural factors influencing academic selection processes and suggest that the explanatory power of SCCT may vary considerably across different cultural contexts.

To address the limitations of SCCT in capturing the complexities of cultural influences on academic and career decision-making processes, future research should prioritize the investigation of cultural background factors and their underlying mechanisms in shaping individuals' educational and vocational trajectories. This endeavor necessitates the development of a substantial body of cross-cultural empirical research alongside the creation of culturally specific models that can effectively capture the nuances of diverse contexts. For instance, in Iran, where women's status is relatively low, science, technology, engineering, and mathematics (STEM) fields are often perceived as pathways to higher income and social status, potentially leading women to choose these fields to improve their social standing (Stoet & Geary, 2018; Michaelides et al., 2019). In contrast, in some Western countries with higher levels of gender equality, girls typically excel across various disciplines and face a wider range of career options. This diversity of choices may result in a lower proportion of girls choosing STEM fields, as they are more likely to make decisions based on their absolute abilities, whereas boys are more likely to make choices based on their relative abilities (Wang & Degol, 2013). As evidence gradually accumulates, it will serve as a foundation for refining and expanding the theory, enabling it to more accurately account for the intricacies of academic selection processes across various cultural landscapes.

Employing Longitudinal Studies to Validate SCCT

The cross-sectional research designs employed by the vast majority of empirical investigations examining the tenets of SCCT pose inherent limitations in their ability to fully capture the dynamic feedback mechanisms central to the theory. Specifically, SCCT posits a complex interplay of feedback loops in which an individual's self-efficacy beliefs and outcome expectations exert a profound influence on their choices and performance. In turn, the consequences of these choices and the resulting achievements serve to reshape future self-efficacy beliefs and outcome expectations, creating a continuous cycle of reciprocal determinism (Lent et al., 1994). However, cross-sectional studies are unable to adequately test these intricate relations of reciprocal determinism.

To fully elucidate the intricate dynamics posited by SCCT, a longitudinal approach is indispensable. Such research designs facilitate the exploration of temporal relations and enable the mapping of individual trajectories across extended timeframes (Ployhart & Vandenberg, 2010). By gathering data at multiple junctures, researchers can delve into the nuanced ways in

which self-efficacy and outcome expectations evolve in response to diverse experiences and interventions, thereby offering a more comprehensive and ecologically valid assessment of SCCT (Navarro et al., 2014). Furthermore, longitudinal studies possess the unique capacity to illuminate the directionality of relations between variables, tackling questions of causality that remain elusive in cross-sectional designs (Zapf et al., 1996).

Integrating Emotional Dimensions to Broaden SCCT

The SCCT has a notable limitation in its insufficient emphasis on the role of emotions in shaping individuals' academic choices. While the theory primarily focuses on explaining these choices from a motivational perspective, highlighting the interplay between self-efficacy, outcome expectations, and interest, it does not adequately address the significant influence of emotions on cognitive functions crucial to academic decision-making. If the value of outcome expectation negatively influences individuals' math achievement, it is challenging to explain using SCCT. However, by incorporating emotion into the SCCT framework, the result becomes plausible. It can be argued that a higher value may induce math anxiety, consequently lowering achievement. More specifically, emotions play a critical role in shaping cognitive processes such as attention, memory, and problem-solving (Lerner et al., 2015), which are essential components of academic-related decisions. Positive emotions have been associated with higher levels of engagement, deeper learning, and improved performance, contributing to stronger self-efficacy and more favorable outcome expectations (Reschly et al., 2008). In contrast, negative emotions can disrupt these cognitive processes, leading to decreased motivation and poorer academic outcomes (Pekrun, 2006). Consequently, the lack of sufficient attention to the emotional dimension within the SCCT framework may limit its explanatory power in fully capturing the complex dynamics of the academic choice process.

To address this limitation, future research should focus on integrating emotional dimensions into the SCCT framework. For example, Pekrun's (2006) Control-Value Theory (CVT) combines motivation and emotion to predict individuals' choices and performance in educational contexts. In CVT, control refers to individuals' beliefs about their abilities, i.e., whether they believe they can complete a task, while value includes intrinsic value (such as interest) and extrinsic value (such as the importance of the task). When individuals perceive their abilities as insufficient (low control) but simultaneously consider the task outcomes to be crucial for them (high extrinsic value), they often experience negative emotions such as anxiety or helplessness, which can adversely affect their academic performance. Therefore, by incorporating emotional factors into the SCCT framework, researchers can more comprehensively explain the dynamic interactions between emotions, cognition, and situations, thus establishing a more realistic theoretical model to describe individuals' academic choices and behaviors. This integration not only expands the theoretical perspective of SCCT but also significantly enhances its applicability to diverse populations and contexts, especially those groups and environments where emotional responses vary significantly.

Integration by Substitution: A Justification Based on Multiplication, Measurement, and Inverse Proportions

Andrew Izsák
Tufts University

Researchers have argued that interpreting definite integrals and their notation as summations of small amounts of a target quantity (Adding Up Pieces) is especially productive for applied problems. Jones and Fonbuena (2024) extended research on Adding Up Pieces by providing an analysis of integration by substitution grounded in quantitative reasoning. The present theoretical paper develops a complementary justification that makes three contributions. First, whereas past research on integration has rarely foregrounded explicit, quantitative meanings for multiplication, the analysis presented here is based on connections between multiplication and coordinated measurement with two units. Second, the analysis presented here uses coordinated measurement to explain how, across diverse situations, small amounts of a target quantity can be understood as products. This supports reasoning about Riemann sums and areas as approximations for definite integrals. Finally, the analysis provides a new justification for integration by substitution that relies on rectangular areas and inversely proportional relationships.

Keywords: Calculus, Integration, Multiplication, Measurement

Introduction

A growing body of research has reported on students' interpretation and construction of integrals, especially when solving problems in physics and other applications outside of pure mathematics (e.g., Cui et al., 2006; Jones & Ely, 2023; Nguyen & Rebello, 2011; Oehrtman & Simmons, 2023; Thompson, 1994a). Recently, Jones and Fonbuena (2024) pointed out that this literature has largely overlooked the central topic of integration by substitution, or u-substitution. They then developed a conceptual analysis of the topic grounded in Thompson's account of quantitative reasoning (e.g., Smith & Thompson, 2007; Thompson, 1990) but, in that analysis, stopped short of discussing explicit, quantitative meanings for multiplication. The present report develops a complementary analysis based on (a) connections between multiplication and coordinated measurement with two different units and (b) inversely proportional relationships. The results add to a growing body of studies that have examined how quantitative interpretations of multiplication based on coordinated measurement can support calculus learning (e.g., Beckmann & Izsák, 2024; Izsák, 2023)

The paper is organized into four sections. In the first, I give a brief review of research on definite integrals that includes a summary of the results reported by Jones and Fonbuena (2024). A main point will be that past research has often referred to multiplication in connection with the $f(x) \bullet \Delta x$ and $f(x)dx$ notations without articulating an explicit, quantitative meaning for the operation. In the second, I give a brief overview of research on multiplication with quantities and point to complexities highlighted in that research that have yet to be grappled with directly in research on definite integrals. In the third, I review recent work on a coordinated measurement meaning for multiplication that can provide coherence across a wide range of problem situations and topics, including situations that often serve as applications of integration. A main point will be that the coordinated measurement meaning for multiplication can support using Riemann sums and rectangular areas to approximate definite integrals across diverse situations. In the

fourth, I explain how the coordinated measurement meaning for multiplication can support a justification for integration by substitution that is based on Riemann sums and inversely proportional relationships.

Review of Research on Definite Integrals

Applying definite integrals to solve problems about physical situations requires reasoning in terms of quantities, such as lengths, time, work, electric charge, etc. Past research has provided a variety of perspectives on such reasoning, and much of it has been grounded in Thompson's account of quantitative reasoning (e.g., Thompson, 1994b; Thompson, 2011). One line of work has focused on different interpretations of definite integrals and their notation. Thompson and colleagues (e.g., Thompson et al., 2013; Thompson, 1994a; Thompson & Silverman, 2008) have argued that interpretating integrals as accumulations from rates of change can facilitate reasoning about the Fundamental Theorem of Calculus. In other work, Jones (e.g., 2013, 2015) has found that college students can interpret the $\int_a^b f(x)\,dx$ notation as indicating addition of small pieces (Adding Up Pieces), denotating boundaries of a region in the plane, and signifying a function whose derivative is the integrand. At the same time, researchers have debated whether or not, when using Adding Up Pieces, students should understand those pieces as composed through multiplication (e.g., Ely, 2017; Jones et al., 2017; Jones & Ely, 2023; Thompson & Harel, 2021).

A second set of perspectives has decomposed reasoning about definite integrals into layers that include ones focused on local relationships (e.g., Oehrtman, & Chhetri, 2015; Oehrtman, & Simmons, 2023; Seeley, 2014; Stevens & Jones, 2023; Von Korff & Rebello, 2012). As one example, Sealey articulated the *Riemann Integral Framework*, which is a mathematical decomposition of Riemann sums and definite integrals into five layers that she called the Orientation, Product, Sum, Limit, and Function layers. She reported that university calculus students had the most trouble working in the Product Layer, which is where students interpret the $f(x)dx$ notation. As a second example, Oehrtman and Simmons proposed *Emergent Quantitative Models* as a tool for tracing how students' attention shifts across three scales—named the Basic, Local, and Global models—when constructing definite integrals. A Basic model relates quantities with constant values, a Local model restricts a basic model to small regions where varying quantities are approximately constant, and a Global model is a sum based on Local models. Thus, similar to the Product Layer, the Local model is where students would reason about products of the form $f(x) \bullet \Delta x$.

Research on definite integrals summarized above has consistently highlighted the importance of reasoning about small pieces of a target quantity but, to the best of my knowledge, Jones and Fonbuena (2024) were the first to analyze such reasoning in the context of integration by substitution. They began their conceptual analysis by decomposing Adding-up-Pieces reasoning into three aspects—*partitioning* a quantity into small pieces (precursors to differentials), *determining the target quantity* in each of those small pieces (similar to the Product Layer and the Local model mentioned above), and *summing* the small pieces of the target quantity to get the total quantity (similar to the Global model mentioned above). Their analysis traced the consequences for each of these three aspects when one changes from one input variable to another. They described these consequences as "conversions" of the partition, integrand quantity, and interval of summation.

Although past research on definite integrals has frequently attended to small intervals where relationships between quantities are approximately linear, to the best of my knowledge, none of

these studies has addressed explicitly an associated, quantitative meaning for multiplication. The next section explains why this omission is consequential.

Review of Research on Multiplication with Quantities

In comparison with the literature on definite integrals, theoretical and empirical research on multiplication is much older. For the present analysis of integration, I concentrate on theoretical results. Theoretical perspectives on multiplication have included classifications of problem situations in which one typically multiplies or divides (e.g., Greer, 1992; Nunes & Bryant, 1996; Vergnaud, 1983, 1988); interpretations, or meanings, of multiplication as an operation on quantities (e.g., Davydov, 1992; Izsák & Beckmann, 2019; Schwartz, 1988; Thompson & Saldanha, 2003); and psychological primitives that include repeated addition (Fischbein et al., 1985), splitting (e.g., Confrey, 1994), and units coordination (e.g., Hackenberg et al., 2023; Hackenberg & Tillema, 2009; Steffe, 1988; 1994). The analysis of integration by substitution presented below makes the most direct contact with the strands focused on classification and on interpretations of multiplication as an operation on quantities.

For classification research, I highlight Vergnaud's (1983, 1988) seminal contribution. He has analyzed mathematical structures for multiplying with quantities and distinguished two primary subtypes. *Isomorphism-of-measure-spaces* (I-o-M) situations are ones where the multiplicative structure consists of a simple direct proportion between two measure spaces, M_1 and M_2 (1983, p. 129). Here the direct proportion is often viewed as a rate of change. *Product-of-measure-spaces* situations (P-o-M) are the Cartesian composition of two measure spaces, M_1 and M_2, into a third, M_3 (1983, p. 134). In anticipation of approximating integrals, notice that Riemann sums use rectangular areas, associated with P-o-M situations, to model both I-o-M situations (e.g., integrating velocity to get distance) and P-o-M situations (e.g., integrating force to get work). One response would be to abandon using rectangular areas as generic models for products. Indeed, some researchers (e.g., Jones & Ely, 2023; Thompson et al, 2013) have claimed that the area-under-a curve interpretation for definite integrals is insufficient for modeling physical situations. An alternative response, pursued in subsequent sections of this paper, is to seek a meaning for multiplication that spans I-o-M situations and P-o-M situations. Such a meaning could help students understand how rectangular areas and, thus, Riemann sums can be used to express products and approximate definite integrals across both I-o-M and P-o-M situations.

Research on interpretations, or meanings, of multiplication as an operation on quantities has consistently focused on the role of units and, by implication, measurement. Izsák and Beckmann (2019) organized these interpretations into two categories, those that emphasize unit transformations and those that emphasize measurement. In one example of the unit transformation approach, Schwartz (1988) argued that when addition is used to model situations both addends and the sum refer to the same unit (e.g., 2 miles + 3 miles = 5 miles) but, when multiplication is used, the units of the factors are transformed into units of the product (e.g., 2 miles per hour • 3 hours = 6 miles). In a second example of the unit transformation approach, Thompson and Saldanha (2003) stated: "By convention, the standard unit of the product quantity is defined as that amount made by one unit of each constituent quantity" (p. 103).

Measurement might be implied in unit transformation approaches but is addressed more explicitly in further quantitative interpretations of multiplication. Thompson (1994b) articulated the following definition of a quantity when introducing his theory of quantitative reasoning: A quantity consists of "an object, a quality of the object, an appropriate unit or dimension, and a process by which to assign a numerical value to the quality" (p. 184). This definition implies that numbers are outcomes of measurement: They express how many units, or how much of a unit,

exhaust the extent of the "quality" in question. We often use the term "multiplication" to refer to this fusion of number and measurement—for instance, we might say that a taller building is three times the height of a shorter building when what we mean is that three of short height exhaust the tall height. Such multiplicative language, based on measurement with a single unit, is often taken as evidence of "multiplicative thinking." In such cases, measurement, numbers, and multiplication are intertwined.

Multiplication as Coordinated Measurement and Riemann Sums

Further research on quantitative meanings for multiplication has emphasized coordinated measurement with two different units (e.g., Beckmann & Izsák, 2015; Davydov, 1992; Izsák & Beckmann, 2019). Davydov argued that the essential situation for multiplication is one where it is impractical to measure some quantity of interest with a given unit because the unit is much smaller than the quantity one wishes to measure. The solution is to coordinate the smaller unit with an intermediate unit purposefully chosen to measure the quantity of interest more conveniently. As an example, if one wished to determine the number of teaspoons in a volume of milk, one might use cups as an intermediate unit, determine how many teaspoons are in 1 cup, and determine how many cups are in the target volume. Here the two measurement units for the target volume are teaspoons and cups.

Inspired by Davydov (1992), Izsák and Beckmann (e.g., Beckmann & Izsák, 2015; Izsák & Beckmann, 2019) have explicated a coordinated measurement meaning for multiplication. Figure 1 shows an equation where N, M, and P are each outcomes of measurement, as discussed in the previous section. The product amount is measured simultaneously in base units, P base units, and in group units, M group units. N expresses the measure of 1 group unit in terms of base units. Consider again our milk example, where a volume is measured in both teaspoons (base units) and cups (group units). If 48 is the measure of 1 cup in terms of teaspoons, and 7 is the measure of the target volume in terms of cups, then 336 is the measure of the target volume in terms of teaspoons. Following the meaning in Figure 1, our $N \bullet M = P$ equation would be 48 (teaspoons in 1 cup) • 7 (cups in 1 target volume) = 336 (teaspoons in 1 target volume).

N	•	M	=	P
How many base units make one group unit?		How many group units make one product amount?		How many base units make one product amount?

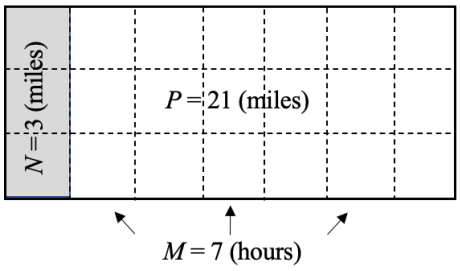

Figure 1. A coordinated measurement meaning of multiplication (Izsák & Beckmann, 2019, p. 91)

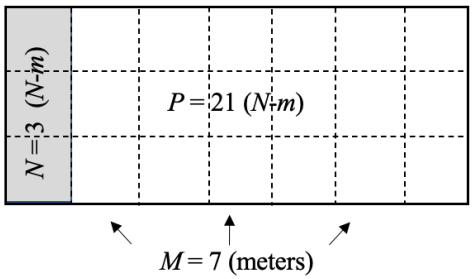
Izsák and Beckmann (e.g., Beckmann & Izsák, 2015; Izsák & Beckmann, 2019) have pointed out that the coordinated measurement meaning for multiplication works with positive real numbers, can tie together diverse situations using a single shared quantitative structure, and challenges the field to rethink several established results. One of those results is the partition of multiplication situations into structurally distinct subclasses—for instance I-o-M and P-o-M situations.

Figure 2 shows how the coordinated measurement meaning for multiplication summarized in Figure 1, combined with rectangular area, can fit both I-o-M and P-o-M situations. The same rectangular area represents a product amount measured both in base units (each small square represents 1 base unit) and in group units (each column represents 1 group unit). One can think of these situations as Basic models (Oehrtman & Simmons, 2023) for two common applications of integration. Figure 2a fits a problem about change in location (a walked distance). If each

small square represents 1 mile (1 base unit) and each column corresponds to 1 hour (1 group unit), then the measure of one column is 3, the change measured in hours is 7, and the change measured in miles is 21. The assignment of units to *N*, *M*, and *P* is in contrast to the more usually assignment of units: 3 miles per hour • 7 hours = 21 miles. Figure 2b fits a problem about change in energy. If each small square represents 1 Newton-meter (1 base unit) and each column corresponds to 1 meter (1 group unit), then the measure of one column is 3, the change measured in meters is 7, and the change measured in Newton-meters is 21. Again, this assignment of units to *N*, *M*, and *P* is in contrast to the more usually assignment of units: 3 Newtons • 7 meters = 21 Newton-meters.



The examples in Figure 2 indicate how attention to two measurement units, made explicit in the $N \bullet M = P$ equation, allows one to see parallels (i.e., there is an isomorphism) between rectangular areas and the two applied situations, one an I-o-M situation and one a P-o-M situation. The same reasoning demonstrated here with a Basic model works equally well with Local models (e.g., Oehrtman & Simmons, 2023). Thus, Riemann sums based on rectangular areas can be used to approximate target quantities in both I-o-M and P-o-M situations. Learning to think about multiplication in terms of coordinated measurement could help students understand how rectangular areas can be used as a generic models for products and why multiplication based on rectangular areas gives the same numerical values as the corresponding multiplication in applied situations. The next section relies on Riemann sums based on rectangular areas to develop a justification for integration by substitution.

Shading corresponds to 1 hour.
Walk is measured in hours (7) and in miles (21).

N	•	M	=	P
3 miles in 1 hour	•	7 hours in 1 walk	=	21 miles in 1 walk

(a)

Shading corresponds 1meter.
Change is measured in meters (7) and in *N-m* (21).

N	•	M	=	P
3 *N-m* in 1 meter	•	7 meters in 1 displacement	=	21 N-m in 1 displacement

(b)

Figure 2. Coordinated measurement and rectangular area. (a) An I-o-M situation. (b) A P-o-M situation.

Coordinated Measurement and Integration by Substitution

The analysis of integration by substitution presented here is based on Riemann sums and, similar to the analysis given by Jones and Fonbuena (2024), is based on a change in the independent variable through function composition. Consider the Moving Truck situation presented below. Speed is taken to be piece-wise constant, and the discussion of Figure 2a above justifies using rectangular areas to represent distances. Figure 3a uses rectangular areas to show distance traveled for each segment of the trip. Think of the graph in Figure 3a as representing a simple Riemann sum.

Three friends are driving a moving truck from Detroit to Boston.

- *Steve takes his turn first and drives 4 hours at a steady speed of 60 miles each hour. At the end of his turn, the friends stop and rest for 1 hour.*
- *Chara takes her turn second and drives 4 hours at a steady speed of 72 miles each hour. At the end of her turn, the friends stop and rest for 1 hour.*
- *Zawadi takes her turn last and drives 4 hours at a steady speed of 54 miles each hour.*

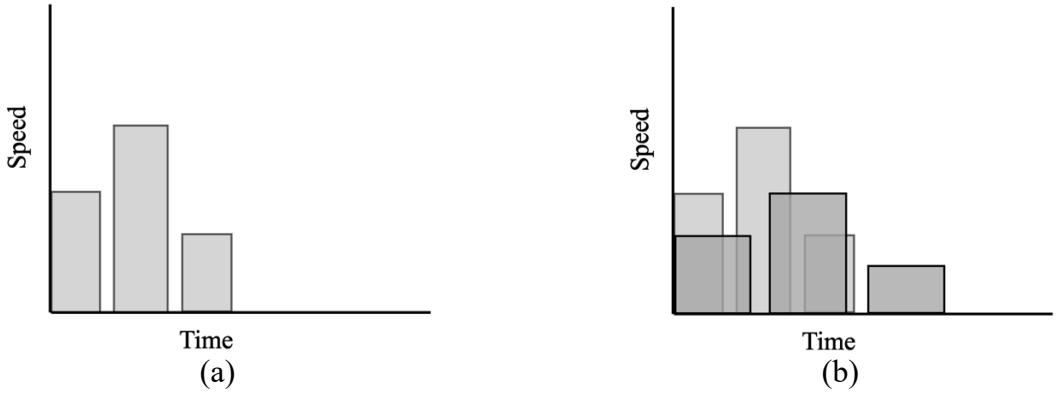


Figure 3.Moving Truck situation. (a) Time measured in hours. (b) Time measured in playlists.

Now suppose that the three friends invent a new unit based on the time it takes to go once through a playlist that they listen to as they drive. Suppose that 1 playlist is 2/3 of an hour. The miles driven in 1 playlist are fewer than the miles driven in 1 hour by a factor of 2/3. Thus, speeds measured in miles per playlist are 2/3 of the corresponding speeds measured in miles per hour. Simultaneously, the number of playlists it takes to measure any given duration of time is 3/2 the number of hours it takes to measure the same duration of time. Figure 3b superimposes onto Figure 3a a second graph of speeds and times for each segment of the trip based on playlists. Think of the graph in Figure 3b as representing a new Riemann sum that expresses distances when time is measured in playlists. Comparing areas when measuring time in hours and when measuring time in playlists, notice that we have an inversely proportional relationship: Shrinking in the vertical direction is offset by stretching in the horizontal direction, the distance for each trip segment measured in miles is the same whether time is measured in hours or in playlists, and the total shaded areas corresponding to the two Riemann sums are the same. Again, reasoning based on a Basic model applies equally well to reasoning based on a Local model.

In the Moving Truck situation, there is a single linear relationship between the original input variable, hours, and the new input variable, playlists. If students used a different unit of time for each segment of their journey, the same argument would work, each rectangle associated with time measured in hours (Figure 3a) would have the same area as the corresponding rectangle with time measured in the new unit. Thus, the Riemann sum depicted in Figure 3a would still have the same area as the transformed Riemann sum depicted in Figure 3b. The statement of integration by substitution is then plausible because the two definite integrals are approximated by the same sequence of values.

Discussion and Conclusion

To the best of my knowledge, the justification for integration by substitution presented here is both original and at odds with more traditional justifications. In traditional calculus courses, integration by substitution is often discussed as the "reversed chain rule," which can be

expressed with the following equation: $\int_a^b f'\big(g(x)\big)\, g'(x)dx \;=\; \int_{g(a)}^{g(b)} f'(u)du$. (A more general statement holds where f is continuous.) The student is tasked with recognizing functions f, g, and g' in the integrand on the left-hand side of equation that afford the transformation to the right-hand side of the equation, an integral one hopefully knows how to compute. One common justification for this transformation replaces $g(x)$ with u and $g'(x)dx$ with du and, thus, associates $g'(x)$ with dx.

In contrast to the traditional justification, which is motivated by how integration by substitution is typically applied, the justification presented here started with a Riemann sum for $\int_{g(a)}^{g(b)} f'(u)du$ and explained why the corresponding Riemann sum for $\int_a^b f'\big(g(x)\big)\, g'(x)dx$ gave the same number. This new justification requires reexamining several common ways of reasoning about integration. I have already discussed how the coordinated measurement meaning of multiplication supports using rectangular areas as generic models for products that span both I-o-M and P-o-M situations. In addition, the new justification consistently interprets integrands as rates. In particular, rather than associating $g'(x)$ with dx, as is common in more traditional explanations, the justification presented here associates $g'(x)$ with $f'(g(x))$ and the entire $f'(g(x))\, g'(x)$ expression is treated as a rate of change. For the Moving Truck example, $g'(x)$ rescaled rates of change represented by the vertical dimension that were caused by a change in the units used for measuring time. This, in turn, supports consistent interpretations of integrands across related topics, including the Fundamental Theorem of Calculus. Finally, although the new analysis is not a proof, it highlights how inverse proportions, a topic from middle grades mathematics, makes the statement of integration by substitution plausible. It is not a rigorous explanation *that* the statement is true but, rather, offers a plausible explanation for *why* it is true.

The analysis of integration by substitution provided here extends recent research on ways that multiplication understood as coordinated measurement with two different units can support coherent pathways from elementary and middle grades topics to calculus topics (e.g., Beckmann & Izsák, 2024; Izsák, 2023). As one example, Beckmann and Izsák argued that the large majority of first-year calculus is the study of situations in which *limiting behavior of co-variation takes place within a structure that coordinates multiplication with two measurement units*. They highlighted two different perspectives on proportional relationships, multiple batches and variable parts, and argued that approaches to rates of change based on multiple batches and unit rates are ill-suited for understanding $\frac{\Delta x}{\Delta y}$ as a single measure that remains (approximately) constant as the differences Δx and Δy tend to zero. Beckmann and Izsák then explained the concomitant affordances of variable parts and measurement rates. Finally, by attending to quantitative meanings for multiplication as a foundation for calculus, the present report resonates with other recent research that has examined sources of students' difficulties with calculus that reach back into middle grades topics (e.g., Boyce et al., 2021; Byerley, 2019; Carlson et al., 2015; Thompson & Harel, 2021). This emerging body of research suggests that a substantial reexamination and revision of how topics related to multiplication are developed in earlier grades could help students be better prepared for studying calculus grounded in quantities.

The Suggestion of a New Framework of Asian Identities With the Critical Perspective on AsianCrit in Postsecondary Mathematics/STEM Education

Minah Kim
Northern Arizona University

This study proposes the critical perspective on AsianCrit (Asian [American] Critical Race Theory) and suggests a new framework for potential research and practices in mathematics/STEM education regarding Asian identities. This study reviews and critiques the traditional views on AsianCrit for postsecondary mathematics/STEM education. Particularly considering Asians' diverse immigrant and citizenship status in STEM, gender identity, ethnicity, and more social identities, this study addresses the complicated relationships between Asian stereotypes, the Model Minority Myth, the intersectional identities of Asians, and the possible ways of empowerment.

Keywords: Critical Race Theory, AsianCrit, Racism, Equity

Throughout Asian discrimination during the COVID-19 crisis from 2019 to the March 2021 murders of eight Asian women in Atlanta and #StopAsianHate—a slogan from 2021 to alert people of Asian hate crimes, scholars have called the need for research on Asian racism in the context of equity and social justice. Then, did those movements bring anything to mathematics and STEM education? It could or could not.

Generally, people perceive that there are many Asians in STEM. How many Asians are in STEM in the United States (U.S.)? There are 17.3 million Asian Americans who make up approximately 5.6 percent of the U.S. population, and around 10 percent of the undocumented population in the U.S. is Asian American (Curammeng et al., 2017). Compared to this information, it could be true that there are many Asians in STEM. National Center for Science and Engineering Statistics (NCSES, n.d.) states that regardless of fields in STEM, the most significant racial group of color in every field of major is non-Hispanic Asians. There are nearly but less than 40% of non-Hispanic Asian graduates in computer and mathematical sciences and nearly but less than 30% of them in engineering. Overall, the historically minoritized racial/ethnic groups—Hispanic or Latin* ethnicity, non-Hispanic American Indian or Alaska Native, non-Hispanic Black or African American, non-Hispanic Native Hawaiian or Other Pacific Islander—are underrepresented in STEM fields except for social and related sciences, compared to non-Hispanic Asian.

Then, does the Asian representation in STEM mean no racism or discriminatory issues toward Asians? Shortly, this study says "No" to this question. Research in Asian [American] Critical Race Theory (AsianCrit) described discrimination associated with Western perspectives, such as Orientalism and the generalization of exoticism, that Asian populations experience. These experiences include being perpetuated foreigners, treated monolithically, perceived as intelligent but socially excluded, and sometimes threatening American society as "yellow peril." Despite these compelling arguments of AsianCrit, there is still little research exploring or employing AsianCrit that fits racial/ethnic issues in mathematics/STEM education regarding Asian identities. So, this study aims to suggest a new framework for future mathematics/STEM education research and practices geared toward diversity and inclusion, consisting of Asian identities. The research question is "How is AsianCrit dismantled, revised, and incorporated to examine Asian identities in postsecondary mathematics/STEM education?"

What and Why AsianCrit?

AsianCrit is one kind of "spin-off" Critical Race Theory (CRT) that aims to aid in addressing and analyzing Asian racial issues, especially in terms of systemic discrimination and inequities in the U.S. (Curammeng et al., 2017; Iftikar & Museus, 2018). According to the assertion of CRT, race is a social construct and a significant factor in deciding inequity, and that intersects with property rights, giving rise to social, systemic, and educational inequalities among people of color (Ladson-Billing & Tate, 1995). CRT is overviewed by the main tenets (Mensah & Jackson, 2018, See Figure 1), and the various "spin-off" CRTs primarily follow themes of CRT.

Table 1. Overview of Critical Race Theory Themes (Mensah & Jackson, 2018, p. 6)

	Solórzano (1997)	Zamudio, Russell, Rios, and Bridgeman (2010)	Delgado and Stefancic (2012)
Theme 1	The centrality and intersectionality of race and racism	Critique of colorblindness	Colorblindness
Theme 2	The challenge to the dominant ideology	Critique of liberalism	Interest convergence or material determinism
Theme 3	The commitment to social justice	Whiteness as property	The social construction of differential racialization
Theme 4	The centrality of experiential knowledge	Interest convergence	Intersectionality and anti-essentialism
Theme 5	The interdisciplinary perspective	Intersectionality	Unique voice of color or counter-stories

According to CRT principles, "Asian" is a collective identity organized around broad commonalities rooted in various ethnicities traceable to points in Asia (Patton et al., 2016). Throughout the ways Asians are racialized in the U.S., the racial/ethnic identity of Asians has been treated monolithically; nevertheless, the populations as racialized as Asians consist of more than 48 ethnic groups (Curammeng et al., 2017; Iftikar & Museus, 2018). Also, the definitions of Asians, Asian migrants, Asian immigrants, and Asian Americans are complicated and often difficult to differentiate, even though those words are not interchangeable (Chen & Buell, 2018).

Given these complicated identities of Asians and racialized issues treated monolithically, why does this study deal with AsianCrit? First, the focus on AsianCrit addresses the limitations of the general CRT. The most significant limitation of the CRT is the Black and White binary in the early stage of the theories (Alcoff, 2003) and the lack of a nuanced and more profound reality of Asians. Second, the investigation of AsianCrit will allow us to challenge stereotypes and discriminatory perceptions of Asians. The stereotypes toward Asians are unique because they sound like "compliments" for Asians. For instance, one of the most common stereotypes is that "Asians are good at math, and they are smart." This does not seem harmful but a compliment; even Asians believe that. However, these stereotypes are not only inaccurate but also harm Asian identities in various ways. (See "Model Minority Myth" below) Therefore, investigating Asian stereotypes with critical perspectives should be pursued more through AsianCrit. Ultimately, the

advance of AsianCrit will debunk White supremacy and systemic racism toward people of color (e.g., anti-Blackness) and let Asians be included as the constitutes of people of color.

Literature Review on the Traditional View of AsianCrit

Summary of the Traditional Asian [American]Crit

In the context of Asian American jurisprudence, Asian Americans' experiences and perspectives became invisible (Curamment et al., 2017). Also, historically, Western perspectives such as Orientalism and the generalization of exoticism have patronized and dehumanized Asian people in the U.S. (Iftikar & Museus, 2018). This racialization of Asian Americans is little salient in the early development of CRT, but the early stage of the conceptualization of CRT was focused on the Black-White binary (Iftikar & Museus, 2018). Thus, scholars have called more attention to the shift from the Black-White binary to the racial-specific CRT with a more nuanced and deeper inquiry-based reality, and this study focuses on Asians. The significant point is that the argument of the limitation on the Black-White binary does not indicate Anti-Blackness. Instead, the way to challenge the Black-White binary is eventually to debunk White Supremacy because the rationale of the Black-White binary in the early stage of CRT blocks the view on genuine racial issues not just about Asians but also the constitution of people of color.

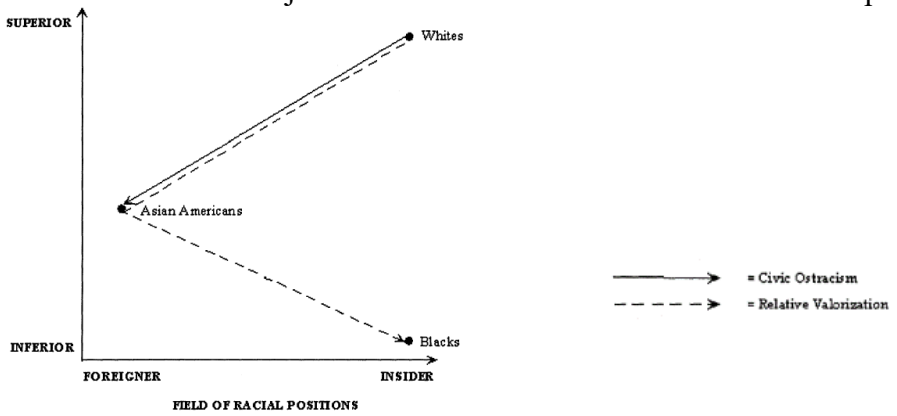

Figure 1. Racial Triangulation of Asian Americans in the United States (Kim, 1999, p. 108)

Grounded on the need for spin-off CRTs for more racial/ethnic specificity, there have been attempts to theorize Asian-specific CRTs. One of the earliest attempts was Chang's (1993) Asian American Legal Scholarship framework. Chang (1993) points out anti-Asian, nativist racist violence and discrimination and the idea of model minorities that exclude Asians from people of color. Also, other attempts to theorize AsianCrit include the law's role in perpetuating forever foreign. Particularly in the literature with educational context, it has been argued that CRT should address the distinguishable racialization between different ethnic Asian Americans and other people of color (e.g., the racial triangulation; See Kim, 1999). Asian Americans are "racially triangulated" by two axes—the superior-inferior axis and the insider-foreigner axis (Kim, 1999, See Figure 4). Kim (1999) argues that this study assumes Asian Americans are racialized in the zone of both civic ostracism—possibly less than Blacks, but still—and relative valorization to make Asian Americans perpetuate foreigners. This racialized position for Asian Americans is distinguishable from the one for Blacks, but the oppressive purpose of this racialization is to reinforce White dominance, privilege, and supremacy.

Model Minority Myth (MMM)

Model Minority Myth (MMM) is a central tenet that AsianCrit criticizes and explains why MMM is problematic. Since the middle of the 20th century, monolithic racial depiction in the U.S. led to MMM (Curammeng et al., 2017). MMM refers to the racial stereotypes usually toward Asian Americans who are hardworking, achieve higher education, and obtain higher socioeconomic status (Poon et al., 2016) than other minority groups such as Blacks or Latin*. Also, MMM characterizes Asian Americans as a polite, law-abiding group who have achieved higher success than the general population through some combination of innate talent and pull-yourself-up-by-your-bootstraps immigrant striving (Blackburn, 2019). So, MMM is strongly interwoven with discriminatory stereotypes and racialized positions from the view of the highest "White" hierarchy in the U.S.

Model Minority Myth in Mathematics/STEM. Despite the harm of MMM, it has rarely been discussed in higher education studies. Poon et al. (2016) found that MMM's original purposes—maintenance of anti-Black racism and White supremacy—are not critically mentioned in research on framing Asian Americans and Pacific Islanders in higher education. Among 112 studies of Asian Americans and Pacific Islanders in higher education in the reviewed literature, only slightly more than 10% of the studies used a critical definition of MMM. Thus, it is crucial to deal with the racialized problems and issues regarding MMM.

One of the most common narratives toward Asians based on MMM is the "Asians are good at math" narrative. Shah (2019) analyzes critically how the "Asians are good at math" narrative imposes the positionality of Asian people in STEM as racialized. The "Asians are good at math" narrative, which is prevalent not just in mathematics/STEM education but also in general society, is little considered as a harmful racial issue but rather a harmless compliment. Nevertheless, the "Asians are good at math" narrative is not a compliment. First, this racialized statement itself is not true—not all Asians are good at math. Second, the "Asians are good at math" narrative does not allow Asians to pursue non-STEM or non-mathematical paths such as arts and sports, which also reinforces another stereotype like "Asians are smart but not creative." Third, the "Asians are good at math" does not normalize Asian students' "failure" experiences in mathematics and STEM. Fourth, the "Asians are good at math" implies non-Asians are supposed to be worse in math than Asians, so it maintains the deficit view on non-Asians of color but also does not threaten Whites' ability and White supremacy.

Grounded on the dismantling of the "Asians are good at math" statement, which is based on MMM above, Shah (2019) states that the type of success of Asian students in STEM indicates a neglected and dehumanized narrative of Asian people and reproduces White supremacy. Instead, it is a compliment; the narrative of "Asians are good at math" presents an ontological cost on Asian people as a threat to personhood (Shah, 2019). Also, the racialization of MMM toward Asians is shifting as "yellow peril," becoming the excuse for a 'new White flight.' Suddenly, Asians, who were once perceived as A+ students and good classmates, are repositioned as "too good at math" and threatening to White students' self-esteem, justifying racial re-segregation. (Chen & Buell, 2018)

Critiquing Traditional View on AsianCrit in Postsecondary Mathematics/STEM Education

This study reviewed the traditional approaches, tenets, and studies on AsianCrit. Still, the general arguments of the traditional views on AsianCrit make sense, but there are limitations of traditional views on AsianCrit. More specifically, the "racially triangulated" experiences of Asian Americans and MMM are intensely relatable to postsecondary mathematics/STEM education. Still, considering the current phenomena and issues in postsecondary

mathematics/STEM education, the traditional views on AsianCrit should be revised toward a "spin-off" version for postsecondary mathematics/STEM education. So, in this part, this study suggests reconsidering AsianCrit for future directions in understanding Asian identities in postsecondary mathematics/STEM education.

First, traditional theories in AsianCrit are limited by the different immigrant statuses of Asian students. Particularly in higher STEM education, involving many Asian international students (e.g., Indian, Chinese, Korean, and students from other Asian countries), how is the AsianCrit applicable without considering international students? Interestingly, Asians involve alternatively larger non-U.S. native-born populations in STEM. Regarding U.S. citizenship status, native-born U.S. citizens are (non-Hispanic) White-dominant; on the other hand, non-U.S. and naturalized U.S. citizens are (non-Hispanic) Asian-dominant. This data result from NCSES (n.d.) indicates that Asians in STEM have a proportionally more "international" student population in terms of U.S. citizenship and immigration compared to other race/ethnicity populations. So, for instance, the view of the "perpetual foreigner" has been criticized with the voice of Asian Americans. Potentially, the "perpetual foreigner" view may create Asian international students' unique experiences to be constantly "others" in their educational experiences, which is not necessarily the same as Asian Americans who were born and raised in the U.S.

The second limitation is that since traditional theories of AsianCrit are more toward pan-ethnic understanding, ethnic diversity within the Asian group is less highlighted. More specifically, understanding postsecondary mathematics/STEM education experiences and dynamics related to ethnic diversity has not yet been deeply dealt with. Also, given the "pan-ethnic" understanding, there are some limitations to traditional investigation or use of the MMM—not just MMM, which is little discussed with the critical perspective in postsecondary STEM education. Still, the pan-ethnic understanding of MMM also has limitations since MMM is applied differently for some Asian ethnic groups. For instance, MMM is applied differently for some certain Asian ethnic groups (e.g., Southeast Asian Americans) as both modeled and deviant (Poon et al., 2016; Iftikar & Museus, 2018).

The third limitation is that the traditional theories of AsianCrit do not necessarily cover issues from multiple social identities of Asians. For instance, AsianCrit may not fully capture how Asian women are modeled and simultaneously racialized and gendered. According to Ong et al. (2011), which is a review of around 40-year scholarships for women of color in STEM areas on postsecondary education by adopting the synthesis method to analyze 116 studies with the intersectionality framework, even though Asian American women look overrepresented in STEM compared to the U.S. population, their representation in the group of academic tenure/leadership positions is the lowest or significantly lower than other demographic groups. There has been little attention that Asian American women are placed in an ironic, paradoxical space in STEM fields, simultaneously overrepresented as Asian Americans and underrepresented as women (Castor & Collins, 2021), so they are "invisible." Additionally, on the gendered issues, AsianCrit was not necessarily used to examine Asian sexual orientations, sexuality, nationality, language, and other social identities.

More specifically, in what ways should Asian identities be investigated? First, this study suggests adopting an understanding of Asian international students and immigrants in AsianCrit. AsianCrit usually refers to Asians as only "Asian Americans." However, due to the increasing number of international students and migrant/immigrant populations in STEM majors in the U.S., the invitation to AsianCrit for Asian international students and migrants/immigrants in higher STEM education is necessary. No consideration of Asians in the context of STEM

postsecondary education is insufficient to address Asian discrimination and racism because "Asian migrants working under the H-1B visa obscure domestic educators' unwillingness to teach students of color, but they also camouflage the failure of domestic educators to provide a rigorous STEM education for students of color" (Chen & Buell, 2018, p. 615). What does Asianness mean in mathematics/STEM in the U.S.? Moreover, what do Asianization and Americanization mean for Asian students in mathematics/STEM in the U.S.? What are the possible tensions within that process? These would be the questions for the future direction of the AsianCrit research mathematics/STEM education.

Second, this study insists on considering more diversity in AsianCrit within Asian groups such as ethnicity. Particularly in mathematics/STEM education, Asian students are usually modeled by the MMM. Still, some partial Asian groups—usually those who have darker skin—are treated as more deficient, such as students who achieve lower than East Asians. This would be coined and explained with "Colorism: [the] practice of discrimination in which those with lighter skin tones are treated better than those with darker skin and [it] occurs not only between groups but within groups as well" (Sue, 2016, p. 184). This means there is some colorism among Asian students. For instance, Asian populations who have darker skin within the Asian group, such as Southeastern Asians and South Asians, are perceived by more deficit views or negative stereotypes. If we disregard the diverse ethnicity of Asian populations, then we cannot genuinely focus on diversity and inclusion in mathematics/STEM education.

Lastly, intersectionality should be adopted actively. Notably, more active use of the intersection between racism and sexism for Asian women in STEM is necessary. The use of intersection is aligned with the argument of examination of Asian diverse ethnicity, languages, and immigrant statuses that I mentioned above. Furthermore, non-heterosexual or non-cisgender, or queer identities should be explored more within the Asian context, as McWilliams and Penuel (2016) assert that queer perspectives invite intersectional perspectives, including race/ethnicity, socioeconomic status, disability status, and age. Based on the suggestions, the following section describes a new suggested framework for future directions for research and practice through the critical perspective on AsianCrit in mathematics/STEM education.

Outline of the Suggested Framework

This study suggests a new framework on Asian identities for postsecondary mathematics/STEM education to address the complicated and interwoven relationships between Asian stereotypes, MMM, systemic racism, intersectional identities of Asians, and the possible ways of empowerment.

Figure 2 illustrates the diagram corresponding to the framework. Asian identities are formed as giant icebergs with their tip and parts underneath the seawater. The tip of ice means the superficial perception of Asians grounded on stereotypes and associated with the monolithic view and MMM. The seawater that hides most of the icebergs illustrates systemic racism and oppression toward Asians, such as nativism, orientalism, exoticism, dehumanization, xenophobia, and White supremacy. The seawater is too cold, deep, dark, and sometimes dangerous, so it does not allow people to explore it deeply. Underneath the water, the hidden but also strongly impacted by racism represent Asian identities, which are diverse and necessary intersectional approaches. The identities consist of the intersections between gender, ethnicity, languages, immigrant/citizenship status, sexual orientation, disabilities, and many more. These hidden Asian identities should rise to the surface to empower Asian identities and debunk the "water."

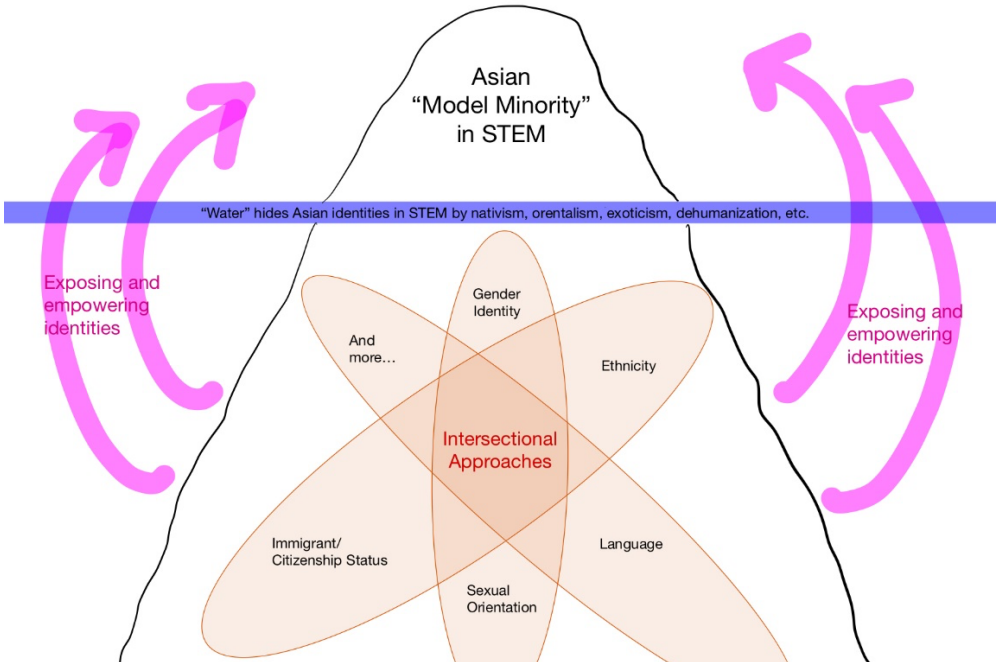

Figure 2. The Suggested New Framework on Asian Identities for Postsecondary Mathematics/STEM Education

Potential Use of the Suggested Framework

Then, what should be the next step in using the suggested framework in postsecondary STEM education? First, the framework can be used to the way to debunk Gap gazing (Gutiérrez & Dixon-Román, 2011), and deficit views frequently happen when Asians are paired with Whites to illustrate the racial achievement gap in STEM. Consequently, Asians are implicated as "honorary Whites," which refers to "signaling that the exits from oppressed minority status and assimilation into whiteness can be incomplete and contingent on fortifying antiblackness" (Martin, 2019, p. 465), and so the racial disparities many experiences are neglected (Poon et al., 2016). Shedding light on multiple interconnections of Asian identities can help dismantle racial disparities and MMM.

Also, not just in mathematics classrooms but also in STEM departmental- and major-wise, student culture should embrace diversity and counter-spaces for minoritized students. To do so, it is suggested to understand intra-racial diversity among Asian students in STEM. An excellent research example is George Mwangi et al. (2016), a study on intra-racial dynamics between native-born and foreign-born black collegians in STEM. According to George Mwangi et al. (2016), native-born and foreign-born Black collegians appreciate peer diversity as a "global" feel provider. Native-born Black students often take a rule to initiate cross-cultural interaction. On the other hand, both native-born and foreign-born Black students reported class dynamics such as native-born Black students' anxiety due to stereotypes regarding Black people in the U.S. and foreign-born Black students' pressure that comes from the academic ability that they should prove or accent or stereotypes of their home country. Based on the findings, George Mwangi et al. (2016) propose that higher education practitioners intentionally provide formalized opportunities for foreign-born and native-born students of color to interact with and learn from each other. Like George Mwangi et al. (2016), there is a potential for understanding the dynamics of Asian interracial students to be necessary for genuine practices for deeper cross-cultural interactions between Asian international students and Asian Americans and other Asian students with diverse histories and backgrounds.

A Relationship Between Actor-Oriented Transfer and Mathematics Self-Efficacy

James White
University of Oklahoma

Bandura's self-efficacy theory notes that self-efficacy determines how much time and effort students will put toward their work, meaning higher self-efficacy will lead to students working harder on their coursework. It should thus be in every mathematics instructor's best interest to understand how they can positively impact a student's self-efficacy related to mathematics. This theoretical report examines the intersection between an actor-oriented perspective of transfer of learning and Bandura's self-efficacy theory. I then propose a merging of the two through the concept of actor-oriented self-efficacy, which emphasizes using actor-oriented transfer methods to better understand students' mathematics self-efficacy levels. I conclude with an example of how one can apply an actor-oriented self-efficacy perspective to a study dealing with students' self-efficacy related to proving.

Keywords: actor-oriented transfer; self-efficacy; transfer

Introduction

Ampadu and Anokye-Poku (2022) confirmed that there is a positive relationship between a student's attitude toward mathematics and their achievement in mathematics courses. Since mathematics self-efficacy has been shown to be a reliable mediator between one's mathematics attitude and mathematics achievement (Randhawa, 1993), improving a student's mathematics self-efficacy may be an area of focus for student growth. Note that self-efficacy refers to a person's beliefs regarding how well they can perform a series of actions given a certain situation (Bandura, 1982). Mathematics instructors should then be concerned about how their instructional decisions in the classroom impact their students' mathematics self-efficacy, since this can directly influence how students perform in their courses. As Randhawa (1993) noted, "teachers should do whatever they can to assure all students in mathematics courses that they are capable and should venture forward in mathematics-related areas of study" (p. 47). If instructors can improve students' mathematics self-efficacy, they can improve students' abilities to achieve in their mathematics courses and how encouraged they are to consider pursuing mathematical-related majors and careers.

Mathematics instructors should also be concerned for their students' mathematics self-efficacy as it plays a significant role in students' decisions regarding pursuing STEM-related fields. Hackett (1985) noted mathematics self-efficacy is a reliable predictor of math-related major choice, meaning one's mathematics self-efficacy has a strong impact on if a student chooses a math-related major in college. Additionally, "a lack of confidence in mathematical ability" has been "a major contributing factor for women's decisions to leave calculus but not men's" (Ellis & Cooper, 2017, p. 7). Mathematics self-efficacy may therefore play a key role in women's decisions to stop pursuing mathematics at the calculus level. An instructor's interest in their students' mathematics self-efficacy may go beyond a desire for their students to perform well in their course, as it impacts each student's discernment process when they are deciding if they wish to continue studying mathematics.

While considering student mathematics self-efficacy, note that a personal efficacy belief is the "conviction that one can successfully execute the behavior required to produce the outcomes (Bandura, 1977, p. 193). It thus does not necessarily matter if an observer believes a student's

self-efficacy has changed; rather, it matters if the student believes their own self-efficacy has grown. Therefore, to explore how instructors can positively impact students' mathematical self-efficacy, it is optimal to understand the impacts classroom decisions have on students' mathematical self-efficacy from the perspective of the students themselves.

As I am interested in the classroom decisions and learning situations that can positively impact mathematics self-efficacy, I am also interested in understanding what situations in the classroom raise students' self-efficacy so that students demonstrate this heightened self-efficacy in future situations. In other words, I am interested in how self-efficacy can be transferred. With this in mind, I consider using transfer of learning, which refers to "the ability to apply knowledge learned in one context to a new context" (Mestre 2003, as cited in Karakok, 2021, p. 103). Transfer of learning focuses on identifying how students learn knowledge in one moment, the learning situation, and apply it in another moment, the transfer situation (Lobato, 2012). Thus, there is a similar notion in studying transfer of learning to that of changing mathematics self-efficacy; there are moments where instructors hope to change self-efficacy and there are future moments where instructors hope to see that raised self-efficacy in action. Moreover, as I am interested in students perceived self-efficacy (meaning student perspective), I focus on one of the contemporary approaches to transfer of learning, namely, actor-oriented transfer framework (Lobato, 2012).

I note that there is a precedent for applying transfer of learning theory to other areas, specifically areas that are individualistic in nature, to better understand them, such as Karakok's (2021) discussion of the similarities between transfer of learning and student creativity. This suggests one can better understand student mathematics self-efficacy by first considering the intersection between the theories of self-efficacy and transfer of learning. Furthering this, Karakok (2021) specifically discussed how a researcher may use an actor-oriented transfer (AOT) perspective to study creativity and the transfer of creativity. While I discuss AOT in detail later, I note that it focuses on viewing situations from the actor's perspective where, in this case, actors are students in the classroom. I thus consider how one may use transfer and AOT framework to understand student mathematics self-efficacy and the transfer of mathematics self-efficacy. Moreover, I discuss how an AOT perspective can aid in our pursuit of understanding student mathematics self-efficacy and what pedagogical decisions impact student mathematics self-efficacy. This theoretical report is thus driven by the following research questions:

1. How can an actor-oriented transfer perspective be used to understand student mathematics self-efficacy and the impacts pedagogical decisions can have on student mathematics self-efficacy?
2. What similarities exist between actor-oriented transfer theory and methods used to study student mathematics self-efficacy?

Literature Review

Mathematics Self-Efficacy

I consider mathematics self-efficacy with Bandura's (1982) notion that self-efficacy refers to a person's beliefs regarding how well they can perform a series of actions in a certain situation in mind. As noted, mathematics instructors should be concerned about their students' self-efficacy, as it plays an important role in determining how much students are able to achieve while studying mathematics and if they choose to continue studying mathematics (Ampadu & Anokye-Poku, 2022; Ellis & Cooper, 2017; Hackett, 1985; Randhawa, 1993). Self-efficacy is also a significant piece of each student's mathematical journey as "efficacy expectations are a major

determinant of people's choice of activities, how much effort they will expend, and of how long they will sustain effort in dealing with stressful situations" (Bandura, 1977, p. 194). Each student's efficacy may directly impact the amount of time and effort they dedicate to mastering their coursework. Therefore, mathematics instructors should understand how their pedagogical decisions impact their students' mathematical self-efficacy, as doing so enables instructors to positively influence the amount of time and effort students give toward their studies as well as students' achievements in mathematics.

To understand how to influence students' mathematics self-efficacy, I first discuss potential sources where students can gain self-efficacy. In his self-efficacy theory, Bandura (1977) outlined four principal sources for one's self-efficacy: performance accomplishments, vicarious experience, verbal persuasion, and emotional arousal. Performance accomplishments, noted as the most influential source, rely on personal mastery experiences; self-efficacy rises through one's own continued successes. Bandura also noted that "improvements in behavioral functioning" through performance accomplishments "transfer not only to similar situations but to activities that are substantially different from those on which the treatment was focused" (p. 195). Vicarious experience refers to observing others doing difficult tasks without adverse results, so that an observer more firmly believes that they can successfully navigate similar challenges. Bandura notes that this source is not as strong as performance accomplishments, and that any self-efficacy gained from it has a greater chance of being diminished later when compared to performance accomplishments. Verbal persuasion, involving suggesting to another that "they can cope successfully with what has overwhelmed them in the past", will also be weaker than performance accomplishments; since there is no actual performance of tasks to base these suggestions off, their self-efficacy is less likely to be impacted than from the previous two sources (p. 198). Finally, emotional arousal relates to emotions that come from stressful situations and the effects they have on one's self-efficacy relating to a task.

Note that Bandura's four sources have been used previously in studies on students' mathematics self-efficacy. Regier and Savic (2020) used Bandura's four sources to identify changes to students' mathematics self-efficacy for proving that were caused because instructors implemented teaching actions that aligned with Sriraman's (2005) principles for fostering creativity. Watkins and Middleton (2021) focused on understanding which of the four sources could successfully predict mathematics self-efficacy in Black college first-year students that attended a predominantly Black campus. Usher and Pajares (2009) worked to validate Bandura's theory of self-efficacy's four sources for students studying middle school mathematics. Parsons et al. (2015) focused on which sources of mathematics self-efficacy (Bandura's and others) engineering students identified as having changed their self-efficacy levels, noting that performance accomplishments were found to be the most important source while verbal persuasion was absent. There is therefore a precedent for researching students' mathematics self-efficacy levels that utilizes Bandura's four sources as a theoretical framework.

Instructors thus have the potential to impact students' mathematical self-efficacy by understanding Bandura's four sources; if a pedagogical decision leads to consequences related to these sources, that decision has the potential to change one's self-efficacy levels. This leads to the following question: how can observers successfully identify the impact that choices made in the classroom have on students' mathematics self-efficacy levels with respect to Bandura's sources? To answer, I turn to transfer theory, which focuses on how certain situations in the classroom impact students (with respect to future situations). This draws a similarity to my question, as it is interested in understanding what students take from a situation (with respect to

their self-efficacy) and how their effected self-efficacy impacts their future ability to perform in the classroom.

The Actor-Oriented Transfer Perspective

To understand which classroom decisions impact students' mathematics self-efficacy (and how they do so) with respect to Bandura's model, I consider utilizing the transfer construct, as this relates to how one event impacts a student's knowledge by considering a future event where they apply that knowledge. More specifically, I consider using an actor-oriented transfer (AOT) perspective to identify what impacts, with respect to Bandura's four sources, have occurred.

The actor-oriented transfer (AOT) perspective engages with the actor's (student's) point of view rather than an observer's perspective; instead of focusing on if a student performs a specific action or acts in a certain way (which an observer has pre-determined to be of significance), it examines the student's actions or behaviors related to a task, where knowledge is applied, regardless of their correctness (Lobato, 2012). Moreover, an AOT perspective aims to understand how previous experiences, where knowledge is learned, lead to a student's decisions, rather than focusing on if previous experiences lead to specific, pre-determined choices by the student (Lobato, 2012). While an observer perspective views "successful or improved performance on transfer task" as evidence of transfer, an AOT perspective believes that "regardless of successful or improved performance on transfer tasks, any influence of prior learning experiences is considered as evidence for transfer" (Karakok, 2021, p. 111). Therefore, AOT's framework values understanding students' perspective regardless of normative correctness so that such an approach could provide means to understanding perceived student self-efficacy. An AOT perspective thus enables observers to use each student's viewpoint when considering if certain pedagogical decisions had effects on a student's self-efficacy levels and, if so, which of Bandura's sources these effects may be related to.

The Intersection Between Actor-Oriented Transfer and Self-Efficacy

Note that AOT's view of 'transfer' is concerned with understanding "the processes by which individuals generate their own similarities" between a learning situation, where they are first introduced to a topic, and a transfer situation, where they attempt to apply their knowledge of this topic (Lobato, 2003, p. 18). Bandura's two most impactful sources, performance accomplishments and vicarious experiences, dealt with improving self-efficacy with respect to one situation so that an improved confidence can help an individual perform better in future situations that they perceive as similar to the prior experience (1977). There is thus a notion of transfer present in Bandura's model, meaning AOT framework can potentially be used to identify when there is a 'transfer' of mathematics self-efficacy between situations. Additionally, the AOT perspective "assumes that learners are making connections between situations nearly all the time, guided by aspects of the situation that they find personally salient" (Lobato, 2003, p. 19). An observer thus assumes learning situations *do* have impacts on students that become present in transfer situations. Applying this perspective to students' mathematics self-efficacy with these situations in mind, it is not a question of *if* there is an impact, but rather *what* this impact looks like and *why* it happened. Moreover, the AOT perspective means relying on each student's input to answer the question of what changes to their self-efficacy have occurred between learning and transfer situations. While an observer could believe that there has been a change from observing a student's time in each situation, studying self-efficacy can benefit from focusing on students' perspectives due to self-efficacy encompassing each person's personal beliefs regarding their ability to perform successfully.

The focus on students' beliefs in AOT agrees with other studies that highlight how the most important data comes directly from the students themselves when considering topics that deal with students' personal beliefs, such as self-efficacy and creativity. When gathering data on what teaching actions influence fostering creativity in a Calculus course, Satyam et al. (2022) note that

> these actions are from the students' (not instructor) perspective. We did not corroborate whether instructors in fact did these actions. Given our lens of creativity and that the individual themselves is the ultimate judge of whether they felt creative (independent of their reporting of it to us), students' judgments of what their instructor did that actively contributed to their sense of creativity are most valuable. (p. 542)

This stands as an example of why research topics focusing on personal attributes (as they depend on each student's beliefs), such as creativity, can benefit from gathering data based on students' viewpoints; it does not matter what the instructor intended to do, nor what an observer believes they see, as much as it matters that an actor believes something to be true.

Additionally, when Regier and Savic (2020) discussed the impacts teaching actions related to fostering creativity have on students' self-efficacy for proving, they coded sources of self-efficacy from student interviews "when a potential source (enactive experiences, vicarious role-modeling, verbal persuasion, physiological reaction) was described in relation to a change in student confidence in proving" during interviews with students (p. 5). Thus, there are previous studies that examine students' beliefs by using evidence of changes in self-efficacy or creativity only when students noted that to be the case.

Merging Self-Efficacy Theory with Actor-Oriented Transfer

After discussing the intersection between actor-oriented transfer and creativity, Karakok (2021) outlined her concept of actor-oriented creativity (AOc). AOc blends actor-oriented transfer and creativity research, as it means to "distinguish students' perspectives on creativity and perceptions of their own mathematical creativity from the ones observed or declared by others" (pp. 121 – 122). Actor-oriented transfer thus has the potential to be integrated with another area of research that can possibly benefit from its methods. With this in mind, I take a similar path by constructing actor-oriented mathematics self-efficacy, which means to consider mathematics self-efficacy through an actor-oriented transfer lens.

I consider using an AOT approach to study students' mathematics self-efficacy levels to highlight the student perspective on what pedagogical decisions could positively impact mathematics self-efficacy. When studying mathematics self-efficacy with Bandura's four sources of self-efficacy in mind, researchers may need to identify when a student's self-efficacy has changed and, if this is the case, the catalyst for this change with respect to the four sources. To do so, I propose the concept of actor-oriented self-efficacy (AOSE) which focuses on understanding each student's mathematics self-efficacy from their own perspective, rather than from that of an observer. This means AOSE requires researchers to turn to the student perspective for information on a) when their mathematics self-efficacy has changed and b) what situations, with Bandura's four sources in mind, led to those changes. Karakok (2021) noted a potential outcome of using actor-oriented creativity stems from how "inclusion of students' perspectives on mathematical creativity and their perception of their own mathematical creativity could help us detect nonnormative instances of students' mathematical creativity and provide processes that are not reported in earlier studies" (p. 121). Similarly, AOSE acknowledges that a student's discussion of what has impacted their mathematics self-efficacy can potentially illuminate researchers to instances that they may not have considered.

This AOSE perspective considers the nature of measuring self-efficacy; as self-efficacy is based on one's own beliefs regarding their ability to successfully perform a task, it follows that correctly determining a student's mathematics self-efficacy levels requires introspection on the student's part. This distinction agrees with Lobato's (2003) note on the usefulness of transfer models: "traditional models rely too heavily on the determination of transfer from an expert's point of view and, as a result, can lead to design decisions that are not informed by the specific generalizations that students have formed" (p. 20). An actor-oriented self-efficacy perspective would thus engage with students' specific generalizations regarding their mathematics self-efficacy and put the emphasis on their perspective, rather than that of any observers. While an instructor or an observer can hypothesize about whether a student's self-efficacy has changed and what it was that changed it, a student is the best person to discern what has happened to their own self-efficacy levels. Actor-oriented self-efficacy thus centers on highlighting students' viewpoints on their own mathematics self-efficacy. This can ensure that pedagogical decisions made with the intent to raise mathematics self-efficacy levels are made with students' perspectives in mind.

Applying Actor-Oriented Self-Efficacy to a Case Study

I apply an AOSE perspective to a previous study (Regier & Savic, 2020) conducted on the effects teaching principles of creativity have on self-efficacy levels related to proving. Regier and Savic (2020) created the Self-efficacy for Proving Scale (SEPS) which "consisted of three specific proving statements in which students were asked to rate their confidence of five subtasks related to proving each statement" and had students "rate their confidence in their ability (on a scale of 0% confidence to 100%)" to do five subtasks related to proving (pp. 4-5). SEPS surveys were given at the beginning, middle, and end of the semester so that results could be used to discuss the students' changes in self-efficacy related to each statement by comparing students' SEPS scores from the beginning of the semester to their scores at the end of the semester.

While the SEPS agrees with AOSE when determining if students' self-efficacy levels changed by asking students for their perspectives on their own self-efficacy levels, it does not ask students what events or teaching actions may have led to changes in their self-efficacy. An AOSE approach would try to understand what caused these changes in self-efficacy levels from the students' viewpoints. Note that Regier and Savic (2020) created another survey, the Five Principles Survey (5PS), that students completed at the end of the semester and contained questions regarding students' experiences with respect to each of Sriraman's (2005) five principles of creativity. Therefore, an AOSE perspective's additional goal could be realized by creating additional questions in the SEPS, like those in the 5PS, that ask students if (and if so, how) any of the principles of creativity impacted their self-efficacy levels with respect to each statement they needed to prove. This addition will agree with an AOSE approach by only identifying principles of creativity as having impacted a student's self-efficacy levels if a student declares them to have done so. This would provide data for the second half of AOSE's goals by creating data focused on how students' self-efficacy levels change and based on the students' perspectives.

Regier and Savic (2020) also conducted student interviews at the end of the semester that asked students "questions about their classroom experience, their relative confidence in proving now, and how they gained confidence in their class" (p. 5). Note that these interviews already agree with an AOSE perspective; they gather data on student self-efficacy levels by asking for the student perspective on if and how their self-efficacy changed because of their experiences in

the classroom. I consider expanding this approach by gathering data on how specific situations in the classroom changed student's self-efficacy levels through an AOSE viewpoint.

Since interviews took place at the end of the semester, they focused on students' overall experience in the course and self-efficacy levels for proving. Therefore, students may not have remembered specific instances that helped change their self-efficacy for proving. Drawing inspiration from AOT's theory of learning and transfer situations, I consider doing interviews during the semester periodically and directly after students work on proving statements related to a subcollection of proving tasks that correspond to recent topics discussed in the classroom (for example, self-efficacy related to proving by contradiction). By using the same questions found in end of semester interviews, adjusted for this suggested timeframe, observers may receive data discussing more moments related to principles of creativity that changed students' self-efficacy levels for proving; it would give students a chance to reflect on more recent classroom content that they may have forgotten by the end of the semester. Overall, this approach would exemplify AOSE's viewpoint further, as it would allow students to reflect on situations that may have impacted their self-efficacy with respect to a certain subcategory of proving. This would mean students could potentially identify more explicit moments that changed their self-efficacy levels, thus giving researchers a better understanding (from the students' perspectives) of when and how principles of creativity impacted students' self-efficacy levels.

Future Work

I hope to apply our AOSE model to a study that examines the effects that teaching actions can have on how one's mathematics self-efficacy changes over the course of a semester. Specifically, I look to consider how the teaching actions stated in Satyam et al. (2022) can impact a student's mathematics self-efficacy in a calculus course setting. Calculus has been noted to be a 'gateway' course that impacts students' decisions to study STEM-related majors or not (Moreno & Muller, 1999). Moreover, Ellis and Cooper (2017) found that women were deciding to stop pursuing STEM-related majors due to experiences in their calculus courses. Thus, using an AOSE perspective to investigate teacher actions' impact on students' mathematics self-efficacy in a calculus course could potentially lead to more students deciding to continue studying STEM-related majors by deepening instructors' understanding of what teaching practices can raise students' mathematics self-efficacy levels.

Does Everything Have to be Gay? Queer Pedagogy in the Undergraduate STEM Classroom

Catherine Davis (they/them)
Michigan State University

Queer pedagogy has been underutilized in mathematics learning contexts, particularly at the undergraduate level, despite offering unique perspectives on gender, sexuality, knowledge, and normalcy that are valuable for scientific inquiry and which support queer students in STEM. In this paper I discuss queer pedagogy, present practical examples of its implementation in STEM courses at the undergraduate level and argue for its necessity as a tool for instruction.

Keywords: queer theory, queer pedagogy, mathematical inqueery, critical pedagogy

Shortly after I moved across the country to start working on my PhD, I called home to tell my parents all about my "new life." As we spoke, I described the gay volleyball team I had joined, the local drag show I had attended and emphasized how happy I was to be living in a city with a vibrant queer community. My father, sounding affronted, said, "Not everything you do has to be gay."

Queer pedagogy has been implemented in arts and social science education for decades as a way to offer homonormative representation and to question the normalization of specific types of authorities, dichotomies, and knowledges (Ferguson, 1989; Letts, 2002; Stafford, 1988; Sullivan, 2003); but queer pedagogy appears to be rare in STEM contexts, particularly at the undergraduate level, despite the opportunities it can provide in supporting queer students, highlighting problematic cultural norms, and contributing to scientific inquiry.

In this paper my aim is to provide a concise explanation of queer pedagogy and to coordinate that explanation with examples of queer pedagogy's implementation in undergraduate STEM contexts. It is my hope that by linking the theoretical and practical realities of queer pedagogy, queer pedagogy can become more accessible and coherent as an educational tool, and that more scholars and educators will feel empowered to queer their research and their classrooms.

Queer, Queer Theory, and Queer Pedagogy

In order to discuss queer pedagogy, it is first necessary to discuss what is meant by the word "queer" and to investigate the origination of queer pedagogy as an offshoot of queer theory. However, the complexity and history of these movements renders any brief overview of them incomplete and reductive. For this reason, I want to acknowledge that the definitions, histories, and descriptions provided here represent a limited interpretation of queerness, queer theory, and queer pedagogy as dictated by the focus of this work. Should you find yourself curious about other interpretations and dimensions of these topics, I encourage you to explore the cited authors, particularly Nikki Sullivan's *A Critical Introduction to Queer Theory*, Davey Shlasko's article "Queer (*v.*) Pedagogy", and Deborah Britzman's book chapter "Is there a Queer Pedagogy? Or, Stop Reading Straight."

Queer

While it was originally a descriptive verb meaning "odd", in the early 19th century the word "queer" gained popularity as a pejorative noun for individuals who existed outside of cisgendered and heterosexual expectations of speech, dress, and socialization (Merriam-Webster,

n.d.; Sullivan, 2003). As Western society demonized and pathologized queer behavior in the late 19th and early 20th century, "queer" became synonymous with "deviant" "diseased" or "perverse" and was used primarily as a slur against gender and sexual minorities until its reclamation by queer activists and academics in the mid to late 20th century (Chauncey, 1994; Foucault, 1990; Sullivan, 2003). Now in the early 21st century, "queer" is used colloquially as an umbrella term to refer to anyone within the 2SLGBTQIA+[1] community, and in most instances no longer implies negative connotations. It is now commonplace for researchers to describe sexual and gender minorities within their data as queer (e.g. Cox & Pinheiro, 2024; Leyva et al., 2022; Voigt, 2022), and many 2SLGBTQIA+ individuals, myself included, proudly self-identify as queer.[2]

Within the academic community the word "queer" expands beyond identity. Morris (1998) proposes that the word "queer" as it is used by queer theorists encompasses three primary meanings: queer as a subject position, queer as a politic, and queer as an aesthetic. Queer as a subject position describes anyone who exists outside of society's normative understandings of sex and gender and is inclusive of the colloquial and historical meanings of queer described above. Ironically, the drawback to establishing queer as a subject position is that it often reaffirms "the heterosexual center" by defining queerness in contrast to "normalcy" (Davis & Sumara, 2000, p. 123), creating a new binary of "queer-not queer" (Morris, 1998, p. 276). Thus, queer cannot be restricted to a subject position and must also be defined politically. Queer as a politic questions the existence of normalcy, defies assimilation, and advocates for the deconstruction of the boundaries which police gender and sexuality (Luhmann, 1998; Morris, 1998; Shlasko, 2005; Sullivan, 2003). Often, the political use of the word queer is in the form of a verb, and to "queer" something suggests an act of disturbing, resisting, and reshaping. Lastly, queer as an aesthetic intentionally reinterprets writing, art, music, and other forms of text as "politically radical" (Morris, 1998, p. 276), a practice which "queers both text and reader" (Shlasko, 2005, p. 124).

This paper, like many writings on queerness, queer theory, and queer pedagogy, will use the word "queer" as an umbrella term, a subject position, a politic, and as an aesthetic without always making clear which definition is being referenced. Often, several of these definitions are applicable at once and they cannot be reasonably detangled from each other. Rather than stopping to redefine queer each time it appears in this text, I encourage you to embrace the word's radical and purposeful ambiguity.

Queer Theory

One way to characterize queer theory is as a theory which concerns itself with queer individuals, the queer experience, and queer topics related to gender, sex, and sexuality (Shlasko,

[1]Two-spirit, lesbian, gay, bisexual, transgender, queer/questioning, intersex, asexual/aromantic

[2]It is notable that while queer may describe an individual's gender or sexual orientation, it often erases or neglects other important aspects of an individual's identity, particularly race and class (Barnard, 1999; Sullivan, 2003). This has resulted in a homogenized view of queerness which favors white middle-class portraits of homosexuality (Mercer, 1994) and reproduces racial marginalization (Barnard, 1999; Leyva, McNeill, Balmer, et al., 2022; Sullivan, 2003). While it is not a focus of this paper, I want to acknowledge that queer studies are frequently complicit in ignoring the racialized nature of queerness. For a primer on this topic, see "Queer Race" by Ian Barnard (1999).

2005; Sullivan, 2003; Voigt, 2022). But more broadly, and consistent with Morris' (1998) definition of queer as a politic, Fifield and Letts expressed that:

> Queer theory shares concerns around sociocultural power relations of life in sexed and gendered bodies while troubling attempts to treat sexuality, or anything else, as a stable and knowable marker of identity. Queer theory includes unruly, deconstructivist perspectives that destabilize dominant norms around sexuality, gender, bodies, knowledge, power, and identity by imagining and inhabiting alternatives that resist being fully known or explicable. (2019, p. 68)

Queer theory can focus on queer topics of gender and sexuality, but it also leverages queerness to criticize anything that society has deemed to be normal and to consider how that normalcy can be disturbed. Queer theory also offers opportunities to reflect on the personal and political nature of identity, and, as Voigt (2022, p. 4) described it, "offer[s] alternative ways of thinking and performing in the world".

Queer theory can also be understood as an epistemological stance which questions what is known and what can be known (Dubbs, 2016; Letts, 2002), a stance which resonates with modern explorations of education, learning, and instruction and which I see as foundational to the development of queer pedagogy.

Queer Pedagogy

As with queer theory, queer pedagogy is not solely concerned with queer individuals or queer representation, going beyond "merely adding authentic or likable portrayals of lesbian/gay icons to an otherwise straight—and already overcrowded—curriculum" (Luhmann, 1998, p. 124). Instead, it can be understood as an application of queer theory and queer politic to instruction. Flessas and Zimmerman (2019, p. 96) explained queer pedagogy as "encouraging critical thought and the willingness to delve into complexity; investigating, questioning, and re-evaluating assumptions; and interrogating processes of normalization…" By this definition, I see queer pedagogy as having a home among the critical pedagogies which have gained popularity in the mathematics education community. In fact, Shlasko (2005, p. 125) citing Spurlin (2002) argued that queer pedagogy is at the "intersection of queer theory and progressive pedagogy" and I contend that many of the critical pedagogies that have emerged as part of the sociopolitical turn in mathematics education are implicitly queer.

Rands (2009) described a queer pedagogy of mathematics as mathematical inqueery[3], which "brings queer theory's interrogatory edge into the intersection with pedagogy and mathematics to mathematize the queer and queer mathematics" (Rands, 2019, p. 64). Mathematical inqueery encourages discomfort with abnormality, and its application has been compared to working with alternate number bases or non-Euclidean geometry (Rands, 2019; Sheldon, 2019). Ultimately, queer pedagogy and mathematical inqueery attempt to trouble normative presentations of gender and sexuality while exploring what can lie outside of "binaries such as homo-hetero, ignorance-knowledge, learner-teacher, reader-writer, and so on" (Luhmann, 1998, p. 128).

[3]Mathematical inqueery is sometimes written as mathematical inqu[ee]ry to highlight the intersections of queerness and inquiry and to emphasize a disregard for conventional grammar (Sheldon, 2019). I enjoy this styling of the word but have chosen not to include the brackets as part of an effort to make this paper more accessible to those who use screen readers.

Queer Pedagogy in Undergraduate STEM Classrooms

There are countless ways to apply queer pedagogy to the undergraduate STEM classroom, and the examples provided in this report are neither exhaustive nor irreproachable. In the words of Letts and Fifield (2019, p. 5) in their introduction to *STEM of Desire,* "we suggest you approach particular definitions of queering STEM education as provisional orientations, not as determinative demarcations of proper and improper queering."

My choice to discuss lessons constructed by Helene Götschel and James Sheldon is twofold. First, I feel that their work illustrates the explicit integration of queer pedagogy into a realistic academic context and can serve as inspiration for undergraduate educators interested in queering anything from a single task to an entire course. Second, Götschel and Sheldon share valuable insights on how and why queer pedagogy was an appropriate choice for their classrooms, insights which strengthen my argument for the necessity of queer pedagogy in undergraduate STEM.

Queering Physics with Helene Götschel

In Götschel's (2019) book chapter "Teaching Queering Physics: An Agenda for Research and Practice" she detailed two of her recent attempts to teach physics "in a queering way" by presenting non-normative versions of typical physics learning tasks.

In the first task Götschel (2019) modified a lesson on angular momentum to feature male figure skater Evgeni Plushenko rather than the female figure skater presented by the textbook. To introduce this lesson to her students, Götschel played clips from several of Plushenko's skating routines. The male engineers in her class were "visibly uneasy" while studying Plushenko's skating routines and giggled as they watched the skater perform incredible feats of athleticism while using his body in "feminine" ways (p. 136). Götschel attributed the discomfort displayed be her students as a result of the masculine body that is expected and upheld in physics classrooms.

In the second task, Götschel (2019) had students work through a standard kinematics exercise, calculating whether or not an antelope running from a lion could escape its predator over a set course of time. Once this calculation was finished, Götschel showed her students a short film featuring several lionesses working together to hunt a zebra and used this film to prompt a discussion of variables like acceleration, change of direction, and the use of teamwork, aspects which are typically neglected in rectilinear presentations of the task. She described this film as giving students the opportunity not just to think about additional kinematic variables, but also as a chance to question the notions of active masculinity and passive femininity as they play out in physics.

Both of these tasks queer physics through the use of queer pedagogy because they "make the familiar strange" and disrupt the culture of physics classrooms and curricula without sacrificing the rigor of the learning objective (Götschel, 2019, p. 126). In the first task, Götschel's (2019) choice to highlight the masculine body in an artistic setting forces students to sit with the discomfort of their own gendered assumptions and to question how physicists evaluate movement scientifically, politically, and aesthetically. In the second task, students are given the opportunity to question what is lost when physics tasks focus on unrealistic and rectilinear presentations of speed and distance while deconstructing the dichotomies of male-female and individualism-collectivism. Götschel's instructional choices within these tasks demonstrate how queer pedagogy does not have to overshadow a lesson's primary focus but can offer a layer of radicality with subtle alterations to existing curricular materials.

James Sheldon's Queer Curriculum of Infinity

In Sheldon and Rands (2013), the authors discussed the queerness of many mathematical topics, naming infinity, topology, imaginary numbers, complex analysis, and decomposition as topics ripe for the queer pedagogy of mathematical inqueery. A few years later, Sheldon (2019) chose to focus on infinity as an inherently queer topic and used queer pedagogy and the queer aesthetic to explore infinity in a five-week course on mathematical problem solving. This course included lessons on counting, modular arithmetic, set theory, and other topics which required an understanding of mathematical infinity, but rather than teaching infinity as a singular lesson at the beginning or end of the course, Sheldon embedded discussions of infinity into every lesson. Sheldon described using the *Hotel Infinity* videos from Dr. Tova Brown, and historical accounts taken from *The Mystery of the Aleph* by Amir D. Aczel to show students the complicated and messy human history surrounding infinity rather than presenting it solely as a mathematical object. As Sheldon described it, he "invited students to feel the sense of the mystery, fascination, power, intrigue, drama, and contradictions that infinity entails. … entangling them in infinity's web rather than straightening out their experience of queer mathematics" (Sheldon, 2019, p. 316).

Sheldon's approach to queer pedagogy, and specifically the use of mathematical inqueery, was embedded in the course's design, shifting the student's focus from *definitions* of infinity to the *history* and *story* of infinity, a choice which I consider abnormal in standard mathematical instruction. This instructional choice is queer precisely because it offers an approach to learning mathematics that is aesthetically oriented while still conveying the necessary material. Sheldon's queer curriculum of infinity also gave students an opportunity to question how definitions and theorems are created and accepted by the mathematical community and to understand mathematics as a human process rather than a scientific eventuality.

The queerness of Sheldon's curricula may seem less obvious than Götschel's, having no direct references to gender, sexuality or identity, but the course's design mirrors epistemological stances in queer theory; it asks what students "cannot bear to know" (Britzman, 2014, p. 214) and invites them to sit with the queer tensions between humanity and infinity.

The Necessity of Queer Pedagogy in Undergraduate STEM: "Queer Students Deserve Nothing Less" (Shlasko, 2005, p. 125)

As Dubbs (2016, pp. 1041-1042) stated, "the ability to consider sexuality irrelevant in the mathematics context is a heteronormatively privileged position; for queer students, their queerness, indeed *other*ness, is intersectional across social contexts." The teaching and learning of mathematics hinges on identity (Gutiérrez, 2013) and every classroom contains queer students who deserve to see themselves represented within the curriculum. STEM subjects are socially, culturally, and politically motivated and reproduce the inequities present within society as a whole; as long as queerness remains marginalized within society, queer students and perspectives will remain marginalized within STEM. I assert that queer pedagogy provides a vital opportunity for students of all genders and sexualities to feel more supported in STEM classrooms, to problematize societal constructions of normalcy, and to reacquaint themselves with the joy of scientific inquiry. In the remainder of this section, I explain how I see queer pedagogy accomplishing these things and specify the importance of this undertaking in an undergraduate setting.

Marginalized students deserve additional support in traditional mathematics classrooms, and queer students are no exception. In a recent quantitative study of queer-spectrum students in undergraduate mathematics courses, Voigt (2022) found that sexual identity had a significant

relationship with a student's mathematical learning experience and their ability to access learning environments when compared to non-queer identifying peers. The study also revealed that when using a regression model, the effect sizes of sexual identity were similar to the effect sizes of race, gender, and first-generation college student status (Voigt, 2022). Additionally, sexual minorities have been found to leave STEM degrees at a higher rate than their heterosexual peers (Hughes, 2018) and in some instances view the pursuit of STEM degrees as dually alienating since they face pressure to remain invisible within the STEM classroom while they are simultaneously underrepresented in queer discourses (Toynton, 2007). These findings support an understanding of queer students as marginalized individuals in the academic environment and suggest a need for practices which support queer students, queered STEM curricula, and queer pedagogy as a visible discourse in STEM.

Consider Götschel's (2019) tasks on queering physics. To my knowledge, students in the classroom, queer or otherwise, were not aware of the instructor's intent to use queer pedagogy. However, because Götschel's tasks were designed to encourage students to face implicit biases in their understanding of gender, movement, and society, I see that she created an opportunity for queer students to connect more deeply with the topics being studied and to see their peers interact positively with topics which are often left outside of the classroom (namely gendered presentation and gendered bodies). Societal expectations regarding gender, presentation, desire, and sexuality oppress and affect *all* students (Götschel, 2019; Gunckel, 2019; Rands, 2013) and I posit that by confronting these topics within the physics classroom (Götschel, 2019), students of all identities were given the opportunity to question the normalcy of these social constructs in a safe and healthy environment without deviating from important curricular topics such as speed, acceleration, and angular momentum.

An additional benefit of using queer pedagogy in undergraduate STEM classrooms is that I see queer pedagogy as being compatible with the tenets of scientific inquiry. Queer pedagogy questions knowledge and reality, exploring alternative ways of knowing and understanding the world, even when those understandings differ from the norm. The same can be said of scientists and mathematicians who, for the sake of argument, I will characterize as creators of tools for learning about and understanding reality. When these mathematicians and scientists take part in the creation of math and science, they are queering (disrupting/interrogating) normalcy, knowledge, and constructs as we currently understand them. In discussing queer theory, Britzman (2014) described what one can know and "cannot bear to know" (p. 214), and to me these words feel just as relevant to scientific inquiry as they do to the field of queer studies.

Sheldon's (2019) queer curriculum of infinity is an excellent example of queer pedagogy upholding the principles of scientific inquiry. His implementation of queer pedagogy encouraged students to question mathematical concepts and definitions, a curricular choice which I feel reintroduces the joy of creation and discovery which is foundational to the study of mathematics. By inviting students to linger in the nonbinary space between knowledge and ignorance (Luhmann, 1998) I posit that Sheldon's students were allowed the rare privilege of acting as mathematicians themselves while learning about mathematicians of the past.

Finally, I must address why my argument is constructed specifically as an appeal to undergraduate educators rather than to educators as a whole. While I firmly believe that queer pedagogy is valuable to students of any age (particularly because queer pedagogy often does not concern queer topics), it is only at the undergraduate level that the long held (and fallacious) argument that discussions of gender and sexuality are not "appropriate" for children (Fla. Legis. House Bill 1557: Parental Rights in Education, 2022) is rendered moot. There is also evidence to

suggest that college students who have positive interactions with queer students are more likely to have positive attitudes towards queer relationships (Liang & Alimo, 2005). To me, this implies that undergraduate classrooms are ideally situated to implement queer pedagogy and provide young people the opportunity to learn tolerance, find acceptance, and expand their scientific mind. Yet, when reading relevant literature on the use of queer pedagogy in STEM, K-12 contexts appeared to be more common. Sheldon (2019) and Götschel's (2019) work were two of a limited number of studies which explicitly cited queer pedagogy in an undergraduate STEM context. For this reason, I find it necessary to encourage the conscious expansion of queer pedagogy into undergraduate STEM curricula, as I see a gap in the field of queer pedagogy at this level.

Conclusion

Queer pedagogy encourages "studying the risks of normalization, the limits of its own practices, and the im/possibilities of (subversive) teaching and learning" (Luhmann, 1998, p. 130), and as mathematics education researchers continue to advocate for more equitable teaching and learning practices, queer pedagogy has much to offer. I contend that queer pedagogy is a powerful tool for studying gender, sexuality, identity, knowledge, and authority, topics which are relevant within the undergraduate STEM curriculum as demonstrated by Götschel (2019) and Sheldon (2019). Additionally, queer pedagogy provides the opportunity to uplift queer voices, support critical perspectives, and encourage students to participate in the interrogative cycle of scientific discovery.

In the future, I intend to study the intersection of queer pedagogy and other critical discourses, and to uplift racialized aspects of queerness which are frequently neglected in the queer community (Leyva, McNeill, Balmer, et al., 2022). To that end, I invite researchers to consider how queer pedagogy might be compatible with their work, and to reflect on how,

> disassociating race, gender, and sexuality … can lead to the production of accounts of race that are (at least implicitly) sexist and or/ homophobic, theories of gender that are (at least implicitly) racists and/or homophobic, and analyses of sexuality that are (at least implicitly) racist and/or sexist (Sullivan, 2003, p. 66).

It is impossible to isolate gendered and sexualized experiences from other experiences of marginalization and I hope to contribute to the coordination of these discourses alongside other scholars who have done exemplary work discussing the racialized and gendered realities of undergraduate classrooms (e.g. Brockenbrough, 2016; Leyva et al., 2021; Leyva, McNeill, & Duran, 2022; McNeill et al., 2022)

I also intend to use queer pedagogy in my research as a tool for queer readings (Britzman, 2014) of proof, queer proof validation, and queer guided reinventions through the use of realistic mathematics education (Freudenthal, 1972). Additional topics which may benefit from the use of queer pedagogy are studies which concern student identity, mathematics identities, and studies which question the construction of mathematics as a stable and fixed.

"Not everything you do has to be gay." At the time, my father's words left me chagrinned, and I was quick to reassure him that my queer experiences represented only a fraction of who I was and what I did. Now I have a better answer to his indictment: Does everything "have to be gay?" Maybe not. But I challenge the idea that there is any value in trying to dissect my life into categories like "gay" and "not gay". My experience of mathematics is a queer experience of mathematics, and my life, my teaching, and my research is all the better for it.

A Framework for Dimensions of Student Mathematical Thinking in Instructional Planning and Teaching

George Kuster
Christopher Newport University

Nicholas Fortune
Western Kentucky University

Sarah Hartman
Middle Tennessee State University

Effective teaching relies on understanding and responding to students' mathematical thinking, enabling educators to build on student prior knowledge and deepen comprehension. While extensive research has established this link at the K-12 level, the research base for undergraduate mathematics education lacks a cohesive framework that integrates student thinking into instructional practices like planning and teaching. This paper addresses this gap by proposing a comprehensive framework designed to embed student thinking more deeply into undergraduate mathematics instruction, with the goal of improving teaching effectiveness and student learning outcomes. We conclude by discussing the implications for both instructional practice and research, as well as outlining the future directions for empirical validation.

Keywords: Student Thinking, Theoretical Framework, Undergraduate Mathematics Instruction

Effective teaching hinges on the ability to understand and respond to how students conceptualize and think about mathematical ideas. This understanding allows educators to tailor their instruction in ways that build on students' existing knowledge and foster a deeper, more robust comprehension of mathematical concepts and skills. Every teacher however, has a unique subset of beliefs that shape their planning and teaching practices (Stipek et al., 2001). These beliefs are crucial as they influence every aspect of the educational process, especially in undergraduate educational contexts (Vishnubhotla et al., 2024). Further complicating this, undergraduate instructors face constraints such as limited time for planning and developing new lessons and activities, and institutional pressures to adhere to a set syllabus that leaves little room for reform-based approaches (Johnson et al., 2013). This makes it difficult to classify particular types of instruction (e.g., inquiry, lecture) as "effective" or "more effective than the other." Rather, we propose that we can address "effective instruction" by addressing how instructional practices are reflective of and/or consider *student mathematical thinking*.

In the complex landscape of undergraduate mathematics education, both researchers and instructors understand the importance of attending to and using student thinking during instruction (Kuster et al., 2024). Anthony and Walshaw (2009) synthesized research literature to develop a research-based "set of principles that underpin the kinds of pedagogical approaches found to develop mathematical capability and disposition within an effective learning community" (p. 148). Some examples of these principles are facilitation of classroom dialogue focused towards mathematical argumentation, building on student thinking, and selection of tools and representations to provide support for students' thinking. Within these examples (and others provided by Anthony and Walshaw (2009)), student thinking is a major underlying theme.

Despite the critical role student thinking plays in instruction, much of the research connecting student thinking with teaching practices has predominantly focused on K-12 education, leaving a gap in the literature at the undergraduate level. Additionally, while there is a great deal of research on how student thinking can be supported during instruction, currently there is not an understanding of how student thinking unfolds in all stages of instruction nor is there consistency with the ways in which student thinking is utilized for the act of teaching by an instructor. In this

theoretical report, we briefly describe how student thinking is situated in literature, and propose a framework that integrates student thinking into the planning and teaching phases of instruction.

Background Literature and Our Goal

Over the past decade, a significant body of research has emerged emphasizing the critical role of student thinking in mathematics education. For our purposes in this section, we briefly outline research in two categories; planning and in-the-moment instruction. In their discussion of planning activities that support effective instruction, Akyuz and colleagues (2013) highlight the importance of five practices: preparation, reflection, anticipation, assessment, and revision. Supporting this work, in a comprehensive literature review regarding lesson planning, anticipating students' thinking and learning was tied to better learning outcomes and improved lesson quality (Cevikbas et al., 2024). Additionally, Vale and colleagues (2019) discuss how anticipating solutions during planning, allows teachers to better elicit student thinking, and to notice and attend to variation in students' responses during instruction. Datnow and colleagues (2021) discuss how gathering evidence of student thinking continually throughout instruction is ultimately valuable for informing planning. Their work also shows how teachers can use evidence of student thinking as data, and reflect on it in conjunction with formal assessment data to identify ways they can better support student learning. This body of work provides a foundation for describing the role student thinking plays in the planning phase of instruction.

Research discussing the importance of student thinking during in-the-moment instruction has focused on specific aspects such as facilitating discussions (e.g., Leatham et al., 2015; Leatham et al., 2021; Smith & Stein, 2011), recognizing productive student ideas (e.g.,Sherin et al., 2010), engaging students in rich mathematical thinking (e.g, Henningsen & Stein; 1997; Jackson et al., 2013) and providing support to early career teachers (e.g., Amador et al., 2022; Stockero et al., 2015). Student thinking can also be thought of more concretely, as data that can be used to inform instructional decisions (Datnow et al., 2021). In line with this, the notion of *responsive teaching* focuses attention on student thinking as an implicit guide to the practice of teaching (Dyer & Sherin, 2016). Responsive (sometimes called adaptive teaching (Gallagher et al., 2022; Parsons et al., 2018; Vaughn et al., 2021)) is a student centered teaching style that involves teachers observing student thinking and adapting their teaching based on their students' needs and abilities. This premise is similar in nature to the principles of generating student ways of reasoning, building on student contributions, and developing a shared understanding from Inquiry Oriented Instruction (Kuster, et al., 2018, 2019). It is clear student thinking plays a central role in a variety of teaching practices as they relate to in-the-moment instruction.

While the current literature base forms a strong foundation, making large strides toward understanding and implementing instructional methods that focus on student thinking, it also presents a few challenges. For instance, there exists a wide array of terms that describe instructional practices related to student thinking — such as eliciting, monitoring, building on, attending to, using, leveraging, understanding, scaffolding, and interpreting — but how these terms are defined or fit together across the field is often unclear. This variation in terminology reflects the multifaceted and complicated nature of the relationship between student thinking and teaching, while also highlighting a lack of clarity and coherence across the research literature. Within undergraduate education, the application of these research concepts is even less clear. Many instructors acknowledge the importance of student thinking with regard to instruction, but in our experience struggle to systematically incorporate student thinking into their instructional

practices. Moreover, there is often inconsistency in the use of these practices even across instructors that report having similar goals and using similar strategies (Kuster, et al., 2024).

Despite the communal value for using student thinking to inform instructional practices, the mathematics education community has yet to fully articulate a cohesive framework that delineates the role student thinking plays across the different aspects of the instructional process. Such a framework would ideally provide a consistent, research-based approach for integrating student thinking into instructional practices and goals, ensuring more effective teaching and improved learning experiences and outcomes in undergraduate mathematics education.

This paper aims to bridge this gap by exploring the intersection of student thinking and instructional practices in undergraduate mathematics education. We propose a framework that builds on current research to embed student thinking into every stage of the instructional process (i.e., planning to teaching). By offering a comprehensive framework and actionable insights, this paper seeks to not only contribute to the academic discourse but also empower educators to make informed, student-centered instructional decisions. When reflecting on our goals as undergraduate mathematics educators, prioritizing an environment that places student thinking at the forefront can unify the discussion regarding 'best practice' of teaching. Ensuring that our teaching and planning practices consistently aim to support and enhance student thinking is critical to effective teaching. Ultimately, our goal is to foster a learning environment where student thinking drives mathematical understanding and success at all educational levels.

Student Mathematical Thinking Theoretical Framework

Before discussing our framework of student thinking, we first provide our definition of Student Thinking. ***Student Mathematical Thinking*** *is any output (verbal or written) where students provide artifacts from which one can determine or infer how they thought or are thinking mathematically; it is the process of thinking, not the product from thinking.* For example, "my answer is 4" is not an example of student thinking whereas, "it cannot be 4 because that violates the axiom" is an example of student thinking. Student mathematical thinking refers to the ways in which students process, understand, and engage with mathematical concepts, problems, and reasoning. It encompasses students' cognitive processes as they solve problems, make sense of mathematical ideas, and develop strategies for approaching tasks.

Our framework on student mathematical thinking describes the ways in which student thinking can be used by an instructor in lesson planning or teaching. Importantly, we view knowledge and learning from the emergent perspective and interpretive framework (Cobb & Yackel, 1996) where knowledge is both individual and collective. Therefore, our framework considers student mathematical thinking both in terms of the individual and collective, but we do not attempt to have our framework delineate a dimension as individual or collective as the use of student mathematical thinking while teaching and planning is both individual and collective.

The framework emerged from previous work on the lesson planning practices of mathematics faculty (Author, 2024). Our findings revealed that though faculty often aligned with a particular teaching style (e.g., inquiry-based, lecture, or a blend of both), this label did not necessarily align with their actual practices. Vishnubhotla and colleagues (2024) had similar observations. We developed this framework centered on student thinking as a means for addressing this issue by being able to characterize key aspects of instruction separate from teaching style.

In our framework we have different dimensions, each is titled with verbs that modify the phrase 'Student Thinking'. For example, Determining Student Thinking. The framework features three dimensions within Lesson Planning, Designing, and Reflecting (Determining, Modeling,

and Preparing) and five dimensions within Teaching (Eliciting, Interpreting, Scaffolding, Assembling, and Reflecting on). This framework evolved from our combined experiences as teachers and researchers across various educational settings. It reflects a fluid approach to both planning and instruction, with each closely intertwined; many in-the-moment teaching decisions are also impromptu planning actions. This framework does not adhere strictly to a linear or circular sequence, as not all steps are always executed, depending on the instructional context. With this framework it is our goal to identify foundational actions in which teachers engage, from which many other practices are composed.

Our full framework can be found in Table 1. Following Table 1 we expand upon each dimension and support it with appropriate research literature.

Table 1. Student Thinking Framework.

Category	Dimension	Definition
Lesson Planning, Designing, and Reflecting	**Determining**	Deciding on the learning outcomes of the lesson, in terms of the student mathematical thinking in which one wants the students to engage related to the topic. Note: We assume course learning objectives have already been decided and agreed upon by the university.
	Modeling	Developing possible ways in which students might mathematically think about the content at various waypoints throughout the progression of the lesson based on past experience, resources, and/or literature.
	Preparing with	Developing and/or ordering a list of possible questions, tasks, lecture points, etc. that can be utilized to elicit or progress student mathematical thinking along this (modeled) pathway.
Teaching	**Eliciting**	Engaging students in tasks, problems, and/or questions (things they do not have the answer or solution method for) with the intent of bringing their thoughts and ideas to the public space.
	Interpreting	Actively listening to students with the intent to figure out and understand their mathematical thinking and how they are using their understanding about a particular concept.
	Scaffolding	Building scaffolds that match with possible pathways students may take based on interpreted student thinking (e.g., how the students are thinking about the concepts) and how it fits with the instructional goals.
	Assembling	Having scaffolded the students' mathematical thinking might develop and lead to more sophisticated understandings, the instructor attempts to move students along that progression through careful consideration of activities that are intended to evoke current thinking in ways that lead to new and more complex understandings.
	Reflecting on	Considering how students thought about concepts and ideas, how those ideas developed throughout the lesson (for them), and how the instructor could have scaffolded questions or tasks that better aligned with that progression.

Determining Student Thinking is the initial step in using student thinking, and involves identifying a lesson's desired learning outcomes (Stephan et al., 2016; Nabb et al., 2018). This goes beyond determining the concepts to be understood and the skills that need to be mastered, and includes identifying targets related to the specific student thinking and learning one wishes to help their students develop;. To determine these goals, instructors may consult research on the topic, engage in thought experiments, or ask colleagues about their prior experiences.

Modeling Student Thinking involves making the implicit reasoning processes of students explicit by developing a blueprint for the ways students are likely to understand and reason with particular concepts or approach certain tasks. Additionally, teachers consider how students may reason with these ideas to construct understandings of more complex ideas. For instance, while students must understand and develop skills concerning limits, function, and average rate of change before they can robustly understand instantaneous rate of change, they must also think about those foundational concepts in particular ways to develop a rich and robust understanding of instantaneous rate of change, or how this can be represented as a function. In the research literature this is often referred to as anticipating student thinking (e.g., Stein et al., 2008). We have chosen the modifier *modeling,* to highlight the need for active engagement with the student thought process and the role modeling often plays in the construction process. Developing foresight into how students might understand and reason about and with a concept or idea is central to this dimension. In the research literature, modeling student thinking is emphasized as a critical aspect of lesson planning, particularly in how it informs the design of instructional tasks, the sequencing of content, and the explicit illustration of how mathematical thinking develops and can be supported (e.g., Carpenter et al., 1999; Jacobs et al., 2010; Ball et al., 2008; Peterson and Leatham, 2009).

Preparing with Student Thinking involves intentionally designing instructional activities that support students in progressing from their current levels of understanding to more advanced levels. These instructional activities (e.g, tasks, questions, lectures) are designed using the previously developed models and understanding of student thinking and learning. During the preparation phase, teachers are thinking forward and backward; forward in the sense that one must create lesson materials that support the students in engaging in the desired thinking and reasoning, and backward in the sense that one must identify lesson activities that support the thinking and reasoning that serve as waypoints to that destination. With our calculus example, teachers that use student thinking to prepare lessons are considering not only the tasks concerning the desired ways of reasoning about instantaneous rate of change, but also sequences of tasks that would support students in thinking about function, limits, and average rate of change in ways that foster student development of instantaneous rate of change. This preparation of lesson activities is discussed in the literature at both the individual lesson level (Stephan et al., 2016) and at the course level (Rasmussen & Keene, 2019).

Eliciting Student Thinking involves drawing out and making students' thought processes, ideas, and understanding observable. The goal is not to simply evaluate what students know but to engage them in deeper reflection and reasoning, helping them to articulate their thinking. Eliciting student thinking takes many forms, such as using questioning, discussions, and tasks designed to engage students in thinking about concepts (Kuster, et al., 2019). Smith and Stein (2011) discuss the importance of using cognitively demanding tasks for supporting mathematically rich student thinking and reasoning. With regard to in-the-moment decision making, teachers cannot identify productive ways to later scaffold or assemble student knowledge without first having access to their current knowledge (Hufferd-Ackles et al. 2004;

Leatham et al. 2015). Along this same vein, they cannot determine the accuracy of their models, or how to best utilize their prepared activities without having an understanding of their students' current thinking.

Interpreting Student Thinking is a critical aspect of effective instruction, as it allows teachers to understand and subsequently respond appropriately to students' conceptualizations and reasoning processes. Research underscores the importance of interpreting students' responses to adjust teaching strategies and support learning. For example, Jacobs and colleagues (2010) highlight how teachers' professional noticing—observing, interpreting, and responding to students' mathematical thinking—enables them to provide targeted support and modify instruction based on real-time insights into students' understanding. This practice is crucial for formative assessment (Franke et al., 2009), and is a key practice in Inquiry Oriented Instruction (Kuster, et al., 2019). Boaler (2016) also emphasizes that interpreting student thinking can uncover diverse problem-solving approaches and reasoning, allowing teachers to adjust tasks and discussions to better meet students' needs. By accurately interpreting students' mathematical thinking, educators can better identify where students are along the path of achieving the intended thinking goals, and what and how student ideas can be combined to support their progression along that path.

*Scaffolding Student Thinkin*g is an important aspect of in-the-moment teaching and is characterized by making decisions based on information from both the planning phase and teaching phase. That is, having interpreted the students' thinking, instructors then make decisions about how to guide and manage the lesson based on the models they developed and the materials they have prepared during the planning phase. When Scaffolding, teachers consider how students are thinking in-the-moment about a mathematical concept, and make in-the-moment teaching decisions regarding how that thinking relates to the instructional goals and how it may be utilized. They may even revise the models they developed or the materials they created in lieu of the new information they received while in the process of interpreting. Effective scaffolding requires the teacher to deeply understand students' thinking (Interpreting), anticipate how that thinking will be able to develop (Modeling), and then making instructional decisions that support that development (Franke et al., 2007; Jacobs et al., 2010).

Assembling Student Thinking can be roughly thought of as the enacting the scaffold; the actions taken by the instructor to utilize the scaffold and build the desired student thinking. This may be actualized with the utilization of a variety of instructional methods such as whole class discussions, intentionally designed task sequences, teacher-directed techniques, selecting and sequencing student presentations, etc. Effective teaching practices involve recognizing and extending students' ideas, creating productive learning environments, and promoting connections between mathematical concepts (Peterson & Leatham, 2009). The flexibility of the specific instructional methods that foster these connections is intentional, but to be Assembling Student Thinking the approach must not only incorporate students' existing knowledge, but also help them to advance their understanding through thoughtful and strategic instructional design.

Reflecting on Student Thinking is a critical aspect of effective mathematics instruction, as it plays a vital role in enhancing teaching practices and supporting student learning. By carefully analyzing students' responses and thought processes, teachers are able to make informed decisions about instructional strategies and adapt their teaching to better meet students' needs. This reflective practice helps identify where students are struggling and allows for adjustments to be made to address these challenges. Carpenter and colleagues (1996) emphasize that understanding students' cognitive processes enables teachers to align instruction with students'

existing knowledge, thereby improving the effectiveness of teaching. Reflecting on student thinking provides teachers with the necessary insights to offer specific, actionable feedback that helps students build more robust and complex understandings. Additionally, Lampert (2001) suggests that this practice supports teachers' professional growth by offering insights into their own instructional practices and identifying areas for improvement.

Conclusion, Implications, and Next Steps

In this paper, we proposed a framework integrating student mathematical thinking into planning and teaching. Our framework emphasizes the importance of Determining, Modeling, and Preparing with Student Thinking during lesson planning, and Eliciting, Interpreting, Scaffolding, Assembling, and Reflecting on Student Thinking during instruction. We propose these as core building blocks from which one can characterize instructional practices across an array of pedagogical approaches. By placing student thinking at the center of instructional decision-making as opposed to teaching style, we hope to enable educators to more effectively foster deeper understanding and more meaningful engagement with mathematical concepts.

Along these lines the framework is intended to offer flexibility, recognizing that instructional practices vary widely across classrooms and teaching styles, while also providing a coherent structure for incorporating student thinking into any teaching approach. By doing so, it empowers educators and researchers to move beyond a reliance on traditional classifications of teaching methods (e.g., inquiry-based vs. lecture) and instead focus on the central goal of supporting student learning; fostering and advancing student thinking.

Despite its potential, the framework also presents several challenges and opportunities. One of the key limitations is the lack of a formal component dedicated to evaluating learning outcomes, a crucial aspect of instruction. Additionally, research is needed to explore how this framework can be adapted and applied across various instructional contexts, content areas, and student populations. We also acknowledge that our framework does not prescribe specific methods or concrete steps, but rather serves as a guiding principle. Future work should focus on empirically validating the dimensions of this framework, as well as exploring the ways in which they interact and evolve during real-time instruction.

The implications of this work are profound, particularly in its potential to unify the discourse around "best practices" in teaching mathematics. Rather than focusing on the form of instruction, we suggest that the mathematics education community should prioritize instructional practices that are steeped in student thinking. This reorientation allows for a more flexible, adaptable approach to teaching while ensuring that student thinking remains central to the instructional process, something research seems to indicate as crucial to effective teaching. As we continue to refine and test this framework, we hope it will contribute to both the research literature and practical teaching strategies, ultimately supporting educators in creating learning environments that promote deep mathematical understanding and success at all levels of education.

Future research should focus on examining how student thinking is operationalized across different types of mathematical content and instructional settings. Additionally, studies that explore how instructors in higher education can develop the skills and knowledge needed to effectively engage with student thinking will be crucial for further developing this framework. Our aim is to inspire both researchers and practitioners to place greater emphasis on student thinking, not just as a peripheral consideration, but as the driving force behind instructional planning, decision-making, and evaluation. By doing so, we can create more effective and equitable learning experiences for all students.

Integrated Cognitive-Instrumental Model: A Dual Framework for Analyzing Cognitive Processes

Antonio Martinez
California State University, Long Beach

Gabriel Fanucchi
California State University, Long Beach

Influenced by Piagetian constructivism and Vygotsky's sociocultural theory, contemporary research has explored both individual cognitive development and the role of tools to mediate learning. In this theoretical report, we propose the Integrated Cognitive-Instrumental Model (ICIM), which synthesizes two prominent frameworks: APOS Theory (grounded in constructivism) and the Instrumental Approach (rooted in sociocultural theory). ICIM combines the strengths of both frameworks, where APOS Theory explains how learners move through stages in their cognitive development, and the Instrumental Approach shows how tools and artifacts shape and support this development. Together, these frameworks allow for a more comprehensive understanding of students' cognitive development by bridging the gap between Piagetian and Vygotskian principles and highlighting the interplay between individual cognitive processes and the socio-cultural environment. ICIM offers a robust, multi-theoretical approach that provides a new perspective into student thinking with the potential to inform both research and instructional practices.

Keywords: APOS Theory, Instrumental Approach, Constructivism, Sociocultural Theory

Introduction

Understanding student thinking has been the cornerstone of mathematics education research for over a century, dating back to the late 19th and early 20th century with Behaviorist theory focusing on observable behaviors and the external conditions under which learning occurred (Thorndike, 1922; Woodworth & Thorndike, 1901). While these early studies laid the groundwork for systematic educational research, they overlooked the internal cognitive processes that are fundamental to meaningful learning and understanding how to support such learning (Erlwanger, 1973). As the field evolved, the focus gradually shifted toward understanding the cognitive mechanisms that underpin students' learning processes, a shift that was groundbreaking in fostering a deeper comprehension of how students construct and internalize mathematical concepts. This shift in focus was significantly influenced by the work of theorists such as Jean Piaget and Lev Vygotsky. Piaget's writings, along with von Glasersfeld's interpretations (e.g., von Glasersfeld, 1984, 1987, 1995), introduced the constructivist approach, which emphasizes the active role of the learner in independently constructing knowledge/reality through a process of action and reflection. Vygotsky's sociocultural perspective, meanwhile, highlighted the critical role of social and cultural contexts in shaping cognitive development, particularly through language, tools, and social interactions with more knowledgeable others (Confrey, 1995; Pugh, 2017).

Drawing on these two theoretical perspectives, we present a framework with the goal of providing a straightforward mechanism to characterize students' in-the-moment cognitive activity. To achieve this, we draw on two frameworks that build on and connect Piaget's constructivist theory of learning and Vygotsky's sociocultural perspectives. In the following sections, we summarize the frameworks used, describe the merger of these frameworks into one integrated framework, and conclude this report with implications, considerations, and questions for the field. By integrating these perspectives, we hope to offer a more accessible and multi-

theoretical understanding of student cognition in mathematics, with the potential to inform both research and instructional practices.

Frameworks

The first framework we are leveraging with this work is APOS (Action, Process, Object, Schema) Theory, grounded in constructivist principles focused on the mental actions, processes, and general cognitive structures involved in mathematical thinking. The second framework is the Instrumental Approach, informed by the sociocultural perspective, which emphasizes the role of tools and artifacts in shaping cognitive processes. In the following sections we present a review of the various components of APOS Theory and the Instrumental Approach, outlining their constructs so that they can later be synthesized together in an integrated framework that we are tentatively referring to as the *Integrated Cognitive-Instrumental Model* (ICIM).

APOS Theory

Drawing on Piagetian principles to characterize students' cognitive activity, we draw on the well-established cognitive framework known as APOS Theory (Arnon et al., 2014; Asiala et al., 1996; Dubinsky 1991; Dubinsky, & McDonald, 2001). APOS stands for Actions, Processes, Objects, and Schema, and describes a constructivist perspective built upon Piaget's theory of reflective abstraction. Central to the theory is the hypothesis that mathematical knowledge is the result of an individual's construction of four key components: a) mental actions, b) processes, c) objects, and d) schemas to make sense of mathematical problem situations. Each of the four key components of APOS Theory represent a distinct stage in the development of mathematical knowledge (Dubinsky & McDonald, 2001). Actions represent external transformations of mathematical concepts. These actions can be thought of as the application of explicit algorithms or memorized procedures. Importantly, actions lack justifications and are not typically connected to other forms of mathematical knowledge. When an action is carried out multiple times through repeated stimuli, and reflected upon, it becomes a process. Processes are perceived as internal, implying that they have meaningful connections to an individual's existing mathematical knowledge. This enables individuals to imagine a variety of transformations, omit steps in their conceptualization of the actions occurring, anticipate results, and provide a justification for their processes. An object is constructed from a process when individuals become aware of the various processes that describe a central idea. More specifically, the learner realizes that transformations can act on the central mathematical idea itself, therefore treating the idea as an object that can be acted upon. The literature refers to these objects as higher-level mental constructions that extend beyond the context in which they were originally formed – in more theoretical terms, they are extensions of Piaget's notion of reflective abstraction (Arnon et al., 2014; Dubinsky, 1991). Lastly, schemas represent a coherent collection of actions, processes, objects, and other schemas that relate to a specific mathematical idea or central topic. Schemas are characterized by their interconnectedness, providing the learner with an internal framework which helps them determine whether a given mathematical situation falls within their scope (Dubinsky & McDonald, 2001).

For the purposes of using APOS theory to understand student thinking, the application involves a cyclical process consisting of *theoretical conjectures, assessment design, and empirical data collection and analysis*. The purpose of this iterative cycle is to continually refine conjectures about the mental constructions of the learner, and is necessary for understanding how they might reason about various mathematical concepts central to the topic of investigation. The

theoretical conjecture phase begins with the development of a genetic decomposition, which is a set of mental constructions that students might make to understand a mathematical concept. For example, students may first construct an action-based approach of logical statements by typing logical statements such as 'True and False,' 'False and False,' and 'True and True' into a text-based programming software such as Python or R to investigate the outputs. This action stage may then be followed by a process stage in which the learner identifies the central idea that the 'and' proposition requires two true propositions to produce a True output. Once the learner identifies this central idea, they may then utilize this as a piece of a larger mathematical process, therefore treating the 'and' operator as a mathematical object. In a teaching experiment investigating undergraduate students' conceptions of set theory and logic, students exemplified these action-process-object stages using the 'and' operator in Python as an object to generate the intersection of three sets (Martinez, 2022). This decomposition is based on the anticipated mathematical activity of the students, given the researcher's understanding of the concept, and it is refined through the subsequent iterations of interactions with the learner. In studies focused on the teaching and learning of a specific concept, typically the goal is to guide the learner through the genetic decompositions proposed by the researchers (Arnon et al., 2014). It's important to note that the progression through the various stages of APOS Theory is not linear. Some students, as they are engaging in the action stage, move to the process stage, but may move back to the action stage to investigate a particular case of the concept (Dubinsky & McDonald, 2001). Below I highlight another example of genetic decomposition for the concept of sets and subsets which we will return to in the next section.

Consider the following question: How can we determine the total number of subsets of a set, S, and is there a way to calculate this for any set? The genetic decomposition starts with the action stage; a student might approach this problem by explicitly listing all the subsets of some set, say $S = \{1, 2\}$. They might list the subsets as $\{\}$, $\{1\}$, $\{2\}$, and $\{1, 2\}$. At this stage, the student's understanding is limited to the concrete actions of listing subsets, and they may not yet grasp the underlying combinatorial principles. As the student gains experience and reflects on the process, they might realize that there is a systematic way to generate subsets without listing them all individually. Ideally, they will begin to understand the process of binary choices: for each element in set S, they can choose to include it in a subset or exclude it. This stage involves interiorizing the process of subset formation. At the object stage, the student has a more abstract understanding in that they can perceive subsets as objects themselves and recognize that these subsets can be operated upon. They can imagine performing operations on subsets, such as finding the union or intersection of subsets. This stage involves encapsulating the process of generating subsets into a coherent concept of subsets as objects. At the schema stage, the student has a comprehensive framework for dealing with subsets. They have a collection of actions, processes, objects, and other schemas related to subsets that they can then use to determine when a problem situation involves subsets and use their schema to address various subset-related problems. As demonstrated, APOS theory can provide a structured approach to understanding how students develop mathematical understanding. However, APOS theory (and Piaget's constructivist theory of learning in general) fails to address social factors such as students interacting with their environment (in the Vygotskian sense), as an integral aspect of one's learning. More specifically, the use of tools and their influence on cognition is missing from APOS Theory. In the next section I describe the Instrumental Approach, a theoretical framework that artfully bridges the work by Piaget and Vygotsky to account for constructivist principles, and the use of tools to describe cognitive activity.

The Instrumental Approach

Grounded in Vygotsky's (1978) concept of mediated activity, the Instrumental Approach broadly serves as a framework for analyzing how individuals expand their cognitive abilities through the use of tools to manipulate their environment. While APOS Theory largely developed through mathematics education research in the United States, the Instrumental Approach emerged within the French tradition of mathematics education research (Artigue, 2002; Guin & Trouche, 1998; Rabardel, 1993a, 1993b; Vérillon & Rabardel, 1995; Trouche, 2004). Vérillon and Rabardel's (1995) work was particularly influential, as they distinguished between subject-object interactions and laid the foundation for understanding how instruments develop through the use of tools, or artifacts. As described by Roorda et al. (2016), artifacts can be a physical object such as graphing calculators, geometry measuring tools or other manipulatives, but they could also be graphs, computational programming environments, images, proofs, formulas, or any other objects that can be used to reason about a given mathematics task. As the learner incorporates the artifact into their activity to solve a mathematical task, the cognitive process of the learner interacting with the artifact transforms the process merely from a subject-object interaction (i.e. learners solving a mathematical task without the artifact) into what we call an *instrumented activity situation*, or an expanded cognitive function that would not otherwise be possible without the artifact.

As Martinez (2024) described, "the development of the instrument involves the learned ability to manipulate the artifact itself (proximal action), in order produce an extended, and meaningful, manipulation (distal action) of the environment in which these actions are taking place" (p. 5). The relationship between proximal and distal actions are central to the development of the instrument (Abrahamson & Bakker, 2016; Artigue, 2002; Trouche, 2004; Vérillon & Rabardel, 1995). Take the example of a child learning how to use a spoon to eat soup, the child needs to understand how to manipulate the spoon (proximal action), even as they keep an eye on the effect it has on the soup (distal action). On its own, an artifact is not an instrument. It is only through the interaction and use of the artifact to solve a mathematics problem does it become an instrument through the manipulation of the artifact to enact a meaningful change in the learner's environment. Figure 1 is a representation of the interactions that are taking place as a learner (subject) solves a mathematical task (object) using an artifact to mediate the cognitive activity which leads to the development of an instrument.

The process of transforming an artifact into an instrument is known as *instrumental genesis*, which involves a bi-directional interaction between the learner and the artifact (Artigue, 2002). What this means is that the learner may be afforded creative and interesting ways to think about a mathematics problem given the potential use cases of the artifact while at the same time being limited by the constraints of the artifact itself which shapes the ways in which the learner may go about solving the task. This two-way cognitive interaction is known as the *instrumented action scheme* (Trouche, 2004) and is rooted in Piagetian constructivist principles. As described by Vergnaud (2009) one's scheme is the "the invariant organization of activity for a certain class of situations" (p. 88). In other words, one's scheme describes the process by which learners apply their existing knowledge to familiar situations and how they adapt or reorganize their thinking when faced with new problem tasks.

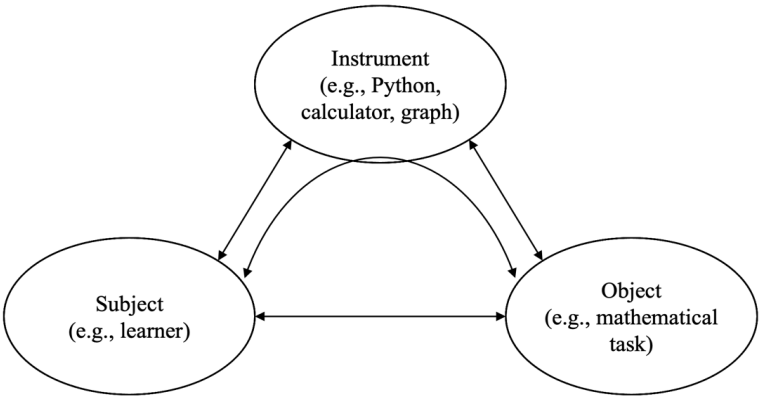

Figure 1. The subject, object, instrument interaction.

In the context of the instrumental approach, schemes consist of four main components (Trouche, 2004; Vergnaud, 2009), paraphrased from Buteau et al. (2020):

1. The goal of the activity: With sub-goals and expectations.
2. Rules of action: Stable behaviors of the learner.
3. Operational invariants: Which can be theorems-in-action (propositions considered as true) or concepts-in-action (mathematical concepts considered as relevant).
4. Possibilities of inferences: These possibilities are essential for the adaptation of the scheme to the specific features of the situation.

As Buteau et al. (2020) explain, a subject's mathematical activity can reveal these elements of their scheme when they state something like, "When I want to do this [goal], I always act like this [rule of action] because I think that [operational invariant]" (p. 1027). While students may not always articulate their reasoning so clearly, we can infer their thought processes through their observable behaviors. For instance, rules of action can be described as approaches the learner comfortably relies on to accomplish a familiar task, which are guided by their beliefs or understanding (operational invariants) of how things work. The operational invariants are divided into theorems-in-action and concepts-in-action. Theorems-in-action are the learner's constructed understandings of how things work, while concepts-in-action relate to the mathematical ideas important for the task. The possibilities of inferences refer to situations where learners modify their schemes by creating new rules of action or operational invariants.

Taken from Martinez (2023), let's consider the same problem scenario from the previous section in which a learner is asked to find all the possible subsets for any given finite set. Let's also imagine that the learner is using a computational programming environment like Python as the artifact which is developed into an instrument. In this case, one potential *rule of action* could be the creation of a loop that creates all the possible subsets. A *concept-in-action* could be the idea that a subset contains only elements from the original set and a *theorem-in-action* could be that sets are unordered, meaning {1, 2, 3} is equivalent to {3, 2, 1}. As for a *possibility of inference*, encountering the empty set (which is not something that a learner using Python may naturally produce) would require the learner to create a new concept-in-action that includes the empty set as a subset.

It is important to note that these conceptual elements, which are inferred by the researcher, must ultimately be supported by the learner's observable actions. Naturally, some elements of a learner's scheme may be overlooked, but the goal is to identify the most relevant concepts tied to each rule of action. Together, these conceptual components form the learner's scheme, but as Roorda et al. (2016) describe, schemes can be observed at two levels of granularity. At the first

level, a scheme may consist of a single rule of action and its related operational invariants, observable through one instance of behavior. At the second level, multiple schemes combine to form an instrumentation scheme related to a specific task (Roorda et al., 2016). In the case of calculating subsets, the learner's overall instrumentation scheme may involve several steps: creating an algorithm, storing subsets in a list, and determining the total number of subsets. Each of these steps can represent individual level-one schemes, while together they form a level-two scheme for solving the subsets problem.

Integrated Cognitive-Instrumental Model

We should note that neither of these frameworks makes claims about the permanence or stability of cognitive behaviors; however, they both provide fine-grained analyses of in-the-moment reasoning at the individual level. That said, from our perspective, each framework has specific weaknesses that could limit its utility in analyzing student thinking. In the case of APOS Theory, the notion of schema – intended to encompass all actions, processes, and objects related to a mathematical topic – can be overly vague. This can make it challenging for researchers, and especially practitioners, to extract practical insights about student thinking. Some researchers have worked around this issue by focusing more directly on epistemological nuances rooted in Piaget's notion of reflective abstraction, such as Sfard's (1991) concept of *reification* and Zandieh's (2000) idea of *process-object pairs*. However, since APOS Theory is grounded in Piagetian principles, we argue that its more pressing limitation is its lack of emphasis on how tools mediate learning, particularly when attempting to provide a holistic view of learners' cognitive processes. In recognizing this gap, we turn to leverage the Instrumental Approach, which accounts for the role that tools and artifacts play in shaping cognitive development. While the Instrumental Approach addresses how artifacts shape cognition, its focus on concepts-in-action and theorems-in-action can sometimes complicate the analysis process. Although valuable in theory, the emphasis on identifying every subtle cognitive detail can make it challenging to construct a coherent account of a learner's thought process as they engage in the instrumental genesis of the artifact.

By integrating both frameworks, we propose a theoretical stance that conceptualizes learning as the cognitive work learners do at the individual level as they move through the Action, Process, and Object stages of APOS theory, in collaboration with the work they do to instrumentalize artifacts to solve mathematical problems. To illustrate how these frameworks can work in tandem, we revisit the subset problem introduced in the previous sections to synthesize the key ideas from both frameworks and demonstrate their natural co-utilization. As a learner engages in the Action stage of APOS theory, they may write out the possible subsets of S – these are rules of action, or stable observable behaviors. The process stage may entail the identification of a combinatorial method of reasoning about the number of subsets a set has – this describes the development of a concept-in-action, for each element in set S, it can either be in a subset or not be in a subset. At this stage in particular, the learner may utilize computational algorithms (their developed instrument) to omit steps or provide additional justification for their ways of reasoning. Finally, as the learner internalizes these actions and processes into their cognitive understanding of subsets, they may encounter a new situation, such as the empty set, where they must determine whether this new situation aligns with their existing understanding, or requires the development of new rules of action and operational invariants. In Table 1 we provide a table that showcases the overlap of the two frameworks, supported by the theoretical perspectives of Piagetian constructivism as well as Vygotskian sociocultural theory.

Table 1. Integrated Cognitive-Instrumental Model.

Component of Learning	APOS Theory (Constructivism)	Instrumental Approach (Sociocultural)	Affordances of ICIM
Cognitive Development	Action-Process-Object stages describe individual cognitive development	Rules of action guide how learners engage with tools, instrumentalizing the artifact to manipulate their environment	ICIM integrates cognitive development with the mediation of tools
Concept Formation and Abstraction	Reflective abstraction leads to the development of schemas for understanding concepts	Operational invariants (concepts-in-action and theorems-in-action) are developed through tool use	ICIM integrates concept formation from both a cognitive and social/mediated perspective
Adapting to New Situations	Accommodation leads to the development of new actions	Possibilities of inferences are influenced by the instrumented action scheme	ICIM highlights how both internal and external factors influence a learner's ability to adapt

As Table 1 illustrates above, the ICIM addresses three main factors of learning: (a) cognitive development, (b) concept formation and abstraction, and (c) adapting to new situations. We argue that integrating the components of APOS Theory and the Instrumental approach across each of these three components of learning provides a more robust characterization of one's cognitive development while remaining flexible enough to account for two theories of learning.

Discussion

We see the ICIM to be particularly useful for researchers wanting to analyze student's cognitive thought processes related to computational thinking. This is particularly relevant given Lockwood and Mørken's (2021) recent call for undergraduate mathematics education research to investigate the role of machine-based computing in the teaching and learning of mathematics. The integration of the two frameworks provides a more holistic view, adding texture to how we can articulate a learner's cognitive thought process, and builds a unique bridge between Piaget's and Vygotsky's theoretical perspectives that do more than merely complement each other. As Simon (2009) described, "The availability of multiple explanatory theories and the use of multiple layers of analysis can, depending on the research, provide a richer set of constructs for accounting for observed phenomena" (p. 484). The ICIM draws on this idea, not only capturing the complexity of learners' individual cognitive thought processes, but also highlighting the crucial role of tools and social context in shaping these processes.

The growth of educational technologies outpaces our understanding of how to promote students' mathematical development with such technologies. It has become increasingly important for researchers to problematize digital tool design so that educators seeking to enrich students' mathematical knowledge with the use of digital tools support, and not hinder, student learning. In this theoretical paper, we draw on existing research on digital tools for mathematics learning to propose a framework that situates to-be-designed tools within a "design space". We argue that an initial conceptualization of tools within this design space can help relate and distinguish tools from the literature that would be otherwise difficult to delineate or compare. We describe the spectra that comprise the digital tool design space, give examples of tools from the literature that fit within clusters of design space, and discuss the utility of such a framing.

Keywords: digital tools, digital task design, student thinking and learning

Over the past few decades, new digital technologies—combinations of hardware and software—have been developed to support mathematics teaching and learning. Over time, the nature of these digital technologies has shifted from standalone software packages designed to support students' learning about a particular mathematical topic (e.g., SimCalc) or provide a specific kind of interactive experience (e.g., Logo) toward interconnected webs of digital technologies utilized by teachers to accomplish a variety of functions. Teachers now use digital technologies for organization and implementation of the work of teaching (e.g., assigning work, producing worksheets, displaying student work), to connect with communities of other teachers that share materials and other resources, to individualize assignments and assessments of previously learned mathematics, and to support new ways of doing and representing mathematics (Sinclair & Robutti, 2020; Clark-Wilson et al., 2020).

At the same time, researchers have studied digital technologies in mathematics education from a wide range of theoretical perspectives and educational contexts. Given the fractured nature of the research literature on digital technologies for mathematics learning, it is important to develop theoretical tools that can be used to connect research findings across studies. This paper is part of a larger project broadly focused on the design of digital tools for mathematics learning at the undergraduate level. By *digital tools*, we mean instantiations of digital technology created within a software environment to support a particular learning goal. As part of our work, we recognized a need for a descriptive framework characterizing attributes of digital tools that could be used to identify commonalities between digital tools that were developed in different software contexts, from different theoretical perspectives, and for different pedagogical and mathematical goals. In this paper, we address the research question: *What dimensions of design can be used to characterize digital tools?* We provide a preliminary framework with three dimensions of design.

Research on Digital Tools for Mathematics Learning

Existing taxonomies distinguish between digital technologies for mathematics learning by classifying them according to their potential use in instructional situations (e.g., Dick & Hollebrands, 2011; Drijvers, 2015; Hoyles & Noss, 2009). For example, Dick and Hollebrands (2011) make the distinction between *conveyance technologies*, which allow students and teachers to present, communicate, and collaborate, and *mathematical action technologies* which "can perform mathematical tasks and/or respond to the user's actions in mathematically defined ways" (p. xii). Whereas this distinction concerns what the tools afford students and teachers, Drijvers' (2015) taxonomy classifies tools by the type of mathematical activity they support for students. Drijvers (2015) distinguishes between digital tools for *doing mathematics* or *learning mathematics*. In the category of learning mathematics, Drijvers (2015) further differentiates between tool use for *practicing skills* and for *developing concepts*. Lastly, Hoyles and Noss (2009) present four categories of digital tools that have differing potential to shape students' mathematical cognition: (1) dynamic and graphical tools, (2) tools that outsource processing power, (3) new representational infrastructures, and (4) tools with high-bandwidth connectivity.

These taxonomies can be useful when networking individual research studies focusing on students' learning with digital tools embedded within a specific software environment. For example, Bray and Tangney (2017) used an elaborated version of Hoyles and Noss' (2009) taxonomy to systematically review empirical research on the use of digital technology in mathematics education. "Such taxonomies prompt researchers to define more deeply the technology under scrutiny to support the reliability and generalizability of findings, a factor that is becoming increasingly important due to the growing complexity and interoperability of emerging technologies" (Clark-Wilson et al., 2020, p. 1126).

However, these taxonomies also tend to be used to describe particular software packages (e.g., GeoGebra), types of software environments (e.g., spreadsheets, clicker response systems), or types of hardware (e.g., interactive whiteboards; motion sensors). This makes it challenging to see how or when findings from one kind of digital technology can be usefully applied to the design or analysis of another. For example, Baccaglini-Frank and Mariotti (2010) studied students' conjecturing processes when engaging with open problems in a dynamic geometry environment. They proposed Maintaining Dragging as a mode of interaction with draggable points that has the potential for supporting particular cognitive processes in the context of Euclidean geometry. For researchers studying digital tools that are not embedded in dynamic geometry environments, there is still quite a bit to learn from this study.

To effectively gain such inter-environmental and inter-software insights, we need theoretical tools that can be used to identify the relevant attributes of digital tools in such a way that they are abstracted from the particularities of the software environment. We propose a framing of *design space* to accomplish this goal. We situate our initial conceptualization of design space using examples from the undergraduate mathematics curriculum because of the rich collection of mathematically complex tools constructible from the undergraduate curriculum. We use definite integration as a primary context to delineate regions of design space according to our identified spectra.

Theoretical Framing

Research on digital technology in mathematics education draws on various theoretical frames (Lagrange et al., 2003), with individual studies often poorly connected to prior work outside of the theoretical framework being utilized (Artigue et al., 2009). In an attempt to integrate disparate theoretical approaches to the study of digital technologies for mathematics education,

the TELMA project endeavored to use specific and shareable language that is "not dependent on a particular theoretical frame, allowing us to communicate" (Artigue et al., 2009, p. 220) across studies examining related phenomena from different theoretical perspectives. To accomplish this, the TELMA group introduced the notion of *didactic functionality* (Cerulli et al., 2006) to describe digital tools for educational purposes. The construct of didactic functionality has three components: (1) the set of tool features/characteristics, (2) a specific educational goal, and (3) a set of instructional modalities for employing the tool in an instructional context toward the desired learning goal. The framework we propose in this paper addresses the first component of didactic functionality by providing a descriptive language for the characteristics of digital tools.

In this paper, we utilize Yerushalmy's (2005) notion of *design space* to theorize dimensions of design for digital tools. A design space is a structured way of representing the space of possibilities for the design of a tool. We conceptualize the design space for digital tools as a 3D space in which digital tools can be placed on each of three axes representing the components of our framework.

A Preliminary Framework for Describing Digital Mathematics Tools

In this section, we introduce a preliminary framework for describing digital tools for mathematics learning. The framework has three main components: (1) the Interactive ↔ Inert spectrum, (2) the Static ↔ Dynamic spectrum, and (3) the Specialized ↔ Generalized spectrum. As is implied by the word spectrum, we intend that digital tools can be characterized as somewhere along a continuous scale described by each component. Using the dynamic label simply means that the tool in consideration is closer to the dynamic end of the spectrum than the static end. Some aspects of a so-called dynamic tool will be more dynamic than its other, more static, components. Yet by having at least some dynamic components, the digital tool lies farther along the dynamic end of the static ↔ dynamic spectrum than if it did not have those components. Likewise, having more dynamic components, or having the same components with more emphasis on its dynamic parts, would place the tool even further down the dynamic end of the spectrum. However, while we characterize each of these three components as a one-dimensional scale, the factors that place tools on this continuum are not well-defined in a mathematical sense that would lend these scales to a total ordering. That is to say, we do not intend for this framework, in its current form, to be used for pairwise comparison of all digital tools along each of the components. A fine-grained comparison such as "Tool A, with two sliders and a moving graph, is more dynamic than Tool B, with one slider and two moving graphs" is not the intention of using the term "spectrum."

Finally, we do not propose a hierarchy of digital tool characteristics within this framework. The quality of a digital tool is determined by its coherence with the pedagogical goals and students' current mathematical and technical capabilities. Although digital tools that are dynamic and interactive may afford students novel opportunities to engage with mathematical ideas compared to the paper-and-pencil environment, they are not inherently better or more valuable than static and inert digital tools. This framework is purely descriptive, and for each of the three spectra, neither pole carries a more favorable connotation than the other.

Interactive ↔ Inert

A key affordance of digital technology is interactivity. Kaput (1992) describes the difference between *interactive* and *inert* media:

> We characterize a medium as "inert" if the only state-change resulting from a user's input is the display of that input. Thus the key difference with notations instantiated in

> interactive media is the addition of something new to the result of a user's actions, something that the user must then respond to. In inert media, the user can only respond to what he or she has directly produced. Any external response to the input must be made by a third party, for example, a teacher, tutor, or peer (p. 526)

We extend Kaput's characterization from a binary categorization to a spectrum. Digital tools can be categorized roughly as more interactive or more inert depending on the overall breadth and depth of their reactiveness to a user's input. For example, a video player has the ability to react to user input regarding stopping and starting of playback at various points in the video feed. However, a traditional video player does not have the capability to capture mathematical input and change the contents of the video feed based on that input. Embedding digital polling, or allowing for swapping of video feeds based on user input, would increase the reactiveness of the digital tool and move it farther along the interactive side of the interactive ↔ inert spectrum.

Static ↔ Dynamic

A second affordance of digital technology is the ability to support dynamic media (Kaput, 1992). With dynamic media, objects can change states as a function of time, which means "time can become an information-carrying dimension" (Kaput, 1992, p. 525). However, in static media, the state of objects remains unchanged over time. Kaput (1992) further suggests that a dynamism range exists, where some notions of "dynamic" are more strongly dynamic than others according to "continuous transition." In our characterization of the Static ↔ Dynamic scale, we expand on the scale's dynamic range.

Our Static ↔ Dynamic scale consists of four classes, ordered from most static to most dynamic: Static, Discrete, Weakly Continuous, and Strongly Continuous. The latter three classes refine "dynamic." To illustrate these four characterizations, we use a recurring example of a digital tool whose purpose is to help students understand the relationship between the definite integral and the area under a curve (see Figure 1).

A *Static* digital tool in this motif is a digital image depicting a generic curve with some area shaded under it, paired with the algebraic representation of a definite integral. We note that a static tool can still be interactive, allowing the user to take some action and get a response from the digital tool, but differing states of the mathematical objects on screen do not have temporal variation. The example in Figure 1a shows an interactive static digital tool that can be used to explore the relationship between a definite integral and the area under a curve. Students can click to place values on the upper limit of integration and see both the symbolic and graphical representations immediately update.

To transform this static tool into a *Discretely Dynamic* tool, imagine that instead of the ability to to click to place values on the upper and lower limits of integration students can drag points to adjust the upper and lower limits of integration on the graph (see Figure 1b). However, the motion of the draggable point is constrained to be only integer values. So when a student wants to adjust the upper limit of integration to be a larger value, they drag the point to the right and see the symbolic and graphical representation update through a series of discrete—but temporally organized—states.

To make this tool *Weakly Continuously Dynamic*, we remove the constraints from the draggable points so that students can adjust the limits of integration by dragging the points smoothly along the x-axis.

Finally, to make this tool *Strongly Continuously Dynamic*, it is converted into an autonomous animation rather than allowing user manipulation. In dynamic geometry software such as

Desmos or GeoGebra, this equates to a slider equipped with a play button that will enable variables to run through a prespecified range of values.

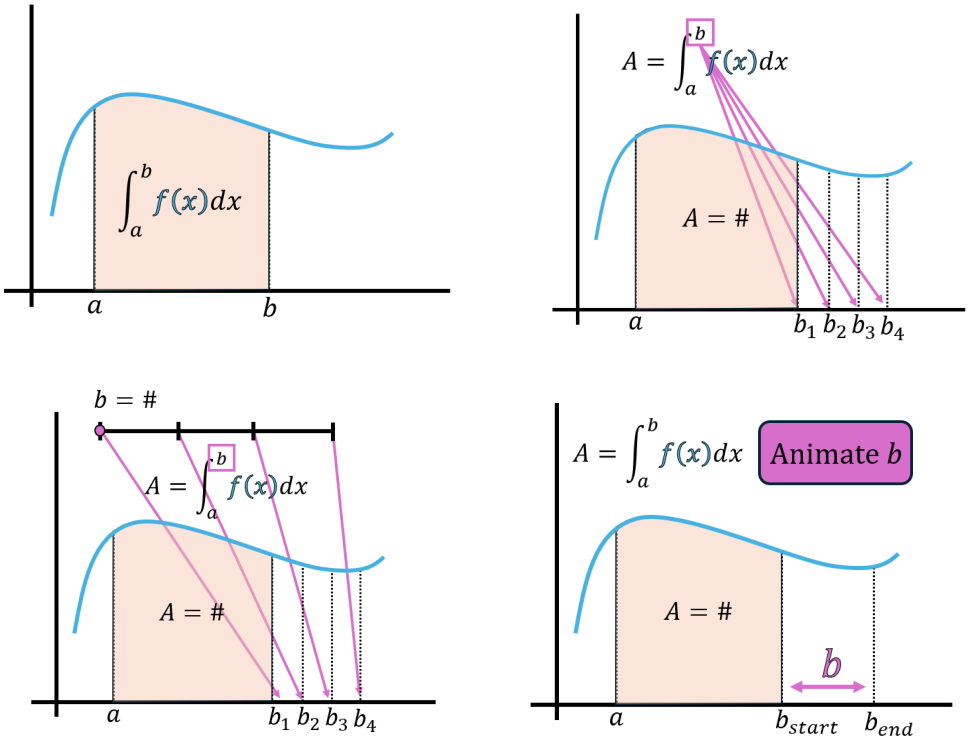

Figure 1: Variations on integration-based digital tools. From left to right: static, static interactive, discretely dynamic, strongly continuously dynamic.

These categories are not mutually exclusive. Each increasingly dynamic category is contained in the preceding static category. For example, a Discretely Dynamic tool has clear Static elements. Each state of the tool is itself a Static digital tool. Thus, when categorizing digital tools along the Static ↔ Dynamic spectrum, we consider the tool's *maximum potential dynamism*—its most dynamic classification within the constraints of its design or software platform.

Specialized ↔ Generalized

Cerulli et al. (2006) argue that digital tools are always developed in relation to some pedagogical goal. We characterize digital tools as *specialized* if they are developed in relation to a specific learning trajectory and *generalized* if they are developed for more general use across a range of pedagogical moments and/or mathematical topics. Examples of highly generalized digital tools are dynamic geometry environments, graphing calculators, and spreadsheet environments. These kinds of digital tools place relatively few constraints on the user's actions and are not necessarily designed to support students in learning a particular mathematical topic. A tool becomes more specialized by placing constraints on students' actions, designing feedback that orients the student toward a particular pedagogical goal, or pairing the tool with a particular mathematical task.

The spectrum of Specialized ↔ Generalized can be elucidated with the example of a definite integral and its connection to the area under the curve. On the specialized end of the spectrum, a digital tool could be hard-coded with a given accumulation function and specific numerical values for the endpoints of the interval over which the area is collected. The graph could further

be linked to a specific context, such as accumulation of distance. Should a designer choose to allow the endpoints to be moved through the frontend of the application, or allow students to choose different accumulation functions, then the digital tool can be used in a broader number of tasks. Yet further down the spectrum, if the accumulation of distance context is dropped, and all possible endpoints and functions are able to be edited by the user, then this can become a highly generalized tool, able to be used in almost any application of definite integrals. However, designing such a tool involves a tradeoff, as it is no longer as directly aligned with particular pedagogical goals for specific tasks.

Discussion and Conclusion

In this theoretical paper, we propose a framework that structures a design space for digital tools to support mathematics learning. Together, all three spectra create a three-dimensional design space in which digital tools can be characterized. To give an idea of how these dimensions coalesce, we give a few prototypical examples of digital tools, and how they would be placed in the framework in a two-dimensional subspace, shown in Figure 2. The Specialized ↔ Generalized axis has been flattened for readability. In the rest of this section, we discuss the implications of the framework and provide an illustrative example of how the framework can support generalization about the design of digital tools across studies from different contexts.

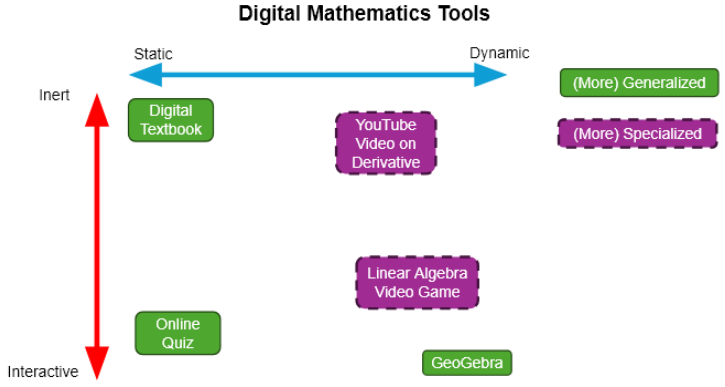

Figure 2. A two-dimensional representation of the design space structured by our proposed framework with examples of digital tool types.

One strength of this framework is its ability to distinguish between digital tools that are quite similar (e.g., built within the same software environment, developed to support the same mathematical goals). The examples shown in Figure 1 are all interactive digital tools that vary in their level of dynamism. According to existing taxonomies of digital tools, these tools would be quite difficult to distinguish. For example, each of the tools could be used to support students in developing concepts (Drijvers, 2015); they are all dynamic and graphical tools (Noss & Hoyles, 2009); and they are all built within a mathematical action software environment (Dick & Hollebrands, 2011).

Despite these similarities, each tool positions students differently with respect to the mathematical ideas at stake. The relationship between a student's perception of time passing and the changing state of mathematical objects embedded within a digital tool is under-theorized but beginning to receive more attention (see Moore, 2024). Early research indicates that the design of digital tools can be linked to students' conception of time as it relates to their conception of a situation involving covarying quantities (Margolis, 2024).

On the other hand, this framework can also be used to draw out similarities between digital tools that are otherwise quite different. Recall that Baccaglini-Frank and Mariotti (2010) wrote about students' interaction with draggable points used to define an interactive geometric diagram embedded within a dynamic geometry environment. Students interacted with the digital tool via a modality called Maintaining Dragging, in which they attended to the trace of the point as they dragged it in such a way that some geometric relationship within the diagram remained invariant.

According to our proposed framework, the digital tools in Baccaglini-Frank and Mariotti's (2010) study would be Specialized, Interactive, and Weakly Continuously Dynamic. In Figure 3, we show a digital tool which was designed to provide students with opportunities to engage in covariational reasoning with graphs and mental constructions of situational quantities (for more details about this task sequence, see Paoletti, 2019). Students are prompted to drag the coordinate point–intended to simultaneously represent the temperature and amount of water flowing out of the faucet–in such a way that only one knob moves at a time. To complete this task, students have to engage in the modality of Maintaining Dragging. And yet, the faucet tool is not built within a dynamic geometry environment and is not designed to support students in making conjectures about Euclidean geometry.

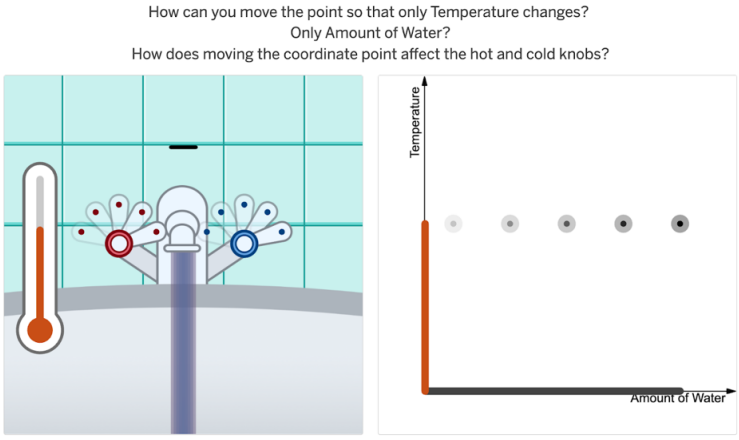

Figure 3. A static image of a student engaging in Maintaining Dragging (i.e., dragging the coordinate point in such a way that the temperature stays constant) with a digital tool.

Although we find this preliminary framework to be promising in our efforts to study the design of digital tools, we do not consider it to be complete. We anticipate that the framework will grow over time as we expand our theorization and analysis of the design of digital tools. For example, we anticipate that a category about the connectivity that digital tools afford communities of learners will be added to the framework soon.

Finally, we consider this framework to be useful for analysis of pre-existing digital tools while also being useful for the process of digital task design. We recommend further research on the affordances of tools across various locations in the design space for students learning.

Reflections on Creativity and Affect as a Vehicle for Writing in a Mathematics Course

Houssein El Turkey
University of New Haven

Ryan Crawford
University of New Haven

We explore how one instructor used reflective prompts in a proof-based Elementary Number Theory course to add a writing component to the course. Students consistently reflected on their creative process and affective domain throughout the course. We share the design of the course, samples of the reflective prompts, and our deductive coding of them using two codes: creative process and affect. A preliminary examination of written responses from two students indicates that reflecting on their creative process had led them to be more engaged in the proving process in this course and other courses. They also reported that the readings and reflections helped them recognize and validate their mathematical actions, processes, and affective outcomes.

Keywords: Writing in Mathematics, Mathematical Creativity, Affect, Reflections

Writing has long been considered a unique and valuable mode of learning (Emig, 1977). To promote writing at the tertiary level, institutions have utilized two ways of fostering students' writing skills: writing in the discipline (WID) and writing across the curriculum (WAC). In WID courses, "writing is occurring in some form as assignments in subjects or courses in one or more disciplines" (Thaiss & Porter, 2010, p. 538). WAC typically is meant to "assist teachers across disciplines in using student writing as an instructional tool in their teaching" (Thaiss & Porter, 2010, p. 538). Using both types, instructors can tailor writing assignments to develop the specific content of a discipline as well as promote students' curiosity, creativity, metacognition of processes, affect, and expression of target material through a student's individual framework.

In this study, we focus on writing in a proof-based undergraduate Elementary Number Theory course. We report on how one instructor designed and implemented various forms of writing assignments in this course. Writing is particularly suited to this course because it offers students opportunities to write proofs through generating examples, using mathematical definitions and theorems, utilizing various symbolic representations, connecting assumptions to conclusions, and explaining reasoning. While infusing writing in proof-based courses has been researched and documented, we highlight how a focus on students' creative processes and affect can both increase student engagement with content and enhance their emotional value in process, while serving as a vehicle for transforming this course into a writing course. Specifically, we address the following research questions: *How to infuse written reflective assignments on creativity and affect into a proof-based math course? How do students interact with and perceive these assignments?*

Background Literature and Theoretical Framing

Writing in Mathematics

It has been reported that writing in mathematics courses provides students with a deeper understanding of mathematical concepts (Rose, 1989; Beidelman et al., 1995; Burns, 2004). Burns (2004) stated, "Writing in math class supports learning because it requires students to organize, clarify, and reflect on their ideas" (p. 30). Burns added, "when students write, their papers provide a window into their understandings, their misconceptions, and their feelings about the content they're learning" (p. 30). Existing literature shows that writing in mathematics courses (e.g., Urquhart, 2009; Taylor & McDonald, 2007; Graham et al., 2020) can take various

forms. Writing assignments can range from short reflective questions (e.g., El Turkey et al., 2023) to daily journals in which students keep their reflections and insights on the course topics (Borasi & Rose, 1989). Other forms include summary writing, writing portfolios, and expository essays. For example, Omar et al. (2019) used writing portfolios in a Combinatorics course where students communicated their solution attempts as well as their reflections on their problem-solving process and creativity. Expository essays are usually assigned so students explain mathematical concepts to others, most often to the teacher.

Many studies explored the use of writing in various mathematics courses. Some discussed writing assignments in general education mathematics courses (e.g., Pinter, 2014), History of Mathematics courses (e.g., Loats et al., 2014), Abstract Algebra (Czerwinski, 1994), Modeling (Linhart, 2014), Complex Analysis (Habre, 2019), or Combinatorics (Omar et al., 2019). In Omar et al.'s study (2019), students were prompted to reflect on their creative process, but writing was not the focus of the study. Beyond that study, we did not find literature focused on infusing writing in a mathematics course using reflections on creativity and affect.

We situate our discussions of using reflections and writing as modes of learning and integratory tools within expressionism (Elbow, 1991), as writing provides space between thought and expression to process the emotional value of information (Flower et al., 1992; Overstreet, 2022). This emotional value is essential to both motivating students to examine target material, and in spurring them to creative thought within a discipline (Auger & Woodman, 2016).

Mathematical Creativity

The creative process for problem solving was described by Wallas (1926) through a four-stage process: preparation (understanding the problem and gathering relevant information for a proof), incubation (taking a break and letting the mind work on a proof subconsciously), illumination (AHA moment, insight, or generating an idea), and verification (verifying the idea is a solution or a proof). Later, Guilford (1950) developed three components of creativity: fluency (number of ideas), flexibility (changing ideas or approaches), and novelty (unique or original ideas/approaches). Torrance (1974) added a fourth component of creativity, elaboration (describing or elaborating on those ideas). These earlier studies led to a plethora of definitions and perspectives of mathematical creativity (Mann, 2006). Some focused on the creative process (Kozbelt et al., 2010) while others discussed a product view (Runco & Jaeger, 2012). Additional studies discussed mathematical creativity that is relative to students versus absolute creativity relative to the field of mathematics (Beghetto & Kaufman, 2013; Leikin, 2009).

In this paper, we adopt a process-oriented relativistic perspective that defines mathematical creativity as a process of offering new solutions or insights that are unexpected for the student, with respect to their mathematics background or the problems they have seen before (Liljedahl & Sriraman, 2006; Savic et al., 2017). Thus, we acknowledge that students "have moments of creativity that may, or may not, result in the creation of a product that may, or may not, be either useful or novel" (Liljedahl, 2013, p. 256). This view of mathematical creativity aligns with the developmental theoretical perspective emphasizing that a person's creativity can and does develop over time and a person's process and actions, as opposed to the product created, should be the focus of investigation (Kozbelt et al., 2010).

Affect

We approach affect broadly in this study following recommendations from the literature (e.g., Tang et al., 2022). Grootenboer and Marshman (2016) acknowledged the difficulty in defining the affective domain but conceptualized it largely as beliefs, values, attitudes, and

emotions that overlap. For this study, affect encompasses feelings (McLeod, 1988) and other constructs such as beliefs, attitudes, emotions, motivation, engagement, and so forth (Middleton et al., 2017). We also adopt Tang et al.'s (2022) definition of an affective outcome as a "collective of any emotions, beliefs, attitudes, and values that students reference" (p. 31). Tang et al. additionally highlighted the importance of examining the intersection of students' mathematical creativity and their affect, which we undertake in this study through the design and implementation of reflective prompts attending to both constructs.

Methods

Study Setting

The study took place in an Elementary Number Theory course at a comprehensive northeastern university in the United States. Ten students were enrolled in the course which met three times a week (50 minutes) on Zoom in Fall 2023. The instructor (first author) characterizes the classes as interactive lectures, each of which began with time for student questions, a brief introduction of new content (on OneNote using a stylus), followed by elicitation of target material through student discussion. In this course, the instructor created and assigned three types of written assignments: pre-class assignments (PA) (N=35), homework assignments (HW) (N=10), and a complete proof portfolio for all proofs from class (N=1). In addition, there were two exams and a final exam. Five of the PAs (PA 8, 11, 18, 23, 35) included reflective questions whereas each HW assignment had the last question as a reflection prompt. Reflective questions were graded based on completion, with some comments from the instructor.

Data

The data collected for this qualitative study includes the assignments, students' work on them—including their answers to reflective questions—and end-of-term interview data with two students. We focus in this paper on the assignments themselves to explore the instructor's design intentions as our unit of analysis to document how the instructor promoted writing within this course. Additionally, we share sample written responses from the two interviewed students.

Data Analysis

Reflective assignments. Using deductive coding (Patton, 2002), we coded the reflective questions (N=15) on the pre-class assignments and the HW assignments. The codes used were creative process and affect. The creative process code encompassed any prompts that referenced actions from Creativity-in-Progress Reflection Tool (Savic et al., 2017) (7 prompts), mathematical creativity in general (3 prompts), Wallas's four-stage process (2 prompts), and AHA/memorable moments (2 prompts). The affect code encompassed any prompts about feelings (6 prompts), attitudes (1 prompt), math story/journey (1 prompt), and teaching actions related to affect (2 prompts). It is important to note that some prompts were coded with both codes. Below we provide a sample of reflective questions with their codes in brackets.

Students' written responses. We report on written data from two student participants who also volunteered for the end-of-semester interview: Amity[1] (pronouns she/they; mathematics major, senior, final grade A) and Smiley[2] (pronouns she/her; actuarial science major, senior, final grade B). In a word count of all their responses to the reflective questions, Amity used around

[1] Self-selected pseudonym

[2] Self-selected pseudonym

2700 words while Smily used around 1600 words. These were in addition to the mathematical writing that they submitted on the various assignments. In the following, we share our deductive coding of their written responses to three reflective questions. We underline certain parts of their responses to capture the creative process theme and use *italics* to capture the affect theme.

> *HW 9* [Creative Process & Affect]: Becoming more aware of creativity and how it functions can lead to deeper immersion in problem-solving or proving processes. Has reflecting on your creative process made you feel more engaged in these processes? Explain (Using specific examples is encouraged.)

In response, both students highlighted how reflecting on their creative process has led them to be more engaged in the proving process. Amity wrote, "trying to find different creative ways to do problems definitely makes me *feel more engaged* in trying to figure out the solutions or proofs and helps me understand it better." Smiley explained, "reflecting on my creative process has made me *feel more engaged* in the proving process. Sitting and actually thinking about how I am solving problems makes me *feel like I am actually apart* [sic] *of the proving process* instead of just skating through it." She then added, "Reflecting gives me the chance to edit and revise my proving process… For example, I now sit in the incubation stage more when I am proving, and I have found that it helps out a lot."

> *PA 11 (part 5)* [Affect]: Please discuss an affective outcome you felt while working on a problem or during class.

On this assignment, the students were asked to read parts of the Tang et al. (2022) article about students' affect when doing mathematics. In response to the above prompt, Amity wrote, "I *feel a lot of enjoyment* while doing work for this class. Figuring out how to prove something always feels like a puzzle to me, and when I finally figure it out it's *so satisfying* and *makes me excited* to do more work for the class." Smiley wrote, "I have *felt confidence* in class when you ask me a question that I am actually able to get right. It makes me *feel good* to know that I am understanding the concepts that are being taught."

> *PA 35 (part 5)* [Creative Process & Affect]: Do you think that creativity affected your actions in the course, e.g. what you do during or out of class when working on math, how you problem solve or prove, etc?

Both students indicated how being aware of their creative process helped them in the course as well as other courses. For example, Amity responded, "the creative mindset I've developed from this class has assisted me in my other math classes as well." She elaborated, "In my Complex Variables class, I have found myself becoming much more flexible in my problem solving and finding solutions when I get stuck on something." Smiley wrote, "creativity affected how I problem solve the most. Creativity allowed me to try numerous ways to solve a problem whether it was attempting different proof methods, finding counter examples, or just using trial and error." She added, "As I do problems in the future, I definitely feel like I will be more creative because of this course."

In one of the questions on this last reflective assignment, the instructor asked students about some takeaways they learned from the reflective questions. Amity wrote, "I learned that there are names for the different mental processes I use and how to better make them work together." Smiley stated, "my biggest takeaway was learning about the four stages of solving a problem." She then elaborated on the preparation and incubation stages of Wallas's four-stage creative process. She concluded, "I will definitely use this four-stage process in my other courses."

Preliminary Results

In addition to fostering students' writing in an advanced mathematics course, two main design intentions or instructional goals were captured in the reflective questions: 1) increasing students' awareness of their creative process; and 2) providing students with opportunities to recognize and acknowledge their affect while doing mathematics. The written responses from the two students indicated a recognition of their own creative process. They elaborated on how reflecting on their processes allowed them to better understand the content and be more engaged in the proving process. Their recognition of the creative process through reflections has also promoted flexibility in trying different attempts or proofs, which has assisted them in other math classes. In terms of affective outcomes, both students reported positive feelings such as enjoyment, excitement, feeling good, and confidence. They also linked the creative aspect of writing proofs to their positive feelings which aligns with findings in Tang et al.'s study (2022). We claim that our reflection prompts provided students an opportunity to closely examine their affect while doing mathematics, a practice that is uncommon in mathematics teaching and learning.

Discussion

The instructor designed numerous reflective prompts utilizing the Creativity-in-Progress reflection tool, Wallas's four-stage creative process, and affect. Through the various assignments, the instructor attended to both WID and WAC components of writing courses. While the context of the study was Elementary Number Theory, we hypothesize that the reflective prompts can be adopted and adapted to any upper-level mathematics course that involves problem solving or proving. It is important to note that the consistency in assigning reflective prompts throughout the semester established a norm and an expectation for students to 'sit and actually think' (Smiley) about how they solve problems. In addition, most of prompts were very specific and aimed at focusing students' attention on a specific mathematical action, an affective outcome, or a moment in the course or their mathematical journey.

In terms of limitations, the online nature of the course added a layer of difficulty in having in-class discussions about creativity and affect. While the instructor integrated conversations about creativity and affect during the Zoom class sessions, there would have been more engaging conversations if the class was in person. Additionally, only two students volunteered for interviews, which limited capturing various students' perspectives about the reflective questions.

Conclusion

Writing skills are central to most professional careers, especially in STEM disciplines. According to the CUPM Curriculum Guide, "Clear communication in oral and written forms is essential; students should develop these skills as undergraduates both through writing courses and by preparing written class and project reports" (CUPM, 2015, p. 47). As a mechanism to encourage writing in mathematics, reflections play an important role in mathematics learning as just completing tasks is insufficient (Wheatley, 1992). With these goals in mind, this study explored the design goals of reflective questions that prompted students to read, think, and write about their mathematical creativity, creative process, and affect. In the future, we will examine the students' interviews to learn about how they perceived those reflective questions. We also plan to provide some recommendations for instructors who plan to integrate writing into their mathematics courses.

How do Mathematicians Explain Conditionals? Diagrams and Explanations for 'if $P(x)$ then $Q(x)$' and '$P(x) \Rightarrow Q(x)$'

Lara Alcock
Loughborough University, UK

At the introduction to proof, Venn or Euler diagrams are commonly used to illustrate concepts in logic. Standard diagrams show $P(x) \wedge Q(x)$ as the intersection of truth sets for $P(x)$ and $Q(x)$, and $P(x) \vee Q(x)$ as their union. But textbooks rarely include a diagram for the conditional, and those that do use a diagram that differs from the standard form. Does this reflect typical mathematicians' thinking? What do they draw when asked for a diagram to represent the conditional, and does this depend upon sentence formulation? This preliminary report describes a pilot study in which mathematicians and mathematics PhD students were asked to draw a diagram and provide a short accompanying explanation for either 'if $P(x)$ then $Q(x)$' or '$P(x) \Rightarrow Q(x)$'. Results show that they all draw essentially the same diagram, representing a true universal conditional. I illustrate variety in the provided explanations.

Keywords: conditional, diagram, implication, logic

Introduction and Theoretical Background

Venn diagrams are common at the introduction to proof, where they appear in discussions of set theory and logic (Antonides et al., 2024). Diagrams for conjunction and disjunction appear in Figure 1, where the circles represent truth sets for $P(x)$ and $Q(x)$, so the shaded areas contain values of x for which the conjunction $P(x) \wedge Q(x)$ and the disjunction $P(x) \vee Q(x)$ are true.

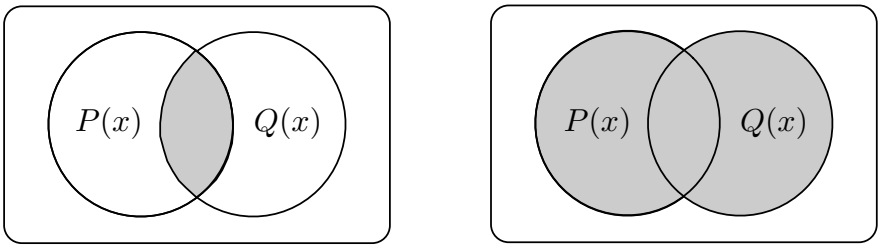

Figure 1. Venn diagrams illustrating conjunction and disjunction.

These diagrams reflect the truth values in Table 1, which additionally shows the truth table of the material conditional 'if $P(x)$ then $Q(x)$', as used in mathematics.

Table 1. Truth tables for conjunction, disjunction, and the material conditional.

$P(x)$	$Q(x)$	$P(x) \wedge Q(x)$	$P(x) \vee Q(x)$	if $P(x)$ then $Q(x)$
T	T	T	T	T
T	F	F	T	F
F	T	F	T	T
F	F	F	F	T

The material conditional is false when $P(x)$ is true and $Q(x)$ is false, and true otherwise, making 'if $P(x)$ then $Q(x)$' equivalent to 'not-$P(x)$ or $Q(x)$'. This leads to a Venn diagram for the conditional as in Figure 2 (Nickerson, 2015) (henceforth, a *truth-value diagram*).

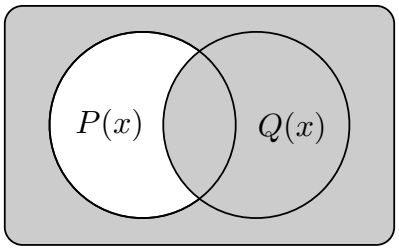

Figure 2. Truth-value Venn diagram for the conditional 'if $P(x)$ then $Q(x)$'.

In everyday language, the material conditional is natural in that we would assert 'if P then Q' when we would assert 'either not P, or P and Q' (Jackson, 1979). But people commonly judge not-P cases as irrelevant to the conditional rather than as cases in which it is true (Newstead et al., 1997). Moreover, they commonly interpret a conditional as asserting an inferential link between its antecedent and consequent, so that 'missing-link' conditionals ('If bats have wings then Paris is in France') sound like nonsense (Bourlier et al., 2023; Douven et al., 2020).

In mathematics, the defined propositional conditional is the material conditional (Durand-Guerrier, 2003). Yet diagrams like that in Figure 2 are rarely seen. Of the 17 introduction-to-proof textbooks most commonly recommended in the UK and the US (Alcock & Sa, in press), only two include a diagram in their explanations of conditionals, and neither use a truth-value diagram. Instead, both give Euler diagrams in which the truth set of $P(x)$ is contained in the truth set of $Q(x)$, as in Figure 3 (henceforth, *inclusion diagrams*).

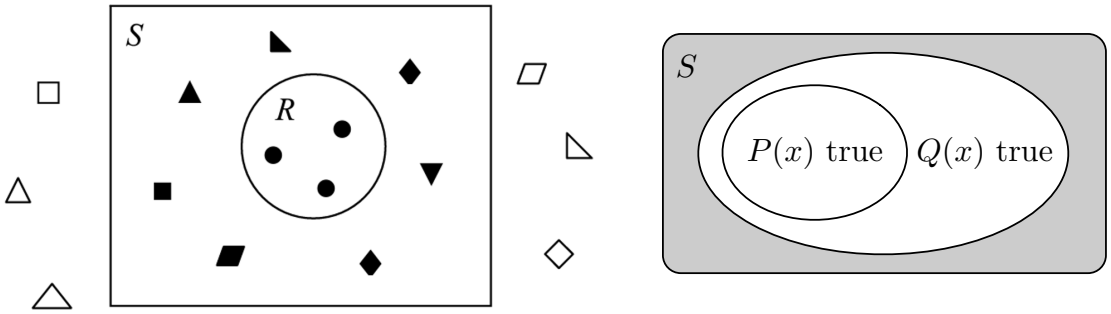

Figure 3. Diagrams for conditionals, formulated as $R \Rightarrow S$ (round ⇒ solid) in Lay (2014, p.5) and as $P(x) \Rightarrow Q(x)$ in Stewart & Tall (2015, p.134).

In inclusion diagrams, the idea of representing all possible combinations of truth values for $P(x)$ and $Q(x)$ is abandoned in favour of a diagram in which the conditional 'if $P(x)$ then $Q(x)$' is universally true (there are no x values for which $P(x)$ is true and $Q(x)$ is false). The reason for this is suggested in the explanation offered by Stewart and Tall:

> "We are really interested only in the case where $P(x) \Rightarrow Q(x)$ is true for all x. In this case, if $P(x)$ is true, so must $Q(x)$ be; that is, if $a \in \{x \in S | P(x)\}$ then $a \in \{x \in S | Q(x)\}$ which means $\{x \in S | P(x)\} \subseteq \{x \in S | Q(x)\}$." (Stewart & Tall, 2015, p.134)

The claim that mathematicians are primarily interested in true universal conditionals is arguably reflected in other textbooks' use of 'P implies Q' or '$P \Rightarrow Q$' as straightforward alternatives to 'if P then Q' (Alcock & Sa, in press). The language of implication puts mathematicians at odds with philosophers, who usually denote the material conditional '$P \supset Q$' ('P hook Q'; Edgington, 2020) and are wary of ambiguity around '⇒' and 'implies', reserving these for argument forms or avoiding them altogether (Smith, 2020). But the mathematical use corresponds comfortably

to natural language for true universal conditionals: where 'for all x, if $P(x)$ then $Q(x)$' is true, $Q(x)$ can be deduced from $P(x)$ (e.g., Epp, 2004).

Of course, it could be that the diagrams in Figure 3 are idiosyncratic: perhaps mathematicians do not typically represent these constructs in this way. Or it could be that formulation matters: perhaps '$P(x) \Rightarrow Q(x)$' invites an inclusion diagram but 'if $P(x)$ then $Q(x)$' would be more likely to elicit a truth-value diagram. I therefore intend to investigate diagrams produced by a wider sample of mathematicians, along with explanations they provide for those diagrams, and features that they and students value in diagrams and explanations produced by others. This preliminary report describes a pilot study addressing three research questions:

1. What Venn/Euler diagrams do mathematicians produce for the conditional?
2. Does this vary between the formulations 'if $P(x)$ then $Q(x)$' and '$P(x) \Rightarrow Q(x)$'?
3. How do mathematicians explain their diagram(s)?

Method

Mathematicians were recruited at the 2024 British Mathematical Colloquium, where attendees are mathematicians and PhD students working largely in pure mathematics. They participated voluntarily in response to invitations in an email and a talk. Each participant read an information sheet and signed a consent form that asked for their main area of mathematical work (pure, applied, statistics/data science, other) and their experience level (PhD student, postdoc, lecturer[1], other). Fourteen people participated, of whom:

- 9 were PhD students in pure mathematics (PhD P in Table 2);
- 1 was a PhD student in applied mathematics (PhD A);
- 1 was a postdoc in pure mathematics (PD P);
- 3 were lecturers in pure mathematics (Lec P).

Participants responded (under no time constraint) to the prompt:

> Please draw a Venn/Euler diagram to represent 'if $P(x)$ then $Q(x)$' ['$P(x) \Rightarrow Q(x)$'].
> Then add a short explanation suitable for undergraduate students.

Half received the 'if $P(x)$ then $Q(x)$' prompt and half the '$P(x) \Rightarrow Q(x)$' prompt; all had most of a page in which to respond. Their responses were analysed qualitatively as below.

Analysis and Results

To address Research Question 1, I first analysed the diagrams. This was a quick process because all participants drew inclusion diagrams. Two then added a truth-value diagram, and one of these offered two further alternative diagrams; these I will present at the conference. The inclusion diagrams varied in three respects:

1. Some labelled the sets $P(x)$ and $Q(x)$ and some just used P and Q;
2. Some framed the sets within a universal set and some did not;
3. Some included extra labelling or shading.

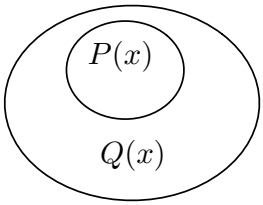

Table 2 summarises the features of each inclusion diagram and shows which participants included a truth-value diagram. It also shows that the answer to Research Question 2 appears to be that formulation of the conditional does not affect the Venn/Euler diagrams that mathematicians draw, at least not in the way anticipated. Participants responded with the same (first) diagram regardless of the prompt, and the two truth-value diagrams appeared in response to the formulation '$P(x) \Rightarrow Q(x)$', not 'if $P(x)$ then $Q(x)$'. Of course, this is a small sample.

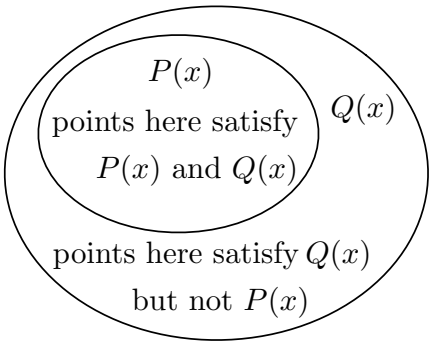
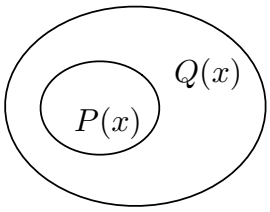
[1] In the UK, the term 'lecturer' is equivalent to the North American 'professor', and people specialise early so that a PhD is a research-only degree.

Table 2. Features of inclusion diagrams: TV = provided a second, truth-value diagram.



Prompt	Participant	Labels	Univ	Extra labels/shading	TV	Explanation
if-then	PhD P	$P(x)$				Basic
if-then	PhD P	$P(x)$				Converse
if-then	PhD P	$P(x)$		P shaded		Background
if-then	PhD P	P	Yes			Converse
if-then	PhD P	P	Yes	specific points		Converse
if-then	PD P	P				Basic
if-then	Lec P	$P(x)$				Background
⇒	PhD P	$P(x)$				Converse
⇒	PhD P	P				Converse
⇒	PhD P	$P(x)$		'x for which $P(x)$ holds'	Yes	Basic
⇒	PhD P	P	Yes			Basic
⇒	PhD A	$P(x)$		'this area is a subset of this area'		Background
⇒	Lec P	$P(x)$		'points here satisfy $P(x)$ and $Q(x)$'		Converse
⇒	Lec P	$P(x)$		$Q(x)$ shaded, $P(x)$ cross-hatched	Yes	Basic

To address Research Question 3, I analysed the particpants' explanations for the inclusion diagrams (Table 2, last column). These varied primarily in whether and how they went beyond a basic explanation of the diagram's structure. Some gave just that basic explanation, as in Figure 4. Some additionally noted that the converse of the conditional might not be true, as in Figure 5. Some provided comments on the background assumed when mathematicians read and write conditionals (cf. Dawkins & Roh, 2024), as in Figure 6.



"if $P(x)$ then $Q(x)$" means that whenever P is true, Q is also true. So every x in the "P circle" has to be in the "Q circle".
Therefore, "P circle" should be inside of "Q circle".

Figure 4. Diagram with basic explanation.

A 'bubble' represents the set of points which satisfy a property. In this case, $P(x)$ or $Q(x)$. Since $P(x) \Rightarrow Q(x)$, all points who satisfy $P(x)$ also satisfy $Q(x)$, hence the inclusion, but there might be points satisfying $Q(x)$ which do not satisfy $P(x)$.

Figure 5. Diagram with significance of area outside inner set.

Note that "$P(x) \Rightarrow Q(x)$" is not a statement (or sentence) as it contains a free variable. So, given a suitable structure and a point, say α, in that structure we can test whether the premise $P(\alpha) \Rightarrow Q(\alpha)$ holds in the structure or not. Namely, whether property P holding at α "implies" that Q holds at α.
Also note that by adding a quantifier we can make this into a statement; for example: "$\exists x\ P(x) \Rightarrow Q(x)$" or "$\forall x\ P(x) \Rightarrow Q(x)$". Normally, or most commonly, we look at the latter, that is
"$\forall x\ P(x) \Rightarrow Q(x)$".
This, in a given structure, is to be interpreted as for all elements property P implies property Q. In other words, the elements that satisfy property P form a subset of those elements satisfying Q.

Figure 6. Diagram with explanation including assumed background.

Discussion

This pilot study investigated diagrams mathematicians draw for the conditional, whether these diagram are affected by formulation of the conditional, and what explanations mathematicians offer for their diagrams. Regardless of formulation, participants all drew inclusion diagrams first, with a small minority adding truth-value diagrams. Both diagrams and explanations reflected those offered in Stewart and Tall's (2015) book in that mathematicians appear to think primarily about true universal conditionals; some additionally explained non-equivalence of the converse and some added material on background assumptions about propositions and quantification.

I plan to extend this work in two directions.

First, I will conduct a study in which a larger number of mathematicians respond to the same prompts, except with a note that they can, if they wish, include more than one diagram. I expect this to confirm that inclusion diagrams are favoured. I will then ask both mathematicians and undergraduates to use comparative judgement to rate the quality of (a selection of) the resulting explanations, coupling the results with a content analysis to identify and compare features of diagrams and explanations that are valued by the two groups (cf. Davies, Alcock & Jones, 2021).

Second, I will ask mathematics students in introduction-to-proof courses to select which of a range of diagrams best represent '$P(x) \wedge Q(x)$', '$P(x) \vee Q(x)$' and 'if $P(x)$ then $Q(x)$'. Asking about all three connectives will permit more sensible inclusion of a wider range of diagrams and might reveal non-standard interpretations. For '$P(x) \wedge Q(x)$', one can imagine that students might select the diagram on the right of Figure 1. For 'if $P(x)$ then $Q(x)$', they might select an inclusion diagram with $Q(x) \subseteq P(x)$ – this would be natural if they imagine restricting attention to P cases and asking whether these must also be Q cases, as in the Ramsey test (Ramsey, 1929) (one participant in this pilot study drew such diagram then crossed it out). This work might also reveal consistency or otherwise in how students interpret shading in relation to truth sets.

I will report progress of research in both directions at the conference.

A Systematic Review of the Teaching and Learning of Quantum Mechanics: Implications for Mathematics Instruction and Research on Undergraduate Mathematics Education

Slade C. McAfee
University of Wisconsin - Milwaukee

Field M. Watts
ETS

Jon-Marc G. Rodriguez
University of Wisconsin - Milwaukee

In this work, we review the literature on the teaching and learning of quantum mechanics situated in chemistry courses with the aim to provide a tool for education researchers and practitioners. We found that much of the research on quantum mechanics in the chemistry context involves students at the secondary level of instruction. Along with this, much of the research leans on mathematics and physics education research to support the claim that students have difficulties with mathematics; however, these claims require further investigation within chemistry education research.

Keywords: Quantum Mechanics, Chemistry, Interdisciplinary

Introduction

Physical chemistry is an upper-division course in the undergraduate chemistry curriculum that is notoriously challenging for students as it broadly focuses on three fundamental chemical concepts: kinetics, thermodynamics, and quantum mechanics (Holme, 2023). Briefly, kinetics is the study of rates of chemical reaction, thermodynamics is the study of energy and its movement in chemical systems, and quantum mechanics is the modeling of atomic and molecular structure. Many studies have been conducted investigating how students learn about thermodynamics (Bain et al., 2014) and kinetics (Bain & Towns, 2016) and have been reviewed to provide a tool for instructors and researchers teaching physical chemistry. In the review on thermodynamics, Bain et. al (2014) found that the literature investigating thermodynamics often posed alternative conceptions for the laws of thermodynamics, along with factors related to success in physical chemistry. Another finding in this study was that many papers focused on the mathematics used in physical chemistry, posing the need for interdisciplinary research collaborations. In Bain & Towns (2016), when reviewing chemistry education research on kinetics, they found that kinetics studies largely focus on secondary-level students' reasoning about chemical concepts. Along with this, they once more call for cross-disciplinary research, specifically between chemistry and mathematics, on students' reasoning of related rates and graphical representations (Bain & Towns, 2016).

The remaining topic in physical chemistry, quantum mechanics, has yet to be reviewed with a focus on the teaching and learning in chemistry contexts; however, outside the context of chemistry, quantum mechanics is a content area that has been widely studied in physics education. For example, a review of the physics education research regarding quantum mechanics found that students have difficulties understanding chemical concepts such as wave-particle duality, wave functions, and atomic structure. Along with this, students were found to have conflating ideas about classical and quantum mechanics (Krijtenburg-Lewerissa et al., 2017).

With this in mind, we aim to synthesize the chemistry education literature that investigates the teaching and learning of quantum mechanics in a chemistry context, with the goal of sharing our implications for practitioners and researchers. In this review, we identify the areas for further research and provide a detailed outline of the mathematical concepts and skills that are utilized in physical chemistry to provide insight to undergraduate-level mathematics instructors.

Data Collection and Analysis

Our approach for identifying articles to include in this review followed guidelines for reporting systematic reviews (Page et al., 2021). Articles were required to be peer-reviewed, empirical research studies (i.e., with research questions/aims, methods, and findings) that primarily focused on quantum mechanics topics, including both secondary and tertiary educational contexts. An overview of the data collection is provided in Figure 1. We searched the ERIC database, *Chemistry Education Research and Practice (CERP),* and the *Journal of Chemical Education (JCE)* using the search terms "chemistry" and "quantum mechanics", with our search last updated on January 13, 2025. After removing duplicates and articles that did not meet the inclusion criteria, we iteratively reviewed the citations and included additional articles that were within the scope of the review. In all, N = 50 articles were included in the review.

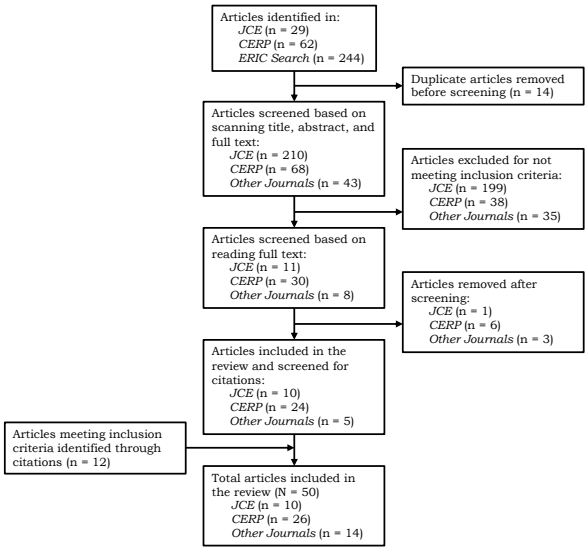

Figure 1. A PRISMA flow diagram detailing the article selection process. JCE is the Journal of Chemical Education, CERP is Chemistry Education Research and Practice, and ERIC is the Education Resources Information Center.

Once the dataset was finalized, we read the articles and grouped them based on the main topics of the articles. Throughout the process of reading the included articles, we took detailed notes and memos on the key findings to identify preliminary categories that arose. The first three categories that emerged were related to the quantum chemical concepts that the articles investigated: (1) Students' reasoning related to atomic and molecular structure; (2) Students' reasoning related to spectroscopy; and (3) Students' reasoning related to commonly discussed quantum mechanical models (e.g., particle-in-a-box, quantum mechanical harmonic oscillator, etc.). Any article that mentioned multiple categories (i.e., students' interpretations of the particle-in-a-box quantum mechanical model and atomic structure) was included in both relevant categories. In consideration of space, we will only discuss findings related to students' interpretations of quantum mechanical models, contextualizing it for the mathematics education research community.

Preliminary Findings

Overview of the Data

The findings presented in this section discuss the preliminary categories stemming from analysis of the data. To begin, we briefly provide an overview of the sample. We found that 48% (n = 24) of the articles used qualitative methods, 6% (n = 3) of the articles used quantitative methods, and 46% (n = 23) were mixed-method. Along with this, we identified the country that where the research was conducted, along with the associated participants' level of instruction. Most of the studies in our review were conducted in the United States (40%, n = 20) with many conducted in Greece (28%, n = 14). As for level of instruction, we found that articles typically involved students in introductory chemistry courses (Figure 2); however, a notable number of the articles investigated students' reasoning at the secondary level.

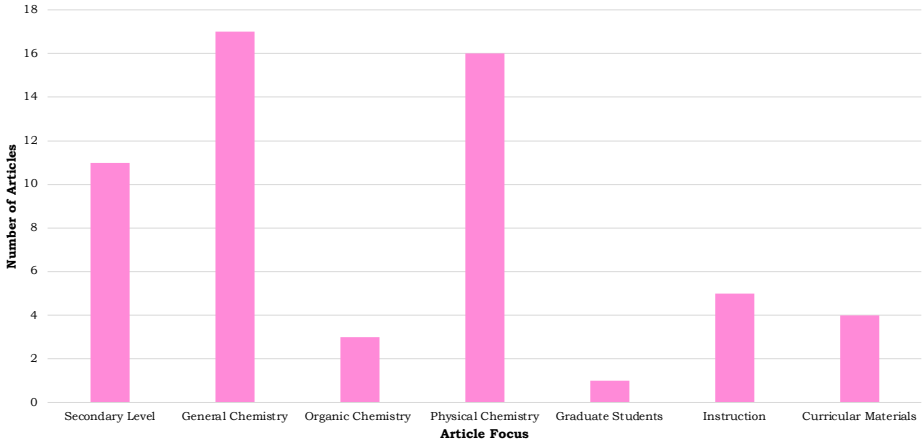

Figure 2. A bar graph showing the focus for each article. The total number of articles in this graph is greater than number of articles in the review, since each article may have multiple datasets.

Students' Reasoning About Commonly Discussed Quantum Mechanical Models

We discuss the key findings related to how students reason about common quantum mechanical models that are presented in a physical chemistry course. Though there are few, for clarity, we structure our discussion around the quantum mechanical model that is under focus.

Particle in a Box. Three articles in the sample focused on students' interpretations of the particle-in-a-box quantum mechanical model (Beck et al., 2020; Muniz et al., 2018; Muniz & Oliver-Hoyo, 2014). This model is often used in physical chemistry courses when introducing quantum theory to students as it describes the translational movement of a particle in a theoretical, one-dimensional box. To describe the particle's movement, students are taught their first application of the Schrödinger Equation, which is an eigenfunction that involves the use of partial derivatives. This eigenfunction takes the sum of the particle's kinetic and potential energy, called the Hamiltonian, and multiplies it by a wavefunction to produce the energy eigenvalue of the model. However, for the particle in a box model, the particle is assumed to have no potential energy, only kinetic energy. During classroom discussions, it is common in physical chemistry courses to discuss the mathematical treatment necessary to normalize and square the wavefunction to find the probability of locating the particle in its one-dimensional box which can be difficult for students. This typically includes walking through partial derivatives and integrations of the wavefunction with students. When students are learning about the particle-in-a-box model, there are many difficulties that have been identified in the literature. The primarily reported challenge is students' conceptualizing that more complex models are more suited, or more accurate, than simpler models (Muniz et al., 2018). Students were also found to struggle with the representations that are used in this model (e.g., eigenfunctions, etc.)

along with conceptualizing the meaning of quantum number *n* (Muniz & Oliver-Hoyo, 2014). It was also observed that students tended to conflate the particle-in-a-box model with other models, which leads to misapplications of the model to real-world phenomena (Beck et al., 2020; Muniz et al., 2018).

Quantum Mechanical Harmonic Oscillator. There were a few studies that investigated students' interpretations of another model, the quantum mechanical harmonic oscillator (Beck et al., 2020; Muniz et al., 2018). This model is another fundamental quantum mechanical model that describes the vibrational movement of particles, which is often taught after students learn about the particle-in-a-box model and requires a similar mathematical treatment. The main difference with this model from the previously described particle-in-a-box model is that vibrational movement requires students to consider how to model kinetic and potential energy with the Schrödinger equation. As discussed previously, students have shown difficulties with model application and model conflation (Beck et al., 2020; Muniz et al., 2018). Along with this, students tended to avoid mathematizing models when possible (Muniz et al., 2018), and when they do use math, they focus primarily on surface features of quantum mechanical models, both lexical (e.g., the language used when describing the model) and complex (e.g., the intensity of the mathematics that is shown in the model) (Muniz et al., 2018). When describing the kinetic and potential energies of the harmonic oscillator, students used classical mechanics to build explanations (Beck et al., 2020).

Two-Dimensional Rigid Rotor. There were a few studies that investigated students' interpretations of the two-dimensional rigid rotor model (Beck et al., 2020; Muniz et al., 2018). The two-dimensional rigid rotor is taught sequentially after the quantum mechanical harmonic oscillator. This model describes the rotational movement that a particle can experience. This model requires a similar mathematical treatment of the Schrödinger equation, including the use of the potential energy component of the Hamiltonian. The main difference in the mathematical treatment of this model is that it includes polar coordinates in the wavefunction. In these studies, students were found to conflate vibrational and rotational motion when applying the model (Beck et al., 2020; Muniz et al., 2018). When using the two-dimensional rigid rotor system to predict and explain molecular rotation, students were found to focus on incorrect aspects of the model causing misapplication of the model (Beck et al., 2020).

Discussion and Next Steps

The three quantum mechanical models described above are not the only models that physical chemistry students learn. After instruction on these introductory models, students move on to find the analytical solution to the hydrogen atom using the Schrödinger equation, discuss the challenges with quantum mechanics that arise with the three-body problem, and learn approximation methods that allow for exact solutions to the Schrödinger equation when modeling multi-electron atoms. As can be seen in our findings, there is a need in the literature for more studies that investigate students' interpretations of the models in physical chemistry.

The models that are taught in physical chemistry require a robust amount of mathematics skills. However, the included studies rarely investigated students' conceptualizations or reasonings regarding the mathematics that they are applying in physical chemistry. When comparing our quantum mechanics review to the quantum mechanics reviews that exist in physics education literature (Krijtenburg-Lewerissa et al., 2017), there is a jarring difference in the way mathematics is discussed. In the physics education reviews on quantum mechanics, findings from investigations conducted on students' use of specific mathematical operations are discussed in detail whereas these findings are largely absent from our review. Instead, the articles

in our sample rely on this prior work as support for understanding and explaining physical chemistry students' difficulties with quantum mechanics.

Although physics and mathematics education research has provided a clear pathway and foundation for this research, there is a need for more research investigating chemistry students' interpretation and use of the mathematics present in physical chemistry courses. Considering the interdisciplinary nature of the topics in physical chemistry, it is necessary for more interdisciplinary education research to be conducted on these topics. With more interdisciplinary research collaboration, a better understanding of students' difficulties with the content in physical chemistry may provide new pathways for instruction. For instructors, we have presented on the mathematics concepts and skills that are relied upon in physical chemistry to clarify how they are used in chemistry courses. The next step for our project includes analyzing the remaining categories that emerged in our study to further review the chemistry education literature related to the teaching and learning of quantum mechanics.

Can Interleaving Enhance Student Outcomes in Freshman Calculus?

Steve Bennoun
University of California Los Angeles

In contrast to traditional homework sets that typically group problems by topics, an approach known as blocking, interleaving consists in alternating the topics for each problem set. Studies in middle school mathematics and college physics report important benefits of interleaving on students outcomes. The goal of the present study is to investigate whether similar benefits can be observed in the context of college calculus. Students in two sections of a Calculus for Life Sciences course received either blocked or interleaved weekly homework. On two surprise quizzes given in the middle and at the end of the quarter, the interleaved group outperformed the blocked group (d=0.18 and d=0.33 respectively). On a quiz given one month after the end of the course, the interleaved group outperformed the blocked group on the second half of the quarter but not on the first half. Limitations of these results are discussed.

Keywords: student achievement, calculus, interleaving effect.

The United States faces an urgent need to improve mathematics and science education in order to meet the future demand of science, technology, engineering and mathematics (STEM) workforce (President's Council of Advisors on Science and Technology (PCAST), 2012; National Research Council, 2013). Over the years, there has been many calls for the development and adoption of evidence-based instructional methods in STEM courses, especially at the college level (e.g., National Research Council, 2000; American Association for the Advancement of Science, 2009). Poor performance in introductory math courses such as calculus has been linked to students' decisions to leave STEM majors (Chen, 2013; Ehrenberg, 2010; Hunter, 2019). Calculus is often considered a "weed out" course (Weston et al., 2019) and constitutes one of the most challenging hurdles for students pursuing STEM majors. Improving student outcomes in calculus is therefore of great importance.

There is strong evidence that active learning can improve student learning compared to traditional methods (e.g., Freeman et al., 2014; Code et al., 2014; Hake, 1998). However, active learning does not by itself guarantee that all students will automatically perform better or earn top grades. It is therefore necessary to investigate other teaching methods that can be used either by themselves or in combination with other instructional approaches such as active learning.

One component of instruction that is often overlooked by teachers and students is how to organize and sequence learning opportunities. A common way of organizing a course is to divide topics into blocks that are then studied and practiced individually, an approach known as blocking (Rohrer, Dedrick, & Hartwig, 2020). In contrast, interleaving consists in mixing the practice of different skills together. Thus, when completing an interleaved homework set, students practice both the individual skills in the current section and also the ability to identify which method (from across prior units) is appropriate to solve a given problem. This is not trivial because similar looking problems may require different strategies (e.g., $\int x(e+1)^x dx$ requires integration by parts whereas $\int e(x+1)^e dx$ requires a U-substitution) and choosing an appropriate strategy is often challenging for students (Ziegler & Stern, 2014). In addition, exams are typically interleaved as they cover a range of different topics and students are not explicitly told which concept or method they should use to solve a given problem. Students are therefore

expected to exhibit on exams a skill that has hardly (if at all) been practiced. There is a growing body of literature from cognitive science and education psychology showing the potential of interleaving to support student learning and performance. The goal of this study is to investigate how interleaving can be concretely implemented in a college Calculus for Life Sciences course and what its impact on student performance is.

Theoretical Background and Relevant Literature

The first study comparing interleaving and blocking for mathematical tasks was conducted by Rohrer and Taylor (2007). Participants in this study learned to compute the volumes of four little-known solids following either a blocked or interleaved schedule. In the blocked group, the participants read a tutorial on how to compute the volume of a given solid and then completed four practice problems on that solid. They repeated this pattern for the four solids. In contrast, in the interleaved group participants first read the four tutorials and then completed the practice problems that were interleaved, or in other words, mixed. In both groups participants received feedback after each problem in the form of the correct answer. The participants took part in two practice sessions that were one week apart. During these sessions the blocked group showed greater accuracy with an average of 89% versus 60% for the interleaved group. However, on the test that took place one week after the second practice session, the scores dramatically reversed with the blocked group having an average score of 20% and the interleaved group 63%.

Two non-mutually exclusive mechanisms have been proposed to explain the benefits of interleaving: the *spacing effect hypothesis* and the *discriminative contrast hypothesis*. Since interleaving consists in intermixing the practice of different topics, an interleaved schedule automatically creates some temporal spacing between two practice problems or practice sessions on a given concept. Many studies have shown the benefit of spacing repetitions over time rather than massing repetitions (e.g., Cepeda et al., 2006; Donovan & Radosevich, 1999; Bjork, 1994). The *discriminative contrasts hypothesis* proposes that juxtaposing problems on different concepts next to each other promotes the comparison between the concepts and makes their discriminative features more salient. Several studies support this hypothesis (e.g., Wahlheim et al., 2011; Sana et al., 2017) and two in particular (Taylor & Rohrer, 2010; Kang & Pashler, 2012) suggest that the benefits of interleaving do not solely come from the spacing effect.

Large-scale studies conducted in the classroom with authentic classroom materials have reported a large positive effect of interleaving. For example, Rohrer et al. (2020) conducted a study with 54 seventh-grade classes involving 787 students. The students practiced four different types of mathematical problems during 8 practice sessions. Each class either followed a blocked or interleaved practice schedule. Students then completed a test 33 days after the last practice session. On that test, the interleaved group significantly outperformed the blocked group with an average of 61% versus 38% (Cohen's d=0.83). While showing a large effect, this study focused only on four topics and was conducted in middle school. One question is thus whether a similar positive effect of interleaving can be observed in a course where all topics throughout the course are interleaved and where the material is more complex.

Samani and Pan (2021) addressed this question by interleaving or blocking homework sets in an undergraduate physics course. During four weeks, students would either complete blocked or interleaved homework sets. Then for the next four weeks they would switch to other the type of homework. Students received a surprise test two days after the end of each stage. On both tests the interleaved group outperformed the blocked group (Cohen's d=0.40 for the first stage, and d=0.91 for the second stage). One should note all problems were computational in nature with a numerical final answer (with units) and involved recalling the appropriate formula. One should

also note that no statistically significant differences were observed on the course exams. In this study students completed three homework sets per week for a total of 27 problems, which is more than the typical one homework set per week, and over 75% of them were seniors.

The goal of the present exploratory study is to test whether interleaving could bring similar benefits in an introductory Calculus for Life Sciences course in which students are mainly freshmen and sophomores and complete one homework set per week. Moreover, questions should also include non-computational questions such as writing the equations of a mathematical model based on the description of a biological system or interpreting a bifurcation diagram. More specifically, I answer the following two research questions:

- What is the impact of interleaving on student performance in a Calculus for Life Sciences course in which students complete one weekly homework?
- What are the benefits of interleaving homework sets after a one-month delay?

Methods

This study was conducted in two sections of a Calculus for Life Sciences course at a large research-intensive public university in the southwest with a total of 491 students. The vast majority of the students (94%) were either in their freshman or sophomore year and over 90% planned to major in biology or the life sciences. The course focused on modeling and how to use mathematical models to better understand biological systems. The instructor used active learning methods in the form of clicker questions with peer instruction (Crouch & Mazur, 2001) and small-group activities. The students also had weekly coding labs led by teaching assistants. During these labs students solved one question similar to a homework exercise in groups, and then spent rest of the time learning to code in SageMath. The course was identical for both sections (same instructor, same lecture materials, etc.) except for the structure of the homework. The ten-week quarter was divided into two four-week stages (the topics of weeks 5 and 10 were not part of the study). During the first stage, one section received blocked homework sets while the other one received interleaved homework sets. Each section then switched to the other type of homework for the second stage.

Blocked and interleaved homework sets were created in the following way. Each lecture was divided into two topics and two or three homework exercises were created on each topic. In the blocked homework sets the topics appeared in the same order as they had been studied in class and the exercises on a given topic were grouped together. For the interleaved homework sets, once a topic was studied in class, one exercise on this topic would appear on the next three homework sets (except for the last two weeks of each stage). The interleaved homework sets thus contained topics from different weeks and two exercises on a given topic would never appear one after the other. Importantly, in each stage students received the exact same homework exercises, only organized differently. Students submitted their homework weekly and homework exercises were graded on a 3-point scale (very good, sufficient, insufficient).

Students received a surprise in-class quiz on the Thursday of weeks 5 and 10. They also had a midterm on the Monday of week 6 (just before the beginning of the second stage) and a final exam on the Monday following week 10. In order to assess the impact of interleaving after a one-month delay, students took an in-class quiz during the first day of the following quarter. This quiz took place 28 days after the final exam. Students were encouraged to do their best on that quiz by being told that it would help the instructors assess their current level of understanding of the material was. They also received a bonus point for completing the quiz. The quiz contained

two questions on material from the first stage and two questions on material from the second stage. The midterm, final exam and quizzes were graded by the teaching assistants of the course.

Results

Quizzes and Exams During the Quarter

For the first surprise quiz, students in the interleaved group outperformed the students in the blocked group with an average of 66.11% for the interleaved group and 62.14% for the blocked group ($p=0.047$, Cohen's $d=0.18$). A similar outcome was observed on the second surprise quiz that took place on the last day of the course with an average of 57.24% for the interleaved group and 50.54% for the blocked group ($p<0.001$). This time the effect size was larger with Cohen's $d=0.33$. One should note that while the second half builds on the first half, the questions asked in each quiz targeted concepts from the corresponding stage. A student can do well on a stage 2 question (e.g., determining the long-term behavior of a given model using linear stability analysis) without necessarily doing well on a stage 1 question (e.g., writing down the equations of a model based on the description of a biological system or estimate the future value of a variable using Euler's method). It thus seems reasonable to assume that the results of the second quiz are primarily (if not only) impacted by the interleaving or blocked condition in stage 2.

For the midterm and final exam, there was no statistically significant differences between the two groups. Specifically, on the midterm the interleaved group had an average of 79.81% and the blocked group of 79.42% ($p=0.78$). For the final exam, restricting the analysis to the questions covering the second half of the quarter, students in the interleaved group outperformed students in the blocked group with an average of 87.68% for the interleaved group and 85.11% for the blocked group. However, this difference was not significant ($p=0.092$). The difference between the two groups on the questions covering the first part of the quarter was not significant either.

Although the lack of statistically significant differences between the two groups on the midterm and final exam may suggest a limitation of the impact of interleaving, two other elements may explain this result. First, it is possible that the unannounced quizzes helped students identify topics they had yet to master and thus prompted them to thoroughly review these concepts. This hypothesis is consistent with results on topics that appeared both on quizzes and the subsequent exam. For example, for the question on the stability of equilibrium points the average was 43.57% on the end-of-quarter quiz and 89.14% on the final exam. Second, even without the unannounced quizzes, students tend to review very intensely shortly before the exam. On surveys students indicated having spent on average 16.63 and 21.63 hours specifically reviewing for the midterm and the final exam respectively. One should also note that there is no indication that study behavior changed between the two groups. For example, the perceived difficulty of the homework reported by the students was not significantly different between the two groups. This suggests that the differences seen on the quizzes does not come from different study behaviors but from interleaved structure of the homework itself.

Quiz After a One-Month Delay

The quiz that was given at the beginning of the following quarter contained four questions, two on material from the first stage and two on material from the second stage. On the first stage there was no statistically significant difference between the two groups ($p=0.79$).

On the second stage the interleaved group outperformed the blocked group with an average of 56.71% for the interleaved group and 51.75% for the blocked group ($p=0.044$, Cohen's $d=0.20$). There is some similarity with the results of the quizzes given during the quarter with

interleaving having a stronger impact on the second half of the quarter than on the first half. This is also in line with the results reported by Samani and Pan (2021) in college physics.

Discussion and Future Work

The results suggest that interleaving can help student performance in calculus (although perhaps modestly) and are consistent with previous studies in middle-school mathematics (Rohrer, Dedrick, Hartwig, et al., 2020; Rohrer et al., 2015) and college physics (Samani & Pan, 2021). These three studies have reported larger gains and one question is therefore where this difference may come from. The first study by Rohrer et al (2015) focused only on two types of problems, graph and slope problems. One interesting feature is that the wording of each type of problem was always the same ("Graph the equation…" and "Find the slope of the line that passes through the points…"). It is reasonable to assume that the problems given on the test again used the same phrasing. While not explicitly mentioned, it seems probable that this same feature was used by Rohrer and collaborators in their (2020) study. This characteristic leaves open the possibility that interleaving may help students better identify keywords or key features of problems but is not necessarily as powerful when problems on a given topic can take different formats. Based on the examples accompanying their article, Samani and Pan (2021) also seem to have used problems that had the exact same wording except for the numbers and names of the atoms involved in the problems. Since their tests involved some problems that combined two topics, it is hard to determine whether the wording of the test problems was similar to the homework problems. However, since in the present study some problems on a given topic could have different format, this could explain the lower effect sizes observed here.

Another notable feature of Samani and Pan's (2021) study is that all problems involved recalling the correct formula(s) and then using it to get to the correct numerical value and units. When looking at their memory sub-measure (whether students could recall the appropriate formula), they found effect sizes of d=0.41 for the first stage and d=0.96 for the second stage, while when looking at the correctness of the answers sub-measure, the effect sizes were d=0.25 for the first stage and d=0.40 for the second stage. While the authors explain that it is not uncommon in introductory physics courses to have a low level of correct numerical answers due to the conceptual and computational complexity of the questions, the difference in effect sizes may suggest that interleaving really helps students recall the appropriate formulas but is not as potent in supporting their problem-solving skills.

One common feature between the current study and Samani and Pan (2021) is that the interleaving effect is stronger for the second half of the course. There is no obvious explanation for this phenomenon, however, one may tentatively hypothesize that interleaving helps students more when the complexity of the material increases. This is something that needs to be further tested. Another question that needs further investigation where do the differences in effect sizes between the current study and the studies by Rohrer et al. (2020; 2015) and Samani and Pan (2021) come from. Is it due to the differences in the format of the problems used as noted above or do other factors also play a role? Finally, future research should further look into why benefits observed on unannounced quizzes do not carry over to exams and if this is indeed due to students cramming before an exam or due to other characteristics of the exams.

Mathematicians' Goals for Their Upper-Level, Proof-Based Mathematics Courses

Ciara Murphy
University College Dublin

Maria Meehan
University College Dublin

Despite significant research efforts focused on the development of student-centered instruction, most mathematicians continue to teach through lecture. Consequently, researchers have called for further examination of the reasons why mathematicians appear to believe in their current teaching practices. Our study builds on previous research addressing this call by examining how mathematicians' in- and out-of-class instructional decisions in upper-level, proof-based mathematics courses reflect their pedagogical goals. Four mathematicians participated in a series of three, one-to-one interviews examining their instructional design of a course they had recently taught. Data analysis is ongoing and is being guided by a deductive form of thematic analysis. In this paper, we provide an overview of literature on mathematicians' pedagogical goals, describe the study design and plans for data analysis, and present preliminary findings in relation to one participant mathematician.

Keywords: Upper-Level Courses, Goals, Resources, Orientations, Instructional Design

Introduction and Background Literature

In their recent review, Melhuish et al. (2022) distinguished between two forms of in-class instruction of undergraduate, proof-based, mathematics courses: those based on a lecture-based pedagogy and those based on a student-centered (or inquiry-based) pedagogy. Many mathematics education researchers have expressed dissatisfaction with lecture-based instruction, particularly its operation on a transmission-based model (Melhuish et al., 2022). Student-centered instruction, which emphasizes engaging students in doing mathematics during class time, has been suggested as an alternative (e.g., Laursen & Rasmussen, 2019). To assist instructors in adopting student-centered instruction, there has been significant research on the development of research-informed curricula for various mathematical content areas (e.g., Larsen et al., 2013; Leron & Dubinsky, 1995). However, "the influence of this research so far has been modest" (Melhuish et al., 2022, p. 4). Most mathematicians continue to teach through lecture (Johnson et al., 2018), despite the alternatives on offer. Additionally, the relatively small number of mathematicians who choose to adopt student-centered instruction are more likely to develop their own materials than to adopt research-informed curricula (Fukawa-Connelly et al., 2016).

The lack of uptake of these materials, despite the significant research efforts that focused on their development and dissemination, led to the call for research to "better explore the reasons that mathematicians appear to strongly believe in their current practice" (Fukawa-Connelly et al., 2016, p. 281). Subsequent research addressing this call (Woods & Weber, 2020) concluded that, in relation to lecture-based pedagogy, mathematicians choose to lecture as they believe in its efficacy as an instructional method and feel it aligns well with their pedagogical goals.

Over the past decade, numerous other studies have investigated various aspects of lecture-based instruction. This means we now have a good understanding of what happens in the 'typical' undergraduate mathematics classroom (Melhuish et al., 2022). However, the time instructors spend in class with students accounts for only one component of instruction. Many mathematics educators agree that, regardless of the format of in-class instruction, the majority of students' learning of advanced mathematics will take place outside the classroom (Rupnow et al., 2021). Therefore, an important aspect of teaching undergraduate mathematics is preparing

students to work independently outside of class (Lew et al., 2022; Rupnow et al., 2021; Wu, 1999). This aspect of instruction has received much less attention in the mathematics education research literature. Rupnow et al. (2021) were among the first to examine how mathematicians assign homework problems in upper-level courses. Six mathematicians participated in task-based interviews in which they were asked to select homework problems from an abstract algebra textbook and justify their choices. The mathematicians' pedagogical goals guided their assignment of homework problems, and they perceived students' engagement with these problems as essential to their learning.

The studies of Woods and Weber (2020) and Rupnow et al. (2021) both address Fukawa-Connelly et al.'s (2016) call by providing insight into how mathematicians' decisions in relation to in-class instruction and homework are guided by their pedagogical goals. However, to date the various components of undergraduate mathematics instruction have mostly been examined independently, with a large emphasis on the in-class component. The goal of our study is to build on existing work and examine mathematicians' goals and pedagogical decision-making in relation to *all* instructional components of their upper-level, proof-based mathematics courses, along with the factors that influence these goals and decisions. Prior research that has surveyed mathematicians, has identified potential influences on their teaching practice, such as their experiences as a teacher and student (Johnson et al., 2018). However, research that has employed qualitative methodologies has demonstrated that mathematicians' teaching goals can vary on the level of the individual (e.g., Johnson et al., 2013; Pinto, 2019). Based on this research, we decided to adopt a qualitative study design to examine mathematicians' potentially varying goals and pedagogical decision-making in relation to all instructional components of their courses. In summary, our study addresses the following research questions:

- **RQ1:** What are mathematicians' pedagogical goals for their upper-level, proof-based mathematics courses and how do their orientations and resources inform these goals?
- **RQ2:** How are mathematicians' pedagogical goals reflected in the instructional decisions they make?

Theoretical Perspective

Given that research has indicated that mathematicians' instructional decision-making is primarily guided by their pedagogical goals (Rupnow et al., 2021; Woods & Weber, 2020), we decided to use Schoenfeld's (2010, 2011) theory of decision-making to inform our study design and data analysis. Schoenfeld proposes that the pedagogical decisions that a teacher makes can be understood as a function of their goals, resources, and orientations. Goals are described as "the things that people consciously or unconsciously set out to achieve" (Schoenfeld, 2011, p. 459) and can vary in terms of size. For instance, an instructor will likely have overarching goals for a course they are teaching, in addition to goals for an individual lesson. Schoenfeld suggests that a teacher's decision-making involves the selection of goals that are consistent with their orientations and resources. Orientations is used as an "inclusive term to encompass beliefs, dispositions, values, tastes and preferences" (Schoenfeld, 2010, p. 15). For example, over the course of their teaching career a mathematician may develop understandings or perceptions about the nature of mathematics, teaching, or students. Schoenfeld also proposes that the availability of resources also influences a teacher's decision-making. He elaborates that "what a teacher can or cannot do in the classroom is clearly a function of what he or she knows, what material and other resources are available, and what constraints are in place" (Schoenfeld, 2010,

p. 10). Schoenfeld's theory emphasizes the interaction among an individual's goals, orientations, and resources and notes that, typically, orientations and beliefs are slow to evolve and change.

Methodology

The study adopted a qualitative, phenomenological (Willig, 2021) research design. Four mathematicians participated in a series of three, one-to-one interviews in summer 2023. The interviews were designed to examine the mathematicians' instructional design of an upper-level, proof-based, mathematics course they had recently taught. Data analysis is in the initial stages.

Participants

Four research mathematicians, employed in a large, Irish, PhD-granting university, participated in the study. We employed purposive sampling (Braun & Clarke, 2013), inviting mathematicians with over 20 years' teaching experience who had taught an upper-level, proof-based mathematics course in the last three years to participate. We endeavored to have a balance in the research areas and institutions of undergraduate study of participants, as well as a gender representation that reflects that of the discipline of mathematics in the university. In this report, we present preliminary findings in relation to one participant to whom we assign the gender-neutral pseudonym Doolan.

Course Context

The four participants in the study were each interviewed about an upper-level, proof-based mathematics course they had recently taught. Given this paper's focus on findings related to Doolan, we provide further contextual details about their course. Doolan teaches a proof-based course covering topics from analysis to third- and fourth-year mathematics students. The in-class component of the course consists of 36 hour-long classes. Doolan lectures in roughly 30 classes, the remaining six classes are recitation classes (referred to as tutorials) in which the homework problems are discussed. There are four homework assignments in the course. Students are provided with a problem sheet consisting of around ten problems and are asked to submit solutions to two problems of their choosing. Each homework assignment is worth 5% of a student's overall grade, with a two-hour closed-book examination accounting for the remaining 80%.

Data Collection

All four mathematicians participated in a series of three, one-on-one interviews with the first author in summer 2023. Each interview lasted an average of an hour and was audio-recorded and transcribed. To add specificity to our interview questions, we asked each mathematician to select a section of content from their course consisting of at least one of each of the following: definition, example, theorem, and proof. We asked that the section of content they picked be reflective of the main focus of the course (rather than introductory material), and feature in the homework assignments.

The participants provided the lecture notes, homework assignments, and past examination questions relevant to their chosen section of content. These were used in the design of the interviews, with the first interview focused on the design of the lecture notes and lectures, the second on the homework assignments, and the third on the assessment component of the courses. As the focus of our preliminary findings is on homework, we provide further detail about the second interview. Based on the interview protocol used by Rupnow et al. (2021), for each problem related to the relevant content topic we asked why the mathematician had decided to

include the problem and what they hoped students might learn from engaging with it. We also asked participants more general questions about how they operationalize homework in their courses and how they view the role of homework. Additionally, the mathematicians were asked if they hold recitation classes on homework problems and, if applicable, to describe the role and structure of these classes.

Data Analysis

Data analysis is in the initial stages. We plan to use a deductive form of thematic analysis, utilizing a method called template analysis (Brooks et al., 2015). Schoenfeld's (2010, 2011) theory of decision-making will inform the coding of the data. We also plan to incorporate the findings of Rupnow et al. (2021) and Woods and Weber (2020) in relation to mathematicians' goals as *a priori* codes (Brooks et al., 2015). To date, the authors have familiarized themselves with one participant's (Doolan's) interviews, with notes written on points of potential analytic interest. Analytic notes, and associated quotes, from the second interview were examined for evidence of pedagogical goals, as well as resources and orientations influencing these goals. This process informed the preliminary findings that we present in this paper.

Preliminary Findings

The aim of our study is to examine mathematicians' goals for their upper-level, proof-based mathematics courses, factors influencing these goals, and how their goals are reflected in their pedagogical decision-making in relation to all instructional components of their courses. In this paper, we present preliminary findings in relation to one of Doolan's pedagogical goals: encourage and support students in engaging with homework problems. We emphasize that data analysis is in the initial stages. Our primary purpose in presenting these findings is to illustrate the nature of our data and to present some of our initial analytic thoughts.

Doolan's reasons for assigning students homework problems broadly align with the findings of Rupnow et al. (2021). Like participants in Rupnow et al.'s study, Doolan downplays summative assessment as a purpose of assigning homework and highlights the learning opportunities engaging with problems can provide. Doolan emphasizes problem solving as a skill that should be developed in an undergraduate mathematics degree, stressing the importance of learning to struggle and persevere with non-trivial problems:

> *Doolan:* The whole point of it is that you hit these problems that you haven't met before, and you don't know if you can solve them. And if all you do is spend like a minute thinking about it and saying, you know, 'I can't do it' then, you know, you're not going to be a mathematician.

Given the importance they attribute to students' engagement with problems, it is perhaps unsurprising that one of Doolan's goals as an instructor is to encourage and support students in their work on homework problems. In this paper, we analyze one of Doolan's instructional decisions that we feel is consistent with this goal: the decision to allow students to select two homework problems from each of the four problem sheets in the course to submit for assessment. This decision appears to be primarily motivated by Doolan's pedagogical beliefs. Doolan proposes that by not assigning students particular problems, they will be encouraged to read, and engage with, all the problems to assess their relative difficulty:

> *Doolan:* If I give two particular problems as the assessment on that chapter, the students might just read those two problems and not bother about the rest. If they read the entire

sheet, even if it's with the viewpoint of finding the easy ones, they do have to think well, 'Is this hard or is this easy?' So, there's a little bit of learning going on just from that.

Additionally, by not requiring students to submit all problems for assessment, Doolan is able to include more difficult problems in the homework assignments. Acknowledging that it is likely that not all students will be able to complete these harder problems, Doolan believes there is still value in students attempting and thinking about them: "it would be a problem that I'd encourage students to think about, but I wouldn't expect them to hand it up for their assessment."

Doolan's decision to allow students agency in selecting their own problems also appears to have been influenced by their own experience as a student. Doolan recalled that as a student in a Ring Theory course, they became captivated by one question on a problem sheet: "one kind of intrigued me and I spent weeks like looking at it. I had a whiteboard at home and I was trying every kind of way." This formative experience as a mathematics student has left Doolan with the belief that "just throwing yourself into one problem like that, at the right time, can be really instructive. And, if it works out for you in the end, gives you great confidence." Doolan acknowledges that the decision to not assign students particular problems may be partly about "allowing a little bit of freedom" so that students have the chance to become similarly interested in problems of their own choosing.

We note that Doolan's decision to have students submit just two homework problems reflects the fact that they are constrained in terms of the time they have available to grade students' work: "practical things come into play. It takes quite a lot of time to grade. Yeah, so two is fair." We also highlight that Doolan's practice in relation to allowing students to select homework problems for assessment has evolved over the course of their teaching career. Doolan mentions that in previous iterations of the course they randomly assigned students particular problems to submit for assessment. The students at the time felt "it was a bit unfair that everyone had different problems to hand up." Based on this feedback from students, Doolan's understanding of students' perceptions of instructional practices developed, and their teaching practice in relation to assigning problems was adjusted accordingly.

Discussion and Conclusion

In this paper, we have outlined some of our initial analytic thoughts on one participant's goals and decision-making in relation to homework. While emphasizing the preliminary nature of our results, we note the apparent alignment between Doolan's instructional decisions and their pedagogical beliefs. This is consistent with prior research indicating that mathematicians can generally offer sophisticated rationales for their pedagogical actions (Melhuish et al., 2022). The implication of this finding is that attempts to change mathematicians' practice are likely to fail if the alignment between instructional interventions and mathematicians' goals is not considered (Melhuish et al., 2022; Woods & Weber, 2020). Consequently, developing a robust understanding of mathematicians' pedagogical goals and decision-making in relation to both in- and out-of-class instruction is important in terms of informing the development of instructional interventions. In this regard, our ongoing work on this study builds on previous research by examining mathematicians' goals and pedagogical decision-making in relation to all instructional components of their upper-level, proof-based courses.

Mathematical Induction: Which Written Proofs or Visual Proofs are More Convincing?

Mario Abel Gonzalez
Texas State University

This study uses a survey to investigate mathematical convictions in tournament-style comparative judgements for written and visual proofs. The survey uses four theorems that can be proven using mathematical induction with each having four proofs: two written and visual. The visual proofs were equally convincing, and the respondents indicated that they believed these visual proofs to be mathematical proofs but not prove their theorems for all values n. The written proofs by mathematical induction were often the most convincing proofs—winning the overall tournament. Familiarity and content seemed to be prevailing factors for judging whether one proof was more convincing than another.

Keywords: Mathematical induction, comparative studies, visual proofs, mathematical conviction

Mathematical conviction (Brown, 2018), the ways in which one is persuaded about the truth of a theorem given a proof, has been deemed a nebulous concept posing challenges to empirical study. This study seeks to gain new insights by exploring how students respond to two types of proofs with specific features: visual proofs and written proofs by induction. Though visual proofs have a contested status as proofs (Brown, 2008), they may offer useful tools for investigating what types of proofs may be convincing (Alcock & Simpson, 2004; Relaford-Doyle & Núñez, 2021). Mathematical induction (MI) has been well-documented as being difficult for students to understand (Ernest, 1984) where issues may arise at any step (Stylianides et al., 2016), but it may also provide interesting insight about when and how students are convinced by it (Brown, 2014; Stylianides, 2007). The purpose of this study is to investigate how these two features influence student proof convictions using comparative judgments (c.f., Brown, 2018).

Background Literature

Most literature focuses on whether students are convinced by proofs or something other than proof (Stylianides et al., 2017). In this study, I am concerned with the features of proof that make them more convincing in comparative judgement tasks.

Components for this Study

There are a variety of studies on mathematical convictions which report a multitude of factors influencing whether and how a mathematical proof is convincing. Common aspects influencing this judgement are familiarity with the content and method (Brown, 2018; Chazan, 1993; Healy & Hoyles, 2000), example-use (Healy & Hoyles, 2000; Weber et al., 2022), and whether one understands that proof (Brown, 2018; Selden & Selden, 2003).

Visual elements may also influence mathematical convictions because those visual elements may convey the same features that written proofs can (Relaford-Doyle & Núñez, 2021; Zhen et al., 2016). This can be done perceptually (Harel & Sowder, 1998; Miller et al., 2022) and might be salient enough for students to gain insight into the argument (Weber, 2010). There is also evidence that visualizations and convincingness interact (Alcock & Simpson, 2004, 2005). Combining recursion and visual elements can also be helpful for becoming convinced by a mathematical argument (Knuth, 2002).

Recursion can provide an entry point into MI (Harel & Sowder, 1998). MI is susceptible to cognitive gaps (Norton et al., 2022) which may be alleviated through example-use (Stylianides et al., 2016). So, combining visual aspects, in the form of proof, and mathematical induction provides the foundation for this study's methods because MI can be formulated to reveal recursive relationships thereby influencing mathematical convictions.

Methods

I sampled from a discrete mathematics 2 course at a large southern university in the United States using a survey which received 15 responses. For four theorems, four proofs were created or adapted from prior literature. Two of these were visual proofs, one that demonstrated how different cases were related (visual induction-promoting proofs, VIPPs), and the other showed a single case to be taken as general, often when $n = 7$ (visual general-promoting proofs, VGPPs). The other two proofs were written proofs: an MI proof (WMIPs) and a non-MI proof (WNMIPs).

Instruments

The survey features a tournament-style comparative judgement design with four theorems with each of these having the previously mentioned types of proofs. Every written proof avoided prompting phrases for proof methods such as "this is a contradiction" or "by the principle of mathematical induction." Figure 1 below shows the general structure for the tournament.

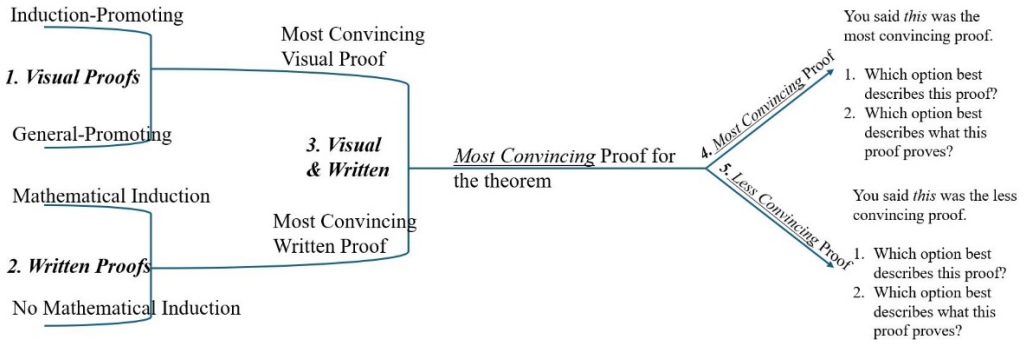

Figure 1. The General Structure of the Survey for the Four Theorems.

In Figure 1, the numbers indicate the order presented within the survey. Visual proofs were always compared first, written proofs second, and then a visual and a written proof third. The order of all answer choices was randomized to prevent a priming effect. The exact phrasing for prompting students to select the more convincing proof was "which proof, in your opinion, is the most convincing? In other words, which proof better persuades you of the truth of the theorem?" (Brown, 2018, p. 8). Students were allowed to select an option that stated both proofs were equally convincing. After the third bracket, the students were shown their most and least convincing proofs and asked what type of proof they were and what they proved. Borrowed from Brown (2018) and Relaford-Doyle and Núñez (2021), these questions confirmed student engagement and how they interpreted the proofs (the type and how general).

The first and second theorem (see Table 1) were intended to be familiar and were often used as either examples or homework problems in ITP courses. The third and fourth theorems were intended to be unfamiliar. That is, these theorems were likely not seen as homework problems or examples in class. All WNMIPs were direct proofs except the one for Theorem 1 (see Brown, 2018, p. 11, Argument 1B). Table 1 presents the four proofs for one of the four theorems.

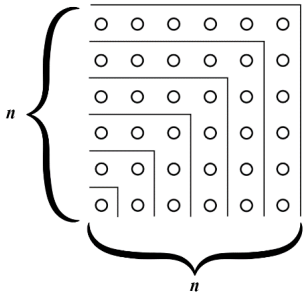

Table 1. Theorem 2 and its Proofs

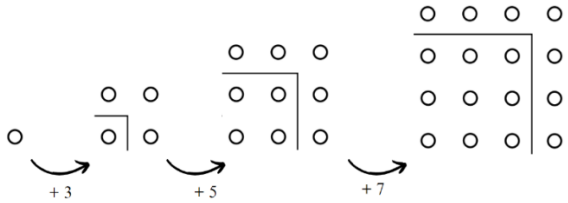
Theorem 2: Let n be a positive integer, then $1 + 3 + 5 + \ldots + (2n - 1) = n^2$



Proof 2A (WNMIP)

$$\begin{aligned} 1+3+5+\cdots+(2n-1) &= \sum_{k=1}^{n}(2k-1) \\ &= 2\sum_{k=1}^{n}(k) - \sum_{k=1}^{n}(1) \\ &= 2\frac{n(n+1)}{2} - n \\ &= n^2 \end{aligned}$$

Proof 2B (VGPP)[a]

Proof 2C (VIPP)[a]

Proof 2D (WMIP)

Let $n = 1$, then $2(1) - 1 = 1^2$.
Suppose that the theorem is true for some positive integer k.
It follows that,
$1 + 3 + 5 + \cdots + (2k - 1) = k^2$.
Thus,
$1 + 3 + 5 + \cdots + (2k - 1) + (2k + 1) = k^2 + 2k + 1 = (k + 1)^2$.
It follows that for all natural numbers n,
$1 + 3 + 5 + \cdots + (2n - 1) = n^2$.

[a] Adapted from Brown (2008, p. 35)

Results and Analyses

There were several preliminary analyses performed. Table 2 was created to specifically see how convincing a type of written and visual proof were for theorems that could be proven with MI. Table 3 was created to follow students' decisions and which proof type was the most convincing. Table 4 was created to investigate how students understood the visual proofs. The current sample size cautions against inferring too much from these frequencies, but I illustrate the analysis to be performed on the larger sample set being gathered.

First and Second Bracket Results

The first and second brackets compared two visual proofs and two written proofs, respectively. These results are summarized in Table 2.

Table 2. First and Second Bracket Results Across the Four Theorems

	First Bracket		Second Bracket		
	VIPP (15)	VGPP (15)	WMIP (15)	WNMIP (15)	Total (30)
Theorem 1	7	5	11	4	27
Theorem 2	6	9	8	6	29
Theorem 3	5	9	11	3	28
Theorem 4	12	3	11	2	28
Total	30	26	41	15	112

The numbers appearing next to the headers indicate the maximum number possible for an entry in that column. The entries in the columns do not always add to 15 because some students said both proofs were equally convincing. In the first bracket, the visual proofs were nearly chosen as often as each other. Theorems 1 and 4 had higher instances of the VGPP chosen as more convincing than the VIPPs whereas Theorems 2 and 3 were the other way around. In the third bracket, the WMIPs were chosen nearly three times as often as the WNMIPs with those proofs

being chosen almost as frequently as each other for Theorem 2. These findings suggest that students had preferences regarding which visual proofs were more convincing, but they did not always align to the distinction between VIPP and VGPP across the tasks. By contrast, students found the MI proofs more convincing, at least within this limited sample.

Overall Tournament Results

The students made a total of 180 selections across the four theorems. These results are summarized in Table 3.

Table 3. Overall Tournament Results Across the Four Theorems

		Student															
		A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	Total
Third Bracket Only (4)	VIPP	0	0	3	0	1	2	0	0	0	0	0	1	3	3	2	13
	VGPP	0	1	0	0	0	2	0	2	0	1	0	0	1	1	1	9
	WMIP	3	1	1	3	1	0	2	1	1	3	3	2	0	0	1	23
	WNMIP	1	0	0	1	0	0	2	0	1	0	0	1	0	0	0	6
Totals Across All Brackets (12)	WMIP or VIPP	8	6	10	9	8	7	5	5	5	8	7	7	6	7	9	107
	WNMIP or VGPP	4	4	2	3	0	5	6	6	5	4	3	2	4	5	3	56

The numbers appearing next to headers indicate the maximum number possible for that row. In the third bracket, students more often selected the WMIPs as the winner of the tournament. This is interpreted as WMIP being the most convincing proof for these 15 students across the four theorems regardless of its content. The last two rows were used to help determine whether the WMIPs or VIPPs were in fact more convincing, in general, than their counterparts. The results showed that, when given the chance, the students chose those proofs as the more convincing nearly twice as much. This also shows that 10 of the 15 students chose the WMIPs or the VIPPs more than half the time while only one student chose the WNMIPs or VGPPs more than half the time.

Students' Descriptions of the Proofs

One component of this study was to determine how students viewed the visual proofs. The fourth and fifth components of the survey structure were used for this (see Figure 1).

Table 4. Students' Descriptions of the Proofs

Question Asked	Option on Survey	VIPPs (34)	VGPPs (26)	WMIPs (45)	WNMIPs (15)
Which option best describes this proof?	Direct Proof	14	9	7	5
	Contrapositive Proof	2	1	1	2
	Proof by Contradiction	1	0	1	2
	Proof by MI	8	7	32	6
	This is not a proof.	2	4	1	0
	Something else.	4	4	2	0
	All values of *n*.	19	17	37	12

Which option best describes what this proof proves?	Specific values of n.	10	8	5	3
	Something else.	2	2	2	0

In Table 4, the numbers in the parentheses next to the headers indicate the number of times that type of proof entered the third bracket therefore entering the fourth or fifth component of the survey. The two most common descriptions for the visual proofs were direct and MI proofs. A few students stated that the visual proofs were not proofs or described them as something else. These latter responses consisted of either uncertainty about the status of the proofs and picture or visual proofs. Notably, the number of responses indicating the visual proofs are mathematical proofs and those indicating that the proof proved the theorem for all values of n do not match. This was interpreted as students being convinced by something that they identified as mathematical proof while providing evidence that it did not meet the generality of a proof.

Discussion and Conclusion

In the first bracket, students chose the visual proofs with almost the same frequency. So, it cannot be yet determined whether one type is more convincing than the other. However, Theorems 1 and 4 had higher instances of VIPP while Theorems 2 and 3 had higher instances of VGPP. On one hand, the students may have "seen" induction (Brown, 2008) in the VIPPs for Theorems 1 and 4 but not Theorems 2 and 3. On the other hand, Relaford-Doyle and Núñez (2021) noted students might understand and reason about a diagram purporting to promote mathematical induction in ways that separate the diagram and their knowledge of mathematical induction. So, the result might be that the diagram can be helpful or convincing but for reasons unrelated to mathematical induction or other formalized methods of proof. Nevertheless, initial findings suggest that students have preferences based on some features of these visual proofs.

In the second bracket, the WMIPs were most often chosen as the more convincing proof. This can be interpreted as students' instruction on MI heavily influencing their choices on matters of conviction. That is, it is easily identifiable and familiar (Brown, 2018). The students' propensity for choosing the WMIP as the winner of the tournament can again be interpreted as students' familiarity with this proof method as a deciding factor for the second and third brackets. Notably, the WNMIPs for Theorems 2, 3, and 4 were not so often chosen. These proofs featured almost exclusively summations, manipulations, and few words. This might suggest that the idea that students value familiarity sanctioned in their classrooms despite prior research reporting its technicalities and difficulty (Ernest, 1984; Stylianides, 2007). In addition to this, the WMIPs and VIPPs were also chosen almost twice as often as WNMIPs or VGPPs throughout the survey. However, WMIPs constituted almost 60% of these selections. This again lends to the idea that the familiarity of written proofs by MI enhanced their convincingness.

For how students viewed the visual proofs, most students either viewed them as direct proofs or proofs by MI. However, not all those who selected an explicit proof type (50 instances) also said the proof proved the theorem for all values of n (36 instances). This is interpreted as those students possibly holding varying definitions or conceptions about mathematical proof (Morris, 2002, 2007; Recio & Godino, 2001). In other words, students may be convinced by something other than what many communities call "mathematical proof" even in more advanced mathematics courses such as discrete mathematics 2 Because these results and analyses had a limited sample set, I am gathering a larger data set this Fall.

Conceptualizing Language for Mathematical Problem Types Across Domains

Nicholas H. Wasserman
Teachers College, Columbia University

Paul Christian Dawkins
Texas State University

In this preliminary theoretical report, we problematize the language used in mathematical problems – in particular, with respect to the objectives and the directives of problems. We use this to conceptualize a set of eight problem types, described in three clusters, that run across mathematical domains. This paper explores the motivation for such work, as well as a rationale for why existing problem classifications in mathematics do not accomplish our intended aims; we identify potential applications of the framework, as well as challenges, for discussion.

Keywords: Problem types, Mathematical domains, Language, Mathematics register

Much of the study of mathematics is reducible to the problems students are asked to solve. While university syllabi identify the content of a course in terms of concepts and topics, the list of tasks assigned operationalize what students must learn and do. Problem solving, and the posing of mathematical tasks, are both central themes of mathematics education (Schoenfeld, 1992); as is the language used within them – which may be referred to as part of the mathematics register (Halliday, 1975; Pimm, 1987) or even its own genre (Bakken & Andersson-Bakken, 2021). However, if we consider the role of language in posing tasks to students, two key issues arise. By the time students take university mathematics they have years of experience with the genre of mathematics problems. Yet, whereas mathematical terms are often both well-defined and consistently used, the language used for posing mathematical problems is neither. For instance, the directive "find" in one problem context might mean perform an operation (e.g., "Find $f(2)$ when $f(x) = x^2$"), in another provide a singular example (e.g., "Find an x such that $f(x) = 4$ if $f(x) = x^2$), and elsewhere solve an equation (e.g., "Find all x such that $x^2 = 4$"). This suggests that decoding the nature and objective of a task could serve as part of a hidden curriculum students must navigate. To lay the groundwork for an investigation of the relationship between the language used in posing mathematics tasks and the actual objective being asked of students, this preliminary theoretical paper considers: *How can we categorize mathematical problems, across a variety of domains, that might help specify the nature of the task assigned?* We wanted categories that applied across domains because students experience the language of mathematics tasks across different courses. Although the current paper – a preliminary theoretical report – does not compare whether the same language is used for different tasks, or whether one task is expressed in various language, it lays the foundation for such investigation.

Motivation and Background

As a somewhat humorous illustration, consider the common meme reproduced in Figure 1 – of a student's solution to a mathematical problem. Here the student interprets the imperative "find" in an everyday sense, rather than according to any mathematical sense(s).

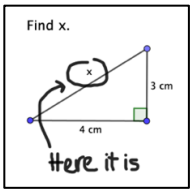

Figure 1. A student solution to the problem's directive to "Find…"

A mathematical problem uses language to give a directive (sometimes in question form) and tends to have a particular kind of mathematical goal associated with it. The problem's directive – e.g., the imperative verb – is supposed to signify this objective to the reader. Yet, we often do not give clear meaning and definition to these problem-posing terms. So, on one side, they are left ambiguous with *no* mathematics-specific meaning, partly because they are part of a meta-language about the doing of mathematics. On the other, we avoid defining them because, as we illustrated above with "find," they are polysemous and may be used to express a variety of goals, depending on the specific task (e.g., Schleppegrell, 2007). That is, an imperative verb can have *many* mathematics-specific meanings. In Figure 1, the task used the imperative "Find…" but the goal is to solve for the real-numbered value(s) of x given the properties of the figure – it is a problem about a solution set.

Rationale, Goals and Assumptions

Why do we need another way to categorize mathematics problems? Naturally, mathematics educators have developed categorizations, which reasonably tend to relate to 1) learning goals, 2) students' prior knowledge, 3) intended solution methods, or 4) expressions of epistemologies or mathematical practices. These features often make the categories specific to a mathematical topic (features 1-3), contextual within an instructional setting (features 1-3), or situated within broader social practice (feature 4). For instance, Schoenfeld's (1992) famous distinction between exercise and problem relates to the solver's prior knowledge. Stein et al.'s (2009) framework for cognitive demand similarly takes student experience into account. "Open" versus "closed" problems (c.f., Bahar & Maker, 2015) tend to account for solution methods, whereas Stanic and Kilpatrick (1989) elaborated five ways that problems can be a means to other ends: problems get used as justification, as motivation, as recreation, as vehicle (for learning), and as practice. This primarily categorizes problems in terms of their learning goals. Of course, one might also specify learning goals in other ways. Many frameworks categorize problems based on content area – whether broad (e.g., algebra, geometry) or more specific (e.g., systems of equations). Others categorize goals in terms of cognitive activities, such as recall or analyze, intended to capture processes. Some do both (e.g., the TEDS-M study, Tatto et al., 2008).

Such frameworks help us understand certain aspects of problems – often informative in textbook analyses (e.g., Gracin, 2018; Herbel-Eisenmann, 2007; Li, 2000). However, although we can imagine similar uses, we instead want categories of what students must produce in response to the problem, regardless of solution method, that can be applied across contexts and without reference to broader practices – which existing frameworks do not accomplish. These choices express our interest in understanding the *nature* of the problem posed in relation to the *language* used in the problem. We do not mean to deny the importance of all of these factors in how students interpret new tasks, as though the language used to express a problem can be isolated from all of these other factors. Rather, we seek to understand what information is (and is not) conveyed by the specific imperative or interrogative language used in a problem. It may be that most of the information about what the problem requires must be inferred from other sources of information, such as prior experience with similar problems. But this would imply that the language used to express a task remains largely inert and could be made more productive.

In setting down this path, we had four underlying assumptions that guided how we developed our framework. First, we wanted a framework that was broadly applicable across domains, which meant we did not want domain-specific problem types (e.g., "Differentiate"). The aim was for problem types to be comprehensible in any area of mathematics. Doing so affords looking at underlying connections across domains, and also allows us to compare across domains.

Second, our goal was to establish a framework that characterizes the core "objective" that students are asked to accomplish in a problem. As such, we were not necessarily concerned with how students might do so – the procedures used to get there. Accordingly, we focused on the general nature of a problem's solution rather than the path to that solution.

Third, we wanted to aim for a coding framework that was less subjective. That is, guessing at the particular ways students might accomplish a problem is challenging, as is guessing at an author's rationale for a problem. We wanted to classify more objective aspects.

Fourth, we sought a framework that would reduce the linguistic complexity in the posing of mathematical problems. We are dubious of being able to exhaust all problem types given the diversity of interesting tasks out there. Since we ultimately cared about the linguistic genre of mathematics problems, we restricted ourselves to common types even if we missed special cases.

Framework Definitions and Descriptions and Examples of Each

Table 1 provides our initial framework of 8 problem types, along with working definitions. We approached this task with a perspective of mathematics as being oriented around sets of objects, and operations on those objects[1]. For collections of objects, we also might talk about descriptions of or relationships between them. This orientation means we need to have clarity about the nature of the elements within those sets to consider problems with respect to our categories. We can understand the 8 types in terms of three clusters depending upon the requested response: something related to a solution set, the outcome of a procedure to be applied, or a statement or justification. We also attempt to convey each category as not being domain specific (i.e., they would cover many problems in most undergraduate mathematics courses).

Table 1. Problem type framework and definitions

Cluster	Problem Type	Definition
Solution set	SOLVE	Respond with *the complete solution set of mathematical objects* that satisfies a given set of properties; the complete solution set may come in a particular representation, such as a variable expression or a graph
	EXEMPLIFY	Respond with *an example solution of a mathematical object* – or demonstrate the existence of a solution – that satisfies a given set of properties; or show no such solution exists
	COUNT	Respond with how many; this may be the *cardinality* of the solution set
	APPROXIMATE	Respond with *an approximate solution* that satisfies a given set of properties; an estimate, sketch, or hypothesis of the solution
Operation output	EVALUATE	Respond with the outcome of a procedure or operation; simplify, compute, or determine the outcome of a specific process
Statement or argument	CONJECTURE	Respond with a mathematical statement about – possibly the answer to a question about – given objects, properties, or relationships between them
	JUSTIFY	Respond with a justification or explanation for a mathematical statement about given objects, properties, or relationships between them
	DERIVE	Respond with a mathematical statement about given objects, properties, or relationships between them [CONJECTURE], and provide a justification or explanation for the truth of that statement [JUSTIFY]

SOLVE, EXEMPLIFY, COUNT, APPROXIMATE

With these four, problem responses can be framed as being chosen from a larger set of objects, with the objective being to identify what objects satisfy a given set of properties. These four problem types specify four different objectives with respect to a solution set. SOLVE means

[1] Granted, we can talk about an operation as also being reducible to a set, but we kept both ideas here.

to specify the entire solution set; EXEMPLIFY to specify one element of the solution set; COUNT to specify how many are in a set; and APPROXIMATE to approximate a solution.

In mathematics, one might think of numbers as the default set of objects under consideration. But in combinatorics it is a set of outcomes; in graph theory it is a graph (a collection of vertices and edges); in geometry it is collections of points, lines, and planes on a particular kind of surface or space; and so on. Solutions to problems, then, might consist of very different types of objects. We classify a problem as a SOLVE problem if it requests all solutions be found. Equations and inequalities common to the domain of algebra (e.g., $x + 2 = 2x - 7$), which specify a relation between two expressions, are common ways we find problems about solution sets, but they are not the only way. In graph theory, for instance, we might see, "Find all graphs (up to isomorphism) with vertex-degree sequence $\{2,2,2,2,2,2\}$." The critical point is that, amongst a larger collection of objects, a given set of properties is being specified and the objective of the problem is related to identifying objects that maintain those properties.

Notably, when we talk about a set of objects, or a solution set, the way in which those objects are represented is not especially important. The problem would still be about a solution set regardless of whether we chose to represent a solution as a decimal or fraction; or an expression (possibly with variables) or a visual representation of that solution as a point on a number line or a Cartesian graph. The representational form of the solution is not a key differentiator.

EVALUATE

In contrast to the first four, this problem type is centrally about an operation. Here, the task instructs students to apply some procedure rather than specifying the properties the final response must satisfy (as do problems of the first four types).

Operations is a broad category indeed. Symbolic expressions in algebra (rather than equations and inequalities), followed by an equals sign, are a common way EVALUATE problems are posed (e.g., $5 + 7 =$, or $\int_0^4 x^2 =$), though certainly not the only way. Here, the "=" is indicative of the directive to perform the operation and record its result. Nonetheless, it puts basic arithmetic in the same category as some calculus problems. There are also many other types of operations in mathematics for which we tend to use words (not symbolic expressions). For example, problems that ask to "Simplify" an algebraic expression or "Transform" a geometric figure similarly indicate an operation for the solver to perform on an object. Frequently, there are reasonably clear procedures to accomplish these operations, but the critical point is that the objective of the problem is to produce the intended output of that operation.

CONJECTURE, JUSTIFY, DERIVE

Especially in collegiate mathematics, students are asked to produce mathematical statements or justifications (in this context, this includes explanations, arguments, and proofs). In most any mathematics course, students can be asked to explain or conjecture – though the proportion of such tasks is often low. The last three categories of problems are distinct because the response should be a statement or justification. Responses to CONJECTURE tasks should be statements specifying properties or relationships, to JUSTIFY tasks should be justifications, and to DERIVE tasks should be a combination of both. Opposite of the first four, in these tasks a (smaller) collection of objects is often given, and the request is to identify distinguishing properties.

Justifications are prominent in proof-based courses such as analysis or algebra, but problems inviting statements and justification can abound in every mathematical domain. In graph theory,

for example, one might be asked to "Justify that a tree with n edges must have $n + 1$ vertices." Providing explicit rationale for any claim is essential across all of mathematics.

Discussions, Opportunities, and Questions

As we hope was evident from the examples, these 8 problem types provide distinguishable objectives that a mathematical problem might set for a student, while remaining general enough to be applicable across the various mathematical domains. In what follows, we comment on the opportunities this theoretical perspective might offer the field, as well as raise some preliminary tensions and questions.

This framework helps (objectively) describe and classify the objective of different types of mathematical problems. It gives a defined set of language that we can compare to the very messy collection of imperative verbs used in posing problems. Such theory would help us inquire into questions about the intersection of language and mathematical problems, such as: *What everyday language is used to convey these particular problem objectives? Is the variety and variation of problem posing language a source of confusion for students in general, or on particular problem objectives?* (In an initial use of the framework coding textbook problems, there were dozens of verbs used for EVALUATE problems, and the imperative verb "find" could have signified *any* of the problem types!) Since the framework is not domain-specific, another opportunity provided by the theory is to inquire into the types of problems commonly asked in various domains. That is, *are there differences between mathematical domains in terms of the types of objectives posed in problems?* (e.g., is it true that algebra is really "solving"-heavy, or geometry more skewed toward "justification"?) The critical point is that we find potential value in pursuing this theoretical development because it affords opportunities to answer questions around the nature of problem prompts and language that do not exist quite yet.

Beyond broad questions for the audience in this preliminary theoretical report (e.g., *What challenges or opportunities do you see with the framework?*), here we highlight two tensions, with the purpose of leading into some more specific audience questions. First, consider a simple equation such as $2x + 5 = 8x - 1$. Very apparently, this is a search for a solution set – a SOLVE problem; which $x \in \mathbb{R}$ have this property? However, one might also conceptualize this as a search for (x, y) *pairs* (in $\mathbb{R}^2$) that are shared amongst the linear solutions sets of $y = 2x + 5$ and $y = 8x - 1$, the x-values of these pairs being solutions. Furthermore, there are also standard algebraic procedures to solve – an EVALUATE. If we consider an equation as our "base" object (and not a real number), then we might simply be performing an operation(s) on that object – and the outcome of performing that operation(s) is indeed the solution set. This points to the need to clarify "base object" in problems with this framework; or, alternatively, to preference one coding over another in specific situations. *Does having to specify base object go against the aim of less subjectivity? Or, alternately, is having to specify those objects in talking about the goals of problems a further benefit to communication?* Second, the inclusion of COUNT seems reasonable, given that there are many interesting questions about "how many" across mathematical domains – e.g., how many solutions to a polynomial of degree n? how many distinct triangles with lengths 4, 5, and 6? etc. However, enumeration would also be very closely aligned with the field of combinatorics. *Does this make the category type too domain-specific? Are all counting problems COUNT, or are some EVALUATE – and, if so, what is the distinguishing line? Moreover, if COUNT is a category, should there be a category that captures, for instance, the essence of the field of probability, which is about assigning likelihood to an event set (e.g., solution set) within a broader landscape of outcomes?*

Exploring Students' Reasoning With Function Composition Using Graphical Representations

Yuxi Chen
Teachers College, Columbia University

In this study, we explore how students reasoned on function composition tasks with and without a dynamic graphical representation. Fifteen graduate students individually participated in the task-based and semi-structured interviews to sketch composite functions given their graphs, equations and dynamic graphical representations. One student's responses were analyzed in this paper. Preliminary results suggest that: (1) incorporating multiple reasoning strategies, especially graphical reasoning, and (2) utilizing the dynamic graphical representation, helped build the student's conceptual understanding of function composition.

Keywords: function composition; graphical reasoning; dynamic graphical representations

Starting from secondary school (cf., CCSSM, 2010), students are exposed to, and taught about, function composition via algebraic substitution. Yet, such procedural approaches are limited in their ability to develop sufficiently deep mathematical understandings of function composition, and sometimes even have detrimental effects (e.g., Ayers et al., 1988; Moore & Bowling, 2008; Chen et al., 2023; LaPlace et al., 2024). In this study, we try to explore the ways students reason about the composition of two functions through graphical and other lenses.

Research Question, Background, and Framework

Specifically, we seek to answer the following research question: *How might students reason about function composition with and without the dynamic graphical representation?*

Function Composition in Extant Literature

As the primary operation in function arithmetic, *function composition* $[g \circ f = g(f(x))]$ is a key content topic in algebra through calculus that helps undergraduate students learn about functions effectively (Ratliff & Garofalo, 2006; LaRue & Infante, 2015). Previous research emphasized the importance of functions and function composition in advanced mathematical topics, such as the chain rule which was described by Webster (1978) as "crucial" and "fundamental" in calculus and its applications (e.g., Abramson, 2021; Clark et al., 1997; Gordon, 2005). However, limited studies have focused on function composition. Studies that have explored students' meaning for function composition across algebraic rules, tables, and graphs largely observe an overreliance on algebraic procedures when engaging with function composition (Bowling, 2009; Engelke et al., 2005; Miller et al. 2015), while also recording the limitations of algebraic approaches (Chen et al., 2023; Meel, 2003; LaPlace et al., 2024).

Dreyfus and Eisenberg (1983) pointed out that without a formula, the graphical representation of function has very little meaning for most students entering calculus. In recent years, increasing numbers of studies have argued that multiple representations might contribute to better conceptualization of function and related topics (i.e. composition), and suggested more attention to graphical perspectives including animated graphs (e.g., Ainsworth, 1999; Artigue, 1992; Chen et al., 2023; LaPlace et al., 2024; Parr, 2023; Van & White, 2004). Furthermore, researchers have claimed that the graphical interpretation would be beneficial for students' understanding of function composition (in chain rule and other calculus topics) (Gordon, 2005; LaRue & Infante, 2015), yet studies have not explored in what ways students might reason about

function composition other than algebraic substitution. In conclusion, there is a dearth of literature on function composition, especially through a graphical lens.

Graphical and Algebraic reasoning

Educators in secondary and college mathematics courses typically approach function composition through algebraic equations $(g \circ f)(x) = g\big(f(x)\big)$. However, traditional instruction through the algebraic substitution of equations does not provide much insight about composing functions when students are provided with graphical representations. Graphs tend to make more visible some properties of functions, such as domain, range, symmetry and continuity. For this study, we differentiate reasoning on equation-based characteristics of functions, which is related to algebraic reasoning (Cuoco et al., 1996; Kriegler, 2008), from reasoning based on graphical characteristics of functions, which is likely similar to geometric reasoning (Crowley, 1987; Cuoco et al., 1996). To help exemplify this difference, a function, algebraically, is often characterized by its equation, e.g., $f(x) = 2x + 1$ (i.e., the structure of the set of points included in the relation); whereas, graphically, we depict a function with a graph (typically a geometric curve in the Euclidean plane), e.g., $f(x)$ is a line.

Methods

To explore how students reason about function composition through graphical and other lenses, with and without dynamic graphical representation, this study employed a qualitative multiple case study through face-to-face and one-on-one task-based and semi-structured interviews between the researcher and participants. As a desirable sample of this study to collect rich and informative data, it would be preferable for the participants to have basic understanding of function composition to be able to reason during the interview. Therefore, university graduate students (n=15) chosen from purposive sampling in a mathematics education program were interviewed.

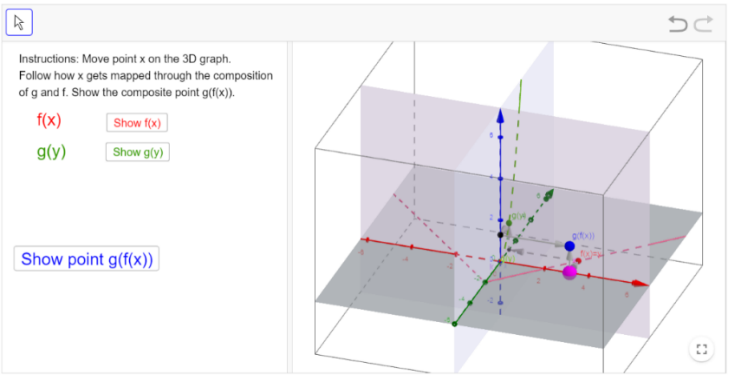

Figure 1. Dynamic Graphical Representation in GeoGebra

The dynamic graphical representation in this study (displayed in Figure 1) is a three-dimensional simulation applet of function composition in GeoGebra. The set up demonstrates a point-by-point analysis of function composition: the user can drag the pink point along the $x-axis$, while the corresponding value of $f(x)$ (absolute value function in red in Figure 1 as an example) will be plotted on the $y-axis$ by an arrow simultaneously; this point is also the input of the function $g(y)$ (where $y = f(x)$). Meanwhile, the value of $g(f(x))$ will be shown on the $z-axis$. Coordinating this point's movement along with the movement of the point on the $x-axis$ (the blue dot in Figure 1) produces the composite function. I aim to explore the affordance of this three-dimensional dynamic graphic representation on students' reasoning, and to study the

possible learning opportunities as well as obstacles when using this representation on solving function composition problems.

The task-based interview contained three rounds. The applet was introduced to participants after the first two rounds, and before the third round where students are asked to use the dynamic representations. Each round of the interview consisted of four function composition problems (due to space constraints, one problem is displayed as an example in Figure 2), and participants were asked to sketch $g(f(x))$ functions given static graphs (Round 1), equations (Round 2) and dynamic graphical representations as well as static graphs (Round 3). There were some shared problems across the rounds in order to make students' responses comparable across the three rounds of interviews. In each round, the researcher asked participants to think aloud while sketching, and students were interviewed at the end of each round with follow-up questions. Interviews were recorded, and video as well as audio data were transcribed. The qualitative data sources included participants' written responses, students' actions when solving the problems, and the transcription of their oral responses.

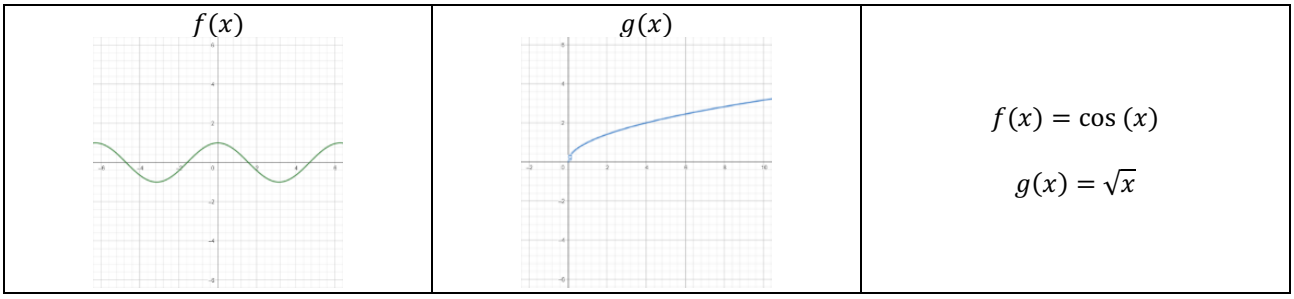

Figure 2. Example: Round 2 Problem 3 (equations only given) and Round 3 Problem 4 (graphs only given)

After initially reading through the interview data, I focused on one participant, Jade (pseudonym), who exemplified rich and interesting strategies of graphical reasoning and other reasoning patterns. The analysis concentrated on identifying the approaches and patterns of reasoning across the problems as well as describing any distinct ways of reasoning graphically in each problem. For the preliminary stage, this study adapted the themes presented in Chen et al., (2023) for the ways students reason function composition. Participant's written and oral responses were coded into categories of: (1) equation related *algebraic reasoning*; (2) graph related *graphical reasoning*; and (3) reasoning through *discrete points*. These were then listed as reasoning steps in chronological order. For example, the participant responded: "I plot some points, 2, 4, 8…and I find it (the graph of $g(f(x))$) grows slower than this one (pointed at the graph $g(x)$), so the graph (pointed at the $g(f(x))$ graph) is like this." This statement above was coded to a step of *discrete points* followed by a step of *graphical reasoning*. In addition, the detailed properties of graphs in the participant's graphical reasoning steps were also identified.

Preliminary Findings

In general, Jade successfully sketched 10 out of 12 composite function graphs. This was an extremely high success rate, especially given results from prior students (e.g., LaPlace et al., 2024). Figure 3 provides an overarching picture of the chronological solving process Jade went through for each problem in each of the three rounds.

Figure 3. Jade's solving process with reasoning steps (algebraic reasoning in yellow, graphical reasoning in blue and discrete points in green)

In most problems (11 out of 12), Jade applied more than one way of reasoning, and half of the problems (6 out of 12) were solved utilizing all three types of reasoning. Figure 3 reveals that, for Jade, different reasoning approaches in one problem were not isolated from each other, instead, the interplay among ways of reasoning drove the solving process forward. In particular, the pattern of alternately using graphical approaches and discrete points is typical (e.g., Round 1 Problem 3). In this pattern, Jade usually repeatedly applied the strategy of: (1) observe certain properties of the general function shape, and then (2) examine her estimation or specify the precise location of the shape by checking specific points on the function graphs.

Jade was an interesting case because graphical reasoning was a leading approach across three rounds (63%, 68 out of in total 108 steps), especially in round 1 and 3 when f and g were given initially as graphs (not equations). It is not surprising that Jade approached problems through algebraic thinking more frequently in round 2 when given equations. Even so, graphical reasoning still appeared in parts of those problems. Jade applied graphical reasoning through the general shape, domain and range, continuity, symmetry, concavity, and periodicity of function graphs. For instance, for domain and range in one problem Jade reasoned: "The first thing I know is because $x \geq 0$ (pointed at g(x)), so we only pick the point above x-axis (pointed at and meant the output of $f(x)$)…" This graphical observation critical for informing for which x the composite function is defined.

Unlike existing literature (e.g., Miller et al., 2015), Jade did not show an overreliance on algebraic procedures. From Figure 3 it can be concluded that her attempts at reasoning algebraically mostly happened at the beginning of the solving process, and then Jade paid more attention to the other two reasoning strategies. This is probably because – particularly with the intentionally unusual and unfamiliar combinations of parent functions in many of the problems – the equation of the composite function is still difficult to use to quickly generate its graph. We do note, however, that Jade incorrectly sketched the composite function to be the line $y = x$ without considering the domain issue, when she algebraically figured $f(x) = \ln(x)$ and $g(x) = e^x$ (Round 2 Problem 1) simply "cancelled out with each other". This mistake coincides with what

the literature raised about the negative impact of relying solely on an algebraic approach (e.g., Chen et al., 2023).

Compared with the rounds without dynamic graphical representations, Jade solved the tasks with fewer reasoning steps in round 3 when she was supported with the dynamic graphical representation (see Figure 3). Moreover, the fewest number of algebraic steps appeared in round 3 as Jade only tried to reason from equations once. The dynamic representation supported her reasoning about function composition without the aid of equations. Jade also developed more sophisticated conceptual understanding of function composition while interacting with the dynamic graphical representations. In Round 2 Problem 1, Jade could not graphically explain why two curves ($f(x) = \ln(x)$ and $g(x) = e^x$) combined to a straight line ($y = x$ on the positive domain). By comparison, with the same problem for Round 3 Problem 1, using the dynamic graphic representation Jade concluded and explained the composition of inverse function will make a line of $y = x$ because: "…when the blue ball moves (point of $g(f(x))$), the pink (point of initial input x) and green ball (point of $g(y)$) moves with the same pace". At the end of Round 3, Jade shared: "…It's like (the dynamic representation is) more direct for me to find (how) the x of $f(x)$ and the y for $g(y)$ make the final composition of the function." From the experience with the dynamic graphical representation, she changed her opinion from previous rounds and concluded that "…for the shape of the final graph, I think we need to consider both two (parent function) graphs."

Discussion and Future Research

This novel study investigated patterns in the way a student reasoned about function composition when given static and dynamic graphical representations. It reported, for the first time, a student's detailed graphical reasoning approaches applied on composing two functions.

The results of Jade's case suggest the benefits of incorporating diverse reasoning approaches. Particularly, one prominent and effective strategy Jade implemented was approaching properties of function graphically, and alternately confirming or refining the sketch of a composite function's graph with discrete points. This finding demonstrates the feasibility and the advantages of understanding function composition beyond algebraic substitution.

Jade's responses also revealed the promising potential of graphical reasoning, as it is fully possible to sketch the composite function graph by reasoning exclusively through graphical lenses without knowing or using the function equations. Jade's reasoning path in Round 3 Problem 4 is one example, where even with her previous experiences with the equations in Round 2 Problem 3, Jade still addressed this problem solely through graphical approaches.

Lastly, yet importantly, the comparison between Jade's reasoning with and without the dynamic graphical representation highlighted the possibility of using this representational form as a viable tool. Almost no algebraic reasoning approach appeared in round 3, which indicates the potential of the dynamic graphical representation to foster graphical reasoning, and to support students in overcoming an overreliance on algebraic equations. More significantly, with the dynamic graphical representation Jade showed a higher-level of understanding on the behavior of function graphs and how the graphs interact with each other when being composed.

I am interested to learn from audience: (1) how can college instructors introduce function composition through a graphical lens? (2) how do you think this approach can benefit or hinder students' learning about advanced calculus related topics, such as the chain rule for derivatives?

Female Minoritized Students' Sense of Belonging in College Algebra and Precalculus Classrooms at a Diverse Minority Serving Institution

Sarah H. Park
University of Georgia

Sense of belonging is an essential factor in supporting student success in undergraduate STEM courses. Female minoritized students, in particular, are less likely to report feeling a sense of belonging due to experiences of isolation, bias, racial and gender microaggressions, and stereotype threat. Although researchers have investigated sense of belonging at the campus or department level at PWIs, HBCUs, and research institutions, less is known about students' mathematics classroom belonging at open-access, racially diverse institutions. In this report, I present the preliminary qualitative results from a mixed methods study regarding the aspects of classroom experiences that foster sense of belonging for Black and Latina female students in college algebra and precalculus classrooms at a Minority Serving Institution. My qualitative findings indicate that sense of belonging is influenced by mathematical microaffirmations, mathematical microaggressions and mathematics self-efficacy.

Keywords: Belonging, Intersectionality, Gender, Race, Minority-Serving Institution

Sense of belonging at the classroom level has been identified as a key factor in supporting student's engagement, persistence, academic confidence, and achievement in college (Wilson et al., 2015). However, minoritized female STEM students are more likely than any other demographic group to feel a lack of sense of belonging to their campus (Johnson, 2012) and to their STEM major (Rainey et al., 2018). Researchers argue that minoritized female students face an additional burden in STEM introductory courses, as they navigate both gendered and racialized experiences due to the "double bind," i.e., their intersecting racial and gender identities (Leyva et al., 2020; Museus et al., 2011). Intersectional work that investigates minoritized women's experiences in STEM exist (Borum & Walker, 2012; Leyva, 2016; McGee & Bentley, 2017), but literature addressing minoritized women's sense of belonging remains underdeveloped especially in diverse introductory mathematics classrooms.

Introductory mathematics courses such as college algebra and precalculus can serve a gatekeeping function, as it is one of the places where students decide whether to stay or leave STEM, especially in open-access institutions (Seymour & Hunter, 2019). There are limited studies on mathematics classroom-belonging that consider race or gender, and even fewer that address the intersection of these dimensions in diverse mathematics classrooms, particularly for female minoritized students. Understanding female minoritized students' sense of belonging, therefore, is a key aspect in better understanding their academic experiences in gateway mathematics classrooms, and by extension, understanding how to better support their persistence and achievement through classroom structures and pedagogies that foster rather than hinder students' sense of belonging (Hurtado & Alvarado, 2015; Museus et al., 2017; Strayhorn, 2018).

Consequently, I examined how minoritized female students with intersecting racial and gender identities experience belonging, in gateway mathematics classrooms in a minority-serving, open-access institution with a racially and socioeconomically diverse student population, a context seldom considered in belonging studies. The following research question guided this study: What aspects and experiences in college algebra and precalculus classrooms

support or hinder Black and Latina female students' sense of belonging at a racially and ethnically diverse open access institution?

Theoretical Perspectives

To explore female minoritized students' sense of belonging and experiences in gateway mathematics classrooms, I framed my study using the two conceptual frameworks: (a) sense of belonging and (b) intersectionality. The importance of *sense of belonging* as a conceptual framework has been well established in the literature (Ostrove & Long, 2007; Strayhorn, 2018). Researchers have connected sense of belonging to student's identity, types of institution, interaction with peers, relationship with faculty, campus climate, engagement, and positive student outcomes (Bollen & Hoyle, 1990; Hurtado et al., 2015; Strayhorn, 2013; Wilson et al., 2015; Zumbrunn et al., 2014). For this study, I used Strayhorn's (2018) definition of sense of belonging: "Students' perceived social support on campus, a feeling or sensation of connectedness, and the experience of mattering or feeling cared about, accepted, respected, valued by, and important to the campus community or others on campus" (p.4).

My second framework, *intersectionality*, is related to one of the core elements of Strayhorn's (2018) theoretical model of belonging: social identities intersect and affect students' sense of belonging, and students experience belonging in different ways. Crenshaw (1989, 1991) is credited with introducing the term "intersectionality," in order to explore how Black women experience double-discrimination on the basis of race and sex. For my study, I used Collins and Bilge's (2020) working definition of intersectionality: "Intersectionality investigates how intersecting power relations influence social relations across diverse societies as well as individual experiences in everyday life. As an analytic tool, intersectionality views categories of race, class, gender – among others – as interrelated and mutually shaping one another" (p. 2).

Background Literature

Research has indicated that sense of belonging is correlated with positive outcomes such as academic achievement, retention, persistence and mental health (Strayhorn, 2018; Gopalan & Brady, 2020). Conversely, a lack of sense of belonging is the primary cause of student opting out from their STEM major, particularly among minoritized and female students, even when achievement is high (Strayhorn, 2018; Good et al., 2012). Frequent validating interactions with supportive faculty, engaging pedagogies, positive interactions with diverse peers, a welcoming campus culture/climate, racial/gender diversity, living on campus, and positive perception of one's cultural identity positively contribute to minoritized students' sense of belonging (Strayhorn, 2008; Hurtado et al., 2015; Gasman & Nguyen, 2016; Hurtado & Carter, 1997; Johnson, 2007; Lee & Davis, 2000; Locks et al., 2008; Museus et al., 2017; Nguyen et al., 2021; Velasquez, 1999). Moreover, when students feel a sense of belonging in their educational environment, they are willing to take risks, challenge themselves, and commit to their major (Booker, 2016).

Although most belonging studies are situated at the campus level, because the classroom is the primary context where student and faculty interactions take place, it serves a critical role in promoting sense of belonging and may even determine which students decide to remain in STEM majors (Riegle-Crumb et al., 2019; Seymour & Hunter, 2019). Studies have linked classroom belonging to self-efficacy, academic motivation, engagement, confidence, achievement, and persistence (Freeman et al., 2007; Kirby & Thomas, 2022; Wilson et al., 2015; Zumbrunn et al., 2014). Moreover, students feel more connected in classes with instructors who are perceived as caring, open, supportive, competent and incorporate active learning pedagogies

that encourage peer collaboration (Wilson et al., 2015; Kirby & Thomas, 2022; Booker, 2007). Despite the importance of sense of belonging, the research remains underexplored for female minoritized students in diverse settings (Booker, 2016; Johnson, 2012; Rainey et al., 2018; Strayhorn, 2018), particularly in the mathematics classroom context.

Recent research point to faculty microaffirmations as a positive factor in students' sense of belonging in STEM (Demetriou et al., 2023; Estrada et al., 2019). Cawley and Wilson (2023) defined *mathematical microaffirmations* as subtle actions or statements that can support students' positive mathematics identity by affirming that they belong in mathematics. Mathematical microaffirmations are more significant when they come from faculty or others who have influence in a learning context and are most powerful when they are specific to the individual student. In contrast, mathematical microaggressions are subtle ways in which instructors convey the message that students don't belong in mathematics which can have profound negative effects (Su, 2015).

Methods

This study was conducted at an open-access, four-year, public college in the Southeast region with an ethnically diverse population of about 12,000 students (12% Asian/American, 32% Black, 27% Latinx, 24% White/ 59% Female and 41% Male). Approximately 40% of the entering freshman class are first-generation students and over 50% are eligible for a Pell-grant. The college has also earned two specific designations under the Minority Serving Institutions Program: Asian American and Pacific Islander Serving Institution and Hispanic Serving Institution. College algebra or precalculus is usually the first math course which STEM first-year students take at the institution.

This report is part of a larger mixed-methods study which integrated both quantitative (pre- and post- sense of belonging surveys) and qualitative methods (mathematics autobiography and semi-structured individual interviews). In the first quantitative phase, 1,135 students completed the presurvey at the beginning, and 639 students completed the post-survey at the end of the Fall 2023 semester in 44 sections of college algebra and 14 sections of precalculus. This paper reports on the second qualitative phase, in which I interviewed 13 students (two Black-Latina students, five Black students, and six Latina students) at the end of the Fall 2023 semester. Of the 13 interview participants, 11 also completed mathematics autobiographies. Each hour long semi-structured interview was audio recorded and transcribed; all students names are pseudonyms.

I analyzed the transcripts and mathematics biographies using Braun and Clarke's (2006, 2021) six-phases of thematic analysis using MAXQDA. I began the coding process using a deductive approach using my two theoretical perspectives, sense of belonging and intersectionality. I then shifted to an inductive state of coding (Esposito & Evans-Winters, 2022) in which I: (a) read through the transcripts, (b) engaged in descriptive coding by assigning one word or short phrase to key moments, and (c) engaged in in vivo coding with the participants' words/phrases. Through this process I constructed themes from combining or rearranging codes. I also kept a research journal to write down reflections, emergent ideas, questions and research progress.

Findings

In examining how Black and Latina female students described their experiences, two major themes emerged as pivotal in affecting their sense of belonging: mathematical microaffirmations/ mathematical microaggressions, and mathematics self-efficacy. Quantitative results indicated

that five students' sense of belonging to their mathematics class increased, four students' belonging stayed relatively the same, and four students belonging' decreased.

Mathematical Microaffirmations and Microaggressions

Three of the four students whose sense of belonging increased, discussed feeling uncertain of their sense of belonging at the beginning of the semester, but felt encouraged by their mathematics professor which helped them believe that they could do the mathematics. Alexa said, "I was just like, I don't know what I'm doing but, she came over and she was like, you're on the right track…you're doing this perfectly…I know what I'm doing and I'm doing this correctly. So, all of this is doable." Marlina also credited her professor for making her believe that she was capable of being successful in her precalculus class:

> He would ask a question and he would look straight at me and be like, Marlina, you're on the right track. And I'd be like, I don't know. And he'd be like, "Okay, well, what are you thinking? And then I'd tell him what I'm thinking. He'd be like, "Yes, that's exactly you are-- you're on the right track. And I always felt encouraged. And then it also made me feel good to go up on the board and do it. I didn't feel like I was bad at math anymore. I felt like if I applied myself, then I could accomplish things… I felt I didn't want to hide and disappear into the back of that wall.

Mathematical microaffirmations also involves listening to acknowledging and validating students' mathematical questions and concerns (Cawley & Wilson, 2024). Tyanna shared how she struggled with mathematics test anxiety and her professor pulled her aside after class to encourage her and give her strategies to deal with it. Tyanna stated, "I felt seen because I didn't know it was a thing. I thought it was just based, like, anxiety about anything because I always have a little bit, but it just felt like, oh, other people experience it, and it's not like I'm being dramatic." Moreover, Tyanna appreciated how her professor was patient and understanding when someone asked a question on a problem even it was "easy."

On the other hand, examples of discouraging mathematical microaggression phrases that students shared which made them feel that they didn't belong in the class were, "Everyone should know this," "This is high school," "This is easy," "You should already know this, so we're just going to skip this step". Participants shared that they felt "stupid," or not as smart as other people in the class, and not wanting to ask any more questions. Anela described how she felt discouraged after experiencing a mathematical microaggression.

> I mean, like, if somebody is telling you over and over in an aggressive tone, this is review, I feel let down because maybe I should know this, but even though everybody in this class is struggling with review topics, it's not something that you should keep calling out we should know this. How about, let's practice this or let's go over this real quick since I see that majority of you are having a problem with it… I felt like maybe I wasn't smart enough because she kept over saying like, oh, you don't get this. Well, maybe you should drop out of the class right now. I take it seriously when it's coming from a professor because I'd rather do the smart thing, you know? So, I did feel a little academically insecure.

Mathematics Self-Efficacy

During the interviews, seven students (three students whose belonging decreased, all four students whose belonging was constant, and one student whose belonging increased) shared that they felt behind, did not feel prepared for their mathematics course, or felt helpless even though they tried their best. For instance, Jess explained that she did not learn key mathematical

concepts in elementary school, which made her feel as if she was getting judged in her college algebra class for struggling. Therefore, Jess did not feel belonging in the class explaining, "everybody would get a question down. I'm still trying to figure out how do you even go about it. It made me feel left behind. I would just slowly move on from the question and going on to the next, so it won't seem like I'm stuck on this question forever during groupwork. If I don't understand it, I'll let someone else take over." Similarly, Faith also shared that everyone else seemed to understand, which made her refrain from engaging in class activities with her classmates. Likewise, Britteny also felt discouraged when she just could not understand a problem: "It wasn't more like anyone made me discouraged. It was like an internal thing. Like wow, how come I don't understand this? You just feel a little bit down, the way he explained it is so easy, but I'm just not getting it, you know?" By the end of the semester, Ana had given up on her college algebra course: "the more that I knew that I couldn't get it, I couldn't do it, it's kind of just discouraging, to where one gives up."

In contrast, all four students whose belonging increased, viewed themselves as capable of doing well in their mathematics class. When asked what made her feel belonging in her precalculus class, Alexa, pointed to "the validation that I can do the work and understand it as much anyone else." Another student, Leslie, described herself as "really good at math," found her professor easy to understand and shared, "I felt like I belonged." For Marlina, at the beginning of the semester it was dreadful going to class, but that slowly changed for her. "I think my sense of belonging increasing definitely made me do better, because if I had continued to feel like, I hate this, I don't want to go to class, and if I continue to have that shadow on myself, I wouldn't have done well in the class. But because I felt like I can do this, like other people are encouraging me, and then I was able to do a lot better in the class, and I enjoyed it, ultimately. I was proud of myself in the end."

Discussion

My study differs from past studies, as Black and Latina female students did not discuss experiencing racial or gender microaggressions explicitly; rather, the participants expressed appreciation of seeing diversity in their classrooms. They did however raise mathematical microaffirmations/microaggressions and mathematics self-efficacy as key to their sense of belonging. Therefore, to increase students' belonging in the classroom, mathematics faculty should consciously include mathematical microaffirmations in their interactions with their students, by noticing and encouraging their efforts, and creating space for students to make mistakes, present their work in small groups, and discuss their thinking out loud with peers during class. They should also avoid unintentionally discouraging students with mathematical microaggressions as it decreases students' sense of belonging.

Although mathematical microaffirmations is critical in increasing students' sense of belonging, it is not sufficient. Students' mathematics self-efficacy is also related to students' sense of belonging, although the directionality between self-efficacy and belonging is less clear. However, preliminary analysis suggests that faculty can influence students' self-efficacy which can support or hinder belonging and vice versa. Participants discussed the following ways in which their professors can help students develop mathematics self-efficacy: (a) frequent informal feedback aside from assessment, (b) approachability and availability of professors outside of class, (c) engaging activities that include peer-collaboration, (d) a classroom environment where questions are encouraged, and (e) opportunities for students to experience small successes in the classroom. These findings provide evidence of the significance of faculty's role in fostering students' belonging through mathematical microaffirmations and mathematics self-efficacy.

Diversity, Equity, and Inclusion (DEI) has become an increasingly important topic in mathematics education and in the professional development (PD) of Mathematics Graduate Teaching Assistants (MGTAs). Currently, little is known about the types of initiatives that are effective in supporting MGTAs' use of equitable and inclusive teaching practices. Based on data from 45 MGTAs enrolled in our DEI-focused PD program, we propose a preliminary framework to elucidate the characteristics of activities that support MGTAs' engagement in DEI issues. We illustrate the utility of the framework by highlighting examples of activities in alignment with the framework, as well as the memorable impact of these activities on the MGTAs who completed coursework in our PD program.

Keywords: DEI, Professional Development, Graduate Teaching Assistants

In recent years, scholars have made numerous calls for improving Diversity, Equity, and Inclusion (DEI) in mathematics education (AMS, 2019; MAA; 2019; Voigt et al., 2023). This involves addressing issues on all levels: societal, structural, departmental, and within the classroom. At the classroom level, enacting teaching practices that advance DEI efforts typically require appropriate training within a supportive system. With respect to Mathematics Graduate Teaching Assistants (MGTAs), the literature is clear that most MGTAs would benefit from more professional development (PD) that enables them to test and adopt new teaching practices (Deshler et al., 2015; Beisiegel, 2019; Speer et al., 2010). The professional development of MGTAs is one of many important areas to focus on in undergraduate mathematics education since MGTAs often lead multiple recitations for large lecture courses or teach lower level mathematical courses as the lead instructor (Selinski & Melbourne, 2015).

Although many institutions publicly state their support of DEI efforts, Cumming et al. (2023) discovered that only 21% of 83 universities that they polled met their DEI goals. This indicates that despite being actively engaged in DEI efforts, there is much to learn about what types of initiatives are effective in supporting DEI efforts, including the adoption of equitable and inclusive teaching practices. While studies on DEI training have increased over the years, the field is still investigating the efficacy of such training (Wang et al., 2024). We investigate one facet of DEI PD, namely design principles of effective DEI PD activities. The goal of this paper is to explicate a preliminary Design Principles Framework for individual activities that promote MGTAs' abilities to enact equitable and inclusive teaching practices, and to argue for the utility of the framework through a) examples of activities that employ the Design Principles Framework, and b) excerpts of MGTAs' experiences with and takeaways from those activities.

Background

At our respective universities, we employ the ELITE PD program which consists of a pre-fall term orientation, a sequence of three courses (each lasting one term, semester or quarter), and

a peer mentoring experience. This professional development program involves developing and advancing MGTAs' teaching practices that foster student engagement and active learning, equity, and inclusivity in the classroom. The authors are the instructors of these PD courses and have observed and reflected on how our MGTAs interacted with the curriculum.

The Design Principles Framework

Based on the literature on PD for teachers, our reflections on teaching, and our analysis of MGTA feedback from surveys and exit tickets, we provide four *Design Principles* when considering whether an activity will be productive in advancing MGTA's abilities to engage in DEI issues. It should be noted that not every activity will 100% adhere to these principles. Instead, we claim that these are useful guidelines that one should keep in mind when preparing an activity for MGTAs. Figure 1 summarizes the Design Principles Framework.

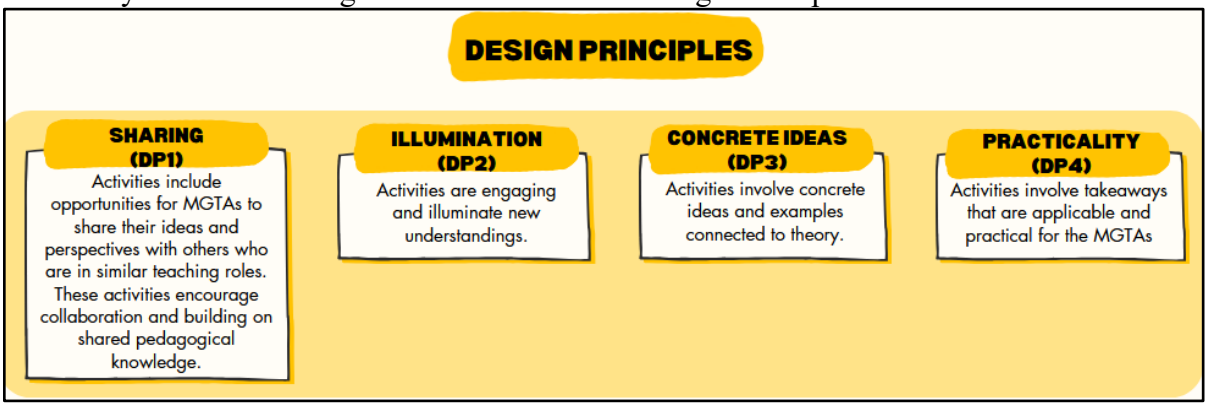

Figure 1. The Design Principles Framework

DP1 Community and Collaboration: Activities should include opportunities for MGTAs to share their ideas and perspectives with others who are in (or have been in) similar teaching roles. These activities should facilitate collaboration and building on shared pedagogical knowledge.

DP1 highlights the importance of the MGTAs as a cohort of educators and learners. Since the MGTAs have a unique composition of backgrounds and experiences, professional development activities should leverage those by providing spaces for MGTAs to share and discuss ideas as fellow educators (Quaisley, 2023; Oehrtman et al., 2009). We have consistently found that the MGTAs appreciate the opportunities to learn not only from us as the instructors, but also from their fellow MGTAs who are in similar positions. Practically speaking, this means that the kinds of discussions questions should be open-ended and in an environment that is safe for MGTAs to share. Additionally, since MGTAs usually have similar teaching assignments, providing the space to discuss their classrooms furthers their sense of community as a cohort of educators.

DP2 Awareness Leading to Enactment and Engagement: Activities should provoke engagement and illuminate new understandings. (How we intend MGTAs will experience and interact with these activities).

DP2 describes how activities should be oriented to productively engage MGTAs in reflecting on issues in DEI. We have observed that MGTAs have stronger recollections of DEI issues when the activities involve self-discovery, illumination of different perspectives, interaction, and/or a form of novelty. In essence, productive PD should not have MGTAs be passive learners, instead activities should have them take an active role (Soto & Marzocchi, 2021; Van Veen et al., 2012). For example, telling MGTAs to "do group work in their classes" and giving them a long list of methods has not been effective in shifting their pedagogy. Instead, we have MGTAs engage with

a few active learning techniques, thoroughly discuss how they can be employed, and create examples of implementation from the courses they teach. Additionally, we also provide hypothetical situations focused on specific equity issues, such as how to support women who are consistently underestimated by their male peers (Grunspan et al., 2016), when engaging in group work activities. These types of activities should support MGTAs in understanding the perspective and experiences of marginalized populations in mathematics.

DP3 Concrete Ideas and Examples Connected to Theory: Activities should not just be about theory, they should involve concrete ideas and examples connected to theory.

DP2 and DP3 are interconnected principles, where DP2 refers to how MGTAs should interact with the activity and DP3 refers to the substance that composes those activities. Specific examples help MGTAs process complex ideas from theory by providing a mental anchor they can associate with these theoretical topics (Darling-Hammond et al., 2017). For example, one activity we use involves MGTAs reading quotations from disabled students about their university experiences. These narratives allow students to learn from actual students about access and design issues that might have been previously imperceptible to them, which allows them to become more aware about the access needs of all students. In essence, effective activities in DEI PD should not be purely lecture and abstract. Instead, providing examples and sample narratives aids MGTAs in understanding the complexities of DEI issues.

DP4 Practicality and Actionable Takeaways: Activities should involve takeaways that are directly applicable and practical for the MGTAs.

While activities should be engaging and involve specific examples, there also needs to be tangible ways to shift their pedagogy. In other words, the activities should meet MGTAs where they are and provide something they can try out or consider in their classrooms (Sims & Fletcher-Wood, 2021). MGTAs need such opportunities to practice new techniques and get appropriate feedback. For example, in one of our classes, we assign MGTAs one active learning technique to learn about (they are given the resources to do so) and then report back on what the activity entails, what situations it is useful for, and a short sample of how they might implement it in their own class. Our MGTAs often reported back to us that they tried the techniques they learned about and mentioned that they were successful in making their classroom more interactive and engaging for the students.

Examples of Implementation

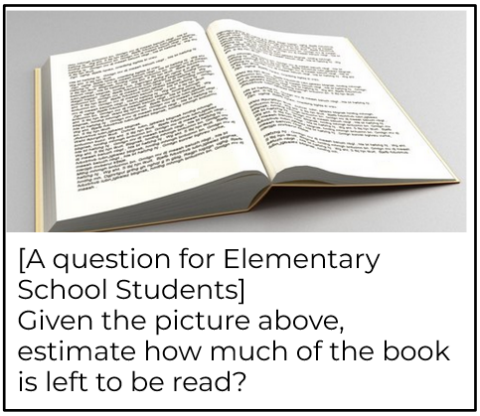
In this section, we provide samples of activities from the PD program that we have observed the MGTAs as finding memorable and impactful. We bolster our claims from data we collected from our 45 MGTAs by means of Exit Tickets from individual classes, End-of-Course Surveys, and Clinical Interviews with the MGTAs throughout the academic school year. To demonstrate the Design Principles in action, we provide two examples of activities that we have employed at our three universities. We provide a summary of the activity, sample discussion questions, and highlight how the Design Principles are employed.

Vignettes

The usage of vignettes, short descriptions of scenarios or teaching clips, has long been utilized in advancing teacher education (Angelides & Gibbs, 2006; Herman, 1998). Throughout the entire ELITE PD program, we employ vignettes to discuss specific topics in equity and issues pertinent to our local institutions. For example, we utilize Yong's (2018) vignette that focuses on an issue prevalent in STEM where women deal with the "chilly" climate by being undervalued and spoken over (Simon et al., 2017, p. 300) (Figure 2).

Rhea said that she found herself the only woman in a group with three men. The students were asked to answer questions on the back of a worksheet, which involved parsing some definitions on the front of the worksheet.

What do you think happened?



The three men chose to forge ahead on the questions without reading the definitions first, referring to them when they needed them. She wanted to read the definitions first and understand them before moving on. They left her behind and she basically worked on the assignment by herself.

How do you think student Rhea felt? How could the TA handle the situation?

Figure 2. Sample Vignette Targeting Equity Issues in STEM

With all the vignettes, our intent is to provide a realistic situation [DP3] that provides insight into a particular area or specific DEI issue [DP2]. Usually we leave open-ended questions such as "what do you think happened?", "how could the TA handle the situation?", and "what could the TA do next time to prevent this issue?" which allows for the MGTAs to share their unique perspective with their peers [DP1] as well as engage in thinking practically about what they would do as the instructor [DP4]. There is a wealth of sample teaching vignettes available online such as the works of Saul (2019) and Yong (2018), but we also advocate for drawing on the MGTAs' experiences in creating scenarios of issues pertinent to the local context.

Problematic Assessments

[A question for Elementary School Students]
Given the picture above, estimate how much of the book is left to be read?

Figure 3. The Book Approximation Problem

In this activity, we have our MGTAs discuss racially biased questions and reflect on what it is trying to assess and who it actually benefits. We start with a problem that we believe our MGTAs would find innocuous (Figure 3). From our experience, the MGTAs would answer in a normative way because of their accustomization in reading left to right, however some elementary school students with international backgrounds answered it incorrectly due to their cultural influence of reading right to left. When told this information, MGTAs start to realize their assumptions (one being the myth that mathematics is purely "objective"). We then move onto other racially biased questions, where we discuss what the question is trying to assess, what it actually assesses, who benefits, and what might an alternative assessment be.

In this activity, the MGTAs go in not knowing the conclusion, which enables them to be surprised by how the book question could be biased and provides an opportunity for them to reflect on their assumptions [DP2]. We have found that the book example as an introduction to problematic assessments has been memorable to our MGTAs in helping them realize different people's backgrounds [DP3]. Additionally, we guide the discussion to give them practical tools

to help them reflect on their usage of assessments. The questions we provide, "What does this question try to assess?" and "Who does this favor?" are easy questions for the MGTAs to ask themselves before deciding on a form of assessment [DP4].

MGTA Reception and Discussion

After implementing the ELITE PD program across several years with 45 MGTAs, we gathered feedback on the program and specific activities through surveys and interviews. Our preliminary data analysis indicates how the Design Principles had positive impacts on the MGTAs in relation to their pedagogy. These excerpts come from the MGTAs responses to questions such as "How has the ELITE PD program helped you thus far?" and "Are there things that really stand out as having a big impact?".

> *The things that had a big impact was I am able to kind of implement within the classroom. For instance, one group talked about series and how they could make that more interactive. So I found that something I could implement within my classroom. In another example, our group talked about the first day of class and how to make an inclusive environment like by asking open-ended questions and validating everyone's opinions that kind of break that math anxiety*. [DP1 & DP4]

> *One thing that really stood out to me was when something was that I hadn't thought about and I'm kind of aware of it. Things like that is like the way the ideas were presented was in a way that halfway through the activity I go "oh, this is important, I should think about that more".* [DP2]

> *We had so many kinds of good examples given, so with each of the lessons, I found that I would find a new aspect of it that I hadn't thought about before. And I think that really is the key of a program like this, it's not about checking things off. But the entire point is to make you think more introspectively, that we learned how to do these things and how to approach them and kind of opening your mind to new forms of pedagogy and examining the ways that we've approached it.* [DP2 & DP3]

Concluding Remarks

Overall, our preliminary data indicates the activities adhering to the Design Principles Framework was effective in making lasting impressions on MGTAs. The majority of the MGTAs stated that the specific examples [DP3] and opportunities to learn from each other were impactful in aiding them to reflect on DEI issues [DP1]. Additionally, the MGTAs valued the ways in which the activities demonstrated how issues of identity and power play out in the classroom [DP2] and that there were clear takeaways they could employ in their classrooms [DP4].

While the feedback from the MGTAs evidence the effectiveness of the Design Principles Framework in a DEI-focused PD, we are cognizant of the need of better assessments to track how MGTAs' teaching shifts in the long-term. However, we see our preliminary Design Principles Framework as contributing to the literature, by taking an initial step of illustrating the potential impact the framework could have on future MGTA PD development.

Questions for the Audience

1) What metrics might capture impactful changes in MGTAs' equitable teaching?
2) What seems important for productively engaging MGTAs in conversations about DEI?

Acknowledgments

Eliciting Students' Informal Ideas About Series: The Partial Sum Sequence Game

Kristen Vroom
Michigan State University

Tenchita Alzaga Elizondo
University of Texas Rio Grande Valley

Series play key roles in calculus and other disciplines, yet research highlights several challenges with the topic, underscoring the need for curricular innovations to support conceptual understanding. In this paper, we introduce the Partial Sum Sequence Game and argue that it, with the guidance of a teacher-researcher, supported a pair of undergraduate students to make important connections between sequences, sequences of partial sums, and series convergence.

Keywords: Calculus, series, sequence of partial sums, guided reinvention

Series play essential roles in calculus, computer science, physics, and other disciplines. However, several reasons are cited in the research literature for why this topic can be challenging for learners. González-Martín (2010) found that their participating instructors (and the textbooks they used) focused on decontextualized, algorithmic procedures rather than promoting conceptual understanding of series. Additionally, learners may need support in distinguishing between sequences and series (Akgun & Duru, 2007; Kung & Speer, 2013) or viewing them both as particular functions with natural numbers as their domains (Martinez-Planell et al., 2012). Some learners describe series as running totals without coordinating them with index values (natural numbers) (Eckman & Roh, 2022; Martinez-Planell et al., 2012). Such a view explains students' difficulties with series convergence (Eckman & Roh, 2022) and solving problems that require viewing series as a sequence of partial sums (Martinez-Planell et al., 2012).

Because series is a challenging topic, there is a need to improve instruction to promote conceptual understanding of series. Toward this goal, scholars have recommended supporting students in obtaining the first few terms of the sequence of partial sums with different representations (Martínez-Planell et al., 2012) and using concrete examples (Morrel, 1992). This paper discusses a task (game) that aligns with these recommendations. We argue that the game, with the guidance of a teacher-researcher, supported a pair of undergraduate students to make important connections between sequences, sequences of partial sums, and series convergence.

Guided Reinvention and the Partial Sum Sequence Game

We drew on Realistic Mathematics Education's heuristic of guided reinvention (Freudenthal, 2005; Gravemeijer, 1999; Gravemeijer & Doorman, 1999) to frame the instruction during our experiment. In particular, we aimed to support "a process by which students formalize their informal understandings and intuitions" (Gravemeijer et al., 2000, p. 237). The "guided" in "guided reinvention" emphasizes that students are not expected to formalize their informal understandings on their own; the students are guided by strategically designed tasks that feature a well-chosen context problem as well as the instructor's moves. Gravemeijer and Doorman (1999) explain that this context problem should "offer opportunities for students to develop informal, highly context-specific solution strategies" that can "function as [...]catalyst for curtailment, formalization or generalization" (p. 117). The context problem does not necessarily have to draw on "everyday-life contexts" but should be meaningful or "experientially real" for students (Gravemeijer, 1999, p. 158). The Partial Sum Sequence Game, is the context problem that we designed to elicit students' informal ideas about series and series convergence (see Figure 1). We intended to design the game to promote informal thinking of series as sequences

of partial sums and series convergence/divergence. In particular, we engineered the game so that students could be supported to determine that a sequence $\{x_n\}$ won if and only if the series $\sum x_n$ converged.

Game:
We are conducting an experiment in which we move an object a certain number of feet north per day. A sequence $\{x_n\}$ will tell us how many feet x_n to move the object north on any given day n. To win the game, accurately predict the object's location if the experiment continues indefinitely!

Playing the game with $\{n^2\}$:

n	1	2	3	4	5	…
n^2	1	4	9	16	25	…
Total distance from starting point	1	5	14	30	55	…

$\{n^2\}$ loses the game since we cannot accurately predict the object's location

Figure 1. Partial Sum Sequence Game.

As mentioned, instructors' task facilitation also provides essential guidance (Kuster et al., 2017; Rasmussen & Marrongelle, 2006; Stephan et al., 2014). A crucial part of the instructor's role is eliciting and building on students' informal ideas. Kuster et al. (2017) explain that teachers "determine which [elicited] ideas (correct or incorrect) are important and relevant to the development of the mathematics, and which ideas can be leveraged to build student thinking that is commensurate with the mathematical goals of the lesson," and importantly, "use these contributions to inform the lesson" (p. 6). Hence, when considering the implementation of the task, we consider not just features of the task that support student thinking but also the instructor's guidance.

Methods

The data for our study comes from a teaching experiment (Steffe & Thompson, 2000) with two first-year undergraduate students - Lara and Stella (pseudonyms), a teacher-researcher - the first author, and an observer/camera operator. Lara was enrolled in Calculus 2 and Stella in Statistics at the time of the study. Both students had passed Calculus 1 the previous semester. There were 11 teaching experiment sessions that were each 1.5 hours. The sessions were recorded in such a way that synched the students' collaborative digital work with a video recording of the students' discussion and gestures.

We focus this report on Sessions 8 and 9 when the students played the Partial Sum Sequence Game with various sequences that they had previously created and explored. In particular, before these sessions, the students generated different sequences and organized them in an Euler diagram with different sequence properties such as increasing, bounded, and convergent (Vroom et al., 2024). As they used this diagram and examples of sequences to make general conjectures about sequences, they also defined sequence and the various sequence properties. Stella and Lara considered a sequence a function with the natural numbers as the domain, defining it as "a list of only natural numbers as inputs, where there is always an output, and the relationship can be defined as some mathematical function." After Sessions 8 and 9, the students wrote a "cheat sheet" for playing the game, which included several conjectures related to different tests for divergence, such as the comparison test and the divergence test (Davis & Vroom, 2024; Vroom & Davis, 2024).

We began our data analysis for this paper by re-watching the video and re-reading the transcripts. As we did so, we noted key moments, which we took to be instances when students articulated an idea that seemed connected to ideas cited in the research literature as important or challenging. For instance, instances when students' discourse suggested seeing series as sequences of partial sums (Martinez-Planell et al., 2012). We then identified how (if at all) we

thought the task and/or the teacher-researcher's moves guided the students to develop these ideas. We present some of these key moments in the following section.

Results

The game with the teacher-researcher's guidance elicited students' informal ideas about series, and in particular, the students' informal ideas about (1) sequences of partial sums, and (2) the convergence or divergence of sequences of partial sums. We discuss these next.

Eliciting Informal Ideas about Sequences of Partial Sums

Playing the game involved Lara and Stella creating various sequences of partial sums, which the students termed total distance sequences. The students (with the teacher-researcher's guidance) (a) identified these as particular types of sequences and (b) represented the mathematical relationship between the daily distance sequence and the total distance sequence in a couple of different ways. A key moment that led the students to identify the total distance sequences as particular types of sequences occurred when the teacher-researcher introduced the students to the game and suggested playing it with $\{n^2\}$. As she asked the students how far the object was from the starting point on various days, she recorded their responses in a table tracking days with the corresponding total distance. After recording a few days of total distances, the teacher-researcher asked if this table could represent a sequence. The students responded yes, and referenced their definition for sequence that they constructed (see Methods for their definition), checking that it could be "modeled by a mathematical function" and the inputs were natural numbers. The table, along with the teacher-researcher's question, supported students in making explicit connections between their work in the context of the game and the concept of sequences. As they continued to play the game, they further emphasized this connection by using various function representations (e.g., tables, graphs) to represent total distance sequences.

The game context also seemed to support the students in representing the mathematical relationship between the daily distance sequence and the total distance sequence in a couple of different ways. A key moment occurred immediately after Lara and Stella decided that the table of total distances for $\{n^2\}$ could represent a sequence. Lara indicated that the mathematical function representing the total distance sequence was $\{n^2\}$. After the teacher-researcher pointed out that on the fifth day, they were 55 feet from the starting point rather than 25 like n^2 would suggest, the pair continued to brainstorm how to represent the relationship. They focused on how each term was the sum of all the previous terms of $\{n^2\}$, as Stella noted: "So we need to add together all the previous days, squared. I don't know how to write that." To further support the students in articulating their idea, the teacher-researcher asked them to write out how they found different total distances on given days. The students then indicated that they added previous terms, such as $1^2 + 2^2 + 3^2 + 4^2$ for the total distance on the fourth day. To further promote connections between the daily distance sequence and the total distance sequence, the teacher-researcher continued the conversation:

> Teacher Researcher: I thought you were doing something a little bit different whenever you were actually calculating. If we were like looking at the eleventh day [it] didn't seem like you were doing $1^2 + 2^2 + 3^2 + 4^2 + 5^2 + 6^2 + 7^2 \ldots$ all the way up to, you know, [11] days. What were you doing?
>
> Lara: Adding the previous total distance?
>
> Stella: Because the previous total distances are all the previous days added together. So, we technically still like are adding all the numbers, it's just shorter.

This led the students to write this strategy as $t_n = t_{n-1} + n^2$. Here, the teacher-researcher gave the students important guidance by (a) supporting them to see that the daily distance sequence representation (i.e., $\{n^2\}$) did not match the values of their total distance sequence and (b) pointing out how their representation did not reflect the strategy they used to find each value of the total distance sequence. After several rounds of the game, the students generalized their idea and noted that the total distance sequence could be represented by $t_n = t_{n-1} + x_n$ where x_n represents terms of the daily distance sequence.

Eliciting Informal Ideas about Sequences of Partial Sums Divergence or Convergence

For Lara and Stella, determining if a sequence won or lost the game was equivalent to determining whether the sequence of partial sums converged. With guidance, the students explained that (a) if a total distance sequence diverged, then the daily distance sequence lost the game, and (b) if a total distance sequence converged, then the daily distance sequence won the game. One key moment that led the students to develop the idea that a sequence loses the game if its total distance sequence diverged occurred as they played the game with $\{n^2\}$. After the students discussed how the total distance sequence was a sequence (see previous section), the teacher-researcher asked if $\{n^2\}$ won the game. Initially, Stella responded, "Yes," but Lara pushed back, saying, "So yeah, wait, no? Well, it's gonna be infinity," and the object was going to be "beyond space." Stella clarified, "So like given a day, yes, we can. I feel like that's what I meant. So, like if they were on day 300 we could figure it out." The students then decided that if the experiment continued indefinitely, then $\{n^2\}$ would lose. Here, we see the students made a key connection: winning or losing the game required them to predict the object's end behavior, not just the location of a given day. The experiment continuing *indefinitely* was an important game feature that supported this idea.

As the students continued to play the game, they articulated that, in general, a sequence loses the game if its corresponding total distance sequence tends to infinity. A key moment that led to this generalization occurred when the students, in response to the teacher-researcher asking the students which sequence they wanted to play the game with next, indicated that they did not want to play with $\{1, 2, 3, 4, 5, 15, 15, 15, 15, \ldots\}$. The students explained:

Stella: Yeah, I don't think we can win this one because you're adding 15 on every time, because it would be going… it would be infinity.

Lara: Yeah, that would be divergent.

Stella: It would be infinity again.

Here, we see the students suggesting that they shouldn't play the game with a sequence that has a total distance sequence that diverges to infinity. The teacher-researcher then continued to support the students in generalizing this idea further, specifically, that a sequence would lose the game if its corresponding total distance sequence diverged in general, not just by tending to (positive or negative) infinity. To do so, she suggested that they play the game with the sequence defined by n^2 if n is odd and $-n^2$ if even. Before calculating the first few terms of the total distance sequence, Stella conjectured that it would lose the game because she expected the total distance sequence to "decrease infinitely." After the teacher-researcher suggested that they calculate the first few terms, Stella noticed that the terms were alternating between positive and negative values and stated, "I take back what I said." She indicated that she still thought the sequence would lose the game because they "would not be able to predict where it's gonna end up" however, it was not because it tended to negative infinity, as Lara elaborated, it was "because it's oscillating, and it's not oscillating by [a smaller amount] … we can't predict it". Here, we see

that by supporting the students to play the game with sequences that would have various types of divergent total distance sequences (e.g., tending to infinity, oscillating), the teacher-researcher reinforced the notion that a sequence loses the game when its total distance sequence diverges.

The students were also guided to see that if a total distance sequence converged, then the daily distance sequence won the game. A key moment that led to this occurred after determining the sequence $\{n^2\}$ lost the game. The teacher-researcher requested that they play the game with $\{½^n\}$. After calculating the first ten terms of the total distance sequence, Stella said, "Dang it, we lost again," presumably noticing that the total distance sequence would not obtain its limiting value of one. The teacher-researcher pushed back, saying "You think so?" and Lara responded, "I don't think so because we're still like converging to one, I guess. So… eventually…" The teacher-researcher connected convergence back to the game, saying, "So if the experiment continues indefinitely, would you be pretty confident to say…" and Stella finished her sentence by saying, "It's just like one." Here, we see that by pushing back, the teacher-researcher supported the students in realizing that a total distance sequence did not need to obtain its limiting value to win the game; it only needed to converge. The part of the game that indicated that the experiment ran *indefinitely* also seemed to support this idea.

The students continued to attend to whether the total distance sequence converged to determine if the daily distance sequence won. For instance, as the students played the game with $\{1/n\}$, the corresponding total distance sequence caused them to pause. The teacher-researcher asked, "What are you trying to notice?" and Stella responded, "If it's going to a certain number," as she tried to determine if it "flattened out." Additionally, when they played the game with the sequence defined by n^2 if n is odd and $-n^2$ if even, the students noticed that they could have a winning sequence that had an oscillating total distance sequence, as Lara explained, "so as long as it narrows into a number." In other words, the oscillating sequence converged. Similar to how playing the game with various losing sequences supported the students in seeing that they generated divergent total distance sequences, playing the game with various winning sequences supported them in seeing that they generated convergent total distance sequences.

Discussion

In this paper, we presented a task that we argue supported, with the teacher-researcher's guidance, a pair of students to make important connections between sequences, sequences of partial sums, and series convergence. We shared how, in the context of the game, the students developed informal ideas related to concepts that have been cited as particularly challenging for students in the research literature. In particular, the students developed informal ideas related to sequences of partial sums and their convergence/divergence.

Further, we highlight how the features of the task and/or moves by the teacher-researcher supported the students in developing these ideas. For instance, to support students in seeing sequences of partial sums as a sequence (a function with the natural numbers as its domain), the teacher-researcher strategically recorded the students' ideas in a function table; Rasmussen and Marrongelle (2006) have conceptualized moves like these as transformational records. We also found that the game experiment ran indefinitely as an important feature to elicit informal ideas about series convergence and divergence. The wording supported the students to connect winning (losing) the game as equivalent to the sequence of partial sum converging (diverging).

The data we presented here are promising first steps towards promoting conceptual understanding of series. In the future, we aim to implement the task in a whole-class setting to continue revising it and suggesting implementation.

Characterization of Student Learning in a Transition-to-Proof Course

Chelsey Van de Merwe
Oklahoma State University

Michael Oehrtman
Oklahoma State University

This research examines the ways students in a transition-to-proof class learn what a mathematical proof is and how to read, construct, and write proofs. We interviewed four university students who had successfully completed a transition-to-proof course about what experiences they thought most influenced their learning about proofs. We then interviewed two instructors of the course about their goals for student learning about the nature of proof and how they devised their instruction to advance those goals. We first describe the activities students engaged in and that the instructors provided for students that supported their apprenticeship into proof-based mathematics. We further analyze how students' characterization of these activities influenced their views of proof.

Keywords: transition-to-proof, cognitive apprenticeship, abstract algebra

The National Council for Teachers of Mathematics includes reasoning and proof as one of five process standards that should be present in curriculum for K-12 students, suggesting that students learn to select and execute a variety of proof structures (NCTM, 2000). Undergraduate students majoring in mathematics or mathematics education must become proficient in both reading and writing proofs in preparation for careers in research and/or education. This proficiency is accompanied by an understanding of what constitutes mathematical proof. This study seeks to add to the growing body of literature on proof by examining the ways students learn what a mathematical proof is and how to read and write proofs. Four university students who had successfully completed a transition-to-proof course and two instructors of the course were interviewed in an effort to answer the following research questions:

1. How do students characterize their learning about what constitutes a mathematical proof in a transition-to-proofs course on abstract algebra?
2. How do instructors characterize student learning about what constitutes a mathematical proof in such a course and adjust instruction to facilitate that learning?

Literature Review

Stylianides proposed a three-part definition of proof that relies on the mathematical community within which a proof is considered (2007). A proof is an argument with the following characteristics: (a) the argument uses statements that are accepted as true by the community; (b) the argument relies on modes of argumentation that are accepted by the community; (c) the argument is represented in a way that is understood and appropriate for the community. We adopt this definition of proof because it attends to varying expectations for the presentation and acceptance of proofs in different communities. It is critical to understand the norms established within the community from which a proof originates, especially for students transitioning from courses that previously focused primarily on computation, modeling, or other forms of mathematical activity. Instructors of the same course at the same university may even have differing goals and beliefs about norms that should be adopted by students, but as suggested by Dawkins & Weber (2017) we anticipate the values that underly those norms are similar.

Universities with mathematics programs often designate a course supporting students' transition into proof-centered mathematics courses. These transition-to-proof (TTP) courses

teach logic rules, proof structures, and set theory (David & Zazkis, 2018). Some TTP courses study specific topics in mathematics (e.g., algebra or analysis) after completing several units about standard proof techniques. A smaller percentage of universities choose to embed all proof instruction within a content area, most frequently analysis.

Theoretical Framework

We consider proof to be a social language, which Bakhtin characterized as "a way of speaking characteristic of a particular group in a particular sociocultural setting (Wertsch, 1991, pp. 95)." One method through which individuals learn a social language is through participation in a *community of practice,* a group of individuals dedicated to refining their practice and training new members (Wenger, 1998). Through interactions with more experienced members, the student engages in a *cognitive apprenticeship of* social expectations, heuristic strategies, and efficiency techniques (Collins & Kapur, 2022).

We adopt Vygotsky's *zone of proximal development* (ZPD) as a theoretical framework for data analysis of sociomathematical development in this study. The standard interpretation of the ZPD is the interplay between what an individual can do on their own and what they can do with the help of a more knowledgeable other (Vygotsky, 1987, pp. 208-209). Vygotsky stresses that all cognitive functions first occur between individuals in a social context (inter-psychological). As an individual becomes more comfortable and knowledgeable about the function, it moves to a psychological context (intra-psychological) (Wertsch, 1991, pp. 88-89).

A complementary framing of the ZPD is based on the interplay of development of spontaneous and scientific concepts (Vygotsky, 1987, pp. 214-222). *Spontaneous concepts* develop through everyday experience, usually without the aid of formal instruction. Ideas within a spontaneous concept are specific and lack conscious awareness, volitional control, and generalization. *Scientific concepts* are those learned through mediated interaction with their meanings, such as instruction. They are more general and systematized but lack the accessibility and applicability of spontaneous concepts. As an individual develops both spontaneous and scientific concepts, the complementary strengths of each support the development of the other.

Methods

Undergraduate and graduate research subjects were recruited for interviews after their successful completion of an Introduction to Abstract Algebra course. This course serves as the transition-to-proof course for the large southwestern university where the study took place. We recruited students who had successfully completed the course within the previous 2-3 years. Four students participated in the research study: Alex, Carly, Dana, and Bennett (pseudonyms). Alex (undergraduate) completed the course 7 months before the interview. She had not taken any other mathematical proof courses. Carly (undergraduate) also completed the course 7 months before the interview. Carly had been enrolled in the same course during a prior semester but withdrew after 10 weeks due to personal reasons. Since her successful completion of the course, Carly had taken introduction to analysis. Dana (graduate) completed the course 7 months before the interview. She took the courses concurrently with introduction to analysis and had successfully completed intermediate analysis at the time of the interview. Bennett (undergraduate) completed the course 19 months before the interview. He had since taken introduction to analysis, two advanced calculus courses, and cryptography.

Each research subject completed one interview lasting 45-60 minutes. Interviews were conducted and recorded via Zoom. Each student interview was divided into 4 parts.

Part 1: Students were asked questions to determine their general understanding of the TTP course's goals as well as specific moments in the course that provoked learning.

Part 2 : Students discussed noteworthy features of two proofs, the first provided by an instructor of the course and the second by the student as an exemplar of their work in the class.

Part 3: Students answered questions about the general nature and purpose of proof, including the context of a proof and the potential evolution of their understanding of proofs over time.

Part 4: The researcher explained the research questions to the student and asked them to describe the process of learning what a proof is and how to read and write proofs.

Instructor interviews contained parallel versions of parts 1, 2, and 4 of the student interviews. Dr. King & Dr. Williams had both recently taught Introduction to Abstract Algebra. Dr. King is an experienced professor who finished teaching the TTP for the first time two months before the interview. Dr. Williams is an assistant professor at the beginning of her career.

All interviews were transcribed for analysis. We reviewed each transcript multiple times, searching for commonalities and differences between student learning experiences. We conducted open and axial coding to identify common themes in the data (Corbin & Strauss, 1990).

Results

Throughout the interviews, students described activities that positively impacted their ability to learn what proof is and how to read and write proofs. The instructors described ways they believed students learn proof and how they facilitated such activities. Each type of activity is described below with examples of how they specifically impacted students' learning of proof.

Conversing with a More Knowledgeable Other.

All four students reported talking to another individual about specific proofs while they were taking the course. In most cases, the more knowledgeable other was the instructor or a student who had been successful in the class before. Alex and Bennett frequently visited their professor's office hours where they had meaningful conversations about homework problems. Bennett claimed that office hours were extremely helpful if an individual prepared for them beforehand. He reported attempting homework problems and going to office hours to discuss specific lines in the proof where he was unable to continue. Bennett's professor tailored his conversations to Bennett's current conception of proof during office hours. The ensuing conversations helped Bennett complete missing pieces of his proof. Carly formed a small study group with another student enrolled in the course. She claimed that simply verbalizing her proof ideas and drafts to her friends often helped push her to more proficient proof production. Carly would put an outline of her proof on a whiteboard and then verbally explain the connections she was going to make throughout the proof. The act of sharing her proof draft with a peer highlighted the importance of making valid mathematical connections in a proof. Carly's social interaction with her peer supported her psychological development of proof writing techniques.

Attending to Written Feedback from the Professor

The students, particularly the three undergraduates, described the utility of feedback from their professor. Most referred to feedback on their homework, which included both a score and comments about the student's work. The inter-psychological experience of obtaining feedback helped support the intra-psychological development of proof concepts. Bennet contrasted the

feedback he received in his first proofs course to feedback in other computation-heavy mathematics courses; he interpreted feedback from non-proof classes as an indication that he was doing something incorrectly. In contrast, he described feedback in his transition-to-proofs class as "the best thing you can be getting." Bennett described the struggle he had adopting the language norms of proof-writing, such as specific sentence structure or vocabulary. He felt that reading instructor feedback taught him many of the linguistic expectations of proof writing.

Carly reported that the instructor of her first transition-to-proofs course provided very little feedback. The second time she took the course, the feedback included edits to her proofs, such as replacing one word with another, which helped Carly understand the language norms of proof writing. If the feedback was unclear, she would speak with the professor to make sure she understood the instructor's intent. Dana claimed that both written and verbal feedback from her professor helped change her mental image of proof.

Dr. King provided extremely detailed feedback to students via Canvas, personalized to each student. He contrasted this with his Calculus courses, where he finds students typically making the same small set of mistakes. The idiosyncratic proof-writing of students in Dr. King's proof course required him to provide feedback that was more detailed repeatedly throughout the semester. His feedback often focused on components missing from student work, such as the presence of a predicate or a variable, and he noted that his students incorporated the feedback to write better proofs by the end of the course.

Consistent Class Attendance

Each of the four students commented about the importance of attending class regularly. Carly took rigorous notes that included the professor's board work and sidenotes referring to the context of classroom discussions. She also reported asking clarifying questions regularly throughout class and claimed that clear instruction and added logical commentary significantly improved her learning experience. Dana learned the value of scratch work alongside a written proof and found it particularly useful when her professor would model such aspects of proof development in class. This instruction helped her shift from memorizing and re-producing a select number of proofs to more engaged problem-solving.

Dr. King claimed that his general approach to instruction in a TTP course was the same as it was in a Calculus course. He discussed familiar concepts, taught them a new concept, and facilitated opportunities for students to experience the new concept productively. In other words, he reminded students of spontaneous concepts, taught a new scientific concept, and then supported the unification of the two. Before engaging in logical mathematical arguments, Dr. King engaged students in considering the logical nature of everyday statements, including using logic to determine the truth value of a statement. He hoped that analyzing non-mathematical statements in a formal, logical way would prepare students to analyze mathematical statements logically.

Exposure to Many Proofs

Each student talked about interacting with many different proofs. This interaction took on a variety of forms including example proofs from instructional materials, proofs found online, and proofs being studied in another course. Alex predominantly worked on her homework independently and in office hours. While working independently she found that reading proofs on the same topic improved her ability to recognize the utility of specific theorems or algorithms. She would search for proofs online that used the theorems she was studying in class. This helped her see how the theorem could be applied in the context of a proof. The perusal of proofs from

online sources also provided her with the opportunity to repeatedly see what a proof looks like and how a proof is structured. She often tried to mimic the structure of proofs found online in her own homework assignments. In preparation for exams, Alex would attempt to prove a statement she had previously proved successfully. She would then compare her proof to one she had previously written, searching for specific missing components in her newly constructed proof. Dana found it challenging when the concepts in her analysis course assumed understanding from the transition-to-proof course she was concurrently enrolled in, but also found it helpful to practice her logic and proof writing skills consistently.

Dr. King felt students needed exposure to many proofs to refine their proof skills. In preparation for exams, he provided extensive study guides with 40-50 problems. His problems were designed to expose students to many types of proof within a wide range of categories, such as contrapositive proofs and proofs by cases. Dr. King said that successful students often worked through these problems and discussed them with him.

Discussion

The activities described above represent ways students are apprenticed into proof-based mathematics. The personalized nature of instructor feedback to students helped students refine their conceptions of proof to more closely align with the norms upheld by the instructor. As instructors made small corrections to student language and mathematical claims, students came to understand the mathematics of proof and the appropriate ways to communicate. Instructors' identification of specific proof components missing in a student proof reinforced the need to attend to a new set of norms of criteria for a valid solution.

Modelling and mentoring played a pivotal role in these students learning of proof. They benefited from instructors modeling not only the structure of a final product but also the problem-solving that accompanies such a product. As students adopted these problem-solving techniques, they grew in their ability to recognize a proof and produce one of their own. Proofs students encountered in other settings, such as proofs found online, also acted as models for what constitutes a proof.

Both students and instructors were aware of the differing needs of students in TTP courses. The needs of students in the TTP course were greater and different in nature than those of students in a computation-heavy courses. Instructors facilitated opportunities for students to converse with more knowledgeable others through office hours, study groups, and written feedback. Instructors were also mindful of the quality and the quantity of proofs students experienced as part of the coursework.

As we continue this vein of research, we will consider data collection methods that investigate social interactions between the student and others, including the instructor and peers. It is perhaps easy to anticipate the positive effects of frequently conversing with the professor of the course. However, it seems that for some students a conversation with a novice may be equally beneficial as a conversation with an expert. When conversing with another novice, the student is perhaps more likely to articulate basic reasoning, which can lead to more concrete formulations of mathematical concepts. Analysis of these critical social interactions will be included in future studies.

Student Validations of Author-free AI-Generated Proofs

Dov Zazkis
Arizona State University

Steven Ruiz
Arizona State University

L. Marizza Stix
Arizona State University

We report on a small-scale clinical interview study of students' validation of AI-generated proofs. During these one-on-one interviews, students were tasked with using ChatGPT to generate proofs and validate those purported proofs. Consequently, neither the interviewer nor the participant knew if the justifications being validated constituted a proof before evaluating it. As such, no two participants validated the same proof. This required the development of novel post-interview analysis methods, which led to some valuable insights into students' proof validation processes. We view the primary contributions of this work to be both the methodology we developed, and our insights gained into how AI-generated proofs provide a different lens for students' validation and error detection.

Keywords: ChatGPT, proof validation, introduction to proof, logic

Proof validation has been a common line of inquiry in proof education research (e.g., Selden & Selden, 2003; Alcock & Weber, 2005; Panse et al., 2018). Typically, participants are presented with some purported proof and asked if it is valid. The justifications utilized within these studies usually fall into one of three categories: 1) researcher-generated justifications that are produced with validation in mind when being constructed (e.g., Selden & Selden, 2003), 2) mathematician-generated justifications that are created for non-validation purposes and then re-purposed by researchers (e.g., Czocher & Weber, 2019), and 3) student-generated proofs that are re-purposed for proof validation work (Moore, 2016). Notably, in some of these studies, the purported authorship of justification misaligns with the actual authorship. For instance, a researcher might generate a justification for participant consideration, but indicate that the justification under consideration has a student author (e.g., Davies et al., 2023).

One notable difference between on-the-spot ChatGPT-generated justifications and the human-generated justification typically found in proof validation studies is the error rate. In many of these studies, the justifications presented by researchers include only relatively few errors. For instance, a twelve-line purported proof presented by a researcher may contain one error, while the number of errors generated by ChatGPT are not dependent on the length of the purported proof and the nature of the errors is not predetermined. It is not uncommon for a short ChatGPT-generated proof to have a dozen errors and for the subsequent proof generated to be error-free. Consequently, when the justifications generated by ChatGPT do not constitute what we would consider a valid proof, there tends to be significantly more opportunities for students to notice a subset of those errors and deem the proof invalid.

In contrast, fewer errors inserted in human-generated justifications create a limited opportunity for students to notice those errors. With these proofs, student validation might hinge on whether a student notices a single error, fabricated by the researcher, that links two lines in a twelve-line proof. In studies that use low error-rate proofs, some researchers have reported that although students do not initially notice an error, when directed to examine a line where an error occurs, students tend to find it without further guidance (e.g., Alcock & Weber, 2005; Selden & Selden, 2003). We argue that expecting students to find a single intentional error in a dozen line purported proof is an unnecessarily high standard. Additionally, noticing such an error is a poor indicator of a student's skill in validating proofs. By using AI-generated proofs, which may

contain significantly more errors, we can better articulate what students view as errors and how adept they are at finding them.

Methods

Six Anonymous State University (ASU) participants participated in one-on-one clinical interviews. Each participant was either currently enrolled in or had completed a transition-to-proof course at the time of the interview. Each interview lasted approximately 60 minutes and was video and audio recorded. Participants were given access to a computer with ChatGPT open to engage with the interview tasks. Students received a printout of the ChatGPT prompt associated with each interview task, but otherwise blank. The handwritten annotations of all participant annotations were scanned to create digital artifacts.

Interview Tasks and Data Collection

Each interview involved the participant using ChatGPT to generate proofs of pre-prepared prompts and subsequently validate them. Each participant received two statements (shown below), one related to number theory and the other to set theory.

1) Show that $7^n - 2^n$ is divisible by 5 for all n.
2) Show that if A and B are subsets of X, then $(A \cap B)^C = A^c \cup B^C$.

Participants were instructed to prompt ChatGPT to generate three proofs to validate—two of statement one and one of statement two. Additionally, we stipulated that the two proofs of statement one use different proof methods. The participants were asked to use their own phrasing for each statement when prompting ChatGPT. Once ChatGPT provided an output, the participant was instructed to study the proof and to think aloud wherever possible. Finally, the participant was invited to speak about their thoughts on the proof's correctness and completeness. They were asked to explicitly cite the features of the proof that led to their decisions. At the end of each interview, the interviewer saved and downloaded the interaction. This downloaded interaction included video recordings of the interview, user inputs entered by the interviewee, and the subsequent outputs generated by ChatGPT. Afterward, these interactions were analyzed.

Data Analysis

ChatGPT generated the purported proofs in this study in direct response to the interviewees' actions. As such, each of the purported proofs generated was unique and dependent on the students' phrasing and its own programming. So, before studying the participants' validation skills, it was necessary to examine each purported proof irrespective of the participant's validation. This timing minimized the influence of the participants' perceptions on those of the expert. This process began with the second author studying each purported proof generated by ChatGPT to glean whether it was valid (from the research team's perspective) and document each error the proof might contain. We documented errors in calculation, grammar, and syntax. Finally, each proof was judged valid (from the research team's perspective) if the logical structure was sound and if it was free of errors that detracted from the strength of the argument. For example, a proof which contained algebraic errors upon which a proof by induction was based was deemed invalid. By contrast, a proof that misattributed a set theory principle to De Morgan's Laws was considered valid because the principle was correct and well-substantiated.

After the research team assessed each purported proof, we examined each participant's engagement with the proofs via the interview recordings. As the participant thought aloud during their assessment of each proof, we specifically noted any instance in which the participant noted a fault in the proof as well as the nature of the error. We also noted the participants' final

decision and justification about each purported proof's validity, correctness, and completeness. After complete annotations of the expert and participant perception of each proof were available, we compared and contrasted them with a particular focus on the errors identified by each and the final decisions on the proof's overall validity. While the expert's search for errors in each proof was meant to be exhaustive, we did not make a similar request to the participants.

Results

In general, students read each ChatGPT-generated proof and noted any errors they found. They commonly terminated their validation process if they found a single significant error or an accumulation of multiple errors that they deemed sufficient to deem the ChatGPT proof invalid. As such, we comment on the proportion of errors found by participants in relation to those found by the research team up until the point the participants stopped reading. The participants identified 25 of the 55 errors – 45% of the errors identified by the research team. This rate is similar to rates reported in validation studies with human-generated proofs (e.g., Alcock & Weber, 2005; Selden & Selden, 2003). As discussed earlier, those human-generated purported proofs typically contain one or zero errors. So, we view that statistic as gesturing toward a parallel between our results and the results of those studies.

Table 1 below compares the research team's validation to the student participants' validation. The instances where the participant and expert disagreed are signified with boxes. In all participant interviews, the expert deemed the first two proofs (of Statement #1) invalid and the third proof (of Statement #2) valid. As can be seen from the table, the participants' final validity assessments were consistent with the research team on 16 of the 18 proofs (89% agreement). Note that on one such disagreement, the participant made their decision based on the weak link between inferences in the proof. The researcher initially noted this lack of detail yet deemed the proof valid. The above agreement rate is notably higher than similar statistics noted in validity studies with human-generated proof tasks (Alcock & Weber, 2005; Selden & Selden, 2003, Panse et al., 2018). Given our small sample size, we cannot make broad statements regarding the statistical significance of this difference. However, we believe this is a result of the higher error rate in the AI-generated proofs. As such, we argue that AI-generated proofs may be more appropriate for studying students' error identification process, whereas human-generated proofs may be more appropriate for studying overall validation.

Table 1. Validation decisions of participants regarding ChatGPT-generated proofs

✓ = Valid Proof	✘ = Invalid Proof	☐ = Disagreement with Expert

	Student #1	Student #2	Student #3	Student #4	Student #5	Student #6
Pf #1a	✘	✘	✘	✘	✘	☑
Pf #1b	✘	✘	✘	✘	✘	✘
Pf #2	✓	✓	☒	✓	✓	✓

In general, participants read proofs looking for any perceived errors and did not appear to be focusing on a particular error type. Their validation processes included highlighting stylistic, logical, and calculation errors. Below is an excerpt from Student #2 investigating an argument based on induction in the first proof of Statement #1. The proof's printout can be found in Figure

1 (OpenAI, 2023). The numbers in square brackets correspond to portions of the proof indicated by Student #2 as he was speaking.

Student #2: It's doing the right process. This [1] is right… It's doing the $m + 1$ case, and then it's going to show that the m^{th} case implies that the $(m + 1)^{\text{th}}$ case is true…
Interviewer: So, where are you?
Student #2: Okay, so I think it lost a term here. I think this completely fell apart. Because we have the 5 + 2 here [2], but then the two term is missing [3]…No, that doesn't make sense because this [4] is a multiple of 7, 7 times 7 times 7 times 2. Those are prime. This [5] is 5 times 2 times 2 times 2 and 2, which are prime, so there's no way that you can make these [5] out of these [2] multiplications. So, I'm going to say that this is an invalid proof.

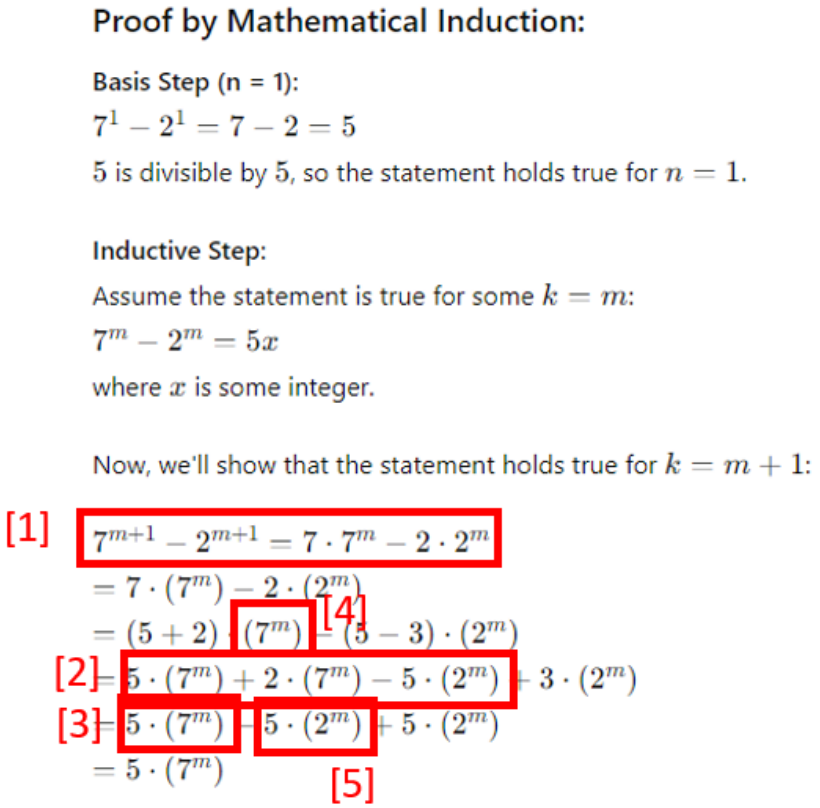

Figure 1. ChatGPT-generated proof #1 from interview with student #2

At the beginning of the transcript, Student #2 attends to the (overall) logical structure of the proof (Selden & Selden, 1995). He affirms that induction is an appropriate proof framework to prove the statement and then proceeds to examine the details of the proof. When he attends to the calculations in the sequence of inferences in the inductive step of the proof, he finds algebraic errors. Since the argument relies on those calculations, Student #2 deems the purported proof invalid. More specifically, since the calculations are what the proof uses to show the "the m^{th} case implies that the $(m + 1)^{\text{th}}$ case," a flaw in that part of the argument causes the purported proof to, "completely fall apart". Notably, the purported proof validly asserts that $7^m - 2^m = 5x$ for some integer x. However, this x, and by extension, the overall induction hypothesis, is not

utilized within the purported proof. This error was noted by the research team but not attended to by the student. Since he stopped reading the purported proof at the end of the transcript, we are unable to comment on whether he would have attended to it if he had been directed to that specific line of the proof (e.g., Selden & Selden, 2003, Alcock & Weber, 2005).

Discussion

We presented students with purported proofs generated on-the-spot by Chat-GPT. This has several consequences: 1) The participants knew that each purported proof was, in a sense, author-free. 2) Neither the participant nor the interviewer knew whether any given purported proof was valid at the time it was generated, and 3) Given the current nature of AI, the purported proofs under consideration tended to have more errors than human-generated proofs used in proof validation studies. The confluence of these consequences creates advantages and disadvantages in studying proof validation.

The method we reported has some notable disadvantages. First, researchers need additional work to assess whether each justification students see is valid before examining students' processes. This contrasts with work that shows the same purported proof to multiple participants across multiple interviews. Additionally, the uniqueness of each AI-generated proof makes comparing work across students more complicated, which is why much of what we discussed here focused on summary statistics rather than cross-interview comparisons.

Despite the potential drawbacks, AI-generated proofs present significant advantages by providing a lens into proof validation that is arguably not colored by authorship, or at least colored in a very different way. It is known that purported authorship of a justification influences validation processes (e.g., Davies et al., 2023; Harel & Sowder, 1998; Weber & Mejía-Ramos, 2011). For instance, a justification purported to be generated by a mathematician is likely to be viewed by participants with less suspicion than a comparable proof purported to be generated by a student. This authorship influences the field's understanding of participants' proof validation processes. For instance, consider what might happen if Student #2 had been given the same proof discussed in the results section but was instead told a mathematician generated it. In that case, it would be reasonable for them not to attend to the proof framework and check for its validity since a mathematician is unlikely to (unintentionally) use an inappropriate proof framework. Instead, we see student #2 determine whether the overall logical structure is appropriate before checking the details. That is, Student #2 examined the proof for various errors that could have occurred, which may be different than the subset of errors they might have looked at with different information about the author of the proof.

Notably, our overall error identification rate is similar to the correct validation rates reported in studies with human-generated purported proofs (Selden & Selden, 2003; Alcock & Weber, 2005; Panse et al., 2018). However, our reported correct validation rate was noticeably higher (ibid). These rates point to the intuitive finding that increasing the number of errors contained within a purported proof increases the likelihood that a student identifies enough of those errors to deem the proof invalid. Additionally, we argue that AI-generated purported proofs have significant potential for studying students' error identification processes, as there are more identifiable errors per line. Such exploration can increase the field's understanding of the relationship between students' overall error identification process and final validity assessments.

Transformational Reasoning in an Introduction to Proofs Course

David Brown
Portland State University

The goal of this preliminary report is to demonstrate students engaging in transformational reasoning in an introduction to proof class. Utilizing transcript data and operationalizing Simon's (1996) definition of transformational reasoning, these preliminary results include descriptions of transformational reasoning in an advanced math context, as well as how students used transformational reasoning in order to accomplish their mathematical goals.

Keywords: transformational reasoning, introduction to proof

Inquiry-oriented instruction (IOI) provides a classroom environment in which students can share and continually refine their thinking. In IOI the classroom mathematical agenda is advanced by building on students' informal ways of reasoning to develop more formal mathematical concepts. One such type of informal way of reasoning that provides a powerful foundation for more advanced reasoning is transformational reasoning (Simon, 1996). Transformational reasoning involves (1) mentally (or physically) enacting operations on objects which result in the objects being transformed and (2) observing the result of the operation, which results in one coming away with a sense of how something works (Simon, 1996).

Scholars have studied transformational reasoning in a variety of math contexts. These include pre-calculus and calculus (Carlson et al., 2002; Johnson, 2012), algebra and geometry (Ellis, 2007; Simon, 1996; Zandieh et al., 2008), and proof and justification (Harel & Sowder, 1998).

Theoretical Perspective

Simon (1996) coined the term transformational reasoning to describe a type of mathematical reasoning that he noticed students were spontaneously engaging in, that resulted in the students coming away with a sense of how something worked. Simon defines transformational reasoning in the following way:

> Transformational reasoning is the mental or physical enactment of an operation or set of operations on an object or set of objects that allows one to envision the transformations that these objects undergo and the set of results of these operations. Central to transformational reasoning is the ability to consider not a static state, but a dynamic process by which a new state or a continuum of states are generated. (1996, p. 201)

This definition includes (a) an object (or objects) that is (are) being transformed, (b) the operation(s) that affect the object (or objects), and (c) results of the operation(s) on the object(s). The process of transformational reasoning involves identifying (a) and (b), which allows one to envision the transformation taking place, and once (c) is attained one can examine them together to draw conclusions about the entire process to understand why it works.

To get a better feel for transformational reasoning, consider the *bisection method*. The idea of the bisection method is to generate (via bisection) a sequence of intervals of decreasing length. One application of the bisection method is to approximate roots of continuous functions with a sign change. In this application, the intervals all share the property that the function outputs have opposite signs at the endpoints, i.e., positive output on the left and negative output on the right or vice versa. The sequences of the right and left endpoints converge to a root of the function.

One might engage in transformational reasoning in this context by focusing one's attention on the intervals as defined above, i.e., the object. The operation is that the intervals decrease in length at each step. The result is increasingly small intervals, the lengths of which converge to zero. The resulting sense for how the bisection method works comes from realizing that the interval length shrinking to zero means that the endpoints will match, and since the function is continuous these endpoints must be a root.

As noted above, it is critical that students consider a dynamic process in order to engage in transformational reasoning. Simon goes on to state that this dynamic process could be imagined or concrete (Simon, 1996, p. 202). Since transformational reasoning results in figuring out how something works, Simon argued that this was different from following a chain of reasoning (i.e., deductive reasoning) or noticing and describing a pattern (i.e., inductive reasoning) (p. 197) but that it may overlap with either deductive or inductive reasoning depending on the circumstances (p. 204).

Transformational reasoning supports the ascertainment of evidence when one is proving. Harel and Sowder (1998) report on a series of proof schemes that explain the ways in which students might engage in proving, one of which is the transformational proof scheme. For the authors a proof scheme "consists of what constitutes ascertaining and persuading for that person" (Harel & Sowder, 1998, p. 244). Thus, a proof scheme contains two parts: (1) how an individual convinces themselves (ascertaining), and (2) how an individual convinces someone else (persuading). Convincing oneself necessitates understanding how something works, and transformational reasoning can support this. Therefore, transformational reasoning supports ascertainment of evidence regardless of the math activity in which one is engaging.

In the present study, students in an introduction to proof class were engaged in the guided reinvention of fundamental real analysis concepts and I explored the students' activity by investigating two research questions: (1) what does transformational reasoning look like in an inquiry-oriented introduction to proof class? and (2) how do the students use transformational reasoning to accomplish their math goals?

Methods

Data for this study come from a large NSF-funded design project ASPIRE in Math (DUE# 1916490). Briefly, the ASPIRE in Math project sought to support students in transitioning to advanced math while also supporting instructors to shift to inquiry-based mathematics teaching. A whole class teaching experiment, in the form of an introduction to proof class, was conducted in Spring 2020 at a public university in the Pacific Northwest of the United States during the beginning of the COVID-19 pandemic. The goal of the teaching experiment was to finalize a curriculum and to begin articulating instructor support materials. The goals of the curriculum included engaging students in the guided reinvention of fundamental concepts in real analysis and developing advanced math practices including defining, conjecturing, and proving. The task sequence for the curriculum involved students proving the Intermediate Value Theorem by repurposing the bisection method for approximating a root of a continuous function (see Larsen et al., 2022).

Each of the 20 class sessions lasted 110 minutes. The research team included a professor of mathematics education, and two doctoral students (one of which is the author of this report). Each class was captured using Zoom recording and screen recording technology. Other data collected included student generated artifacts from various tasks that were recorded on Google Docs, slideshows, and Jamboards. The students (all names are pseudonyms) would record

conjectures, informal definitions, informal proofs, and images created or screenshots in these documents.

Data analyzed for this preliminary report came from transcripts of two different class days, and associated Google Docs. These two days were selected because of the content of the mathematical discussions. The episodes analyzed include students identifying sequences generated by the bisection method, students conjecturing about properties of the sequences, and students justifying that the left endpoint sequence converges.

I conducted a two-phase analysis. In the first phase I sought to ascertain and describe instances of transformational reasoning in terms of the components (i.e., objects, operations, results) and the resulting "sense of knowing how things work". Within student utterances I coded for (1) objects that make up a model (Lesh et al., 2000), (2) operations that transform the objects in the model, (3) observations about the outcomes of the operations, and (4) mentions of structural features (e.g., referring to a sign change, knowing that the midpoint becomes an endpoint of a subsequent interval, etc.) of the model. Structural features were used to identify when students were primarily explaining the process for implementing the bisection method. The second phase involved analyzing how students used this reasoning to address their mathematical goals.

Initial Results

Students used transformational reasoning to identify sequences, conjecture about sequences, and justify that the left endpoint sequence converges.

Identifying Sequences Generated by the Bisection Method

The class session began with a demonstration of how the bisection method can be seen to generate sequences, by showing how the left endpoint sequence is generated, followed by formally defining *sequence*. Then the students were invited to come up with as many sequences as they could (see figure 1).

1. Sequence of left-endpoints, a_n.
2. Sequence of right-endpoints, b_n.
3. Sequence of function values at c_n.
4. Sequence of midpoints, c_n.
5. Sequence of $f(a_n)$ values.
6. Sequence of $f(b_n)$ values.
7. Sequence of step numbers.
8. Sequence of the number of digits at each step in the midpoint.
9. Sequence of $b_n - a_n$
10. Sequence of the distance c_n is from the root (sequence of errors).
11. Sequence of number of matching digits after each iteration.

Figure 1. List of sequences identified by the students in class

Leo offered sequence 8 (see figure 1). Leo's explanation showed signs of transformational reasoning. He stated that "when you do the bisection method, you add, decimals are added at each step, and if you have a calculator that could keep up, then you could count those." Here Leo's object of focus was the midpoint sequence (i.e., the root approximation at each step in the method). I conjecture that the transformation he was envisioning is the computation of the midpoint at each step, and the outcome of this transformation is the addition of new digits in the midpoint at each step. Leo's description implies that he had a feel for how the midpoint sequence

works and that allowed him to identify a sequence that counts the number of digits in the midpoint at each step.

Conjecturing About Properties of the Sequences

Later, students were asked to conjecture any properties about the sequences that they noticed or limits the sequences might have. Maya and her groupmate Kevin worked together to produce a lengthy document with several observations about each sequence. A sample is provided in figure 2.

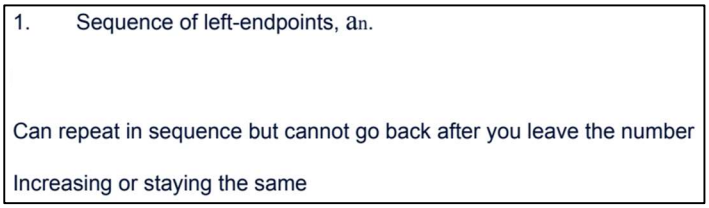

Figure 2. Sample conjectures from Maya and Kevin

Maya and Kevin's description of the sequence behavior indicated that they were engaging in transformational reasoning. Maya and Kevin identified the object they were focusing on in the bisection method as the left endpoint sequence. In the remark "can repeat in sequence but cannot go back after you leave the number", the pair identified an operation that takes place as the left endpoint sequence is generated in one step. I conjecture that the transformation they envisioned is one step in the process, and they observed that the left endpoint sequence either stands still ("repeat") or moves forward, but "cannot go back". Then, as a consequence of this one step, I further conjecture they envisioned generating the entire left endpoint sequence which resulted in an understanding of how the left endpoint sequence works which they encode as either "increasing or staying the same".

Justifying that the left endpoint sequence converges

A few class-days later, the students come to the conclusion that the left endpoint sequence converges, and then they are asked to articulate why this is the case. Maya's explanation builds on her previous transformational reasoning discussed above.

> *Maya*: So, when you're doing this method, each next term of the left endpoint sequence that you're making is either going to be the same as the term you were on because the other one changed, or it's going to go halfway to the other term, right? So um, you're either adding zero to it if it stayed the same, or you're adding the difference between it and b sub the same n.
>
> *Teacher*: And what is the remaining difference?
>
> *Maya*: So, it's $\frac{a_n + b_n}{2}$, or if you're thinking about it in terms of what you're adding to a_n, it's $\frac{b_n - a_n}{2}$, and the limit of that as n goes to infinity becomes zero, so you end up adding smaller and smaller things. So, you know that long run a_n has to stop moving or have a limit.

Maya's use of transformational reasoning results in a justification for why the left endpoint sequence converges. She begins by utilizing the transformational reasoning she arrived at in the

previous section. However, Maya was not imagining the formation of the left endpoint sequence in the same way. Her description was more specific. It went from "can repeat in sequence but cannot go back" (see figure 2) to "it's either going to be the same as the term you were on… or it's going to go halfway to the other term". Then, since she had a feel for how the left endpoint works, she transitioned to focusing on a new object that is within the left endpoint sequence, namely what gets added onto the previous term: 0 or $\frac{b_n - a_n}{2}$. I conjecture that the transformation she envisions is that the terms in the left endpoint sequence are growing because they are accumulating small amounts. The result of which is that the sequence converges because the amounts that are accumulated become smaller and smaller. By understanding how the left endpoint sequence works, she was able to home in on the feature of the sequence that explained her intuition that the sequence converges.

After this activity, students were asked to generalize their justifications into conjectures about general sequences. This was done by identifying the properties that were used to justify their thinking and written in the form "If [property or properties] then x_n converges." Then these conjectures were evaluated for plausibility with examples and counterexamples after which they would work to prove some of the conjectures. For example, the class established that Maya's argument could work but only if it is made more specific by comparing the amount "added on" to the terms of a geometric series.

Concluding Remarks

My results demonstrate two main things: (1) what transformational reasoning looks like in an intro-to-proof context, and (2) how students use transformational reasoning to engage in advanced math activity. In terms of the first research question by identifying objects, operations, and results in student utterances, I was able to describe how students came to know how things worked. This method provides a means for other researchers to unpack transformational reasoning in other math contexts.

Engaging in transformational reasoning supported students to accomplish their math goals. Students identified sequences that are generated by the bisection method and conjectured and justified properties that the sequences have. My results indicate that students might use a two-step approach to engaging in transformational reasoning that allows them to advance their ideas further, as in the case of Maya. Maya and Kevin's two-step process involved first imagining how to go from one term to the next, and then using the results of that reasoning to further reason about the generation of the entire left endpoint sequence. Maya's justification that the left endpoint sequence converged has a similar structure.

Maya's activity demonstrated that transformational reasoning could support the identification of key ideas (Raman, 2003, 2004). Maya began by articulating how the left endpoint sequence worked. Once she knew it had to converge, she used her sense of understanding to ascertain *why*. The key idea for Maya what gets added on to the previous term converges to 0.

The instructional materials used in the teaching experiment here also engage students in algorithmatizing, defining, and proving general conjectures. The next phase of my analysis will be examining these other mathematical activities for instances of students engaging in transformational reasoning. The presentation will include an expanded data set.

The Effect of Mathematics Anxiety Interventions on Mathematics Achievement: A Meta-Analysis

Maryam Aswad
University of New Hampshire

Sheree T. Sharpe
University of New Hampshire

Matthew Mauntel
University of New Hampshire

Mathematics anxiety is detrimental to student achievement in math. This study uses a meta-analysis to investigate the effectiveness of various mathematics anxiety interventions on improving mathematics achievement of college students. We include intervention studies on college math classrooms with quantitative measures of both mathematics anxiety and achievement. Only RCTs and QEDs written in English are included. We use ERIC as a database. 8 studies were included in the extraction involving 800 participants. Studies generally indicated a moderately positive effect of math anxiety interventions on math achievement (p = 0.00124).

Keywords: mathematics anxiety, classroom interventions, meta-analysis

Mathematics anxiety is common, normalized, and has the potential to sharply change the career trajectory of those who have it. Mathematics anxiety is the feeling of tension or fear provoked by math, mathematical problems, or mathematical situations (Ashcraft & Moore, 2009; Jiang et al, 2021). Individuals with math anxiety suffer from physiological tension and discomfort under mathematical situations (Ashcraft & Krause, 2007; Ramirez et al, 2013). As a result, they display avoidant behavior both in the short term and long term, sacrificing accuracy to rush through math tests, and avoiding math-heavy courses, college majors, and even career paths (Alkhateeb, 2002; Ramirez et al, 2013; Ashcraft & Krause, 2007). Neurological research shows that even brief exposure to mathematical symbols triggers a neural response associated with threat avoidance (Weed et al, 2021).

Students often make pivotal career decisions during college, taking different classes or trying different majors before deciding where to take their career. This gives a unique significance to math anxiety for college students. On the one hand, a negative experience in an introductory math course may turn students away from STEM careers or careers involving math. On the other hand, a positive experience with a math anxiety intervention may convince a student to stick with a STEM career choice. The purpose of this meta-analysis is to investigate the degree to which mathematics anxiety interventions improve the mathematics achievement of college students.

Literature Review

Theoretical Perspective: Mathematics Anxiety and Mathematics Achievement

Literature repeatedly demonstrates a negative correlation between math anxiety and math achievement (Ashcraft & Krause, 2007; Ashcraft & Moore, 2009; Samuel & Warner, 2021). There are three main theories on the cause of this relationship (Codding, 2023). *Cognitive interference theory* suggests that high math anxiety induces excessive cognitive load on the student, taking up working memory and therefore lowering their capacity for reasoning through mathematical tasks (Ashcraft & Krause, 2007; Ashcraft & Moore 2009; Ramirez et al, 2013). *Deficit theory* suggests that the relationship is instead caused by a perceived achievement deficit (Carey et al., 2016; Gunderson et al., 2018; Wang et al., 2015). Under this model, the student performs below her own expectations on some mathematical task, and begins perceiving herself as mathematically incompetent. The student then develops negative feelings around

mathematical activities. The final theory suggests that the relationship is *bidirectional*, with math anxiety detracting from a student's math performance, and subpar achievement causing further anxiety for the student.

Present Study

Interventions on Mathematics Anxiety

Given the three theories above on the relationship between math anxiety and math achievement, interventions aiming to mitigate the effect of math anxiety on student achievement in math can either target math anxiety or math achievement (Codding, 2023). Interventions that target anxiety (behavioral interventions) include affirmations, breathing exercises, stretching, music, and any non-content related activity that can help relax the student's nerves. Interventions that target math achievement (knowledge interventions) include instructional strategies, study strategies, and other interventions that help students break down and understand the content more effectively. By observing how these two types of interventions affect math anxiety, we can contribute more evidence to discern the relationship between math anxiety and achievement.

Research Questions

Q1: How do mathematics anxiety classroom interventions affect mathematics achievement in college students?

Q2: Do combined type interventions affect mathematics achievement differently from behavioral interventions?

Methods

Eligibility Criteria

We use the PICOS framework to define eligibility criteria for this study. The *population* for included studies is college or university students. We choose this population because of their closeness to decision-making moments in their careers. For *interventions*, we choose studies with classroom math anxiety interventions. "Classroom interventions" refers to interventions associated with a course, like beginning lectures with affirmations, incorporating writing exercises in homework, or using group work as part of the class structure. These were chosen because they can be flexibly and cleanly applied by instructors. To accept an intervention as a "math anxiety" intervention, we just check that the authors refer to it as such. For *comparison*, we require a control group that did not receive the intervention by the time the post-intervention measure is taken. For *outcomes*, we check if the study includes quantitative measures for both math achievement and math anxiety. For *study design*, we check that studies are intervention studies with Randomized Control Trials or Quasi-Experimental Design to maintain a baseline for quality. We did not limit the publication date or location of the study, but we did require that studies be written in English.

Database search

We searched ERIC for studies of interventions on math anxiety in college or university math classrooms. We limited the number of screened studies to only the first 150 studies (out of a total 283 found) in the ERIC search results. These included published studies as well as dissertations. With additional time, we would have searched ProQuest for more gray literature to further minimize publication bias. The following search string yielded the results:

(university OR college) AND (mathematics OR math) AND anxiety AND (intervention OR program OR strategy$ OR treatment$) AND ((classroom$ OR school$ OR education$) OR (pedagogy$ OR teaching$)) AND (achievement$ OR performance$ OR test score$ OR outcome$)

The studies were moved to Zotero, where an initial PDF search was conducted. Next, they were moved to Rayyan (https://www.rayyan.ai/) to begin screening.

Screening

The screening was done in two stages. First, 150 studies were taken through title and abstract screening. At this stage, the first author checked the language, population, intervention, and outcomes. 103 studies were excluded, and 47 studies passed to full text screening. For this stage, the first author checked the study design and inclusion of a control group in addition to the rest of the criteria. Only 8 studies passed this screening into extraction (denoted with a * in the citations).

Extraction

We extracted descriptive information on studies (title, authors, and publication year), effect size information (means, group size, and standard deviations on the quantitative achievement measure for each treatment and control group). We also coded the type of treatment (behavioral, math knowledge, or combined), and who delivered the intervention (researcher, teacher, computer, or other) for use in the moderator analysis. A nested structure was used for effect sizes. For example, suppose a study included two treatment groups and a control group, and then measured the effect with three exams. Then the two treatment groups would be coded as "group 1" and "group 2," and each would have an effect size for "outcome 1," "outcome 2," and "outcome 3," and all of these would fall under a single "study ID".

Analysis and Results

Effect Size Analysis

The interventions in these studies vary in type, delivery, date, and location, so there are factors other than sampling error affecting extracted effect sizes. We use a random effects model to account for that in the meta-analysis. We use Cohen's d analysis with the Hedges' g correction to analyze pooled effect sizes. A multivariate model is used for the entire analysis since some studies include multiple treatment groups or multiple achievement measures, causing dependencies between the effect sizes.

We use the metafor package in R with the robust standard error correction from clubSandwich to compute the result. This produced a pooled effect size of 0.373 with a standard error of 0.076 ($p = 0.00124$, $df = 12$). The extracted studies therefore show a significant, moderate effect of the interventions on student math achievement. The heterogeneity test shows significant heterogeneity in the sample, affirming the choice of the random effects model.

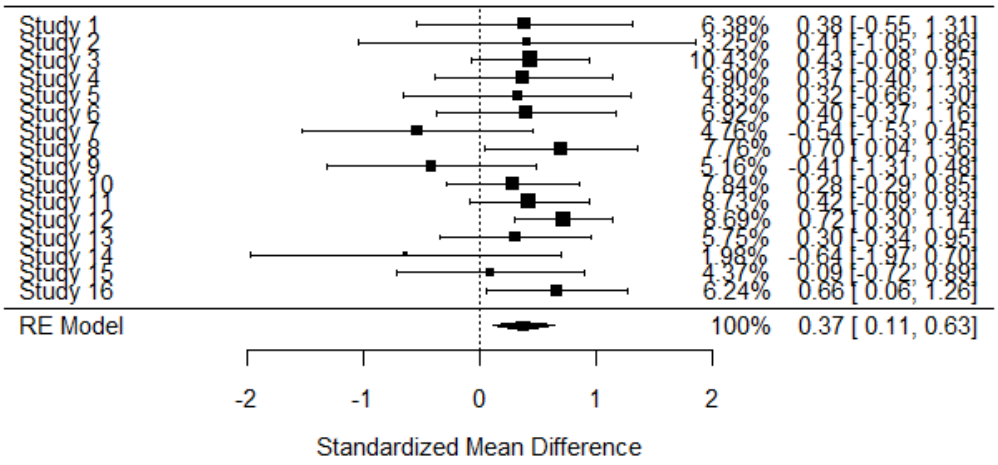

Figure 1. Forest plot of the means in the meta-analysis.

Moderator Analysis

The moderator analysis is performed through a meta-regression. There was not enough data to analyze effectiveness on mathematics anxiety or who delivers the intervention as moderators, but treatment type was analyzed. The test of moderators showed that treatment type was indeed a moderator in this study ($p < 0.05$). In particular, while "behavioral only" and "combined type" interventions both had moderate positive results on student achievement, the effect was only found to be statistically significant for the combined type. There were not enough "math knowledge only" interventions for that effect to be analyzed. This is likely due to the eligibility criterion requiring the interventions to be math anxiety interventions.

Table 2. Descriptive results of meta-regression.

Treatment Type	Effect Size	SE	Z-Val	P-Val
Behavioral only	0.3483	0.2083	1.6718	0.0946
Combined	0.3814	0.1765	2.1603	0.0307
Regression coefficients	$\boldsymbol{\sigma}_1$	$\boldsymbol{\sigma}_2$		
	< 0.0001	0.0863		

Descriptive Results

The studies analyzed were published between 1982 and 2020, with a total of 800 participants. These studies were generally set in a university course, with an intervention applied throughout a semester. Post-intervention results are taken after the end of the course. All studies found a significant effect of the intervention on mathematics anxiety. Of the 16 effect sizes, 10 were based on a combined treatment type and 6 were based on a behavioral-only intervention. Studies generally found math anxiety interventions to have a positive effect on math achievement.

Answers to Research Questions

Q1:How do mathematics anxiety classroom interventions affect mathematics achievement in college students?

A: Mathematics anxiety classroom interventions have a moderately positive effect on mathematics achievement for college math students.

Q2: Do combined type interventions affect mathematics achievement differently from behavioral interventions?

A: Treatment type does moderate the effect of math anxiety interventions on math achievement. In particular, combined math-knowledge + behavioral interventions have a more significant positive effect on mathematics achievement than behavioral-only interventions.

Discussion and Implications

The results of the meta-analysis demonstrate that classroom math anxiety interventions have a moderately positive effect on math achievement, with the result for combined behavioral + math knowledge interventions being more significant than behavioral-only interventions. Therefore, we can recommend that college math instructors implement combined-type interventions to break the hold math anxiety has over their students. This paper suggests that even students taking their one required math course in college can improve their math performance and be relieved from their math anxiety through a classroom intervention. Students impacted by math anxiety can be better prepared to choose and succeed in STEM majors and math-heavy career paths (Ashcraft & Krause, 2007; Ramirez et al, 2013).

There are some important limitations for this study. First, the screening and extraction was done by one person only, so mistakes are inevitable. The three stages of screening help mitigate this problem, and the first author reviewed decisions for each stage of screening and the extraction. However, two more papers had to be excluded during extraction due to full-text screening errors. It is possible there are more mistakes that were not caught. Second, with so few studies, most of which come from published journals, there is a plausible potential for publication bias. Publication bias is the phenomenon where studies are more likely to get published if they find statistically significant results, especially small studies or studies with lower power (Palmer et al, 2008). This can bias the results of a meta-analysis to produce a higher effect size.

The final major limitation is the number of studies included. The goal of the moderator analysis was to provide additional data to inform the theories on the relationship between math anxiety and math achievement. While a more statistically significant effect was observed for combined treatment than behavioral-only treatments, the effect sizes themselves were close (0.34 vs 0.38). It is possible that behavioral-only interventions simply have a wider confidence interval (larger standard deviation) and would show significance with a larger sample. A significant effect of behavioral-only interventions on math achievement would corroborate interference theory, as targeting math anxiety without math knowledge improves expressed knowledge (Ashcraft & Krause, 2007; Ashcraft & Moore 2009; Ramirez et al, 2013). Moreover, no math knowledge-only studies were included, and this was because of the eligibility criterion requiring math anxiety interventions. Expanding the pool of studies may resolve this, but it may be more effective to instead search interventions more generally, and code the treatment type on all of them (with the same behavioral, math knowledge, and combined types as codes).

Overall, while the results of this study are promising, a study amending the above limitations would be well-positioned to give better recommendations on types of interventions a college instructor might try with her students as well as a deeper understanding of the relationship between math anxiety and math achievement.

Criteria for proof are important because future teachers will need to evaluate students' arguments as proofs or nonproofs. This preliminary report examines how a group of prospective and practicing teachers in a reasoning and proof course began to collectively construct criteria for proof. Given a set of hypothetical student arguments, their initial criteria differed, despite common mathematics coursework, including an introduction to proof course. Ongoing analysis uses documenting collective activity to understand how collective criteria and definition were constructed.

Keywords: proof definition, prospective teachers, practicing teachers, proof criteria, argumentation

Proofs are an essential component in doing, communicating, and recording mathematics (Schoenfeld, 1994). Hersh (1993) contrasted proofs from a mathematical point of view and in a classroom setting. Within the creation and development of mathematics, proofs are social constructs for convincing others such that "without complete, correct proof, there is no mathematics" (p. 396). From a humanistic view, a proof is an explanation. Considering the role of proof in a classroom setting, Stylianides and Stylianides (2009) described proof as "general, valid, and accessible to the members of the community" (p. 239). Notably, Stylianides (2007) viewed proofs as mathematical arguments with certain properties: 1) proofs contain statements which are familiar to all students in a classroom, 2) the reasoning behind the steps of the proof should be valid for and known to all students in the class; and 3) the representation of the proof should be accepted by the classroom community.

The National Council of Teachers of Mathematics (NCTM, 2000) asserted that reasoning and proof "should be a consistent part of students' mathematical experience in prekindergarten through grade 12" (p. 56). Along with the consideration of proof within a classroom setting, the Common Core State Standards for Mathematics (CCSSM, 2010) further emphasized that students need to build a logical progression of statements to explore the truth of their conjectures by justifying their conclusions, communicating and responding to the arguments of others, and recognizing and using counter examples. Notably, students are expected to develop a proof conception that involves "a person's ability to prove and analyze proofs and their beliefs about proof and justification" (Conner, 2007, p.11). Thus, teachers are asked to embed proof as a core practice in their daily mathematical instruction (NCTM, 2000).

However, previous research has shown that secondary school students, collegiate students, and pre-service teachers mostly focus on empirical arguments while constructing proofs (e.g., Knuth, 2002a, 2002b; Reyhani et al., 2012; Sears, 2019). Despite their beliefs about the limitations of empirical examples (e.g., Stylianou et al., 2015), students have difficulties in distinguishing proofs from non-proofs. They have a tendency towards considering generic arguments and pictorial representations as non-proofs (e.g., Lesseig et al., 2019), and they consider the role of proof as mostly a verification of the truth of a mathematical statement (e.g.,

Lesseig et al., 2019; Likando & Ngoepe, 2014; Varghese, 2009). Though research has shown that some practicing teachers considered proof as socially constructed (Knuth, 2002a), some prospective teachers did not consider proof as a product of collective engagement (e.g., Sears, 2019; Varghese, 2009). On the other hand, research has shown that given education, students' and prospective teachers' conception and comprehension of proofs can be developed (e.g., Belin & Karagöz Akar, 2020; Miller, 2020). These results align with Stylianides et al. (2017):

> "There is a great need for interventions to introduce students of different ages to an appropriate set of criteria for judging whether an argument meets the standard of proof…Unless the field of mathematics education designs effective ways to instill in students expandable as well as developmentally and mathematically appropriate views of what proof means, it is unrealistic to expect that students will make sustained progress in their learning of proof during their mathematical education" (p. 257-258).

Taking this as a challenge and building on the previous studies, in this study, we further investigated how prospective and practicing mathematics teachers come to collectively develop criteria for proof, by which we mean criteria to determine whether an argument can be considered a proof. Acknowledging that defining proof and identifying proofs and non-proofs are important components of knowledge for teaching proof (Steele & Rogers; 2012) and considering that teachers are key figures in the education of future generations (NCTM, 2000), we specifically investigated the following research question: *How do practicing and prospective teachers come to collectively construct and use a community definition of proof?*

In this paper, we show how teachers and prospective teachers who had a significant amount of mathematics coursework prior to the course, often disagreed as to whether an argument was a proof or not. We include an excerpt of our data that depict how at times their written and verbal work seemed to disagree. These data exemplify why it is important for a class to have explicit collective criteria for proof as they continue to evaluate arguments. We are interested in how different individual warrants and criteria for proof evolved into a collective understanding or definition. At the beginning of the course, we observed that when presented with the same student work, teachers can have very different understandings of what constitutes proof; ultimately in the course, they constructed a collective definition. We are in the process of analyzing how the teachers moved from the initial activity shared here to the collective criteria.

Methods

We collected data from a reasoning and proof class that the third author taught in the fall semester of 2024. The class was comprised of 12 students who were prospective or practicing secondary mathematics teachers. The participants had previously completed an introduction-to-proofs course as well as several other mathematics courses. The class met weekly alternating between 165 minute in-person classes and asynchronous classes. The asynchronous classes were weeks 1, 3, 5 and 6, and the in-person classes were weeks 2, 4, and 7. We only collected data from the three in-person classes. The data consisted of videos of three groups of four participants each (except for week 2, in which one group had three), videos of whole class discussions, pictures of participants' written work, and pictures of whole class board work. Because we are focused in this paper on the first part of our research question regarding the construction of a collective definition of proof, we only describe the activities and tasks that preceded the agreed upon class criteria for proof.

In the first class, the participants completed three tasks. For the first task, we gave them 16 solutions to the question "How many 3 x 3 squares are there in an n x n square?" and asked them to discuss in their groups whether they were convinced by each solution and what modifications

they would make to the solution. For the second task, we gave the students 23 arguments for "Prove that when you add any 2 odd numbers, your answer is always even" and asked them to sort the arguments according to their underlying ideas. For each of their sorted groups, we asked them to determine if the underlying idea had merit for proving the statement and to select the best argument in the group. The participants had written their own solutions to these two problems in preparation for class, so they were familiar with the problems. The third task we gave included 10 arguments for the statement "the sum of two odd numbers is even" and asked students to decide if the argument is a proof and write a rationale for their decision. An example of the conversation around one of these arguments is presented below.

At the end of the first class, the participants were asked to write down, as a group, criteria for determining if a given argument is a proof. These criteria were shared with the whole class and compiled by the instructor into a list of 14 criteria. The participants were then asked to refine the class list to include fewer criteria, which they were unable to finish due to time constraints. We began the second in-person class (week 4) by asking them to revisit the class list and to consolidate the list into a set of three criteria. As a result of small group and whole class discussion, the participants agreed on the following criteria for proof: 1) makes logical connections using mathematical and community-appropriate evidence, 2) accounts for all cases, and 3) comes to the conclusion of the initial conjecture.

Our analysis examined the participants' arguments as they discussed each presented argument. We used Rasmussen and Stephen's (2008) Documenting Collective Activity (see also Cole et al., 2012; Rasmussen et al., 2015) to examine how the class collectively constructed their understanding of criteria for proof. In this method, the data, claims, and warrants are identified and recorded; three criteria are then used to examine when ideas begin to function as if shared in the classroom community. To ascertain when an idea or way of reasoning is functioning as if shared in a community, we used three criteria: 1) when the warrant was initially present for a claim but is no longer necessary; 2) when a part of an argument serves a different function in a later argument (i.e., a claim originally needed justification but is later used as data or warrant for another claim); 3) when an idea is used as data or warrant for different claims in multiple arguments (Rasmussen & Stephen, 2008; Cole et al., 2012). Our research team members individually examined participant small group discourse, making tentative codes for data, claim, and warrant. We then came together and constructed argumentation logs of each small group and whole class discussion, discussing and reconciling differences. Note that our analysis was conducted from the perspective of a participant, so we assigned ideas the function that we believed most closely aligned with the participant's intent. Thus, warrants sometimes preceded claims, and statements were not assigned a function based on how we would construct an argument but by what the participants seemed to intend with their utterances. At times, the participants included qualifiers and rebuttals in their arguments, which we captured in our argumentation log. We also included participants' written arguments in our argumentation log. These were usually easier to identify because we specifically asked for claims and reasoning.

Results

Participants were given 10 arguments purporting to prove that the sum of two odd numbers is even, each from a hypothetical student. The following excerpt is from one small group's discussion of Student E's argument (see Figure 1), which was the fifth argument in the list.

Student E

Any odd number can be written as 2x + 1. So let's add two odd numbers.

2x + 1 + 2x + 1 = 4x + 2
4x + 2 is even since 4 and 2 are both even.
Or 2(2x + 1) shows that 4x + 2 is even.

Figure 1. Student E's work shared with participants for their evaluation of whether the argument is a proof or not.

1 *Lindsey:* Nooo! (shaking her head and mouthing in response to reading Student E's response)
2 *Chloe:* I feel like it is almost there.
3 *Debbie:* It is almost there.
4 *Lindsey:* Yeah, but it is adding two of the same number.
5 *Chloe:* Mm-hmm (affirmative).
6 *Lindsey:* They also don't tell you what *x* is.
7 *Chloe:* I feel like if they use *x* and *y* (inaudible).
8 *Lindsey:* Yeah, yeah.
9 *Chloe:* If you used two different variables. And they don't really say why 4*x* + 2 is even.
10 Well, I guess they say because four and two are even. Having that four times *x* is
11 like they don't really say what that represents.

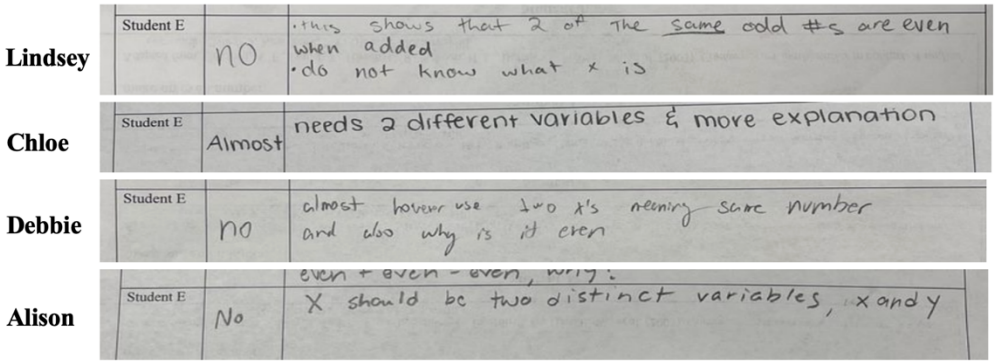

Figure 2. Participants' written responses to Student E's work.

We inferred that Chloe and Lindsey had two different claims. Notably, Chloe claimed that Student E's work was "almost there" (line 2), and Debbie supported her claim (line 3); Lindsey was very assertive, saying "noooo" (line 1), to claim that Student E's work was not a proof. In lines 4 and 6, Lindsey provides warrants for her claim that this was not a proof; the other members of the group seem to agree and accept this as a warrant for their claim that it is almost a proof. That is, each one of them seemed to be interpreting the same warrant as a warrant for their personal claim (potentially without realizing that the other person was using the warrant in their own way). Analysis of the participants' written work (Figure 2) further suggested that they did not come to consensus on whether Student E's work was a proof or not. Interestingly, although Debbie agreed with Chloe during their discussion, in her written response, she made the claim that Student E's work was not a proof. She made a definite claim, but she also explained in her warrant "almost however use two x's meaning same number" (see Figure 2).

Discussion and Conclusion

Our preliminary conclusions about the participants' initial criteria include that participants came into the course with their own somewhat idiosyncratic criteria for whether a student argument was a proof. At times, it seemed that participants translated their own criteria for proof into an assessment of a student argument by suggesting that they could tell what the student "meant" by something that was not necessarily correct. They also wondered if the grade level of a student impacted whether an argument could be considered a proof, suggesting that even if the argument would not be a proof for themselves, it could be for a student. This is consistent with the perspectives of other prospective teachers who have examined student arguments (Suominen et al., 2018).

In our analysis, we have begun to see groups of participants use previous claims as they assessed additional students' arguments. Although we have not completed our analysis of how ideas began to function as if shared, we have preliminary evidence of such ideas even within small group discussions. We believe it is important to document that the participants began their discussions with differing conceptions and criteria for proof. Otherwise, coming to consensus and shared criteria would not be necessary. In our presentation, we will include additional evidence of initial difference as well as ideas that began to function as if shared, culminating in our whole class discussion of criteria for proof. We will engage attendees in examining initial criteria for proof from our data and ask attendees to discuss the following questions:

- What criteria for proof would you expect undergraduate students to use at the beginning of a course?
- How are criteria from advanced mathematics classes translated to expectations for students' proofs?
- Have you attended to students' initial and developing criteria for proof?
- On the surface, students can seem to have a consensus, but in our case, students had different claims (even with a similar warrant). How do you engage with these kinds of situations in your own practice?

In this study, we are investigating how prospective and practicing teachers come to collectively construct and use a community definition of and criteria for proof to evaluate different student arguments. We shared some data from the beginning of the study to show that the participants did not necessarily begin with a shared set of criteria for proof. In fact, our analysis of the data showed that using the same explanations (warrants), the participants made different claims about the same argument. We suggest that this lack of consensus provides a rationale for investigating how a collective definition and set of criteria can be constructed. The Committee on the Undergraduate Program in Mathematics (CUPM, 2015), appointed by the Mathematical Association of America, emphasized that mathematics undergraduates, including prospective teachers, "should learn to read, understand, analyze, and produce proofs at increasing depth as they progress through a major" (p. 11). This further provides motivation for mathematics teacher educators to consider how a learning environment may influence practicing teachers' and prospective teachers' conceptualizations of proof for different audiences. This is especially important because teachers have difficulties in distinguishing proofs from non-proofs (e.g., Lesseig et al., 2019), and some do not consider proofs as a product of collective engagement (e.g., Sears, 2019; Varghese, 2009).

Where is the Calculus in Calculus-Based Introductory Mechanics: A Textbook Analysis

David Robles
CSU Fullerton

Maxwell Ichinose
CSU Fullerton

Michael Loverude
CSU Fullerton

This paper describes a study of where and when calculus concepts and skills appear in the first semester of introductory physics. Following similar work in differential equations, engineering, and chemistry, we have adopted the Calculus Concept Framework and used the framework to identify which concepts and skills appear in each section of the first twelve chapters of a standard introductory physics textbook. Each section of each chapter was coded independently by three researchers and results were collated and discussed.

Keywords: physics, calculus in disciplines, textbooks

Calculus is a prerequisite for many courses in introductory physics. The sequence of courses taken by physical science and engineering students is frequently referred to as 'calculus-based' and has two or three semesters of calculus as pre- and co-requisites. (There is a parallel sequence of courses that do not require or use calculus, sometimes described as 'algebra-based' or 'trig-based.' These courses are generally taken by life science majors and pre-health professional students.) However, the nature of the relationship between calculus and introductory physics is undergoing renewed examination by scholars in both fields.

Introduction and Previous Research

There has been a significant body of work examining the use of mathematics in physics courses, for both introductory and more advanced levels. Redish and Kuo note that mathematicians and physicists use mathematics differently: while physicists load physical meaning onto symbols and equations, mathematicians tend not to (Redish and Kuo 2015). Thompson's quantitative reasoning framework describes the representation of measurable quantities with units (Thompson 2011). However, Biza and colleagues suggested that calculus in the disciplines could be a *filter* or *scaffold*: in the former case, calculus is used to determine who is qualified for later coursework; in the latter, it is useful as supporting knowledge to enhance success in later coursework (Biza et al., 2022).

Several prior studies have investigated student understanding of concepts and skills from calculus in introductory mechanics. (Here we focus on work in first-semester introductory mechanics, noting that there is a substantial body of relevant work in later courses.) For example, researchers have described a relationship between a limited understanding of definite integrals and difficulties in physics, in contexts including kinematics graphs (Beichner 1994, McDermott et al., 1987, Bajracharya et al., 2023). RUME scholars have reported that the conceptual understanding of integration that students need in physics is often not an outcome of standard calculus instruction (Orton 1983, Ferrini-Mundy & Graham 1994). Jones and colleagues have shown that most students leave calculus with a conceptualization of integrals as area under the curve (Jones 2015). However, more than half of the integrals in US physics textbooks used an adding-up-pieces conceptualization, and under 10% used area (Piña and Loverude 2019).

Several authors have reported that students perceive differences between practices in physics and calculus. Hitier and Gonzalez-Martin (2023) reported that "in mechanics, ready-to-use formulas are provided, so students can solve these problems without using knowledge from derivatives nor thinking in terms of covariation." Noah-Sella, et al. (2023) described a number of

differences in the ways that students perceive related problems in physics and calculus, including the perception that physics problems require 'more thought' than calculus.

In the related field of engineering, faculty assessed the value of calculus "for mathematical maturity more than just the actual calculus" content, because "the way [the engineering course] is taught, you can do it without calculus." (Ferguson 2012, Faulkner, et al. 2019). Tague et al. (2013) collected data from engineering faculty on mathematical expectations and reported areas of priority and perceptions of students' competence. Areas of priority included evaluating solutions, using units and dimensions, knowing how to create and interpret graphs, performing algebraic manipulations, conveying engineering relationships mathematically, and using symbols instead of numbers. Faulkner et al. (2019) noted that faculty teaching engineering courses having mathematics courses as prerequisite or corequisite agree that their students have difficulties with: using and interpreting mathematical models; choosing and manipulating symbolic and graphical expressions; and, using computational tools. Participants identified students' struggles to "set up integrals and derivatives to describe physical situations" and described students' perception of calculus as just equations, preventing them from "capturing the underlying physical principles".

Scholars in several disciplines have posed the question of where exactly calculus is used and what calculus concepts and skills are used in courses for which calculus is pre-requisite. Many prior studies have adopted the Calculus Concept Framework [CCF] (Sofronas 2011), which was developed as the result of several interviews with experts. The CCF identifies a list of concepts and skills that are essential to calculus understanding and that are generally taught in a calculus course sequence (the concepts and skills are the first two sections shown in Figure 1, respectively). Czocher used the CCF to investigate what concepts and skills from calculus were used in a course in differential equations (Czocher et al., 2013). The work was replicated in additional contexts, including introductory engineering (Faulkner et al., 2020), and general chemistry (McAfee and Rodriguez, 2024). No similar analysis exists in introductory physics, which this study seeks to remedy.

Research question and methodology

For the sake of this study, we sought to investigate the research question: What concepts and skills from calculus are encountered by students in introductory calculus-based physics, and when are they encountered? For this initial effort, we made two choices to limit the scope of the project, allow for preliminary discussion of results, and establish a baseline for future research.

First, we chose to limit ourselves to the topics covered in the first semester of introductory physics, which is generally limited to classical mechanics. Most students take a sequence of introductory physics courses that are two- or three-semesters or a three- to five-quarters. Mechanics is generally the first course in the sequence, with electricity and magnetism, optics, and modern physics coming in subsequent courses. Some of these topics (notably electricity and magnetism) have different mathematical demands than the first-semester course and results for those will vary. In subsequent work we will extend this analysis to later topics.

Secondly, we chose to use the presence or absence of concepts and skills in the textbook assigned for the course as a measure. We recognize that focusing on the textbook is only a proxy for what students might realistically encounter in the course, as instructors might increase or decrease the emphasis on mathematical formalism in lecture or homework exercises. Future work will seek to characterize instructor practice as well and document what calculus concepts and skills students actually encounter in class and in homework.

We chose a standard physics textbook (Resnick et al., 2014). We chose to code chapters 2 through 12, which are the chapters generally covered in the first semester course. We omitted chapter 1, as it is purely a discussion of units and includes no calculus. We stopped after rotational motion and equilibrium. We excluded fluids or thermal physics, which are not covered in the first-semester course at our university but are sometimes included at others. The edition chosen was a matter of convenience; a later edition of the text is currently in use, but the older edition was more readily available. A quick comparison of selected chapters suggest that the newer edition would lead to nearly identical results.

We created a spreadsheet with the concepts and skills from the CCF and cells for each section of the chosen chapters for the first semester course. For early meetings, we chose a single chapter to code and the following week to compare results. When any of the three coders disagreed, we discussed the coding and how each coder was interpreting the prompt. While many codes were uncontroversial, some needed further discussion. Based on this discussion, we negotiated and clarified coding practices. For example, we had to decide whether the codes should reflect the use of concepts and skills in homework exercises at the end of a section, or just the narrative and sidebars. We chose to code based on both homework exercises and section text, noting that this might lead to over-estimating the experience of students. While a limitation, this also suggested avenues for further research that we are beginning to pursue.

We also observed that aspects of mathematical practice that were adjacent to calculus were present. As a result we added several extra categories that were not present in the CCF. While these are not calculus concepts and skills, they were clearly elements of the practice in using mathematics in the context of the physics textbook. These included the presence of graphs or figures, the use of function notation, the use of the vector concept and unit vector notation, and the explicit attention to units or dimensions. These should be considered supplemental to the main focus of calculus topics, but also fruitful topics of further study.

After a few weekly meetings focused on a single chapter, the researchers moved on to multiple chapters within a single week, and reconvening to assess how in agreement we were. As we came into alignment of definitions there was an increase in agreement with the topics covered in each chapter. By the end of the first-semester analysis, the agreement between coders very high. For example, of 243 cells in the Chapter 11 spreadsheet, all three coders independently coded the same result on 236 (97% agreement). Remaining disagreements generally included the presence of a concept or skill ‘hiding’ in a homework exercise.

Results

We describe the results in tabular form below. In the table, the numbers in each cell refer to the number of sections in which the concept or skill appears. Since chapters have different numbers of sections, the shading indicates frequency relative to the number of sections in a chapter, with solid green indicating a high fraction of incidence and solid red indicating none.

Below the table we make some observations and claims that summarize the results of our coding. Broadly speaking, in the calculus concepts and skills there are more red entries than green. The three most-frequently coded items from the CCF are arguably not even calculus: algebraic manipulations; facility with definitions and notation; and trigonometric manipulations.

Figure 1. The prevalence of calculus concepts and skills in the introductory physics textbook. The color indicates fractional prevalence, ranging from solid red (no occurrence) to solid green (present in all sections).

There is considerable variation in the frequency of calculus skills and concepts. The most prevalent calculus concept in our sample was the derivative. Derivatives appeared in 8 of the 11 chapters that we coded, and in 20 of the 62 sections (just over 30%). Integrals appeared in 5 of the 11 chapters, and 11 of 62 sections (just under 20%). In contrast, there was not a single epsilon-delta proof. Limits appeared in only four chapters (and 9 sections) and sequences and series in two sections of a single chapter. (The latter does become important in later courses, see Loverude 2024.) While the concepts of derivative and integral were somewhat prevalent, the skills of computing derivatives and techniques of integration were less frequently encountered. Even in calculus-based physics, derivatives and integrals are less-frequently encountered than algebra and trigonometry. Algebraic manipulations was coded for in every chapter, and 61 of 62 sections. Trigonometry was coded for in every chapter but one (chapter 2, one-dimensional kinematics) and appeared in 27 different sections.

The sequence of topics in introductory mechanics is mismatched to the sequence in calculus prerequisites, in terms of the use of calculus skills and concepts. Depending on prerequisite structures, students may be enrolled in first-semester calculus at the same time they are taking introductory mechanics. However, the most calculus-intensive sections of the text come very

early. In the text, students encounter integrals in Chapter 2, which would come in the first or second week of the course. Integrals are covered later in the calculus sequence. Dot and cross products appear in first-semester physics not until Calculus III.

The calculus concepts and skills in use vary considerably across the semester. Not all chapters present the same level of calculus usage. Chapter two (one-dimensional kinematics) was one of the highest in terms of CCF concepts and skills coded, and chapter 4 had the highest prevalence of derivatives, though fewer limits and no integrals. The chapters on Newton's laws (5 and 6), in contrast, did not include a single limit, derivative, or integral. After chapter 2, students do not see another integral until chapter 7.

There are mathematical skills and concepts in physics that are not part of the CCF. While some of the skills and concepts identified in the CCF appeared rarely (or never appeared) in our analysis, we found that the mathematical practices were not fully captured by the CCF. As a result, we expanded our analysis to include additional categories that were relevant to the course but not included in the CCF: function notation, reasoning involving units, and unit vector notation, as well as the presence of graphs and diagrams. Notably, units and vectors were considerably more prevalent than core CCF concepts of limits, derivatives, or integrals. Units appear in nearly every section. Vectors are common as well, including dot and cross products.

Function notation is used early in the text, and then largely disappears. As the table shows, function notation is used in beginning sections, but the use of this notation diminishes, even though functions are present throughout the course. In later sections, function notation disappears entirely, even though expressions are complicated and identifying independent and dependent variables is not trivial. There is some reason to believe that different usage of function notation is a tension point for students in physics (Taylor and Loverude 2022).

Discussion

The results show that many sections of the introductory physics textbook do not use calculus skills or concepts, and the presence of calculus is not uniform. This raises some questions about the role of calculus prerequisites for this course, and whether those serve as scaffold or as filter. If calculus is to serve as scaffold, rather than simply a filter, instructors and textbook authors might wish to consider the mismatch between calculus and physics practices and the sequences of topics. We intend to compare our results with an analysis of texts that do not explicitly require calculus to see the extent to which these differ.

We note that the frequency of these concepts and skills in the textbooks might not reflect the experiences of students. Calculus concepts and skills appeared in derivations of equations or in certain examples and homework problems. Depending on instructor preferences, student experiences might vary greatly. Some students might see calculus in derivations but never need to evaluate a derivative or integral if relevant problems are not assigned. We have begun to probe the extent to which these data match the experiences of instructors and students at our university.

By focusing on the first semester, we have not included the significant presence of calculus (including multivariable and vector-valued functions) in the electricity and magnetism portion of the course. This will be another focus of future analysis.

Metacognitive Processes of Undergraduate Students During Mathematical Proof Construction

Sarah Sparks
University of Northern Colorado

This phenomenological case study explores the metacognitive knowledge of undergraduate students that they accessed while constructing mathematical proofs, and the related actions they take in their proof process with that knowledge. Two pairs of undergraduate mathematics majors completed two proof-construction task-based video-recorded interviews and engaged in follow-up qualitative interviews asking them to watch clips of their work and reflect on their thinking. This preliminary report discusses the qualitative data analysis process that has explored the control actions taken related to metacognitive knowledge of one pair of students during the first proof task.

Keywords: Metacognition, Problem Solving, Proof

In mathematics, conjecturing and proving new theorems is how humanity's mathematical knowledge is expanded and communicated (Ernest et al., 2016; Hamami, 2022). Undergraduate mathematics proof-based courses aim to imbue the necessary mathematical knowledge, writing and reasoning skills for students to read, construct, and analyze proofs. Development of these skills is not confined to individual courses but is an overarching goal of undergraduate mathematics programs (Committee on the Undergraduate Programs in Mathematics [CUPM], 2015). Students' proof skills impact and are impacted by both communication with others and their own reasoning about mathematics (e.g., Hanna & Barbeau, 2008). Previous studies note a relationship between one's metacognitive skills and success in problem-solving tasks (e.g., Mamona-Downs, 2002; Schoenfeld, 1994; Zhao et al., 2019). This study seeks to expand the body of mathematics education research by considering metacognitive processes of undergraduate mathematics students during the proof construction process.

I consider *metacognition* as "any knowledge or cognitive activity that takes as its object, or monitors, or regulates any aspect of cognitive activity; that is, knowledge about, and thinking about, one's own thinking" (Lerman, 2020, p. 608). The meta-level (where metacognitive knowledge resides) and object-level (anything external to the meta-level) interact through monitoring and control. *Monitoring* occurs when the information taken in influences the meta-level whereas *control* occurs when metacognitive knowledge impacts external cognitions and actions (Nelson & Narens, 1994).

I define *proof construction* to be the process of using a series of logical assertions deduced from a set of premises and previous assertions, and/or a set of instructions that when followed are representative of these deductions, where this collection of assertions and instructions results in an argument that "justifies a claim to oneself and others" (Blanton et al., 2003, p. 113). *Proof* is then defined to be this collection of assertions. Research has explored cognition related to the proof construction process (e.g., Hanna, 2020; Inglis & Alcock, 2012; Moore, 1994; Weber, 2001). What remains is how individuals examine their own thoughts and skills related to proof, and how their judgements impact their decisions during the proof construction.

Literature on metacognitive processes in mathematics education has predominantly focused on problem solving. It is established that metacognitive skills play an important role in students' development as problem solvers (e.g., Downs, 2002; Schoenfeld, 1992, Zhao et al., 2019).

Students employ metacognitive skills during all stages of the problem-solving process including the orienting, planning, executing, and checking phases (Carlson & Bloom, 2005).

Views differ among researchers on how problem solving and proving are related (Mamona-Downs & Downs, 2011). Some mathematics education researchers consider proving to be a subset of problem solving and use problem-solving frameworks to study proof construction (e.g., Savic, 2015; Selden & Selden, 2013; Wulan et al., 2021). However, research also suggests that some components of the proof construction process are not inherently addressed in problem solving. It remains unclear if and in what ways metacognition in problem solving compares to that in proof construction. Specifically, mathematical proofs constitute their own genre (Selden & Selden, 2013) and the language, deductive reasoning, and formatting can differ from other problem-solving tasks. These set proving apart as a specific case of problem solving, suggesting that proving requires a separate line of metacognitive research (Raman, 2003; Savic, 2015).

To gain insight into students' metacognition, I seek to identify students' metacognitive knowledge and processes during proof construction. More precisely, with this phenomenological case study, I aim to address the following research questions: What declarative, procedural, and conditional metacognitive knowledge do students demonstrate or claim to have and use during construction of a mathematical proof? And what monitoring and control processes do undergraduate mathematics students engage in during construction of a mathematical proof?

Theoretical Perspective and Methodology

I approach this research with a social constructivism theoretical perspective, concerned with individuals' constructed conceptions while also viewing their experiences and dialogue with self and others as integral to their learning process. This concern for social and cultural contexts distinguishes social constructivism from other forms of constructivism (Patton, 2002). I specifically considered intramental and intermental thinking, (i.e., the internal and external respectively) (Ernest, 2010). I claim that metacognition is a key component of intramental thinking as it centers on an individual's interactions with their own cognition.

Vygotskian social constructivism asserts the appropriation and use of signs (language) and tools (strategies) (e.g., Ernest, 2010; Vygotsky, 1987). The process of appropriating sign and tool use allows restructuring of conceptions and impacts others' knowledge through the use of tools and signs (Grossman, 1999). I claim that the process of restructuring one's own conceptions requires metacognitive monitoring, and access to metacognitive knowledge regarding what one already knows, so that alterations can be made. Additionally, the metacognitive process of control informing the individual's use of signs (language) and tools (strategies) in practice, mediate the collective appropriation of such knowledge towards agreed upon social practices.

A phenomenological study examines the "meaning, structure, and essence of the lived experience" (Patton, 2002, p. 104), in this case the phenomenon being studied is individuals' cognitive and metacognitive processes during the construction of mathematical proofs. I conducted a qualitative phenomenological case study to examine two pairs of undergraduate students' metacognitive processes as they construct proofs, through in the moment verbalization of their thinking and later reflections on their proof construction experience. The four undergraduate student participants were from proof-based undergraduate courses at a mid-size university in the United States. Prior to interviews, students were paired based on similar mathematical backgrounds and experience working on mathematics collaboratively together.

Data Collection and Analysis

As individuals' conceptions "are formed through their interactions with each other as well as by their individual processes" (Ernest, 2010), this study had pairs of participants engage in collaborative proof-construction tasks using think-aloud protocols. Each pair was given version A or version B of a task and asked to prove or disprove the claim. Version A provided a true claim, and version B provided a falsified version of the true claim. Students were audio and video recorded and remotely monitored via Zoom©, and Livescribe© pens were used to record written data. Once participants completed the task, I returned to the participants to ask follow-up questions based on my observations during the task. I then determined portions of video where metacognitive processes may have occurred by utilizing the Model of Sign Appropriation and Use (Ernest, 2010, p. 44) for possible social location and ownership of utterances. Participants were invited to an individual follow-up interview a couple days after the paired interview to watch these selected video clips, reflect on their thinking during that part of the task and answer reflection questions about their experiences.

The preliminary results presented in this paper are the analysis of Lola and Harper's experience with version B of the first task. Figure 1 is an abridged version of the task, adapted from Gilbert and Larson (2012). Note that due to a typo, I had to step in to make a minor correction to the claim that only one of k or l had to be greater than 1.

> **Task 1 version B prompt.** A gamekeeper gives player A a positive integer. The players then take turns changing the integer they are given to a smaller integer, and then pass that smaller integer back to their opponent, player B. If the integer you received and are changing is even, the two legal moves are:
>
> ○ Subtracting 1 from the integer, *or* Dividing the integer by 2
>
> If the integer you received and are changing is odd, the two legal moves are:
>
> ○ Subtracting 1 from the integer *or* Subtracting 1 from the integer, then dividing this result by 2
>
> The game ends when the integer reaches 0, and the player who makes the last move (changing an integer to zero) wins the game.
>
> *Prove or Disprove the Claim:* Assume the starting integer is given to player A. Any starting integer that when factored is written as $2^k \cdot l$, where k and l are both odd integers greater than 1, will guarantee that player A wins the game.

Figure 1. Task 1 version B

Both the task and follow-up interviews were transcribed. Data analysis and use of each code is shown in Figure 2. I first used deductive methods, keeping in mind the Model of Sign Appropriation and Use (Ernest, 2010, p. 44), to determine whether each transcript excerpt described internal thought processes (coded as Intramental), or other external happenings (coded as External). The intramental data was analyzed to determine if the subject of each excerpt was their own thinking (coded as metacognitive) or was about the object-level (coded as cognitive).

From the metacognitive data, I then sought to determine actions taken due to metacognitive reasoning, as this would be indicative of a control process. To do this, I separated the metacognitive excerpts into two categories, one for excerpts that were followed by an action (coded as having a relevant action), and one for any metacognitive knowledge stated apart from any action taken (coded as stand-alone).

From the relevant action data, inductive coding was used to categorize each indicated action. Each piece of data was individually coded by a description of the action taken, and then codes that were similar were combined. Because these actions were taken following the indication of metacognitive knowledge, they were coded as control actions.

Apart from relevant actions, I also used deductive coding on all data coded as metacognitive to determine if the metacognitive knowledge indicated was declarative, procedural, or conditional. At this point all data was placed into case files for each participant based on whose metacognitive knowledge was indicated in the transcript, whoever initiated the discussion of their reasoning.

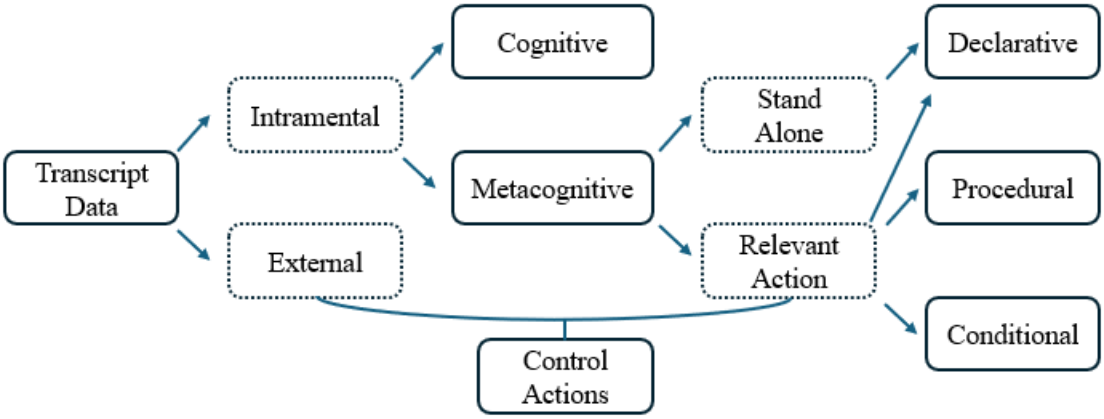

Figure 2. A Flow Chart of the Data Analysis Process

As an example of the data analysis, consider this quote from Lola, "I don't know, the most efficient way to write this? Let's - let's write out the tree and then. Yeah, so B can give two." Lola and Harper then had a lengthy discussion of how to order their disproof from the stages of their tree diagram. Since this excerpt describes Lola's internal thinking about writing, this was coded as Intramental. Because the subject of her statement was her own knowledge, uncertainty that she knew the most efficient method, this was coded as metacognitive. There was a relevant action in this statement the decision of her proof organization.

Preliminary Results

As Lola and Harper began, Harper read the task aloud. Lola then began writing generalized versions of odd numbers for k and l. Harper suggested trying some examples, with each of them as the two players in the game. Lola, in her follow-up interview, noted that she often likes to write down the given information and relevant definitions when beginning a proof. In her follow-up interview, Harper stated she often begins by trying concrete examples. In the paired interview, Lola commented trying examples might be a way to determine if a counterexample exists. They decided on the starting value six, and played the game for a couple of rounds, to work out possible outcomes from allowable moves. They determined six was a counterexample to the claim. Working through other examples, they found a starting number of eight is also a counterexample. Harper suggested drawing tree diagrams of each possible decision in the game. Lola added arrows to these diagrams to indicate which player was "giving" a number that round. Lola was the first to indicate a desire to write a proof that the claim is false using their examples. When unsure how to begin writing, Lola suggested they follow the order of how each turn played out in their tree diagram. Harper ended up being the one to write the proof on paper, but both Harper and Lola went back and forth stating what should come next in their written proof.

Throughout the task and follow-up interviews there were instances of metacognitive knowledge and related actions that were inductively coded as types of control actions. The

control actions from Lola and Harper included Reading Aloud, Re-reading the Prompt, Checking Work, Re-working, Evaluating Strategy, Generalizing, Using Math Drawings, Organizing Proof, Writing Proof. A few of these codes are in Table 1 with descriptions and corresponding example quotes. Both participants engaged in most of these actions with a few exceptions. Only Harper demonstrated Reading Aloud, and only Lola demonstrated Generalizing and Writing Proof.

Table 1. A table of a few demonstrated control actions participants took.

Metacognitive Control Process Actions During Proof Construction		
Control Actions	Description	Example Transcript Data
Re-Working	Reviewing why their work was useful	"wanting to go back and run through the logic again, remembering what I was trying to prove"
Evaluate Strategy	Actively considering the value or effectiveness of their current approach	"I don't know if this general tree thing is ever going to end…Any pattern…has probably already showed up and we just didn't notice it. Let's go back to actual numbers."
Organizing Proof	Determining what will be included in the proof or the order	"I don't know, the most efficient way to write this? Let's hit let's write out the tree and then. Yeah, so B can give two…"
Writing Proof	Deciding to move from "scratch work" to writing down a proof or part of a proof	"…I write chaos all over the place on a page just to give myself a sense of what's going on…then I…write it out using more formal language and a series of steps that you can follow…"

There were notable patterns in the metacognitive knowledge utilized in each task that will be more thoroughly verified in continuing data analysis. Most often the metacognitive knowledge related to Harpers actions was procedural, related to possible strategies usefulness in this context. While metacognitive knowledge was not always clearly demonstrated, Lola frequently initiated a pause for various forms of reflection during the task. These intentional pauses may be indicative of further metacognitive monitoring and control processes that are not explicit in the data.

Discussion and Questions for the Audience

The preliminary results indicate that undergraduate mathematics students are accessing metacognitive knowledge during proof construction, and their metacognitive knowledge impacts their choices during the proof construction process. The two proof specific control actions observed indicate that there are control processes unique to proof construction. This preliminary result solidifies the need for considering metacognition in proof tasks specifically. The exploration of the declarative, procedural, and conditional metacognitive knowledge is ongoing with the second pair's data. I will complete the analysis with constant comparison of each case. My questions for the audience are: were there any instances of data in the presentation you felt should have been coded as metacognitive that were not? In your teaching and research experience, have you observed metacognitive knowledge or actions specific to proving?

Exploring Discrepancies in Mathematicians' Use of Programming in Teaching and Research

Jan-Fredrik Olsen
Lund University, University of Oslo

Tor Ole Bigton Odden
University of Oslo

Elise Lockwood
Oregon State University

We present preliminary findings from an ongoing investigation into the discrepancies between how university-level mathematicians incorporate programming into their research versus their teaching. Motivated by earlier studies that highlight a gap in the use of programming between research and teaching, we explore this tension through interviews with mathematicians at a university recognized for supporting programming in science and mathematics teaching. Specifically, we draw on Engeström's Cultural Historical Activity Theory to analyze the interview with one mathematician who illustrates this discrepancy. Our preliminary findings suggest connections to more deeply held epistemic beliefs about which tools and purposes are considered legitimate in mathematical practice.

Keywords: Mathematicians, Programming, Mathematical Practices, Activity Theory

Background

In this paper, we present preliminary findings from an investigation into the underlying causes of the discrepancies in how university-level mathematicians use programming (writing and executing computer code) in their research versus their teaching. A motivation for this project is a survey of 302 Canadian mathematicians by Buteau et al. (2014), where 43% reported using programming in their research compared to 18% in their teaching. In a follow-up interview study, Broley et al. (2018) found institutional factors commonly cited as barriers to using programming in teaching (e.g., students do not know how to program). However, other research (e.g., Iannone and Simpson, 2022) indicates that mathematics students generally have access to courses in programming, suggesting the significance of factors beyond institutional issues.

In an interview study with six mathematicians, Lockwood et al. (2019) found that the mathematicians mainly used programming in their research to gain intuition into problems or to provide numerical results where analytic methods fell short. This suggests that the discrepancy between the use of programming in teaching and research could be linked to a previously established tension between the high-value mathematicians place on intuition in research and the comparatively lower emphasis on intuition in teaching (e.g., Burton, 2004; Hersh, 1991).

To explore this question, we conducted interviews with 15 mathematicians at a site with long-standing and recognized institutional support for the use of programming in teaching. While it was immediately clear that the interviews confirmed the existence of a discrepancy between the use of programming in teaching and research, we aimed to probe deeper for underlying causes by drawing on Engeström's Cultural Historical Activity Theory (CHAT). Here, we present an analysis conducted on one of the interviews that exemplified this discrepancy.

Specifically, we explore the following questions:

- What features do we see in the data when using CHAT as an analytic lens to compare how a mathematician describes their teaching and research activity systems as they relate to the use of programming?
- Is additional data needed to further support these findings?
- Should we modify or further refine our operationalization of CHAT?

Theoretical perspective

Engeström's Cultural Historical Activity Theory (CHAT) builds on the activity theory of Vygotsky and Leon'tev (Engeström, 2015). Given the scope of this paper, we focus on operationalizing Engeström's extended activity triangle (Figure 1).

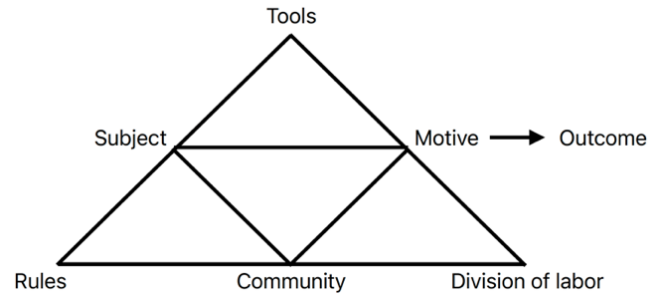

Figure 1. The extended activity triangle (Engeström, 2015).

Engeström's activity triangle expands Vygotsky's mediating triangle by emphasizing the collective aspects of activity (rules, community, division of labor). Activities are defined as enduring, motive-driven, situated, and collective human endeavors, such as mathematical teaching and research. To provide an analytic lens, we follow Mwanza and Engeström (2005) in operationalizing Engeström's triangle as a checklist of questions to ask the data (see Table 1).

Table 1. Operationalization of the nodes of the activity triangle.

Node	Example of questions
Subject	What role does the subject identify with as part of the activity?
Motive	Why is the subject pursuing the activity?
Tools	With what means does the subject pursue the activity?
Rules	What rules and norms regulate the subject's pursuit of the activity?
Community	Who does the subject see as supporting their pursuit of the activity?
Division of Labor	What power structures affects who does what in the activity?
Outcome	What is the 'output' of the activity as perceived by the subject?

Following Leon'tev, Engeström views the motive as the activity's reason for existence and a force that drives all other components. Our analysis, therefore, begins by focusing on the motive, using the other nodes to add layers of detail. The aim is to identify certain cultural tensions, called dialectic contradictions, that serve as historical driving forces, such as the tension between applied and pure mathematics. While we see the nodes as acting like the diagnostic tools of a physician, dialectic contradictions are not issues to be 'cured' but mechanisms to be understood and leveraged for change and innovation within the activity.

Methodology

We conducted semi-structured interviews with 15 mathematicians at the department of mathematics of a major northern European research university, who were sampled purposefully to represent a wide variety of mathematical research orientations (pure, applied, and computational). Each interview lasted 1.5 – 2 hours and addressed programming in their research and teaching, as well as institutional issues. All interviews were audiotaped and transcribed. To ensure a high level of communication, the interviews were conducted by the first author, who has

a background as a research mathematician. Additional data, such as CVs, examples of publications, and webpages of taught courses, were consulted to support the analysis.

In this paper, we analyze the interview of an applied computational mathematician, given the pseudonym Emil. He was selected because he uses programming extensively in research but much less in teaching. Using our operationalization of CHAT over repeated readings of the full interview transcript, we generated descriptions of his teaching and research practices. We then compared these descriptions, looking for tensions indicating dialectic contradictions that relate to the discrepancy in the use of programming exemplified by Emil. These findings were discussed among the authors and compared with prior analyses of the complete data set.

To protect Emil's anonymity, we have altered quotations to obscure specific details about his research focus and the courses he has taught.

Findings

To save space, we combine our interview analysis with a description of Emil's teaching and research activity systems. The main points are summarized in Figure 2.

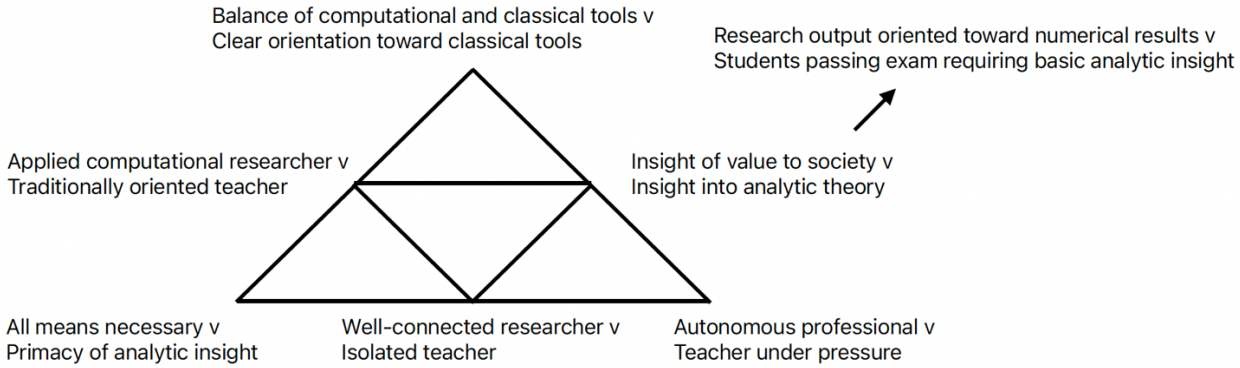

Figure 2. The main features of Emil's research (top) and teaching (bottom) activity systems.

Description and comparison of Emil's two activity systems

Subject. As a researcher, Emil explicitly identified as an applied computational mathematician. As a teacher, his preference to avoid programming in introductory courses suggests a more classical focus where students are to work analytically with pen and paper.

Motive. Regarding research, Emil stated that "the end product is that I want a deep understanding of how a physical phenomenon behaves, based on an approach that integrates an analytic and numerical approach with the use of real-world data." In discussing his teaching, Emil gave additional details, saying that, ideally, he would want students to have the same combination of abilities so that they can "piece them together into an end product that is useful for the industry and society." This motivation was tempered, however, by his low expectations of the capabilities of first-year students: "I have to say that the challenge for students to get through the first-year course that I teach, it is not their ability to use a computer, on the contrary, it comes down to their ability to understand how basic mathematical objects behave."

Tools. As a researcher, Emil said, "If I did not have computers and programming as tools, then I would not be able to do anything." He explained that analytic approaches to applied mathematics ran out of steam 50 years ago, and since then, progress has been entirely reliant on computers and programming. As we noted in the motive node, Emil was skeptical of whether it was possible to leverage programming in the same way in teaching first-year students. The following quote indicates that not being able to tap into this synergy bothers him:

> I think that being able to use a computer to represent the mathematics you do is very advantageous. If you can do it in concert with your ability to represent the same things using your head, paper, and pencil, I think you will get further. […] I wish our students would reach such an advanced level that we could begin to talk about synergies. However, [that is] aiming far higher than what we are able to get in [my course].

Rules. In his research, Emil views computers as indispensable for doing research in applied mathematics. However, when talking about first-year students, he stresses the primacy of analytic mathematics over the use of programming. That is, he seems to insist that any use of programming in mathematics must be guided by analytic intuition or insight - it does not work the other way around. He explains this as follows in his own words:

> … programs are, to a larger degree, acting like black boxes. And there is no reason to believe that these researchers have written their own programs either. They just sit and use it as a black box that someone else has programmed. Then, I get worried because I feel that they miss some of the deeper analytic insight that I am used to having. So, personally, I prefer that you not just show the result of the numerical simulation but also have some deeper analytic understanding. And maybe, I think it is, there is something to implementing a simple model rather than just implementing the full equation governing the physical system. Because then you can focus on what a simple model... how it behaves, as I think, deep down, can give you more insight.

Community. In his research, Emil collaborated with fellow researchers, contacts in the industry, and MSc and PhD level students. This is corroborated by a look at his publication record and personal webpage. As a teacher, the level of collaboration with colleagues seems less pronounced (which is also a recurring theme in the other interviews).

Division of labor. Emil expressed significant autonomy concerning his teaching and research. However, there are some discrepancies. Although he interacts with a network of collaborators in his research, he adopts a more independent stance in his teaching. In his research, Emil expressed the absolute necessity of using computers. In his teaching, he expressed the difficulty of using programming based on his impression of his students' analytic proficiency level. He also pointed to continuous reorganizations, both within the university and externally, as taking so much energy that he did not feel the strength to look at the 'big picture.'

Outcome. In his research, the outcome is research papers of interest to the industry, with numerical simulations at the forefront. In his teaching of first-year students, the outcome is that mathematics students pass exams that test what Emil considers basic analytic skills.

Discrepancy between activity systems

In the above analysis, we see that Emil, as a researcher, desires insight into physical phenomena based on a combined analytic and numerical approach that allows him to work with real-world data. He does mathematics to contribute to our understanding of the real world and he does it using programming, as it would be impossible otherwise.

While Emil wants students to have 'the whole package,' he is concerned that their lack of analytical mathematical ability makes it difficult for them to pass courses in their first year. Therefore, he teaches classical analytical mathematical content using pen and paper, without involving computers, except for using ready-made tools for visualizations. He believes this approach gives students the necessary insight required to work numerically.

We interpret this as a discrepancy related to tensions in the epistemic dimensions of the motive of the activity and by what means the activity is pursued. We represent this in the 'epistemic matrix' shown in Figure 3. We note that while Emil would like students to use 'the whole package,' he seems to feel pressured by circumstances outside his control (such as his perception of students' low analytic proficiency) to adopt another, more classical, stance concerning his teaching.

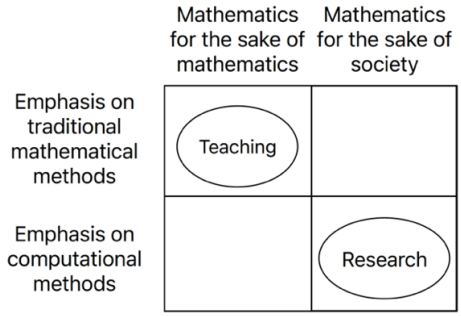

Figure 3. An 'epistemic matrix' representing the discrepancy between Emil's research and teaching activities.

Discussion

Using CHAT as an analytic lens, we are naturally led to focus on Emil's motives for research and teaching, highlighting discrepancies between the 'reasons why' of the nodes. The most conspicuous discrepancy concerns the use of programming. While Emil views his mathematics as something that should serve society, with programming as a necessary tool to handle real-world data, he believes that any use of numerical methods must be guided by analytical ability. For Emil, students must first learn basic analytic skills before being tasked to program anything. Thus, he emphasizes traditional methods in teaching, not because he devalues programming, but because he sees analytic ability as a prerequisite for insightful use of programming. This observation resonates with and connects the findings of Buteau et al. (2014), Broley et al. (2018), and Lockwood et al. (2019), which we discussed in the background section. We propose the epistemic matrix as a tool to explore the gap between the use of programming in mathematics research and teaching. Our findings suggest that this gap stems from a tension between Emil's belief in the primacy of analytic ability and his perception of first-year students' skills.

A first natural question is whether the dimensions of the epistemic matrix are strongly correlated. This does not seem to be the case, as preliminary analyses of other interviews suggest that there are mathematicians corresponding to other areas of the matrix. A second question is whether the dimensions of the epistemic matrix represent dialectic contradictions (i.e., historical driving forces of the activities). To understand this, analyses of additional interviews, a closer look at institutional factors, and a review of related results in the philosophy and history of mathematics are necessary.

While one might argue that using CHAT to analyze a single individual is a contradiction in terms, as it is a socio-cultural theory meant to analyze *collective* activities, we maintain that if the goal of the analysis is to uncover epistemic dimensions, then the relevant collective component is chiefly how the subject *perceives* the collective dimension, which may be different to how peers report the collective dimension.

We conclude with potential questions for the audience:

1) Does our use of CHAT seem useful and appropriate as we have operationalized it?
2) Do you see the epistemic matrix as having a potential to inform mathematics education?
3) Are there other frameworks than CHAT that are better suited for our analysis?

The Guided Reinvention of Equivalence Classes and Equivalence Relations

Kaitlyn Stephens Serbin
University of Texas Rio Grande Valley

Tenchita Alzaga Elizondo
University of Texas Rio Grande Valley

Rosaura Uscanga
Mercy University

We present a preliminary local instructional theory of students' guided reinvention of equivalence classes and equivalence relations that has resulted from engaging in one iteration of the design research cycle. We leverage the instructional design theory of Realistic Mathematics Education (Freudenthal, 1991) to design a task sequence in an experientially real setting that can guide students to reinvent equivalence classes, equivalence relations, and their properties. In this paper, we present our revised task design describing the rationale, task implementation in a classroom setting, and analyses of student reasoning. Further, we conclude by discussing our plan to reimplement the tasks in another iteration of the design research cycle.

Keywords: Realistic Mathematics Education, Equivalence, Guided Reinvention

Equivalence is ubiquitous in mathematics, particularly in abstract algebra. Students are introduced to notions of equivalence, like equality, as early as elementary school (e.g., Alibali et al., 2007; Kieran, 1981; Knuth et al., 2006). As they progress through their mathematical careers, students encounter more complex notions of equivalence like congruence and isomorphisms in abstract algebra. Researchers have explored undergraduate students' interpretations of notions of equivalence (e.g., Cook et al., 2021; Mirin, 2019) and reasoning about equivalence across domains (Cook et al., 2022). More domain-specific research has investigated productive ways of thinking about equivalence in combinatorics (Lockwood & Reed, 2020) and the notion of sameness in the context of isomorphism and homomorphism in abstract algebra (e.g., Rupnow, 2019). Despite this recent work, little is known about how students reason about equivalence relations and equivalence classes in abstract algebra. We aim to contribute to this literature through our design research-informed (Gravemeijer et al., 2003) local instructional theory of students' guided reinvention of equivalence relations and equivalence classes. Guided reinvention (Freudenthal, 1991) is an instructional design principle from Realistic Mathematics Education involving "an instance of psychological explication whenever students already possess some intuitive or less formal understanding from which they construct formalized meanings" (Dawkins, 2015, p. 67). Scholars have investigated students' reinvention of various abstract algebraic concepts, like groups (Larsen, 2009, 2013), quotient groups (Larsen & Lockwood, 2013), isomorphisms (Larsen, 2009, 2013), rings (Cook, 2012), integral domains (Cook, 2012), fields (Cook, 2012), (ir)reducible elements (Serbin et al., 2024), and unique factorization domains (Bae et al., 2024). However, scholars have not yet explored students' guided reinvention of equivalence relations and equivalence classes, which we address. In this preliminary report, we present our revised task sequence and analysis of student reasoning after one iteration of the design cycle. We address these research questions: *Which ways of reasoning do students engage in as they reinvent equivalence relations and equivalence classes? How does the task sequence in this local instructional theory evoke these ways of reasoning?*

Theoretical Perspective

Design research (Gravemeijer et al., 2003) involves a cycle by which researchers design an instructional task sequence, implement it in an instructional setting with a teacher-researcher

guiding students, analyze the student reasoning that results from engagement with the task sequence, and revise the sequence to improve its subsequent use. Design research can be used to create a *local instructional theory* (LIT), "the description of, and rationale for, the envisioned learning route as it relates to a set of instructional activities for a specific topic" (Gravemeijer, 2012, p. 107). Realistic Mathematics Education (RME) is an instructional design theory that can inform such design research (Freudenthal, 1991; Gravemeijer, 1999). RME has three design heuristics that researchers consider as they design task sequences: experientially real context problems, guided reinvention, and emergent modeling. RME-informed task sequences have problems set in experientially real contexts that have accessible entry points for students to engage in intuitive mathematical activity. These tasks should also provide the opportunity for students to create a model (e.g., a physical object, manipulative, or symbol) of their mathematical activity that they can use as a model for further abstract mathematical reasoning. This shift in the emergent model, accompanied by progressive mathematization, supports the student in reinventing a mathematical concept. Students "reinvent" a mathematical concept with the guidance of a teacher by progressively formalizing their informal, intuitive understandings. Overall, this design theory of RME informed the design of our LIT.

Methods

Our design research (Gravemeijer et al., 2003) began with designing the RME-informed task sequence to engage students in the guided reinvention of equivalence relations and equivalence classes. We aimed for them to develop intuitive, informal understandings of those concepts and transition to formally define those concepts. We conducted a teaching experiment (Cobb, 2012), where we implemented the task sequence in a class setting, analyzed students' reasoning about the tasks that were evident in recordings of class discussions, and revised the task sequence and its rationale to potentially better support students in reaching the intended learning outcome.

We collected data in a Mathematics for Secondary Teachers course at a large public university in the southern US during the Spring 2024 semester. This course contained 23 students who were junior and senior mathematics majors. The task sequence was administered in the beginning of the hybrid course over four classes; two in-person and two on Zoom. These classes were recorded and transcribed. The recordings could not capture group work discussions, so we only analyzed the student reasoning shared in whole-class discussions. The projected/ shared screen was recorded. Pictures of student work on whiteboards were also collected. We performed a qualitative video analysis (Lesh & Lehrer, 2012), in which we wrote content logs of the class discussion videos and memos of students' ways of reasoning evident in the videos. These memos also included reflections of how the tasks seemed to evoke these ways of reasoning. Each author individually wrote these content logs for the four classes, and we met to compare our interpretations of the videos and our analyses of student reasoning. We discussed how effectively the tasks guided the students' reinvention and decided how to revise them.

Results

We present our revised task sequence based on this analysis. We describe each task, its rationale, and examples of student reasoning exhibited on the task. We then present additional tasks 6-11, which were added to the task sequence during the revision, along with their rationale.

Task 1: Coloring task

Our LIT begins with a number line coloring task, which leads students to create a set of equivalence classes under congruence modulo 3 on the set of integers. The task states that each

number on the number line is colored either red, blue, or green and outlines two rules: 1) The negative (opposite) of a red number must be colored blue and 2) the sum of two blue numbers (not necessarily distinct) must be colored red. Students are tasked to find a coloring of the number line that meets these conditions. A coloring using all three colors and meets these conditions will successfully divide the number line into a repeating green, red, blue (or green, blue, red) pattern (see Figure 1). This task engages students in an experientially real task setting of coloring an integer number line. We aimed for students to use the colored number line as an emergent model of their activity that they could mathematize to reinvent equivalence classes.

In line with the exploratory nature of the task, students used a trial-and-error method, leading to correct and incorrect strategies. A common incorrect strategy was to start by making all negative numbers blue and all positive numbers red (or vice versa). When using this strategy, students noticed that it led to problems and contradictions like: "We chose red to be the positive numbers and then the blue ones to be negatives, and when we add two negative numbers, we can't end up getting positive." The group noticed that since they colored the negative numbers blue, their sum should be colored red (condition #2) which means the sum should be a positive number. However, given that the sum of two negative numbers will always be negative, this leads to a contradiction. A successful strategy that was used by a couple of groups was to build up the coloring based on the two conditions, as one student explained it: "We started with 1 and from there we went and said 1 plus 1, since the sum of it is 2, then it's red [condition 1]. So since 2 is red, then the opposite has to be blue [condition 2], so -2 would be blue." This system resulted in some numbers not being assigned blue or red, so the group decided to color these numbers green. Once students shared this strategy, the instructor had the rest of the groups use it to color their number lines to develop the class's shared understanding of the strategy.

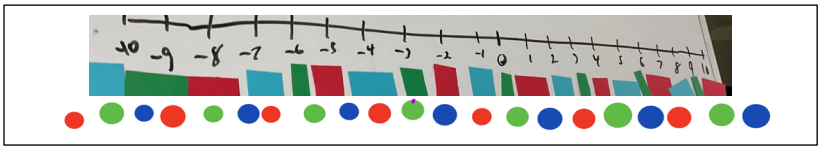

Figure 1. Students' patterned colorings (green-blue-red or green-red-blue) of the integers number line in task 1.

Task 2: Make a rule for each color

Task 2 guides students to develop rules to determine what color any integer will be according to the pattern. This task anticipates the formalization of the equivalence classes since the sets of integers with green dots, blue dots, and red dots are each equivalence classes on $\mathbb{Z}$. We saw two strategies for articulating a rule. First was a student's "jumping the number line" strategy:

> Whenever it starts at 0, you can just add 3, so it would be 0, 3, and then plus 3, 6, plus 3, 9, plus 3, and so on and so forth. However, if you start at 1, then 1 plus 3 would be 4, which is red. 4 plus 3 is 7, which is red. And then 7 plus 3 is 10. And the same thing works for 2. So, 2 plus 3 is 5, 5 plus 3 is 8, and so on.

Using the number line model, the student considered the starting point for a color as 0, 1, or 2 and made jumps of size three to find the next number with the same color. Others mathematized this idea with set notation, writing $\{3k|k\in\mathbb{Z}\}$ to represent green, $\{1+3k|k\in\mathbb{Z}\}$ for red, and $\{2+3k|k\in\mathbb{Z}\}$ for blue. The second student strategy involved modular arithmetic. Students noticed the numbers could be distinguished by their remainder when divided by 3. As their rule, one group wrote "*Let $n \in \mathbb{Z}$, for this to find the nth color we use, green: (n mod 3) = 0, red: (n mod 3) = 1, blue: (n mod 3) =2*". To develop a shared understanding of these rules, the task next had students use these rules to determine the color 534, 2156, and -74 (green, blue, red, respectively).

Task 3: Develop an informal definition of equivalence and equivalence class

For the next task students develop a personal definition of equivalence with the goal of 1) connecting the dot activity to the notion of equivalence and 2) begin transitioning to more formal mathematics. Most students' personal definitions of equivalence involved the idea of sameness; for example, "Classified as the same under some condition" or "They produce the same results with certain conditions." The instructor prompted students to describe what their definitions had in a common and a student suggested "sameness." The instructor then asked students to elaborate on whether elements in the same class had to be exactly the same. A student said, "It doesn't necessarily have to be the same exact thing…we have multiple different objects that you can have that will satisfy these conditions. As long as those conditions are met, you have an equivalence class." The instructor connected students' informal notions of equivalence to the number line coloring activity, noting that dots of the same color are equivalent, so integers of the same color are in the same equivalence class. The instructor then wrote an informal definition of equivalence class as *the set of elements that are equivalent to each other under some rule*.

Task 4: Establish a rule for two integers being equivalent modulo 3 and use it

After the instructor claimed students' green, blue, and red-dot equivalence classes $\{3k|k\in\mathbb{Z}\}$, $\{1+3k|k\in\mathbb{Z}\}$, $\{2+3k|k\in\mathbb{Z}\}$ were sets of elements that are equivalent modulo 3, task 4 prompts students to complete the claim, "For any $a, b \in \mathbb{Z}$, a is equivalent to b modulo 3 if and only if:". The goal of the task is for students to create the equivalence relation for equivalence modulo 3. Students contributed a variety of answers like "a and b have equal remainders [when divided by 3]" and "3 divides $(a - b)$." After students shared their ideas, they chose a rule and used it to determine whether 216 and 487 were equivalent modulo 3. To ensure students could use these rules, the task prompted students to find two integers that are not equivalent modulo 3 using their rule. Students successfully found a non-example and a correct justification. One group used 11 and 13 and explained that the remainder is not the same when dividing by 3. This task helped students recognize that equivalence classes of integers with the same color contained integers that were equivalent according to some rule, which will be formalized as an equivalence relation.

Task 5: Relating Equivalence Classes and Partitions of $\mathbb{Z}$ and Defining Partition

For Task 5, students discuss what they notice about red, green, and blue dots. The goal of this task is for students to use their number line model to develop an intuition for the properties of equivalence classes on $\mathbb{Z}$, namely that they form a partition of $\mathbb{Z}$. This activity anticipates the formal definition of partition: A partition of a set X is a collection of nonempty subsets of X such that (i) the union of those subsets is X and (ii) the subsets in the collection are pairwise disjoint. Students first noticed the pattern of the colored dots on the number line repeating green, red, blue. They noticed the cardinality of each of the sets of {red dots}, {green dots}, and {blue dots} was infinite. The instructor elaborated: "We noticed that this pattern goes on for all of the integers, and so that means if I put together all those sets, of the greens, the reds, and the blues, I get all of the integers." She prompted students to restate that idea using more precise language or notation. A student claimed, "the union of equivalence classes makes up the set of integers." Another student said: "each set is distinct from each other since one is just red, one is just blue, and one is just green." The instructor revoiced that indeed the sets are distinct and disjoint, and she pointed out that this is a special property she wanted them to notice. She mentioned that this has to do with the intersection and asked what the intersection of these sets is. Three students replied that it is the empty set, so the sets have no common elements. The instructor claimed that these two criteria were axioms in the definition of a partition and guided students to define

partition. She asked why the color dot sets form a partition of $\mathbb{Z}$. Students replied it was an assumption of task 1 that a number cannot be more than one color, which implies the sets are disjoint. Also, since all integers could be assigned a color, the union of those sets is $\mathbb{Z}$.

Newly Designed Tasks

We designed new tasks to conclude the sequence: *Task 6)* Find examples and non-examples of partitions of $\mathbb{Z}$, $\mathbb{R}$, and $\mathbb{N}$. *Task 7)* Use the following rules on $\mathbb{Z}$ to create subsets of elements that are equivalent under the rule. Do these subsets form a partition of $\mathbb{Z}$? If yes, verify using the definition of partition. If not, state what part of the definition is not satisfied. $x \sim y$ iff a) $x^2 = y^2$, b) $x = ky, k \in \mathbb{Z}$, c) $x \neq y$, d) $xy \geq 0$. *Task 8)* Rules with corresponding equivalence classes that form a partition of $\mathbb{Z}$ are called equivalence relations. Part 1: What properties do these rules need to have to be equivalence relations? Part 2: Create a definition for an equivalence relation. *Task 9)* Now that we have defined equivalence relation, we can refine our definition of equivalence class to make it more formal. *Task 10*) Consider this collection of subsets for the given set. Does this collection form a partition? Could these subsets form equivalence classes? Use the definitions of equivalence relation, equivalence class, and partition to justify your claim. Ex: $\{1,2\},\{2,3\} \subset \{1,2,3\}$. *Task 11)* a) What do you notice about the relationship between equivalence relations and partitions? b) Write a conjecture that formalizes what you noticed.

These new tasks guide students to 1) reinvent and formalize the definition of equivalence relation and 2) articulate the connection between equivalence classes and partitions of a set. Task 6 gives students an opportunity to become familiar with the definition of partition that is established in Task 5. Task 7 begins students' reinvention of equivalence relation by exploring different rules that do and do not satisfy the three properties of equivalence relations (reflexive, symmetric, and transitive). In Task 8, students reflect on this work and articulate these three properties, which they then use to write a definition of equivalence relation. In Task 9 the instructor uses this definition to redefine equivalence class formally (*Let ~ be an equivalence relation on A. Let $x \in A$ The equivalence class of x is $[x] = \{y \in A | \, y \sim x\}$).* In Task 10, students explore subsets of a set and are guided to notice how subsets that fail to be partitions also fail to be equivalence classes since their corresponding relation fails properties of equivalence relations. Task 11 guides students to articulate this and establish the Fundamental Theorem of Equivalence Relations: Let A be a non-empty set. 1) *if ~ is an equivalence relation on A then the set of equivalence classes of ~ forms a partition of A.2) if $\{A_i \, | i \in I\}$ forms a partition of A then there is an equivalence relation on A whose equivalence classes are the sets $A_i, \; i \in I$.*

Discussion

This preliminary report shares our findings from only one iteration of the design cycle in our attempt to create a local instructional theory on the guided reinvention of equivalence relations, equivalence classes, and partitions. Our analysis of student reasoning on the tasks informed our revisions and additions to the task sequence. The added tasks serve to further engage students in defining (Zandieh & Rasmussen, 2010), which was absent from the first implementation of the tasks. To further refine the tasks, we will implement the tasks in a classroom setting again as part of a new iteration of the design cycle. We will provide a theoretical contribution to the field regarding characterizations of key ways of reasoning that are milestones in reinventing equivalence classes, equivalence relations, and partitions. We hope for instructors to be able to use our task sequence to guide students to reinvent those concepts. We pose this discussion question to the audience: What feedback do you have for our design of the task sequence?

Reasoning Beyond Content-Specific Objects: A Case Study of One Student's Structural Thinking

Kyle Flanagan
Virginia Tech

Michael D. Hicks
Virginia Tech

In all levels of mathematics, especially beginning at the undergraduate level, structural thinking is pivotal for deeper understanding or more complex reasoning about the relevant mathematical concepts. In this preliminary research study, we investigated the structural thinking of one advanced undergraduate mathematics student as he conjectured the definitions of various concepts in graph theory. We observed various affordances and obstacles to his structural thinking. Affordances included his attention to a general structural property and his use of analogical reasoning with corresponding structures in group theory and point-set topology. Obstacles included utilizing a constrained example space and relying on his familiarity with previously encountered mathematical concepts.

Keywords: Abstraction, Analogy, Graph Theory, Structural Thinking

The ability to think *structurally* in undergraduate mathematics is an invaluable skill. Spurred by David Hilbert's insistence on conforming to a structural approach to studying mathematics in the early 1900s, the evolution of mathematical thinking to conform to the flexible recognition of underlying structure of objects has been a purposeful endeavor in modern research (see Hausberger, 2018). The shift toward structural thinking also played a significant role in the development of the mathematical subjects we offer to undergraduate students today. Take, for example, the subjects of abstract algebra and point-set topology. Before the expansion of structural thinking in the early 1900s, such subjects were difficult to access for both students and professional mathematicians alike. Despite the modern focus on structure in mathematics, educational research has revealed that students struggle to articulate certain concepts often associated with structural thinking, such as quotient group (Dubinsky et al., 1994). However, we wondered about the development of students' *structural understanding* as a separate phenomenon as opposed to their content-specific understanding. In this paper, we present a preliminary investigation of what one student, Isaiah (a pseudonym), understood about structure after having taken courses in introductory abstract algebra and point-set topology.

Literature Review and Conceptual Framework

At the center of this research study are the notions of structural thinking, analogy, abstraction, and the deep connections between them. Mac Lane (1996) stated, "Structure is essentially a list of mathematical operations and relations and their required properties…, and often so formulated to be properties *shared by a number of possibly quite different specific mathematical objects*" (p. 174, emphasis added). In this rough definition, there is already implicit reference to a type of relational structure between mathematical objects that share certain properties.

To investigate structure more directly, Linchevski and Livneh (1999) introduced the notion of structure sense, which aimed to capture one's ability to recognize the same structure flexibly and creatively across various contexts, specifically in the context of high school algebra. Novotná and Hoch (2008) extended this concept to structure sense in abstract algebra, further elaborating on the structure inherent to the set and binary operation of algebraic structures such as groups. Recently, Hicks and Flanagan (2024a) further extended structure sense to more

targeted structures, including sub-structure sense, sense of structure preservation, and quotient structure sense (see also, Hicks & Flanagan, 2024b). Additionally, to provide a way to analyze students' reasoning across related structures (e.g., subgroup and subring), we introduced analogical structure sense, which aimed to "parse students' attention to structure during analogical reasoning" (Hicks & Flanagan, 2024a, p. 4).

Hicks, Flanagan, and Park (2023) investigated the relationship between analogy and abstraction, which culminated in two ways that students may abstract structure during the process of analogical reasoning (see also, English & Sharry, 1996). This suggested that a certain level of abstraction may be required when engaging with analogical structure in widely different domains, such as between groups and topological spaces. This preliminary study aims to further contribute to this growing body of literature on the connections between structural thinking, analogy, and abstraction, by investigating how one advanced undergraduate student reasoned about developing structures in graph theory. To do this, we proposed the following two research questions:

1. What were the affordances and obstacles that an undergraduate student elicited while conjecturing the definitions of structures (sub-structure, structure preservation, quotient structure) in a new context of graph theory?
2. In what ways did the student utilize his prior experience with analogous structures in group theory and topology when conjecturing the definitions of structures in graph theory?

Methods

Because our goal was to investigate students' structural thinking after having taken courses in higher mathematics, we solicited participation from all students in an introductory point-set topology course in which abstract algebra was a prerequisite. Of the eight students that were contacted, only Isaiah responded. The data for this study was collected from a one hour, task-based interview with Isaiah, conducted by both authors digitally over Zoom. The interview was intended to serve as a pilot for future data collection and comprised of four distinct parts: a brief introduction to the concept of a graph and a determination of what Isaiah already knew about graphs from his previous coursework, followed by requesting Isaiah to create each of the concepts of subgraph, graph homomorphism, and quotient graph. During the interview, we asked clarifying and probing questions when needed.

The interview was subsequently transcribed and analyzed by both authors. While Isaiah was creating his graph-theoretic structures, we found that he presented several affordances and obstacles to his structural thinking. Affordances for Isaiah's structural thinking included features of his thinking that helped drive him forward in creating structure or reasoning about underlying structure. By contrast, obstacles included features of Isaiah's thinking that led to impeded creation of structure or resulted in incomplete or inconclusive reasoning about underlying structure. We note here that we did not directly attend to Isaiah's graph-theoretic thinking, meaning that we were not looking for affordances and obstacles to his understanding of concepts in graph theory. Rather, we wished to capture the affordances and obstacles to his more general thinking about the underlying structure of the graph-theoretic concepts. In this way, it was possible to identify affordances for Isaiah's structural thinking that would perhaps be considered obstacles to his graph-theoretic thinking. Likewise, certain aspects that might be affordances to

his graph-theoretic thinking (i.e., recalling what he knew about graphs from his previous coursework), might have also resulted in obstacles to his structural thinking.

Results

The analysis revealed two primary affordances and two primary obstacles to his structural thinking about the three graph theoretic concepts. We provide individual evidence for each of these affordances and obstacles. As stated above, our analysis attended to structural thinking rather than his content-specific thinking about each of the relevant graph theoretic concepts.

Attention to a General Structural Property as an Affordance

Throughout the interview, Isaiah attended to a general, overarching property that described the structure of graphs. For example, when developing the concept of a subgraph, Isaiah stated, "So, I think there would have to be... vertices still being adjacent in the subgraph." This was the first indication that Isaiah identified adjacency as the overarching structural property for graphs. The act of establishing this property proved to be an affordance to Isaiah's structural thinking throughout the interview, specifically by helping him to make headway with establishing access for creating the subgraph, graph homomorphism, and quotient graph structures. For example, when working on the graph-theoretic homomorphism concept, Isaiah stated:

> So, when I hear of homomorphism or homeomorphism, it's the idea of structure preserving, or you know, isomorphism. So, in a graph, I guess this structure is what stuff is adjacent to, if that makes sense, I think. So, I'd have to think about how to define it so it actually makes sense.

Furthermore, present in Isaiah's structural thinking was also a fair amount of flexibility (see Lee & Heid, 2018) for what constituted the general structural property for graphs. Specifically, he was open to revising his understanding of the general structural property as he continued his constructions of graph-theoretic concepts. While he initially focused on adjacency as the primary property, he slightly modified this property as he explored the graph homomorphism concept:

> I'm trying to think, because I probably want to just look at stuff, what it's adjacent to, and then have to work through the graph in order to define the homomorphism. So, I would have to send one vertex to a vertex in another one [graph] such that it has the same number of neighbors... Yeah, I guess that's, that makes sense. I think, if I say, a graph is homomorphic if there a function, say f , going from the vertices of one to the vertices of another one such that, and then I'll say, if, I've seen this notation before, so if the [number of] neighbors of V is equal to the [number of] neighborhoods of f of V , so $N\,V$ [$N(V)$].

Thus, Isaiah's structural thinking was afforded by first establishing a central structural property for defining graphs which subsequently undergirded his graph-theoretic constructions. We note here that although Isaiah was technically shifting away from the normative graph-theoretic property of graph homomorphism itself, his structural thinking was afforded by his attention to the general structural property, as well as his openness to revising the criteria as he progressed.

Analogical Reasoning as an Affordance

During his reasoning about graph-theoretic concepts, Isaiah's structural thinking was afforded through analogical reasoning with group theory and topology. While constructing the subgraph concept, Isaiah noted the following:

> But I guess because I mean in both of them, it's all the elements are coming from whatever, a group, a subgroup, all the elements are also elements of the group. In the

> topological space, at least the set, all the elements are coming from the set... I think this [subgraph] is more similar to a subgroup type of definition where that makes sense.

Here, Isaiah is recognizing that in the same way that the subgroup and subspace concepts are defined by a subset relation, the subgraph concept also possesses the subset relation. In this way, Isaiah had constructed the subgraph concept by first identifying that there should be some notion of a subset involved. However, Isaiah also attended to specific differences, further emphasizing the role of analogical reasoning in his structural thinking. In particular, he made an observation regarding how the subgraph was related to the parent graph structure. He stated the following:

> So, in a subgroup, the binary relation, you're still going to have that I guess. And then a subgraph, you don't need to include all the edges, I think, so it's a little bit different because you can just remove one edge from the graph and that still should be a subgraph. But, in a group, you can't remove a binary [relation], you can't remove one of the relations, I guess, and still have it be; it wouldn't be a group then. So, I guess there's a little bit more freedom in a subgraph than in a subgroup or a subspace.

Isaiah appeared to make an analogical connection between the edges between vertices in a graph and the binary operations between elements in a group. By attending to this, he observed that there was "more freedom" when determining subgraphs as opposed to determining subgroups. The fact that Isaiah not only leveraged similarities between contexts, but also made fruitful observations about the differences between contexts, meant that Isaiah's analogical reasoning served as an affordance to his structural thinking.

Constrained Example Space as an Obstacle

Throughout the interview, Isaiah appeared to rely on a constrained collection of examples for graphs. In particular, whenever there was more than one graph present in his reasoning, he almost always chose the second graph to be a subgraph of the first graph. This proved to be an obstacle for his reasoning about the structure of graphs, and specifically the meaning of structure preservation. While testing his definition of graph homomorphism, which he conjectured to require preservation of the number of neighbors, he stated:

> Let me try and see if this definition even holds up with what I'm thinking exactly...Maybe I'll try and do a subgraph of this. I think that may be a better approach...Actually, I think I should change this definition a little bit to be bijective too.

Since he only looked at examples with subgraphs, his current working definition of graph homomorphism would always be bijective. In particular, by attending to only the specific examples including subgraphs, Isaiah was no longer thinking about the underlying structure of graphs, but rather only considered a special case where bijectivity was always present. Even though this was correct reasoning from Isaiah in the context of this example, he did not consider how this addition of structure impacted his definition beyond those cases where subgraphs were present. Instead, he appeared to forcibly add an extra condition due to the result of a single constrained example. Thus, this presented an obstacle to Isaiah's structural reasoning because rather than flexibly considering the validity of his original definition, he chose to add conditions to his definition to satisfy his limited set of examples.

Prior Mathematical Familiarity as an Obstacle

Multiple times during the interview, Isaiah would reference mathematical concepts he had encountered before. Although prior familiarity with concepts can act as an affordance for structural thinking, such as was the case with Isaiah's analogical reasoning about previously known concepts in the domain of group theory and topology, we found that an obstacle also

arose from his desire to inject familiar concepts into unfamiliar situations. A primary example of this included when Isaiah was working through his definition of graph homomorphism. He recognized the importance of preserving the structure of adjacency but kept returning to the number of neighbors because he had "seen this notation before." For instance, he stated:

> Say you have two edges that are both adjacent in the one graph and you apply the function, I think they should end up being adjacent in the other graph as well. I think I could probably prove that by. Yeah, no. So, I don't know. I think the structure and graph is probably pretty, very related to I guess the number of neighbors that stuff has.

Similarly, when working through the concept of quotient graphs, Isaiah expressed how he had seen the "power set of graphs" before, which primarily guided his construction. Unlike Isaiah's reasoning by analogy, which involved calling forth a more tightly connected collection of structural knowledge about group theoretic and topological structures, we found that Isaiah's reasoning in the above examples relied on singular concepts disconnected from any structural foundation. Thus, Isaiah's structural thinking was limited by the concepts he used to conjecture the definitions that were called from memory with no appeal to their structural purpose, causing his prior mathematical familiarity to act as an obstacle to this kind of thinking.

Discussion

The results and analysis from this preliminary study shed further light on the importance and value of structural thinking, especially at the undergraduate level. Beyond this, the results provide evidence that content-specific reasoning and structural reasoning do not always coincide. Particularly, an affordance to one's structural thinking may be an obstacle to their content-specific thinking, and conversely. Isaiah used meaningful, constructive structural reasoning without the correct graph-theoretic definitions. We conjecture that an affordance to both one's structural and content-specific thinking would help generate effective, meaningful learning. However, a more detailed study would be required to address this. Moreover, this study further supported the value of students leveraging analogical reasoning when engaging with new-to-them mathematical concepts (Hicks & Flanagan, 2024a; Lee & Sriraman, 2011). Also, if students can meaningfully construct an abstracted structure for certain concepts, such as sub-structure, they can use that structure to reason structurally in a new context (Hicks et al., 2023).

The results of this study also provided support that learning and understanding concepts in abstract algebra and point-set topology are difficult for undergraduate students (e.g., Larsen, 2009; Melhuish et al., 2020; Serbin, 2023), especially quotient concepts, like quotient groups (e.g., Hicks & Flanagan, 2024b). However, in contrast, these results also revealed that students can generate productive structural reasoning, despite having challenges with the content-specific definitions. In addition, the results highlighted the importance of a flexible example space for structural reasoning, especially in the context of conjecturing new definitions (e.g., Lynch & Lockwood, 2019). When reasoning through concepts with example-related activity, it is imperative that there exists coherence between an individual's structural reasoning within the examples and the general structural property for the concept itself. Finally, Hazzan (1999) claimed that undergraduate students tend to reason with "familiar objects," which can sometimes be an unproductive strategy for them (pp. 76-77). The finding from this study that prior mathematical familiarity can be an obstacle to structural thinking supports this claim.

Using Math Literacy Strategies in Calculus: Amplifying Undergraduates' Understanding of Partial Derivatives

Alexandra Cuadra
Purdue University

Rachael Kenney
Purdue University

Mathematical literacy is a critical component of teaching mathematics as its own language. In this paper, we share the use of a writing to learn mathematics (WTLM) activity to help college students communicate their mathematical thinking and understanding. We conducted an embedded single-case study with two sections of undergraduate students enrolled in a Calculus II course focused on integral and multivariable calculus topics. Three WTLM activities were integrated into the course to provide opportunities for students to explain their symbolic, procedural, and conceptual understandings of partial derivatives and related topics. In this paper we share the framework and tools developed for this study and the data analysis plan and preliminary analysis steps.

Keywords: partial derivatives, concept definition, concept image, math literacy

Traditional teaching practices often limit how students are asked to communicate their mathematical understanding. When considering mathematics as a language, and teaching it as such, we can use practices like those used in language learning to develop mathematical communication skills by paying attention to notations as our alphabet, concepts as our ideas, and mathematical statements as sentences (Alfaro Viquez and Joutsenlahti, 2020; Bruun et al., 2015; Roepke and Gallagher, 2015). Considering mathematics as a language allows instructors to focus on developing students' ability to communicate mathematically by "unpacking" and "repacking" mathematical concepts, procedures, and representations (Viquez & Joutsenlahti, 2020). This ability is one of the components of mathematical literacy, which is "an individual's capacity to formulate, employ, and interpret mathematics in various contexts[including] reasoning mathematically and using mathematical concepts, procedures, facts, and tools to describe, explain, and predict phenomena" (OECD, 2018, p. 67).

In this study, we examine the use of writing to learn mathematics (WLTM) tools to provide opportunities for students to share their concepts beyond traditional representations and procedures and build their mathematical literacy. We focus specifically on the concept of partial derivatives as introduced and used in a combination Calculus II and III course. This topic is important to address in the mathematics classroom because of how applicable partial derivatives are in both math and other STEM disciplines (Becker and Towns, 2012; Bucy et al., 2007; Emigh and Manogue, 2017). We addressed the research questions: (1) What are students' concept definitions and concept images when initially learning about partial derivatives in calculus? and (2) How do topics that use partial derivatives add to students' conceptual understandings? This work is part of Cuadra's larger study using three distinct WTLM activities as data collection sources. In this paper, we share the framework and the data collection tools that we have designed for this study as well as the analysis plan.

Framework

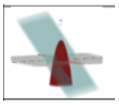
One way of strengthening students' understanding of mathematical phenomena is by associating a concept definition or properties with a strong concept image. A *concept definition* is "a verbal definition that accurately explains the concept in a non-circular way" (Vinner, 1983,

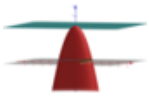
p. 293). A concept definition is similar to the usual notion of a definition in mathematics, except the concept definition includes attributes and properties that the writer of that definition deems important. A *concept image* "a set of properties together with a mental picture" and generally refers to a visual representation or depiction of a particular concept (Vinner, 1983, p. 293). This image may be an illustration, diagram, graphic, or any visual medium that conveys and communicates the essence of a specific idea or abstract notion. Focusing on concept definitions and concept images, we can restructure the teaching of mathematics to become conceptual as well as procedural. As Tall (1992) states ``the individual's method of thinking about mathematical concepts depends on more than just the form of words used in a definition" (p. 496). Hence, students' experiences factor in when they are developing ideas about a mathematical concept. By attending to concept definitions and concept images, students can develop a deeper and more meaningful connection with the material.

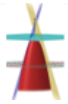
Zandieh (2000) created a framework to study students' concept definitions and concept images of derivatives in a first-year calculus course. Her framework combined different representations of derivatives (e.g., graphical, verbal, symbolic, and physical) and process-object layers of the derivative. The latter come from Sfard's (1992) idea of processes as operations on previously established objects. Zandieh included process-object layers of the concept of derivatives (e.g., ratio, limit, and function) that can be viewed both as dynamic operational processes and as static structures objects.

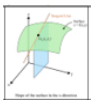
Emigh and Manogue (2017) used Zandieh's framework to analyze students' interpretations of partial derivatives in undergraduate math and physics courses through interviews. Two common interpretations from the students were that partial derivatives relate to slope and change. Roundy et al. (2015) also modified both the content and the structure of Zandieh's framework to study students' concept images of partial derivatives and included content-specific items like experimentally measured quantities. Their framework was developed using what they learned about experts' concept images of partial derivatives.

Following the work done by Roundy et al. (2015), we adapted Zandieh's original framework by using the representations and process-object layers related to partial derivatives as students first learn about them in calculus. To determine the different process-object layers, it is helpful to think of the underlying mathematical concepts that support an understanding of partial derivatives. As partial derivatives are an extension of single-variable derivatives, the original process-object layers for single-variable derivatives found in Zandieh's (2000) framework are still applicable for partial derivatives, namely (a) ratio, (b) limit, and (c) function. In addition, we consider (d) single-variable derivatives as an important added process-object layers of partial derivatives. One key modification is the incorporation of covariation reasoning into the existing framework. as this is a critical underlying concept that supports students' understanding of partial derivatives. Mkhatshwa (2021) used a covariational reasoning framework when studying students' procedural understanding of quantities represented by partial derivatives and found that students tended to shift from interpreting them as rates to interpreting them as amounts. The framework in Figure was used to guide the research design and analysis for this study.









Process – object layer	Graphical	Verbal	Symbolic / Numerical	Physical
	Slope	***Rate of Change***	***Independence of Variables / Ratios of Change***	***Optimization***
Ratio		**Average rate of change**	**$\Delta f/\Delta x$ numerically**	
Limit		**Instantaneous rate of change**	**$\Delta f/\Delta x$ with Δx small**	
Function		**Rate of change at any point/time**	**$\partial f/\partial x$ depending on x**	**Extrema analytically**
Derivative		**Rate of change of f as x changes**	**Treat y as a constant when applying the differentiation rules**	**Extrema graphically**
Covariation	**Direction**	**Coordination**	**Quantitative Coordination**	
Non-layer	**"slope"**	**"rate of change"**	**"independence of variables"**	**"optimization"**

Figure 1. Framework guiding the research design for this study

Methods

Participants for this study included 43 undergraduate students enrolled in an applied calculus course that combined topics from both Calculus II and Calculus III curricula. Cuadra served as the teacher-researcher for two sections of this course.

This study is designed as an embedded single-case study to examine students' understanding of partial derivatives (Yin, 2003). The single case of focus is calculus students' understanding of the concept of partial derivatives. This study is bounded by the topics covered within the Applied Calculus II course and the students participating in the course. Since mathematics is a cumulative subject, it is important to look at the building blocks that encompass partial derivatives, such as single-variable derivatives and functions of several variables, as embedded cases that provide richer information on students' understanding of partial derivatives. In addition, topics that are dependent on deep understanding of partial derivatives including higher-order partial derivatives, extrema(s) of two variable functions, Lagrange multipliers, and double integrals also serve as avenues of inquiry as these applications of the concept can influence understanding. Students used the data collection tools below for each of these building blocks and application topics as well as for the specific concept of partial derivatives. We have a complete set of data from 43 students collected over the course of a semester.

Data Collection

Data was collected using three WTLM math literacy activities intended to help students communicate their mathematical thinking in math courses (Porter & Masingila, 2000). WTLM gives students an opportunity to reflect on their own thinking about the mathematical ideas covered in the class and to communicate their understandings. For this study, Cuadra developed three tools: (a) "The Important" Prompt, (b) an Aspects of Mathematical Phenomenon chart, and (c) learning logs. Roepke and Gallagher (2015) adopted the "The Important" prompt from

Margaret Wise Brown's *The Important Book* (1949) for usage in mathematics classes. In Brown's book, she takes everyday objects and describes what makes each object special. Roepke and Gallagher (2015) adopted this idea in the following activity. First, the students complete the sentence "The important thing about (insert topic) is..." by writing at least five things they found important about that mathematical topic and then write what they found "most important" about the topic. This activity allows students to think beyond the typical "compute" exercises and analyze an idea beyond computation.

The second WTLM tool is one we are calling the *Aspects of Mathematical Phenomenon (AMP)* Chart. It is based on the vocabulary development tool known as the Frayer model (Frayer et al., 1969) which had four quadrants surrounding a featured vocabulary word written in the middle. In mathematics classrooms, scholars have adapted the Frayer model quadrant labels to include things like definitions (in your own words), facts, pictures, examples, and nonexamples (Kenney et al., 2005; Roepke & Gallagher, 2015). Since students are not accustomed to being asked to share a concept image, we have extended this kind of model by creating the AMP Chart to allow students to unpack the aspects of a mathematics concept across six cells and captures a snapshot of their concept definition and concept image. Figure 2 shows an example of a completed AMP chart.

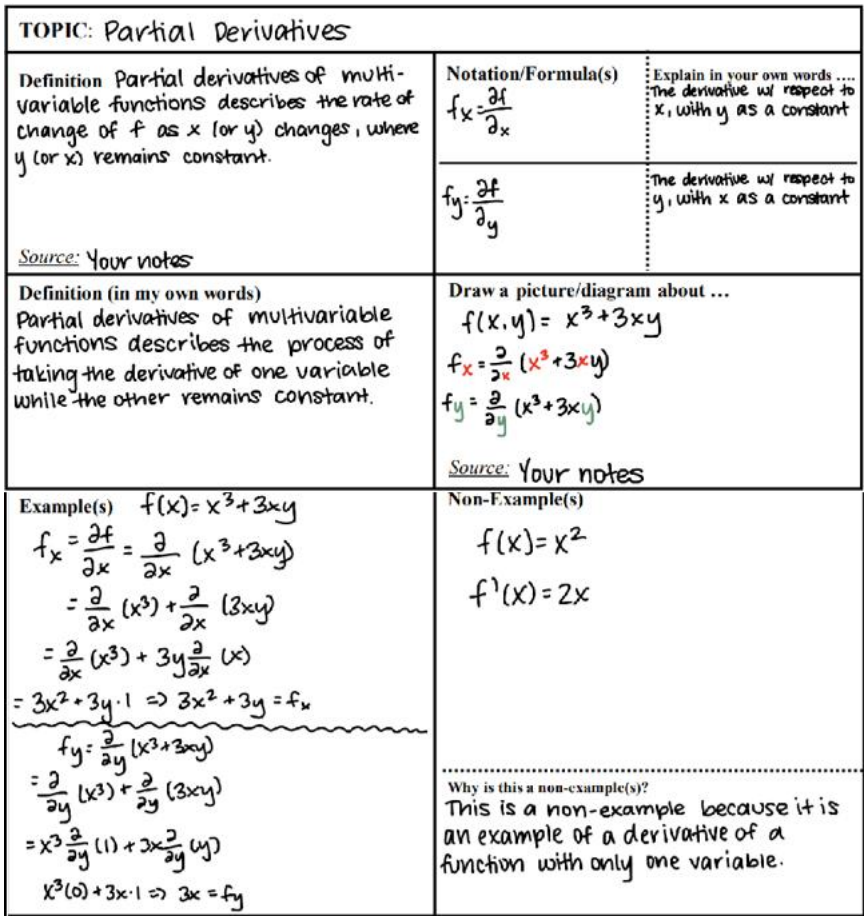


Figure 2. Example of a completed AMP chart by a Calculus II student.

The final WLTM tool used were learning logs, or journals that serve as a collection of student-generated ideas that examine the thinking processes and conceptual understanding of the

students (Carter et al., 1993, p. 87). A key reason to use learning logs that they create connections between language and mathematical literacy (Carter et al., 1993). Learning logs here are reflection prompts that students write to share how their understanding of partial derivative changes after they engage with different representations and applications of partial derivatives.

Data Analysis Plan

As this is a preliminary report, data analysis of the significant amount of data collected is ongoing. We intend to analyze the WTLM activities that students did for partial derivatives and then for topics dependent on partial derivatives (i.e., Lagrange multipliers, higher-order partials, extrema, and double integrals).

We are using a *concept mapping* approach for analysis (Butler-Kisber & Poldma, 2010; Daley, 2004; Moreno, Guthrie, & Strickland, 2023). For the AMP charts, for example, we cut up the chart into six individual cells and are making a concept map for each cell, looking for connections and distinctions across the students' responses. This approach to analysis allows us to consolidate the data into manageable pieces (Daley, 2004) and map our interpretations of the data as these emerge (Butler-Kisber & Poldma, 2010). We deconstruct the students' responses to see what connections the whole group (as our single case) is making to the mathematics topics. Looking across the resulting concept maps for each of the cells of the AMP charts then helps us build a picture of the concept images developing surrounding partial derivatives. A similar process will use the Important Prompt to build a representation of the concept definition of partial derivatives that emerges when students first learn about it. Finally, the learning logs allow us to look beyond a single snapshot of this concept definition and image and see how they are evolving as new topics related to partial derivatives are presented in the course. Figure 3 shows an example of one initial concept maps that we have generated after examining the "Definition" cell of the AMP Chart. Using the Framework described above in Figure 1 allows us to see which process-object layers the students are attending to in these cells.

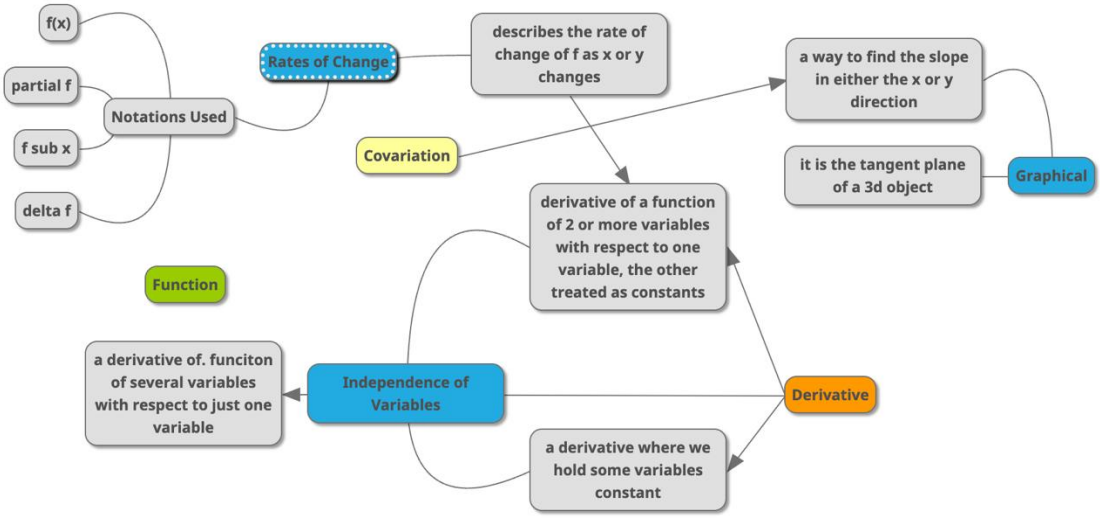

Figure 3. Concept map of students' definitions

Though data has been collected, we are currently just beginning analysis of the data and are eager to discuss ideas about this interesting work with the RUME community.

Here's What "I" Do: Investigating the Actions Students Take in Proof Comprehension Tasks

Lino Guajardo
Texas State University

Kristen Lew
Texas State University

Kate Melhuish
Texas State University

Literature around the reading of proof has focused on experts and the strategies they use to understand the texts they are reading (Fang & Chapman, 2020; Paul, 2018) or in comparing students to experts in what the reader focuses on as they read using eye-tracking technology (e.g., Inglis & Alcock, 2012). Few have investigated the students and their strategies (Weber, 2015). In this preliminary report, we describe the most frequently seen actions taken by participants during various proof comprehension tasks. Our findings indicate that students use a variety of possible strategies to make sense of proofs they are reading. Some of these possible strategies are found to be used by mathematicians and secondary mathematics teachers, while other possible strategies are found to be used in general reading practices.

Keywords: Proof Comprehension, Reading Proof, Student Perspective

Investigations into what students do as they attempt to understand proof can provide insight into how students think about proofs, such as what it means to understand a proof, as well as identifying what strategies students commonly rely on when they arrive at a confusing part of a proof. Both math education and literacy scholars have investigated various ways in which mathematicians read proof (e.g., Fang & Chapman, 2020; Inglis & Alcock, 2012; Paul, 2018; Weber & Mejia-Ramos, 2011), though few have investigated how undergraduate students read proof (Inglis & Alcock, 2012). In proof comprehension, scholars focus on assessing or improving students' comprehension of proof (e.g., Hodds et al., 2014; Mejia-Ramos et al., 2017; Roy et al., 2017), with less attention on what the students do as they read proof for understanding (Dawkins & Zazkis, 2021; Weber, 2015). Considering the student and the actions they take can provide important information in the development of interventions. These interventions can be aimed at further developing these skills by building on student starting points. In this preliminary report, we set out to answer the following research question: What actions do students take to help with their understanding of a given proof during proof comprehension tasks?

Literature Review

Scholars have investigated various ways in which mathematicians and students read mathematical text. These could be through comparing what experts and novices attend to while they read proof using eye tracking for proof validation tasks (Inglis & Alcock, 2012), how mathematicians determine the validity of a proof (Weber, 2008), why mathematicians read proofs (Mejia-Ramos & Weber, 2014; Weber & Mejia-Ramos, 2011), or in what mathematicians do as they read a proof about unfamiliar material (Wilkerson-Jerde & Wilensky, 2011).

Literacy experts have also investigated the reading habits of mathematicians and secondary education teachers. Fang and Chapman (2020) discuss a case study of the reading strategies employed by one mathematician as they read a journal article. Paul (2018) describes the different reading strategies used by various secondary education content teachers, one of which is a mathematics teacher. They both report various strategies such as annotating, evaluating and verifying, corroboration (such as using prior knowledge or other texts), and strategic reading (such as rereading, sectioned reading, or skimming).

The studies described above focus on comparing mathematicians to students or focus purely on experts in how they read and the strategies they may employ as reading. Little has been conducted to see what students do as they read mathematical text. One exception is Weber (2015) who investigated what strategies students use as they read proofs. Weber (2015) and Samkoff and Weber (2015) report seven strategies used by the students or recommended to be used by mathematicians. Mathematicians recommended readers should make sure they understand the definitions of all terms (Samkoff & Weber, 2015), while students were reported to see if the proof can be broken into independent parts, identify what proof methods are being used, and see why confusing statements are true with a particular example (Weber, 2015).

Theoretical Framing

Afflerbach et al. (2008) defines reading strategies as "deliberate, goal-directed attempts to control and modify the reader's efforts to decode text, understand words, and construct meanings of text." (pg. 368) Within the realm of reading proofs, we define a strategy as deliberate acts from the reader with the goal of understanding some subset of a given proof. Thus, we define a proof comprehension strategy as any action of the reader that is done outside of the proof's text with the goal to understand some portion of a given proof (inclusive of the whole proof). By outside of the proof's text, we mean the student is engaging in furthering their understanding through actions that are not done or recommended within the proof. In this preliminary report, we focus on the actions the students take that may make up a proof comprehension strategy.

Methods

The study described here is part of a larger dissertation study investigating the strategies students use to understand proof. In this section, we describe the methods pertinent to the results. Eight participants were recruited for this study, each of which had completed an introduction to proof (ITP) course the semester prior to data collection. Table 1 shows participant information using participant chosen pseudonyms.

Table 1: Participant Information

Participant	Race/Ethnicity	Gender	Grade Received in ITP
Adrian	White or Caucasian	Non-binary	B
Claire	White or Caucasian	Female	B
Erik	White or Caucasian	Transman	A
KTRM	Latin/Hispanic	Female	C
Marie	Latin/Hispanic	Female	A
Olivia	Mixed Race	Female	B
Tifanni	Latin/Hispanic	Female	A
Zeus	Latin/Hispanic	Male	B

Each participant was met with for seven semi-structured interviews. Four of those interviews involved a proof-comprehension task where participants were asked to read a provided complete and correct proof and to think-aloud as they tried to understand the proof to the best of their ability. Table 2 shows the four theorems for context of the study (proofs have been excluded due to space). After finishing the task, participants were asked various questions on their beliefs of their understanding of the provided proof, the difficult parts of the proof, and about the actions taken as seen by the interviewer.

Interviews were video and audio recorded. Video recordings were open coded (Strauss & Corbin, 1998). Instances were first coded by the first author based on ostensive cues (verbal,

written, or gestural indicators). Through the initial open coding, code names and descriptions were given to each instance. Once all instances were open coded, a second round of coding was done by the first author to refine code names (actions), and subcodes were also given during this time to further differentiate the actions taking place.

Table 2: Theorem Statements for Proof Comprehension Tasks

Theorem	Theorem Statement
1	If $a, b \in \mathbb{N}$, then there exists integers k and l for which $gcd(a, b) = ak + bl$.
2	Suppose R is an equivalence relation on the set A. Then the set $\{[a] \mid a \in A\}$ of equivalence classes of R forms a partition of A.
3	Let $f: A \rightarrow B$ be a function. Then the inverse relation f^{-1} is a function from B to A if and only if f is bijective. Furthermore, if f is bijective, then f^{-1} is also bijective.
4	The sets $\mathcal{P}(\mathbb{N})$ and $\mathbb{R}$ have the same cardinality.

Results

Through open coding of the instances, 34 different actions were found amongst the 8 participants across all four proofs. Due to limited space, we focus our results to the most frequently used actions. To determine this, we set a lower bound of 5% of the total final actions coded (1096) and required the actions to be done by at least five out of the eight participants. Seven actions were found to meet these requirements: Asks for Meaning, Creating Warrant, Identifying Proof Structure, Making Connection, Marking Proof, Rereading, and Writing Information. Table 3 shows the frequency of each action per participant, with each student's highest frequency bolded.

Table 3: Action Frequency per Participant

Student	Coded Action						
	Asks for Meaning	Creating Warrant	Identifying Proof Structure	Making Connection	Marking Proof	Rereading	Writing Information
Adrian	11	**39**	9	13	0	14	9
Claire	6	**36**	5	13	1	11	25
Erik	5	**20**	18	6	4	5	19
KTRM	4	**15**	0	4	2	6	7
Marie	5	**22**	14	15	9	14	17
Olivia	11	15	3	6	11	16	**25**
Tifanni	7	11	8	8	10	**32**	8
Zeus	10	12	16	4	**41**	9	7
Total	59	170	73	69	78	107	116

The creating warrant action was the most frequent action taken by all but three participants (Olivia, Tifanni, and Zeus). In these instances, participants focused on justifying an explicit or implicit claim made in the proof. The justifications presented by the participants were coded even if the justification was incorrect or incomplete (such as deciding to move on from the claim without finishing their justification). The data used to warrant a claim varied amongst instances, such as filling in skipped algebraic steps, using a previously self-made conjecture, using the definition of a concept, using a self-made diagram, using a self-made example, using their own reasoning, using a previous part of the proof, or using their own previously made written work.

The most frequent action for Olivia was writing information, which was among the top seven actions for all remaining participants (except Adrian). This action consisted of a participant

writing information either on a separate sheet of paper or on the sheet of paper containing the proof. This action was coded specifically when a participant wrote information that was already presented to them (such as a definition that was given to them by the interviewer on a separate slip of paper, the defining of a set or function in the proof, a claim made within the proof, or the rewriting of an example they created) or when the participant wrote a conjecture of their own. Further variety was seen through the reasoning behind the writing of the information. Participants commonly stated they wrote information for two reasons, either to keep track of important information for ease of referencing or to help them understand information presented to them. Figure 1 shows the notes Olivia took during their time reading Theorem 4's proof. In these notes, Olivia wrote the function f that is used, initially doing this to keep track of the function and have an easier time referencing it. She later used this written work to make sense of the function in what values n and a_n could be.

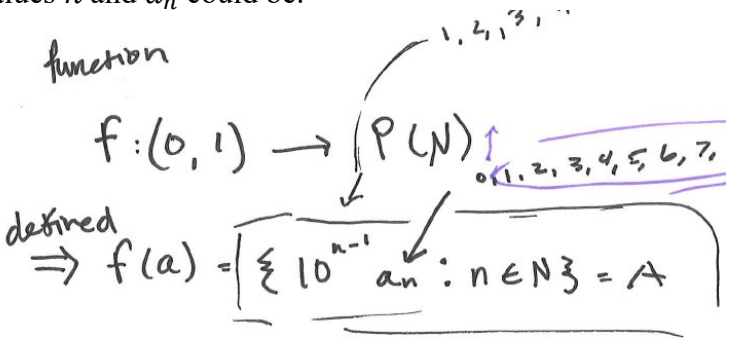

Figure 1: Some of Olivia's Notes for the Proof of Theorem 4

The most frequent action for Tifanni was rereading, which was among the top seven actions for all participants. These instances varied in what was being reread, such as rereading some part of the proof or a provided definition. If rereading some part of the proof, participants could have reread the whole proof (including or excluding the theorem statement) or a line, paragraph, or theorem of a proof. Participants would at times also have specific styles of rereading. Two such styles were rereading but stating the highlights, as if creating a summary of the proof (categorized as a subcode), or purposefully rephrasing (subcode) a line of the proof for ease of reading. For example, as Tifanni's read the proof to Theorem 3, she reads the line "Let $b \in B$" as follows: "Let bee exist in bee, oy [sic], let little b exist in big b." Here Tifanni is making a distinction in the letters noting "Which b am I talking about? Like in my head. Because of course I'm seeing them, but since I'm reading it, I'm like, so I'm talking about *this b*, not *this other b*" (emphasis added). Participants frequently reread to better understand what they just read, either immediately or after having established more information from later text or a definition.

Marking the proof was the most frequent action for Zeus and within the top seven for Marie, Tifanni, and Olivia. This action commonly consisted of participants underlining, dotting, or boxing parts of the proof. This was typically done to draw attention to key claims made in the proof – such as in Theorem 3's proof with the final claim of an argument being that f is onto. Participants would also use these markings to highlight parts of the proof they were still confused about. Erik, Marie, Tifanni, and Zeus had identifying proof structure in their top seven most used actions. Identifying proof structure actions varied between what the participants were identifying. These ranged from identifying independent parts of the proof, what the proof needed to show to prove the theorem, what proof method was being used, or what purpose a part of the proof was playing towards proving the theorem.

Making connections was in the top seven most frequently taken actions by all participants except for Olivia and Zeus. When making connections, participants would identify a relationship (typically through similarities and differences) – or lack thereof – between various texts or concepts. Participants commonly discuss a noticing between the proof and some other text – such as an example the participant created, another part of the proof, the theorem statement, or a definition of a concept. For example, Theorem 2's proof uses a contrapositive argument to show that equivalence classes are disjoint. Participants frequently discussed the differences between part of the definition of partition (that if two sets are not equal they are disjoint) and the start of one of the paragraphs of the proof (assuming two equivalence classes are not disjoint).

Lastly, asking for meanings was in the seven most frequently taken actions by all participants except Claire, Erik, and Marie. Participants would ask the interviewer for the meaning of a definition, notation, or theorem referenced in the proofs. Participants commonly discussed needing the definition to remind themselves of a concept or to help make connections between the proof and the definition. For example, participants frequently stated they needed to use the definition of partition to help see the structure of Theorem 2's proof, as they commonly could not recall (or were unfamiliar with) the definition of partition.

Discussion

Participants took a variety of actions as they attempted to understand the four proofs they were shown. Similar to Weber (2015), participants created warrants for claims, identified different proof structures, or attended to the meaning of terms used within the proof. Though, in our study we see more distinctions in the warranting of claims and expand on these distinctions. First, our participants warranted claims in a variety of ways. Either through examples, diagrams, definitions, their own reasoning, or using prior parts of the proof. This shows students are using more than just examples to make sense of claims they do not see immediately. Additionally, participants not only attended to the meaning of terms within the theorem statement (as described by Samkoff & Weber, 2015), but this extended into the proof itself. Participants frequently ask for definitions they were able to (and did) recall, as a way to ensure their thinking was correct. We also identified actions novel to Weber (2015), such as rereading, marking proof, writing information, and making connections.

Though novel to Weber's study on undergraduates, these actions can be seen being used by mathematicians and secondary mathematics teachers in literacy studies. Fang and Chapman (2020) describe their mathematician participant corroborating (making connections), rereading, as well as evaluating (creating warrants). Paul (2018) describes secondary mathematics teachers rereading, annotating (writing information and marking proof), and corroborating (making connections). Our study shows that students are doing actions similar to those found in the literature by taking general reading strategies and using them while reading proof. That is, novice provers bring a rich array of strategies for comprehending proofs. By identifying the strategies students bring into the proof setting, we are taking the first step in developing a theory of what strategies students use, what contexts lead to the use of certain strategies, and when and how particular strategies serve to be productive for students to generate insights. This can lead to targeted instruction and support for students to develop their emerging proof comprehension strategies. Future research from the larger dissertation study will be to describe these strategies in what kinds of strategies students use, how they are used, and how they may differ between uses. Limitations to this study are that participants saw a finite set of proofs and the actions they took may have been due to the types of proofs or in their familiarity with the content as they had just completed an introduction to proof course.

Instructors' Vulnerability, Curiosity, and (Dis)trust of Data Informing Critical Transformations in Mathematics

This preliminary report examines the reactions of mathematics instructors in Networked Improvement Communities as they engaged with student experience data to inform critical transformations within mathematics. Data-driven decision-making is promoted for improving equity; however, without a specific critical focus such efforts will likely fail. Examining data critically requires instructors to grapple with, at times, painful experiences of students, and their role in shaping these experiences. Using critical ethnography, we analyzed field notes to identify ways that instructors responded to data in meetings held from Spring 2023 to Summer 2024. Findings show that instructors' reactions to data often fall into two categories. Ego threat, characterized by reactions such as discomfort and defensiveness, effectively delegitimized student data. In contrast, some instructors exhibited curiosity and vulnerability, viewing students as experts of their experiences. Ongoing research will explore how ego threat shapes critical efforts and how fostering openness can enhance critical data-driven decision making.

Keywords: data, decision making, equity, critical transformations, mathematics instructors

Although the term "data-driven" is prevalent in research, data do not drive themselves (Bensimon et al., 2007); data are collected and analyzed by people with their own experiences, perspectives, agendas, and biases. In the context of education, instructors and institutions hoping to engage in data-driven decision making (DDDM) may inadvertently reinforce ideologies that perpetuate existing inequities in education (Datnow, 2017; Dodman et al., 2021; Taylor Jr., 2020). As such, Dodman et al. (2021) argue that a critical approach to DDDM is necessary in equity-focused transformation efforts. However, because a critical approach requires challenging dominant practices and interpretations, educators may struggle to enact a critical approach to DDDM. The purpose of this study is to examine the data use practices of mathematics instructors as they worked within Networked Improvement Communities (NICs) that specifically encouraged DDDM to identify critical transformations needed within their mathematics programs (Hagman et al., 2024). NICs (Martin et al., 2020) are networked communities of people using data to work toward a common improvement goal. For this preliminary report, we asked: How did mathematics instructors respond to data about student experiences in the context of making critical transformations in mathematics?

[1] Authorship is based on four levels: Bennett and Funk contributed equally as first authors (Level 1); Fantin-Hardesty and Tremaine contributed equally as Level 2 authors; Callahan, Quaisley, and Smith contributed equally as Level 3 authors; and Courtney, Hill, and Hagman contributed equally as Level 4 authors.

Theoretical Perspectives

Dodman et al. (2021) argue that a critical approach to data-driven decision making practices (CDDDM) is necessary to help achieve social justice and equity aims. Within their framework, a teacher's data use practices are viewed to be a function of their identities and beliefs about data, students, and their own agency or efficacy to address inequity in and outside the classroom. As such, CDDDM demands that educators reflect upon and challenge their identities and beliefs; this can be a vulnerable and uncomfortable process, similar to the process that educators must go through when learning to engage in equitable teaching practices (e.g., Tuitt et al., 2018). Indeed, engaging in critical transformation work demands vulnerability (Gilson, 2011). Drawing from work on whiteness and emotional politics, we view vulnerability as the capacity for "hearing, seeing and feeling (being affected by and affecting) experiences of oppression" (Wale, 2019, p. 1194). In the context of this study, we specify that vulnerability may come into two forms: (a) pedagogical vulnerability is the capacity to be open with a group of peers collectively engaged in critical transformation efforts informed by data and (b) emotional vulnerability is the capacity for being affected by and affecting the experiences told by students through data. Both forms of vulnerability necessarily require understanding one's own role (and at times complicity) in these experiences: people have to be in a "brave space" (brown, 2017) of admitting the status quo is not good enough to themselves and to each other--their teaching is not good enough, their department is not good enough--to engender more equitable mathematics teaching and learning.

Pedagogical vulnerability resides in the interactions among instructors (Mangione & Norton, 2023). Due to the vulnerable nature of critical work, effective NICs must foster a culture that supports vulnerability and encourages critical action. NICs do not automatically result in pedagogical vulnerability; such a state is achieved only when the members intentionally build a space of trust where they have a willingness and openness to explore their vulnerability with others (Kelly, 2013). Within the NIC literature, relational trust is a strong indicator of health of a NIC, and crucial to supporting exploration, experimentation, and change (Henrick et al., 2017).

Because engaging in CDDDM may bring discomfort, some people may experience "ego threat", a threat to one's self-image or self-esteem, (Gregory & Mebane, 2020) when they encounter data or situations that challenge their professional self-efficacy or teaching identities as "good" teachers. Common responses to ego threat are denial (devaluing the meaning of the data), avoidance (ignoring or dismissing data), defensiveness (making excuses for the discrepancy between role expectations and the data outcome), or attack (challenging the validity of the data or confronting the person sharing the conflicting opinion). Within a community of fellow mathematics instructors, discomfort may also bring about efforts to comfort one another or absolve each other's role in the negative experiences of students - we view this as similar to what Applebaum (2017) describes as the practice some teachers engage in of comforting discomfort students may face in a social justice classroom.

Methods

This study uses data from the ACT UP Math project (NSF DUE-2201486) involving university mathematics departments with NICs engaged in critical transformation efforts. Kappa University, a private doctoral-granting institution in the Southeastern United States, and Tau University, a public doctoral-granting institution in the Southern United States, are the two institutions of focus for this analysis. Our research utilizes critical ethnography (Palmer & Caldas, 2015) as its methodological approach. As part of a research-practice partnership (Coburn et al., 2021), we are deeply immersed in the data, acting both as ethnographic researchers and participants. Since Fall 2022, we have collaborated closely with the NICs to gain insights into

their institutional environments and objectives concerning critical transformations toward diversity, equity, and inclusion, while systematically documenting all interactions. While NIC membership evolved over two years, the Kappa and Tau NICs maintained 8-11 members each composed of mathematics instructors, administrators, and students.

To determine the critical transformations needed to make their introductory mathematics programs more equitable, each NIC explored institutional data and engaged in a critical, data-driven decision-making process. The NICs began collecting new institutional and classroom-level data in Spring 2023, and continued to discuss data collection and analysis as they met in subsequent semesters. For this analysis, we initially reviewed the structured field notes from all monthly NIC meetings between Spring 2023 and Summer 2024 to identify instances in which data about student experiences were explicitly discussed. We engaged in multiple rounds of open and theory-driven coding (Maxwell, 2005). Each of the field notes were initially open coded by two researchers; then, we independently aligned our open coding with the theory referenced above and met to discuss salient themes. The themes of instructor responses included: curious, vulnerable, reflective, questioning, devalue/dismiss, defensive, doubt/skepticism, attack, disappointment, (un)surprise/shock, and planning/action. We sorted the themes into larger categories and discussed the wide range of responses and the multiplicity of particular codes. We present these themes in our findings and later discuss multiple avenues for continued analysis. All names used in the following sections are pseudonyms.

Findings

We sorted our themes of NIC members' responses to data into two categories. Several of the reactions of NIC members to data could be classified as responses typical of ego threat (Gregory & Mebane, 2020) and other reactions of NIC members conveyed open dispositions (curiosity and vulnerability) toward the data. We elaborate on these two overarching themes below.

Related to Ego Threat and Comforting Discomfort

We first present two conversations among members of the Tau NIC and the Kappa NIC that illustrated doubt, dismissal, and devaluing of the data. The first exchange occurred during the Tau NIC's first summer meeting in 2024, as members viewed the survey data collected from their students in the spring semester. The survey included items about engagement during and outside of class, sense of belonging, expected final course grade, and demographic information.

> *Jordan (Instructor)*: If we look at the average [of student engagement data…], it seems to contradict what we see from final exam grades. Students say, "We are engaged. We are doing the work." I put some questions in the [review] that are the same as the final exam, and I was surprised to see that the majority of students failed those questions on the final. So this contradicts what I see. This [data] is aspirational, not real.
> *Olivia (Admin/Instructor)*: It's our data!
> *Jordan*: Students are not giving their true data.

In this conversation, Tau NIC members expressed distrust, either of the students providing the data or of the representation of the data. Viewing the quantitative data as "not…true" or "aspirational" justified their responses to dismiss the student feedback presented.

The second conversation occurred among Kappa NIC members in Fall 2023 as they examined institutional data about student experiences in mathematics courses gathered through a large-scale survey. Senna questioned how useful or legitimate the data were:

> I'm not saying it's invalid data, but I think we've tried– made a lot of efforts since then to try to fix things? Obviously, they're still not where we want them to be, but I wonder if […] student morale was even worse then.

The discussion continued as other instructors asked when the data were collected and suggested that they administer the original survey again, since "that was all pre-COVID" and "a long time ago." When presented with data that indicated low student morale, the Kappa NIC dismissed this finding by acknowledging the data was older and possibly not reflective of more recent reform efforts. Senna, an instructor, implied that student morale has improved in light of their efforts, while also admitting that their efforts are "still not where we want them to be."

In both the Kappa and Tau NICs, there were instances where data from student focus groups were dismissed due to assumptions about students. During one Kappa NIC meeting in Spring 2024, one member described students' perspectives from a student focus group as "ridiculous" and not valuable when those suggestions advocated for dispelling certain normative practices in mathematics education, such as administering exams or collecting homework. Some of the Kappa NIC members continually asserted that "students love to complain," and in turn, they dismissed some of the focus group students' experiences and ideas. Similarly, during a Tau NIC meeting, one NIC member (an instructor) shared that "students said that other students should take easy classes along with mine," other NIC members consoled him that "students always complain" that their class is too hard. We found these instances noteworthy as both NICs pushed back on the suggestions from students and sought to comfort each other when facing critiques.

Related to Curiosity and Vulnerability

In some instances, data exploration fostered curiosity about student experiences and department practices. For example, Tau members recorded their own teaching and shared their observations with the NIC. Olivia reflected on their receptivity to make data-informed changes: "I think it may be impacting the rest of the NIC to be able to see someone else [another instructor] being vulnerable and being curious and willing to try something different in practice." Olivia noted the influence of NIC members' attitudes about the data on one another. At Kappa, student focus group data revealed that some students struggled to take calculus with peers who had already taken the course before. This prompted curiosity from instructors about department practices (e.g. "How does the department decide what to recommend students take?").

At times, NIC members displayed vulnerability in responding to data, particularly as it connected to their own instruction. For example, during a Tau meeting, Garrett presented a qualitative analysis of his students' responses to a survey administered in Fall 2023. In response to some of the data, he shared "I got my feelings hurt." But Garrett also shared that his approach to data had shifted from the prior semester, in which he reacted defensively to focus group data: "the purpose of this [data analysis] is not to confirm I'm doing a great job. [I] wish I had that mindset with the focus group [data collected in Spring 2023]." These quotations from Garrett represent a shift in perspective about data - from expecting that data would "confirm" his beliefs, to using data as a tool for questioning teaching practices. At Kappa, an undergraduate student NIC member shared an anecdote about the way in which students bond over "hating on math." Skylar said that "I'm into bonding. I am happy to be the brunt of jokes for bonding." Her sincerity in welcoming such bonding demonstrates her willingness to validate students' perspectives and experiences, even when it leaves her as "the brunt of [their] jokes."

The following conversation further highlights how NIC members remained open to the data through receptiveness and a willingness to (re)consider their roles in conversation with the data:

Connor (Instructor): I don't see anything revelatory in this data. Waiting for you all to disagree with me.

Natalie (Instructor): I would love to. Partially using this as confirming what I expected. Not sure how this informs what we should do. Maybe we're seeing it wrong - maybe it's about us not seeing what we want in the data.

Connor: What did we do?

Natalie: This is like a control, baseline. What can we change to change these data?

Jordan (Instructor): I would expect the STEM students to outshine the non-STEM majors, but it's not that way.

Natalie: I'm going to go back to the questions - the data is not revelatory. I'm wondering about - maybe we should stop looking at the confirmation of what's working. I'm wondering if there was one thing I did, verbally or in class work, or in feedback on exams, how could I, if I intentionally went in to increase students' sense of belonging.

In this exchange, Tau NIC members exhibit curiosity about what the data are saying and even question their own assumptions. They think about how the data from students can inform their practice and seem receptive to making changes.

Questions for Discussion and Directions for Future Work

Our preliminary findings illustrate how mathematics instructors reacted to data with responses characteristic of ego threat (Gregory & Mebane, 2020) and curiosity and vulnerability. One future direction of this work is to use an ego threat framework as a way to address how threats to professional self-efficacy, self-esteem, and the identity of being an mathematics instructor manifest in the delegitimization of data within equity-oriented reform efforts. There are legitimate reasons for distrusting or being skeptical of both qualitative and quantitative data; however, we wonder to what extent responses that align with ego threat hinder the progress of the NICs to make data-informed decisions. In our previous work which focused on students as experts of their own experiences and as partners in institutional change efforts (Hagman et al., 2024), we noted how some instructors easily delegitimized data about students' experiences when students were viewed as dishonest, "complainers," naive, or, in other words, not as experts. We plan to continue this work by examining how anti-deficit perspectives influence the positioning of students as partners and how that impacts the progress of the NICs. Other directions for future exploration related to CDDDM include:

1. How can instructors be supported in being vulnerable to what students share about their experiences during data collection?
2. What data do instructors find compelling or convincing and for what purposes (e.g., to inform implementation)?
3. What are the implicit arguments, beliefs, etc. shared by instructors as they engage with and make use of the data?

Dodman et al. (2021) suggested that CDDDM is influenced by an instructor's identity and beliefs. We plan to analyze other sources of data (e.g., interviews, journal entries) to study the connection of beliefs and the arguments made by instructors as they work toward CDDDM. In this proposed preliminary session, we would like to engage in dialogue with fellow scholars to brainstorm ideas for further exploring these questions.

An Analysis of the Conceptual and Authentic Opportunities in Calculus I Textbook Tasks

Erin Barno

Devon Kinsey
ETS

Gatekeeper mathematics courses, including calculus, historically prevent marginalized students from pursing STEM majors by often focusing on procedural fluency over conceptual depth. Efforts to better prepare students for future career pathways include using tasks that emphasize authentic application contexts. In this study, we analyzed application tasks within the first half of the derivatives unit for two commonly used undergraduate Calculus I textbooks. Our analysis identified both the authenticity of the application context, and the conceptual understanding required to solve each task. By juxtaposing these task features, we found notable discrepancies between the degree to which tasks presented conceptual opportunities within authentic, real-world applications. These preliminary findings inform the need for further research investigating the relationship between conceptual understanding and authenticity in application tasks. This work can inform the design of novel tasks which appeal to both features, thus better preparing students to succeed in both calculus and future degree pathways.

Keywords: calculus, textbooks, authentic applications, conceptual understanding

Introduction

Entry-level collegiate mathematics courses, such as Calculus I, often function as gatekeeper courses because they are historically documented to prevent students marginalized by their racial and/or gender identities from pursuing STEM majors (Battey et al., 2022; McNeill et al., 2022; 2023; Leyva et al., 2021). Considering the importance of such courses for students' success in a variety of career pathways, there is a need to investigate approaches to make such courses mathematically rich, contextually relevant, and accessible. One approach to address this problem is to understand if tasks within these courses present opportunities for conceptual mathematical engagement within authentic applications (i.e., tasks with a real-life context where a concept from a mathematical course is being used in a way that is relevant to that context). While there have been studies about the opportunities for conceptual learning available to students in gatekeeper courses such as Calculus I via textbooks (Palm et al., 2006; Tallman et al., 2021), there has not been an analysis that identifies those opportunities as presented within authentic applications. Identifying if those opportunities exist, even just within textbooks, can impact whether undergraduate students engage with mathematics concepts as relevant within contexts outside the mathematics classroom. Furthermore, such an analysis can shape curriculum writing and assessment development to address the problem of gatekeeper courses. Therefore, this paper attends to this problem by asking the following research question: *In problems available within the derivative lessons of Calculus I textbooks, how do the tasks in textbooks compare in terms of conceptual understanding within tasks with real-life applications?*

Literature Review

Much of the existing research on gatekeeper courses focuses specifically on calculus, which is often considered to represent the thinking necessary to thrive in ambitious, STEM-forward

careers. The body of literature suggests different interpretations of what is considered a relevant and meaningful task for students within the calculus context. First, calculus courses vary in terms of which standards are covered and how those standards are sequenced, which has led to high attrition rates (Barr et al., 2022; Schmidt et al., 2022). Second, among those standards covered, calculus courses often focus on learning outcomes that exceedingly prioritize procedural accuracy (NCES, 1995). Both structural elements of calculus courses contribute to *weeding out* students who are assumed unable to thrive, demonstrating the current role of calculus as a gatekeeper course (Ellis et al., 2015; Larsen et al., 2016; Leyva, 2021). Finally, although calculus courses are deemed critical steppingstones for students to access STEM careers, there is evidence that minoritized groups are underrepresented in the enrollment and completion of such courses (Adelman, 1999), and that the coursework does not include clear connections to students' interests or lived experiences (Adiredja, 2021; Alzaga Elizondo & Larsen, 2024; McNeill et al., 2022). Together, the combination of inconsistent content standards and mathematical expectations leads to course-wide structural decisions that, intentionally or unintentionally, push students out. This, alongside evidence of the under-enrollment of minoritized students, suggests a need to intervene in how calculus concepts are shared.

One place to intervene is to investigate whether the mathematical tasks available in gatekeeper courses can challenge students' prior experiences with conceptual and application-based tasks. In elementary and secondary mathematics classes, students develop habits to find and complete computational steps on tasks that include applications without considering or acknowledging the context provided (Schoenfeld, 1989). After secondary mathematics courses, students further develop habits to ignore how the numbers, units, and operations within real-world problems conceptually relate to the challenge presented within context (Reinke et al., 2024; Schoenfeld, 1989; Verschaffel et al., 2000). Even the intention to interweave conceptual ideas to real life applications can be irrelevant if the tasks can be solved by only attending to the associated procedural computations. Although not a complete solution, understanding what tasks are commonly available for professors to assign students provides an initial step toward mitigating courses like Calculus I from gatekeeping students.

Methods

To identify opportunities for students to engage in conceptual understanding within authentic applications, we focused on the sections introducing one core calculus concept, derivatives, across two textbooks. We selected the textbooks by surveying publicly available syllabi to create a sample which reflects different approaches used across calculus courses, being a traditional textbook (Rogawski, 2011) and a problem-based textbook (Boelkins, 2013). For the analysis, we examined problems specifically within sections that (1) introduced to the derivative and (2) introduced to the concept of the derivative as a function. To select problems to answer our research question, we examined whether problems included text outside of the expression, equation, or directions that was situated in some real-life context. We adapted two frameworks (Greene & Shorter, 2017; Palm, 2008) into deductive coding schemes (Fereday & Muir-Cochrane, 2006) to measure conceptual richness and authenticity, which were used to assign each for conceptual rigor, based Greene & Shorter's (2017) conceptual understanding weighting system (CUWS), and another for the authenticity of the application, based on Palm's (2008) research on authentic applications (AA).

To rate a task's conceptual understanding (i.e., CUWS score), a task could earn a point for the *skills* required (i.e., if the task did not involve only computational or algebraic skills or memorized facts, and required understanding of the concept), the *method* required (i.e., if the

task could not be answered completely using a method that the student might have developed in prior coursework), and the *conceptual rigor* required (i.e., if the task involved interpreting the meaning of mathematical characteristics, making connections between different representations of mathematical characteristics, and/or proving or justifying mathematical statements), with a maximum of 3 points available. To rate the authentic application (i.e., AA score), a task could earn a point for each of the following: the *event* (i.e., if the real-life scenario described in the task was an actual event, and not a statement about a relationship between two variables in a context), the *question* (i.e., if the question inherent to the task was one that might be reasonably asked outside of the classroom), the *purpose of the task content* (i.e., if answering the question about the event would provide clarity regarding the event), the *language use* (i.e., if the language specific to the event did not hinder answering the question), and *the existence, realism, and specificity of data* (i.e., if the information provided contained realistic values that could be considered close to corresponding values in real life), with a maximum of 5 points available.

Each task was coded by the first and second author in three stages: first, using the original adaptations of the two frameworks for each task; second, adapting the framework based on any discrepancies identified by the coders (Campbell et al., 2013); and third, to complete consensus coding (Watts & Finkenstaedt-Quinn, 2021).

Preliminary Findings

Between the two analyzed textbooks, there was a difference in the prevalence of tasks with some application context. For the traditional textbook, 15 out of 198 tasks examined (7.5%) included an application context; for the problem-based textbook, 29 out of 66 tasks examined (44%) included an application context. After analyzing the conceptual richness and the authentic application of each task including some application context, we additionally found differences in the average CUWS and AA scores between both textbooks (Table 1). First, the central tendency descriptions of the CUWS scores for tasks within each textbook varied, with the traditional textbook having a mean and median CUWS score in the lower third range and the problem-based textbook in the upper third range. However, there was not a noticeable difference in the mean and median AA scores. This suggests that both textbooks presented similar opportunities for authentic applications, but with varying conceptual richness between textbooks.

Table 1. Analysis of Derivative Tasks in the Traditional and Problem-Based Calculus I Textbooks

		CUWS Score		AA Score		Absolute Difference	
Textbook	Number of Tasks	Mean	Median	Mean	Median	Mean	Median
Traditional	15	1.27	0	3.33	3	2.27	3
Problem-Based	29	2.52	3	3.58	4	1.31	1
Difference		1.25	3	0.25	1	0.96	2

Contrasting Characteristics: Absolute Difference between CUWS and AA Score

The differences most pronounced in the average absolute difference between a task's CUWS and AA score (Table 1). This value emerged as we collected the combinations of CUWS and AA scores, noticing that the range between one score and another indicated an important variation between problems that happened to have the same CUWS score (for instance) and a different AA score (and vice versa). In other words, the absolute difference denotes if there exists a difference in the intensity of a task's CUWS and AA score, where larger values indicate that a task is lacking in either its conceptual complexity or its authentic application, despite having a stronger score in the other category. In what follows, we illustrate the differences in the contextual richness of two tasks that cover similar Calculus I content with a similar degree of authenticity.

The two tasks described represent the variation possible in CUWS score for tasks with the same AA score. One of the tasks is drawn from each textbook; the tasks were in similar sections in which the derivative had been defined and introduced but not yet calculated. The task in the traditional textbook, Task A, had a 0-3 score (CUWS-AA) and asked students to use the symmetric difference quotient (SDQ) to approximate the derivative at a certain point within the context of vapor pressure and water temperature. The task in the problem-based textbook, Task B, had a 3-3 score (CUWS-AA) and focused on the US census in Grand Rapids, MI, asking students to compute the average rate of change over an interval that gets smaller. Task A was given a CUWS score of 0 because the task only involved computational and algebraic skills; the task provided the formula to compute the SDQ as a more accurate way to estimate the derivative than the difference quotient, and the context of vapor pressure was irrelevant as long as the student used the given temperature values. Task B, on the other hand, was given a CUWS score of 3 because the task could not be completed using only computational skills or a method from a prior class; instead, the task required students to interpret the meaning of the derivative within the context of population growth. Like Task A, Task B provided formulas to compute the average rate of change and model the population as a function over time. However, the task required students to not only identify the average rate of change but to situate that change across multiple intervals and describe how their calculations contextualize what might have been happening in Grand Rapids within the different time periods. Despite the differences in CUWS scores, the tasks received similar AA scores because they were situated in authentic contexts in which estimating the derivative would provide useful information about the given application.

Contrasting Characteristics: Likelihood of Particular Score Juxtapositions

Across all tasks identified in both textbooks, we also identified the juxtaposed pairs of CUWS and AA scores (Table 2). In the traditional textbook, the most common juxtaposition found was 0-3 (CUWS-AA). Note that this score was given to 8 (53%) of the tasks analyzed in the traditional textbook; in contrast, for the problem-based textbook, this score was given to only one task analyzed (3%). For the problem-based textbook, there were nearly an equal percentage of tasks that were scored 3-5 and 3-4, for a total of 17 tasks (59%). These scores were less common in the traditional textbook, given to three problems analyzed (20%).

Table 2. Analysis of the Most Common Score Juxtapositions of Tasks in the Traditional and Problem-Based Calculus I Textbooks

CUWS Score	AA Score	Tasks in Traditional (N = 15)	Tasks in Problem-Based (N = 29)	Total
0	3	8	1	9
2	3	2	2	4
3	3	2	4	6
3	4	1	9	10
3	5	2	8	10

Discussion

The preliminary findings from our analysis indicate potentially impactful differences between traditional and problem-based calculus textbooks. In the textbook sections introducing the derivative concept, we observed differences in the overall prevalence of tasks including an application context and the degree to which such tasks (1) required conceptual understanding and (2) lent authenticity to the application context. Our findings additionally suggest that discrepancies often exist, for individual tasks, between the degree of authenticity and the degree of conceptual understanding required. While providing an authentic context can enhance students' perceived relevance of calculus, such tasks must *also* engage students' conceptual understanding to improve student learning. Together, these findings suggest the potential impact of the textbooks that calculus instructors select for teaching their courses. Importantly, including more authentic, conceptually rich tasks can create learning environments where students can both recognize the relevance of calculus for their future careers and engage with tasks that support their conceptual understanding.

In the future, we intend to expand our preliminary analysis to include more textbooks and to encompass additional calculus concepts for a more thorough exploration of calculus tasks. This will include investigating the relationship across tasks between the CUWS score and different components of the AA score (i.e., event, purpose, etc.). We will use the combined framework focusing on both conceptual understanding and authenticity of application to provide a structure for developing new tasks across mathematical domains that are both conceptually rich and authentic. Careful attention to the nature of assessment tasks along theses dimensions will provide one pathway to help transform gatekeeper courses, such as calculus, into *gateway* courses that can support students with achieving success in their chosen career pathways.

Student Challenges in Proof by Mathematical Induction: A Preliminary Analysis of a Generalizing Study

Elly Nelson
Colorado State University

Hannah Fluckiger
Utah State University

Sindura Kularajan
Utah State University

Seth Poulsen
Utah State University

Many studies have investigated the challenges students face during proof by mathematical induction (PMI). However, the majority of these studies are drawn from a small sample size. In order to generalize the findings from previous literature, we draw from a study of over 1000 proofs to develop an analytical framework for identifying common student challenges in PMI. In this preliminary analysis, we report our finding from analyzing 180 written responses for three types of PMI tasks.

Keywords: Proof by Mathematical Induction, Student Challenges

It is well documented in the literature that students often find proof by mathematical induction (PMI) particularly difficult (Styliandines et al, 2007; Norton and Arnold 2019; Baker 1996). The majority of these studies have used qualitative techniques to analyze students' written proofs, student interviews, and/or classroom recordings and observations from a small sample of data. However, to advance the field forward in terms of the generalizability of previous findings (Melhuish and Thanheiser, 2018), a study on student challenges in PMI using a larger data sample is yet to be conducted. In light of this, in this preliminary study, we document our efforts in analyzing student challenges of PMI by analyzing a subset of data from a larger sample. We first discuss existing findings on student challenges in PMI, report our study where we analyzed 180 out of 1019 proofs, and finally discuss implications of our findings and our future steps.

Empirical Background

Many scholars have investigated students' cognitive gaps surrounding proof by mathematical induction using a variety of methods (e.g., Dubinsky, 1986; Styliandines et al., 2007). For example, in a study with 40 high school and 13 college students, Baker (1996) reported that students displayed a variety of challenges including in mathematical content and deductive knowledge. For instance, Baker (1996) reported that students had difficulty in connecting the significance of proving the base case with the formulation of the inductive hypothesis, students applied the inductive step to all cases of the inductive statement, and students relied mostly on procedural techniques over the conceptual understanding of the proof strategy. Through a classroom-based study with pre-service teachers, Davis et al (2009) found 4 main challenges students experienced during PMI: problem-solving, connecting information from multiple areas, validating others' proofs, and infinite iteration. In a different study, through analyzing 67 student responses and interviewing 8 of those students, Taitra (2023) found that while most students in the study were able to set up the inductive step, the students found proving the inductive step to be challenging. Reid's (1992) study on students' understanding of proof by induction revealed a key finding: students struggled to connect induction with recursive thinking. Studies have also shown that students often take a results-oriented approach to writing induction proof (Harel, 2001). That is, students may use examples to verify the truth of statements (Baker, 1996; Harel,

2001), use a backward strategy while writing proofs (Baker, 1996), or treat proof by induction as a list of steps that need to be checked (Harel, 2001; Styliandes et al, 2007; Knuth, 2002). Building on our prior work (Authors, Year), we intend to contribute to and extend the research on student challenges in PMI by analyzing 1019 student responses to proof by inductions surrounding divisibility, summation, and recursive relations. In this preliminary study, we address the following research question: *What challenges did students face in PMI as identified from our analysis of 180 written responses across three types of PMI tasks?*

Methods

Data for this study comes from a larger project, where the project goal was to measure the effectiveness of completing Proof Blocks, a software that enables students to construct proof by arranging pre-written statements, over reading a book chapter (see Poulsen et al., 2024). As part of the larger project, in total we collected 1019 written responses for the proofs shown in Figure 1 from students enrolled in a discrete mathematics course (The full data set can be found in Poulsen, 2024).

Divisibility: For any natural number n, $2n^3 + 3n^2 + n$ is divisible by 6.

Recurrence: Suppose that $g : \mathbb{N} \to \mathbb{R}$ is defined by
- $g(0) = 0$
- $g(1) = 4/3$
- $g(n) = 4/3\, g(n-1) - 1/3\, g(n-2)$, for $n \geq 2$.

Use induction to prove that $g(n) = 2 - 2/3^n$ for any natural number n.

Sum: Claim: $\sum_{p=0}^{n}(p \cdot p!) = (n+1)! - 1$, for all natural numbers n.

Figure 1. PMI tasks

In this preliminary analysis, we analyzed 180 proofs (60 divisibility, 60 summation and 60 recursive) with the aim to develop an analytical framework that can be applied to the entire data set. To identify student challenges in proof by mathematical induction, we initially coded our data using an *a priori* framework derived from the literature. Four research team members independently applied these codes to sections of the data and convened weekly to address any discrepancies. Resolving these disagreements often resulted in adjustments to the existing codes or the development of new ones. Adjustment to existing codes took the form of expanding the definition of each code, condensing multiple codes into one. When aspects of student work could not be coded by existing code, a new code was created and defined. The new codes and modification of existing codes were checked against the already coded data set to ensure consistency in our use of the codes. In the following section, we present the codes as findings of student challenges in PMI that we have developed up to this point of the study.

Findings

We present the overview of the themes, the corresponding sub codes, and their definitions that emerged during our analysis in Table 1. Due to space constraints, we illustrate four of the sub-codes.

Table 1. Label

Major Themes	Sub-codes	Definition
Quantification Related challenges	The induction variable, k, is used without quantification	Proof uses a variable that represents the specific value the inductive hypothesis (IH) to be true up to, without defining that variable beforehand

		(e.g. indicators include the proof not having explicit language such as "for some k..." or "there exists k...")
	Conflating between the roles of n and k.	Uses the same variable in the inductive hypothesis to represent an arbitrary value and a specific value.
IH Related Errors	Assuming the IH true always (instead of for a particular value)	Assumes the IH without quantifying the variable or allows the variable to be any natural number. The proof must have some IH in order for this code to apply.
	Mismatch between values assumed in IH and value proved in inductive step (IS).	Value proved in IS is not the successor of the value assumed in the IH.
	IH is to be proven, not assumed	The proof shows no indication that the IH is something that is assumed, and instead claims that either have proved it or will prove it.
	Using IH inductive hypothesis without assuming it	No assumption is made for the statement being true. Proof jumps right into proving k+1, with no basis for k being true.
	Confuse recursive definition with IH	Proof assumes the definition of the recursive function rather than assuming that the recursive function is equal to the closed form equation for some k.
Base Case Related	More base cases than necessary	Proved for 2 or more base cases when only needed 1, or 3 or more when only needed 2
	Not enough base cases	Proved for 1 base case when they needed 2.
	Not proving the property is true for base cases of the recurrence relation	The proof does now show that the recurrence relation is equal to the closed form for base cases. In particular, there is no evidence shown in the proof that the closed form expression for 0 and 1 are equal to $g(0)$ and $g(1)$ respectively as defined for the recurrence relation.
Domain-specific knowledge	Showed knowledge of PMI outline, but not filled in	Proof outlines the complete steps of PMI, but didn't provide details.
	Developing an understanding of the summation sign	Incorrect use of the summation operator in the proof.
General Logic Errors	Treating an expression or function as a proposition	The proof treats an expression which does not have a truth value in place of a proposition which does have a truth value.
	Backwards proof	Starting with the equality to be proved and manipulating both sides (rather than starting

	from one expression, and manipulating it to show it equal to the other)
Incorrect lower bound for induction variable	The lower bound for the inductive variable doesn't allow the IH to be soundly applied to complete the proof.
Proof by example	No rigorous proof is given. Proof is instead given by a few examples, implying that proving few examples proves the entire statement.
Assumed only $g(k)$ when they also needed to assume $g(k-1)$	The proof only prioritizes one recursive relationship in the IH and does not assume the IH to be true for the previous two recursive relationships.

Implicit Quantification of the Induction Variable

In this vignette, we provide an example proof (Figure 2) where the induction variable k is used without quantifying it. Here, the student seems to understand that, in the IH, the equation holds true for all natural numbers up until an arbitrary value, (represented by the variable k), but the proof does not define this variable. While the student's intentions of using k in this context may not be difficult to determine, the proof shows no evidence that the student may have an understanding of the significance of defining k in PMI.

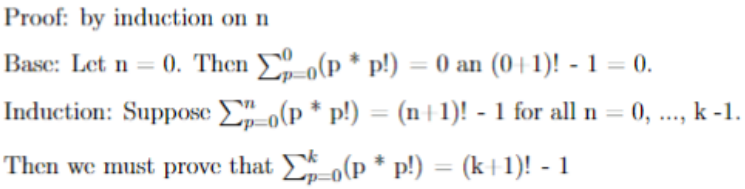

Figure 2. Student proof for summation task where k is used without quantification

Incorrect Lower Bound for Induction variable

In this vignette, we provide an example proof (Figure 3) where an incorrect lower bound for the induction variable is used. In the proof in Figure 3, the base case is proven for when $n = 1$. Therefore, the induction variable k, should iterate between the 2nd case to the nth case. However, in the proof, the student sets the lower bound for k as n, in their IH statement.

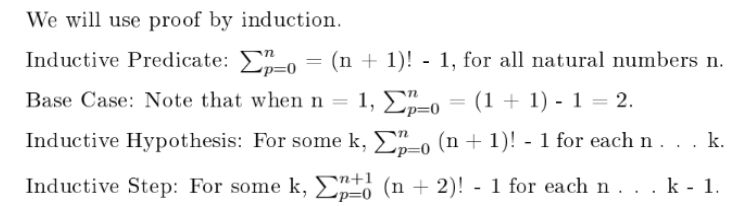

Figure 3.Student proof for summation task with incorrect lower bound for induction variable.

Mismatch Between Values Assumed in the Inductive Hypothesis and Values Provided in the Inductive Step

In this proof (Figure 4), the value shown in the inductive step is not the successor of the value assumed in the inductive hypothesis. The proof assumes that the inductive hypothesis holds true for values from 0 to k. However, while the goal is to prove the statement for $k + 1$, the proof only proceeds to prove it for k, as indicated by the "need to prove" statement.

next, suppose the hypothesis that for some k, $\sum_0^n$ (n * n!) = (n + 1) ! - 1
in k = 0, 1.....k

we need to prove that $\sum_0^k$ (k * k!) = (k + 1) ! - 1

Figure 4. Student proof for summation task where there is a misalignment in values

Assuming the Inductive Hypothesis is True Always (Instead of for a Particular Value)

In this proof (as shown in Figure 5), the inductive hypothesis is assumed to work for all natural numbers. This assumption makes the proof concerning $n + 1$ obsolete, as $n + 1$ is an element of all natural numbers, which was already assumed.

Base case: n = 0. $\sum_{p=0}^{n}(p \times p!) = 0 = (n+1)! - 1$.

Inductive hypothesis: Assume that the claim works for all natural numbers n, and prove that it works for natural number $n + 1$.

Inductive steps: $\sum_{p=0}^{n+1}(p \times p!) = (n+1)(n+1)! \times \sum_{p=0}^{n}(p \times p!) = (n+1)(n+1)!((n+1)! - 1)$. Then, we can rewrite the function, so it will be $(n+2)! - 1$.

Figure 5. Student proof for summation task where inductive hypothesis is true always

Discussion and Conclusions

In this report, we presented our preliminary findings from analyzing 180 written proofs that were drawn from a larger data set comprising 1019 proofs. Our objective is to utilize the analytical framework presented here for the remaining proofs, while continuously refining and enhancing it to ensure the development of a comprehensive and rigorous analytical framework. Some of the findings reported here comport with previous findings from the literature. For example, Baker (1996) also found that his students used specific examples to complete PMI. Similarly, Stylianides et al. (2007) found that the pre-service teachers in their study relied on a list of steps to prove PMI. This, we believe is similar to what we identified as "showed knowledge of PMI outline, but not filled in," re-affirming students' procedural over conceptual understanding of PMI. Additionally, we also found some student challenges in PMI that were not reported elsewhere. For example, developing and understanding of the summation sum, mismatch between values assumed in IH and value IS, using IH inductive hypothesis without assuming it, and treating an expression or function as a proposition were unique to our data set. These newer themes may be attributed to our sample size, type of proofs (i.e., proofs that require summation operation and recurrence relations), and students' mathematical background. However, we acknowledge certain limitations to our findings. First, the data sources were only written proofs. These data sources are limited for uncovering the thinking behind students' mathematical decisions. Therefore, our claims may not accurately reflect students' understanding of PMI. Second, to determine whether or not a code/theme truly represents a common challenge faced by students during PMI, we need information about the prevalence of that code/theme. Our future study includes examining the frequency of all codes. Adopting an asset-based perspective (Adirejda, 2019), we echo other scholars (e.g., Norton et al., 2023) in emphasizing the need to explore the underlying reasons for students' difficulties and further advocate for research that examines the effective strategies instructors of PMI can employ to address these challenges.

"Why Would a Woman Put Themselves in This Situation:" A Discourse Analysis of Gender and Pronouns in Solving a Hat Problem

Jeremy Bernier
Clemson University

The language we use to talk about, do, and learn mathematics informs how we socially construct our understandings thereof. This preliminary report discusses an instance from a different study where the use of feminine pronouns to describe smart logicians in a particular mathematical problem resulted in various reactions from participants. I analyzed participants' interactions with the given task using an approach to discourse analysis that examines how the grammatical structures of language are used to construct particular meanings. Preliminary findings showcase how participants' responses to the task reflect broader cultural understandings of who can be a smart logician. These findings are linked to the need for representation in curricular materials and the use of hat problems in the learning of logic and problem solving.

Keywords: word problems, logic, pronouns, gender, discourse analysis

Language is our primary medium for talking about, doing, and learning mathematics; as such, the mathematical language we use informs how we socially construct our understandings of mathematics (Planas et al., 2021). Knowing this, we may strive to use language to forward particular goals in mathematics. When teaching, we may use established formal mathematical language to enculturate students into a community of professional mathematical practice, or we may create new mathematical language to be culturally responsive to the backgrounds of our current students. When constructing mathematical word problems, we may choose to vary the demographic characteristics of characters to subvert the white cisheteropatriarchal and masculinized nature of mathematics (Leyva, 2017, 2021). One such variation through the subtle deployment of the feminine pronoun *her* is the catalytic element for this manuscript.

While conducting another study (see Bernier, 2024), I asked participating undergraduate students to engage with mathematical tasks from a collection by Roeder (2018). The focal task discussed in this manuscript is excerpted here (emphasis added):

> Three *smart logicians* are standing in a line, so that they can only see the *logicians* in front of them. A hat salesman comes along and shows the three *logicians* that he has three white hats and two black hats. He places one hat on each *logician*'s head and hides the remaining hats.
>
> He then says to the logicians, "Can anyone tell me what color hat is on *her* own head?" No one responds.
>
> He repeats, "Can anyone tell me what color hat is on *her* own head?" Still no answer.
>
> A third time: "Can anyone tell me what color hat is on *her* own head?" One of the logicians speaks up and gives the correct answer.
>
> Who spoke, and what color hat is on *her* head? (Roeder, 2018, p. 21)

When I designed the study, the fact that the problem used feminine pronouns to refer to the smart logicians was not noted as significant or unusual. Yet, as students arrived at this task in their

respective interviews, they reacted to it in ways that seemed notable and reflective of broader mathematical and societal discourses.

After completing the earlier study, I decided to examine this phenomenon further. In this manuscript, I report preliminary findings from a discourse analysis examining how participants used gendered language in discussing and solving this problem. Before I discuss my analysis procedures and preliminary findings, I briefly discuss hat problems and the matter of representation in curricular materials.

What Color Hat is on Her Head? – Hat Problems

Hat problems, like the one included in Roeder (2018), are a common type of logic puzzle used across various works and contexts (Brown & Tanton, 2009; Howse et al., 2018). These problems involve the use of logical deduction and mathematical induction to determine the color of a hat on a particular character's head through the progressive dissemination of information and elimination of impossible scenarios. They can be made increasingly complex by altering the quantities of participants, colors, and hats, and the means of dissemination of information (Brown & Tanton, 2009). The iteration of the problem used in Roeder (2018) is isomorphic to one that has existed at least since 1995, with a previous iteration using male prisoners as the characters in place of smart logicians (Gerald & Mario, 2000).

Representation in Curricular Materials: It Matters

All learners deserve to see themselves and others reflected in the materials they use to learn (Gutiérrez, 2017). Indeed, many scholars have discussed at length the need for curricular materials to carefully and appropriately reflect a diversity of identities in order to promote equitable learning (Hickman & Porfilio, 2012; Macintyre & Hamilton, 2010; Mills & Mustapha, 2015). Given that cultural images of mathematical professionals are overwhelmingly masculine (Mendick et al., 2008), mathematical tasks which depict women as mathematically capable could be useful in encouraging women to participate in mathematics. The task as published in Roeder (2018) may (or may not) have been written with that intent, given its logical equivalence to but narrative distinction from earlier-stated hat problems. The problem was originally a reader submission (Roeder, 2017), but the provenance of the reader's version is unknown.

Discourse Analysis

For this manuscript, discourse is taken to be the use of language, spoken or written, to communicate ideas and actions (Johnstone, 2018). Analyzing discourse is a worthy endeavor because discourse is both shaped by and shapes people and social structures (Johnstone, 2018; Planas et al., 2021). Learning in undergraduate mathematics classrooms involves discourse (Hetrick et al., 2023; Rios, 2023) – both the discourse occurring in the room and the Discourses (Gee, 2014a) which comprise what it means to be a student, a learner, or a mathematician.

Of course, given the broad definition of discourse above, most modes of qualitative analysis constitute an "analysis of discourse." Indeed, many different forms and approaches to discourse analysis have been developed and pursued across the social sciences and within educational research (Johnstone, 2018; Warriner & Anderson, 2017). I largely adopt Gee's (2014a, 2014b) approach, where the structure of the discourse is critical to its analysis and where "meaning [is] an integration of ways of saying (informing), doing (action), and being (identity), and grammar [is] a set of tools to bring about this integration" (2014a, p. 8). In particular, I draw on the "tools" which Gee (2014b) characterizes as "specific questions to ask of data" (p. 2).

Methods

This manuscript examines a phenomenon that occurred while I was researching another phenomenon (see Bernier, 2024). As such, the data for this manuscript was not collected with the analysis presented here in mind. The relevant aspects of that study are described here, as well as the analytic approach I used for this manuscript.

Study Context and Data Extraction

The larger study from which the relevant data is extracted sought to deepen our understanding of how undergraduate students can engage in play when solving puzzles and mathematical problems (Bernier, 2024). To do so, I conducted a series of four clinical interviews (Hunting, 1997) one-on-one with six undergraduate students (Table 1). In these interviews, participants either played digital puzzle games or solved mathematical tasks taken from collections of "mathematical puzzles." The second interview included three problems from Roeder (2018), including the task discussed in this manuscript.

Table 1. Summary of participants

Pseudonym	Gender Identity	Pronouns
Batman	Woman	she
Daniela*	Woman	she
David Wallace	Man	he
Pattakoby	Non-binary	he/they**
Shane	Man	he
Timothy Burns	Woman	she

*All participants chose their own pseudonym, except Daniela who declined to do so; the name Daniela was chosen arbitrarily.
**For readability, I use only masculine pronouns for Pattakoby.

For this manuscript, I pulled data from the transcripts already used for prior analyses. I located within each participant's second interview transcript any discussion of the relevant task and extracted all such lines in chronological order. I then placed the extracted segments into a single Microsoft Word document for analysis.

Analysis Procedures, or, What's in my Toolkit?

My approach to data analysis here was primarily guided by four tools from Gee's (2014b) toolkit: the Deixis Tool (p. 16), the Fill In Tool (p. 18), the Why This Way and Not That Way Tool (p. 53), and the Figured Worlds Tool (p. 177). The Deixis Tool involves identifying and examining the shifting references (deictics) such as pronouns used by speakers. Since the gender of the logicians in the task was communicated via deictic, these seemed especially salient. I identified each use of a gendered pronoun and changed the font to an assigned color – orange for he/him/his, turquoise for she/her/hers, and purple for they/them/theirs. I also underlined other gendered words which took on "deictic like properties" (Gee, 2014b, p. 16), like guy and person. This process identified many (though not all) utterances worthy of further analysis.

While the Deixis Tool allowed me to identify critical moments in the data, the Fill In Tool and Why This Way and Not That Way Tool allowed me to get at the deeper meaning. According to Gee (2014b), these two tools examine the unstated implications of speakers' grammatical choices. With the Fill In Tool, I examined different segments for "[w]hat is not being said overtly, but is still assumed to be known or inferable" (p. 18). The Why This Way and Not That Way Tool led me to consider how else a participant might have said or phrased the same sentiment, and what the implications are of their chosen phrasing. To apply these tools, I read through the extracted segments, highlighting and annotating moments where the implications of their speech and choices were apparent. For example, this included highlighting each instance of an incongruous pronoun being used (e.g., he or they being used to describe a singular logicians). Comments then discussed the apparent implications of these grammatical choices.

Finally, I linked the local discourses in my data to larger discourses by applying the Figured Worlds Tool. To use the Figured Worlds Tool, one must "ask what typical stories or figured worlds the words and phrases of the communication are assuming and inviting listeners to assume" (Gee, 2014b, p. 177) In this case, the relevant Figured World seemed to be that of doing logic/mathematics and/or being a logician/mathematician

Preliminary Findings

Apparent throughout all interviews was a tendency of all participants – and myself as an interviewer – to at least sometimes refer to the logicians using incongruous pronouns. In some cases, these are fairly well explained by considering the aesthetics of the utterance. For example, Shane made the utterance: "there's three people, five different color hats, and one of them knows what color hat they have. In this utterance, Shane's use of them is congruous with the logicians being women, because it is being used as the third-person plural. The use of they, on the other hand, is incongruous, because its referent is "one of them," a singular smart logician. But, saying "one of them knows what color hat she has" could feel awkward or unintuitive.

On the other hand, some of the instances where participants used incongruous pronouns seem less innocuous. Pattakoby, for example, read the task aloud – but when he did, he verbally replaced "her" with "their" initially, and later used masculine deictics:

> He places one hat on each logician's head and hides the remaining hats. He then says to the logicians, "Can anyone tell me what color hat is on their own head?" No one responds…
>
> …and because the one in the middle knows that the guy standing in front of him has a white, possibly the guy in the middle can guess…

Pattakoby and Shane did not ever verbally acknowledge the use of feminine pronouns in the task description. Applying the Why This Way and Not That Way Tool and the Figured Worlds Tool leads me to conjecture that they did so because in their figured worlds a "smart logician" would be a man – perhaps to the point of not even accurately parsing the words in front of them, or implicitly assuming that the use of feminine pronouns was a mistake.

Several of the other participants did make note of the use of feminine pronouns, with many of them questioning the meaning of said use. Batman and David Wallace both phrased their questions similarly, with Batman asking, "Who is her?" and David Wallace asking "Why does he say her own head?" My responses to Batman and David Wallace did not acknowledge the gender of the characters and were intended to clarify the problem:

> Yes, they were supposed to see if they can figure out what color hat is on their own head. So each person in that line is trying to, from whatever they can see, figure out if they know what color hat is on their head, which they can't see what color hat is on their head.

Using the Fill In Tool and Why This Way and Not That Way tool, it seems I misinterpreted these questions during the interview as being requests for clarification of the task goals. But, Batman and David Wallace both made the use of the word her central to their question, which implies that they were particularly confused about the use of a feminine pronoun to refer to the smart logicians. My own use of gender-neutral pronouns in my response is likely reflective of not having carefully considered the task's use of pronouns prior to the interviews and internalized subconscious biases I hold within my own Figured Worlds.

Finally, Timothy Burns and Daniela both noted the gender of the smart logicians explicitly. Timothy Burns asked the question in the title of this manuscript: "Which type of scenario is this and why would a woman put themselves in this situation?", while Daniela initially thought the use of her was meant to supply some sort of clue regarding the solution to the problem:

> It does say that the person who spoke up and gave the correct answer was a girl because it says, who spoke and what color is on her head? I don't know if that's important though because it doesn't mention anything about gender besides that. Or, wait, actually they might all be girls because he says, the salesman asks all of the logicians. Can you tell me what color is on her own head?

Applying the Fill In Tool, both Timothy Burns and Daniela observe that the logicians are meant to be women. However, neither seems to be evaluating this problem as a plausible scenario in the first place, with Daniela seeming to interpret the task like a language riddle while Timothy Burns seemed to reject the whole problem as absurd. In other words, their reaction to the task did not relate as much to their understanding of *who* can do mathematics, but instead, of *what* features of a mathematics task are and are not important.

Limitations and Implications

Given preliminary findings based on a secondary and unplanned-for analysis to observe a phenomenon, I must be extremely cautious in suggesting implications of this work. Especially important is my lack of use of the Frame Tool (Gee, 2014b, p. 44), which notes the importance of considering ever-increasing layers of context when conducting discourse analysis. I have not fully considered, for example, how what I know about participants' backgrounds and prior experiences may have informed their reactions to the task, nor how the interview context might be different than the classroom context in informing these reactions.

Still, I believe this analysis illustrates a broader notion that work to subvert inequities in mathematics is never easy or free. I cannot speak to the intent of whoever decided that the logicians in the problem should be women, but I know that I myself have made similar changes in producing curricular materials. The intent of this, on my part, has been that small changes to make materials more representative might help to undermine established cultural images bit-by-bit. What we see in this analysis, though, is that changes which are too small may be overlooked or ignored. While it is compelling to not want to make a "big deal" about representation – and a desire to avoid tokenism or otherwise "singling out" representation of women and other marginalized groups – it seems there is a danger too in being too subtle. At a minimum, instructors and researchers should be careful – more careful than I was – in examining the potential implications and anticipating the reactions of learners when interacting with tasks that include characters from marginalized groups and subvert cultural expectations or norms.

All My Work is Right, Why Didn't I Get the Right Answer? When Logarithmic Identities Fail

Calum Heldt
University of Nebraska – Omaha

Keith Gallagher
University of Nebraska – Omaha

When learning about logarithms and solving logarithmic equations, students often misapply logarithmic identities. In some cases, misapplying an identity leads to the deletion of solutions or the introduction of extraneous solutions. This results from applying an identity without first checking that all logarithms in that identity are defined on the same domain. In this preliminary work, we examined 14 websites that College Algebra students might use when learning how to solve equations using logarithms, looking for mentions of the domains of definition whenever identities were stated or applied. Of the 11 websites that stated a logarithmic identity, only 4 mentioned domains of definition. Of the 11 websites that showed an example logarithmic identity application, zero mentioned domains of definition. We hypothesize that this lack of emphasis on domains of definition in teaching and learning logarithmic identities may lead to confusion when working with logarithms and in mathematics as a whole.

Keywords: Logarithms, Identities, Domain, College Algebra, Solving Equations

Understanding logarithms and using logarithms appropriately are common stumbling blocks for students, starting in introductory algebra and often continuing into calculus and beyond. Although some research has investigated undergraduate students' understandings of the concept of logarithm (Berezovski & Zazkis, 2006; Leopold & Edgar, 2008; Liang & Wood, 2005; Park & Choi, 2013; Rafi & Retnawati, 2018), little research has focused on undergraduates' knowledge related to logarithmic identities (sometimes also called *logarithm properties* or *logarithm rules*).

Consider the equation $\log(x^2) = 2$. Simply applying the definition of the base-ten logarithm, we obtain that $x^2 = 100$, and thus find that $x = \pm 10$ gives all solutions to the original equation. Checking both solutions in the original equation confirms that both values are indeed solutions to this equation.

However, a common solution path for students taking a course in College Algebra might be to apply the logarithmic identity $\log(m^n) = n\log(m)$ to the original equation to obtain $2\log(x) = 2$. From this point, dividing both sides of the equation by 2 and applying the definition of the base-ten logarithm suggests that $x = 10$ is the only solution to this equation, though we know from the previous example that this equation has at least (indeed, exactly) two solutions.

A student might wonder: "If everything I did was correct, then why didn't I get the right answer?" But the expert observer will note that there is a caveat to the logarithmic identity applied by our hypothetical student: it is true that $\log(m^n) = n\log(m)$, but only when $m > 0$. In particular, it is true that $\log(10^2) = 2\log(10)$, but it is not true that $\log[(-10)^2] = 2\log(-10)$, as the function $f(x) = \log(x^2)$ is defined for all $x \neq 0$, but the function $g(x) = 2\log(x)$ is defined only for $x > 0$. While experts are likely to notice this error, students who are still learning about logarithms and their properties are likely to overlook the solution $x = -10$, and they may even reject it outright due to the fact that one "can't take the log of a negative number."

Our research begins to answer the following research question: How do resources targeted toward College Algebra (or high school algebra) students attend to issues related to function domains when teaching about logarithmic identities? In this study, we explored websites College Algebra students might use as reference materials when learning how to solve problems using

logarithmic identities. We focused our attention on the extent to which these websites acknowledge the importance of the domains of the logarithmic functions involved in making a logarithmic substitution during problem solving as in the example presented above. We present some preliminary findings and discuss implications for the teaching and learning of logarithms as well as mathematics more broadly.

Students' Understanding of Logarithms

Logarithms are notoriously challenging for students, both in concept and in application. Park and Choi (2013) argued that learner's difficulties with logarithms are often overlooked due to prevalent calculator usage. Indeed, Leopold and Edgar (2008) found that only 21% of university students enrolled in a second-semester introductory chemistry course responded correctly to mathematics questions about logarithms on a standard, calculator-free, university assessment.

Berezovski and Zazkis (2006) proposed interpretive frameworks to explore high school students' understandings of logarithms, based on Confrey's (1991) interpretive frameworks that were designed to explore learners' understandings of exponents and exponential functions. These frameworks were designed to investigate the different conceptualizations and approaches students may use when simplifying expressions or solving problems related to or requiring logarithms. In a sample of 17 students' responses to the task of simplifying $\log_3 54 - \log_3 8 + \log_3 4$, 12 students reached the correct answer, but 9 of those unnecessarily applied the change-of-base formula, suggesting that a calculator was used to reach their final answer. It is therefore suggested that only 3 of 17 students in this sample understood the meaning of logarithms well enough to solve this problem without the aid of a calculator.

There is some evidence to suggest that the correct application of logarithmic identities is challenging for students. Liang and Wood (2005) found that students commonly assumed that $\frac{\log(x)}{\log(y)} = \log\left(\frac{x}{y}\right)$ and that $\log(a+b) = \log(a) + \log(b)$, a finding echoed in the work of Rafi and Retnawati (2018). Liang and Wood (2005) also observed students treating the "log" notation as a sort of "common factor" that could be canceled when it appeared in the numerator and denominator of a fraction, as in the example $\frac{\log(100)}{\log(10)} = \frac{100}{10} = 10$. Indeed, this may suggest that students sometimes do not view logarithms as functions at all or understand the significance of logarithms as functions.

Little other research has investigated students' understandings of logarithmic identities and applications of logarithmic identities in solving equations. Furthermore, in light of the misconceptions outlined above, the accuracy and clarity of the resources students use to support their learning is paramount. Our work begins the process of examining those resources to gain a more complete picture of the information students may consume.

Methods

We performed a preliminary content analysis (Cohen, Manion, & Mason, 2013) on 14 websites. For this introductory study, we chose to focus our attention on websites (as opposed to textbooks or classroom curricula) as these resources are available to all learners regardless of their instructor or the physical resources made available to students. Future studies will explore other sources of content.

To select these websites, we created a Python web scraper that would fetch the top 8 Google results for any given search term(s), as we assumed that most students would select websites from among the top search results for a given search query. We then determined 5 phrases that a

student new to the topic of logarithms and logarithmic identities might search to gain a deeper understanding, and we used these as search terms. These search terms were as follows: (a) "Properties of logarithms", (b) "How to use a logarithm", (c) "Logarithms in college algebra", (d) "Logarithmic identities", (e) "Logarithm rules". For this preliminary investigation, we excluded any apps, comment-based websites such as Reddit and StackExchange that lack a systematic content review process, and video resources such as YouTube and KhanAcademy, as we felt that these kinds of resources deserved a more thorough treatment than the preliminary exploration provided in this report. These resources will be explored in more comprehensive future research on this topic. Of the websites left, we chose the top 3 for each search result, yielding 15 websites that we further examined for their treatment of domains of logarithms.

Next, each of the 15 websites was analyzed for the following events: (a) logarithm defined, (b) logarithmic identity stated/defined, and (c) logarithmic identity invoked (e.g., when working through an example). Whenever one of these codes was applied, we then applied one of the following subcodes: (a) domain(s) explicitly defined/stated, (b) domain(s) not mentioned, or (c) only 0 addressed as an exclusion from the domain. To validate the analysis technique of a single author, each author individually coded the same 3 websites, and codes were compared and discussed until 100% agreement was reached on all codes. Note that we only analyzed the specific web pages that were identified by our web scraper. We did not include in our analysis any web pages that were linked to within those web pages.

Table 1. Codes used in our analysis, with possible subcodes corresponding to domain mention.

Codes Examined for Domain			
Codes	Logarithm Defined	Log. Identity Stated	Log. Identity Invoked
Subcodes	Domain explicitly defined	Domain not mentioned	Only 0 explicitly mentioned

Originally, we also looked at occasions where graphs were shown, or extraneous solutions were acknowledged, as these could be considered as implicit mentions of domains of definition for the logarithmic functions involved in a given problem. However, both events occurred very few times (2 each) and these websites did not explicitly discuss these aspects of the problem in relation to function domains. Furthermore, neither of the websites that acknowledged extraneous solutions attributed their emergence to the expansion of a function's domain due to the misapplication of a logarithmic identity; they simply verified that these solutions were extraneous with no discussion of their origins.

After each of the 15 websites was analyzed, we excluded one that defined logarithms once, did not explain the domain on which they are defined, and did not define or use any logarithmic identities. This left us with a total of 14 websites included in our analysis; we present the results of this analysis below.

Results

Once we analyzed the 14 websites in our sample for the above events, we calculated relevant statistics.

Table 2. Coding scheme and instances of occurrence within the 14 websites analyzed

Results			
	Logarithm Defined	Log. Identity Stated	Log. Identity Invoked
Domain mentioned	5	4	0
Domain not mentioned	3	7	11
Only 0 explicitly mentioned	1	0	0
Totals	9	11	11

Most websites from this sample defined a logarithm, and even more stated or invoked logarithmic identities. A small majority (55.55%) of websites that defined a logarithm also stated the entire domain on which logarithms are defined ($x > 0$). One website (11.11%) that defined a logarithm only stated that logarithms are not defined at $x = 0$, but did not indicate that logarithmic functions are undefined for negative x-values. The remaining websites that defined logarithms (33.33%) did not mention any domain.

Although a website in the sample was equally likely to state and invoke a logarithmic identity (78.57%), some websites only had one event or the other. Of all 14 websites, 8 (57.14%) of them both stated and invoked an identity. Given a website that stated a logarithmic identity, it was 36.36% likely the website also stated the domain on which that identity holds. Similarly, given a website that stated a logarithmic identity, it was a 63.64% chance no domain of definition was mentioned.

Finally, given a website invoking a logarithmic identity, there was a 100% chance that the website did not acknowledge any possible changes to function domains that might have been introduced through the application of that identity. This means that, in a website containing an example application of an identity, there was never any discussion about why the identity was (or was not) valid to invoke or how a change in the domain might introduce extraneous solutions or delete solutions. Two websites that invoke a logarithmic identity (18.18%) applied an identity that altered the domains of the functions in the equation. This produced extraneous solutions, which were then discarded. For instance, one website solved the equation $\log(2x + 3) + \log(x) - \log(12) = 0$ using the product and quotient identities for logarithms. This yields one solution, $x = 2$, and one extraneous solution, $x = -3$. The extraneous solution was generated through the application of the product rule to combine $\log(2x + 3) + \log(x)$ into $\log(2x^2 + 3x)$, which changed the domain of the left-hand side of the equation from $(-\frac{3}{2}, \infty)$ to $\left(-\infty, -\frac{3}{2}\right) \cup (0, \infty)$. Websites that did not include examples of extraneous solutions did not mention that they were a possibility. Furthermore, no websites gave examples in which the application of a logarithmic identity caused the deletion of a solution, as in the example we gave in our introduction.

Overall, our data suggest that when a website's goal is simply the definition or introduction of the concept of a logarithm, the domain of the logarithmic function is likely to be included. However, when the focus of the conversation is on logarithmic identities, the domains of the functions involved are unlikely to be mentioned.

Discussion

Our work suggests that websites College Algebra students might use as reference materials when learning about logarithmic identities do not place much importance on the domains of definition of the logarithmic functions used in those identities. It is important to note that logarithmic identities are theorems, and that the satisfaction of the hypothesis of a logarithmic identity requires checking the domains of the functions to be used in that identity. In our earlier example, we can (and perhaps should) restate the power rule for logarithms as follows: "If m $>$ 0, then $\log(m^n) = n\log(m)$". Although we cannot confirm or refute that $x > 0$ in the equation $\log(x^2) = 2$ before we know the solutions, the formal statement of the theorem serves as a warning that, if this equation has negative solutions, applying this identity will cause us to delete them.

As suggested by Berezovski and Zazkis (2006), learners' grasp of logarithms and logarithmic identities is often tenuous. For the hypothetical student who asks, "Why did I get the wrong answer if all my steps were correct?", it may be frustrating to learn that their first step of applying a logarithmic identity led to an error caused by inattention to the domains of the functions involved in the substitution.

In upper-division proof-based courses, a strong emphasis is placed on checking that the hypothesis of a theorem is met before applying the theorem. However, in College Algebra courses, theorems like these are often not even stated as theorems, and students are often instructed to apply them with no regard to their hypotheses. We argue that this sort of "fast and loose" way of doing mathematics at lower levels can lead to confusion at higher levels and reinforces the belief held by some students that mathematics is simply a set of arbitrary rules for moving symbols around on paper.

Future Work

This work is the first step in a program of research that will probe College Algebra students' understandings of logarithms. A key consideration of this research is what information is presented to students in the resources they use to support their learning. Future work will explore the contents of algebra textbooks, comment-based websites, and video resources such as YouTube and KhanAcademy. We will investigate College Algebra students' understandings and perceptions of the applications of logarithmic identities when completing various types of routine exercises given in College Algebra courses. We will also explore instructors' ability to detect these sorts of errors in student work and explore the feedback they provide to their students.

We will also expand this work to attend to other situations in which equality is sometimes claimed by experts or students, but domains are often left implicit, including trigonometric identities and applications of the "factor-cancel" method for simplifying rational functions. We will explore the extent to which domains are acknowledged when using these algebraic and trigonometric tools and how experts and learners react when they encounter unexpected results that arise from their applications.

(Re)Humanizing Mathematics for Historically Minoritized Learners: Narratives of Community College Students in Noncredit Bearing Developmental Math

Ranza Veltri Torres
University of Minnesota-Twin Cities

While many community college (CC) students come to higher education with specific career or life goals, these aspirations may be forced to change if students are not able to get past the gatekeeper of developmental mathematics. Racially minoritized students are disproportionately tracked into developmental mathematics classes upon entering CC, and often become trapped in a financial and emotional cycle of take-fail-repeat, with student debt linked back to developmental coursework totaling over $1.3 billion per year across the U.S. (Jimenez, Sargrad, Morales, & Thompson, 2016). This report presents a subset of data from a larger narrative inquiry project that focuses on humanizing stories from an intimate group of CC students, uncovering how they came to know themselves as learners and doers of mathematics. Findings provide insight into how mathematics learning experiences can function to dehumanize, while also paving the way to creating more humanizing undergraduate mathematics learning spaces.

Keywords: mathematics identity, narrative inquiry, developmental / remedial mathematics, community college

Supporting mathematics educators to engage with and act on issues of social and racial justice requires an understanding of the lived experiences of their students, particularly as these experiences relate to mathematics learning and doing. One key aspect we can turn to as a first step to developing these understandings are the storied and lived experiences of historically minoritized mathematics learners as they choose to tell them. This report features data from a larger project that explores the mathematics narratives of an intimate group of community college students who have taken non-credit bearing developmental mathematics coursework, as they describe their experiences learning mathematics, their ideas about what mathematics is, and their self-perceptions as influenced by these experiences and ideas. By centering the self-narrative, we can focus our attention on the following research question: How do current practices in undergraduate mathematics learning spaces function to humanize or dehumanize our students as learners and doers of math?

The larger project from which this study comes focuses on community college (CC) students in noncredit bearing developmental mathematics (NCBD) coursework for a few key reasons. Firstly, these students' specific career or life goals may be forced to change if students are not able to get past the gatekeeper of developmental mathematics coursework. Secondly, racially minoritized students are disproportionately tracked into NCBD mathematics classes upon entering college, and often become trapped in a financial and emotional cycle of take-fail-repeat, with student debt linked back to developmental coursework totaling over $1.3 billion per year across the 50 states and D.C. (Jimenez, Sargrad, Morales, & Thompson, 2016). And thirdly, despite this, mathematics as a field of study has been positioned as more important than ever before for a diverse pool of learners, all while inequitable access to quality mathematics-learning experiences prevails.

This positioning of mathematics as a high stakes subject within schooling systems begins in elementary school and continues throughout grades K-12 and into undergraduate education. School mathematics requirements have evolved historically out of a movement to privilege

mathematics as a field of study because of its ties to national, capitalistic goals. As such, mathematics has gained a reputation as being necessary for the formation of citizens who are able to contribute to the economic success of our country in innovations requiring knowledge of science, technology, engineering, and mathematics (STEM) (Gutstein, 2003; Schoenfeld, 2004; Secada, 1989; Vashchyshyn & Chernoff, 2018; Washington, et al., 2012).

Theoretical Framework and Methodology

Because students' descriptions of their mathematical learning experiences are central to understanding how they understand their mathematical selves, I call upon the theoretical frame of narrative mathematics identity (Langer-Osuna & Esmonde, 2017; Larnell, 2016), taking a humanizing approach to the exploration of CC students who are currently enrolled in NCBD mathematics coursework. Using narrative inquiry as a tool to learn about students' identities as mathematics learners and doers, I explore narratives of an intimate group of five community college students (including four BIPOC students and one white, disabled student), uncovering how they came to know themselves as learners and doers of mathematics. While the broader study contains stories from these five diverse individuals, this report focuses on excerpts from a single participant, Marty, in order to provide a deeper view of one participant's story within the scope of this paper, as opposed to just grazing the surface of all five participants' experiences.

The self-narrative provides insight into how experiences and actions related to school mathematics starting in elementary school and evolving over the life course through the undergraduate years may shape what students see as possible for themselves. This humanizes the stories about how not just undergraduate developmental mathematics, but school mathematics more broadly as it exists today, can serve as a filter, removing certain students from educational opportunities.

With the idea of humanizing research at the heart of this project, participants were recruited through voluntary response sampling via in-class announcement, as well as a YouTube video posted to the course websites in NCBD mathematics courses within a large community college system in a small Midwestern City. Recruitment took place in 2021-22, at a time when most mathematics courses at this particular community college were being offered virtually, but with live instruction, due to the COVID-19 pandemic. I also had IRB permission to recruit via social media, so I posted recruitment flyers on Facebook and sent emails to my personal networks with permission to reshare. Through this, I recruited six participants, but five followed through and completed the full study. Participants took part in both a survey and two interviews, which were semi-structured in nature, leaving space for various lines of questioning and a more natural conversational flow, rather than just sticking to a script.

Interviews were offered either in person or virtually, not only in light of the COVID-19 pandemic, but also for participant accessibility and preference. Students were given a small token of appreciation for their participation.

After interviews were sound recorded, transcribed, and de-identified, member checks were performed to support participants in telling their stories, and to be sure the story that is re-told reflected what they would like to put forth.

To analyze participants' stories, I call upon Danny Martin's Central Themes of Mathematics Identity (2000), as well as honoring the themes that arise from within the narratives of my participants. Martin's themes include:

> (a) references to the instrumental value of mathematics, (b) references to motivation to attain mathematical knowledge, (c) references to opportunities to learn mathematics, (d) references to strategies to learn or participate in formal and informal mathematics

contexts, (e) references to constraints or barriers on participation within mathematics-learning contexts, and (f) references to one's own capacity to perform in mathematics-learning contexts. (2000)

Transcriptions were coded according to these themes, as well as a few themes that arose from the ground up and appear in data from the larger study (not within the scope of this paper). Participants were sent copies of the analyses of their stories and were given opportunities to provide any feedback they'd like to offer on thematic analysis of their narratives. Pseudonyms have been used to de-identify and protect participant identity, with participants being given the option to choose their own pseudonyms.

Select Interview Data and Analysis: Marty's Story

Apparent throughout my conversations with participants were examples of how students have been trained to identify mathematics quite narrowly, limited only to practice involving numbers, formulas, equations, and the like, whereas creative problem solving, guessing and checking, or other less "formal" methods would go unrecognized as mathematics. Take for instance the following quote from my interview with "Marty" (pseudonym), my focal participant within this report.

Marty: I told a professor years ago that I'm afraid, or I want to learn how to build properly, but I want to learn how to build in a way that I don't have to use mathematics regularly, because I'm not good at it, and he straight up told me that he never does math, and he totally understands, because he hates it. (Interview 2)

Marty identifies as a Latina furniture maker and woodworker who, at the time of the interview, was in her early 30s. At the time of our interview, she had been accepted into art school and was in her first year after transferring. Her narrative focuses on her mathematics identity through activities and feelings she has around mathematics learning and doing over the life course. Marty knew from a young age that she wanted to be an artist and identified furniture making, woodworking, and teaching these trades as her desired goals, all which she believed were possible for herself through art and in spite of mathematics.

Marty was born to Cuban immigrants and grew up in South Florida with one brother. As she shared, she always envied him for being "stupidly good" (Interview 1) at math, as she describes him; a reflection of her own perceived capacity of her ability to perform in mathematics-learning contexts (Theme F). Marty says she struggled with school mathematics growing up, but she was tracked into the "normal classes" (Interview 1). This reflects Marty's own perception about her capacity in mathematics (Theme F). It also reflects how she understands the opportunities she had to attain mathematical knowledge through coursework (Theme C). Marty's self-perceptions of her lower ability in mathematics reflect her mathematics identity. As she worked her way through grades K-12, she started approaching high school graduation knowing that she wanted to go into the arts, and knowing that she wanted to teach one day, which meant college, and specifically art school, was the route she would need to take.

Marty: I decided that I wanted to go to community college because I still didn't know where I wanted to go to art college, and so while making that decision um, it was also like, let me do this. Get all of the credits that are necessary, but unnecessary really, out of the way, and um, and I'll just be able to focus on making my work later. (Interview 1)

I asked her what she meant by "necessary, but unnecessary," and Marty describes how required general education coursework, such as mathematics, science, or language arts, are often centered around art when you take them in art school. Rather than an arts-based interdisciplinary education being an incentive for Marty to attend art school straight out of high school, she says

this was instead a deterrent, along with the high financial burden of paying for general education coursework at an art school.

> *Marty:* …they're [general education courses] really expensive to take at the university, so I decided to do it at the community college. And when you take those classes at an art school, they shape the class around art. Like, the science class would be, um, like, on color, you know. And I remember seeing some of the homework, and I was like, that's kind of dumb. Like, I enjoyed my, like, my science classes where I took, and it was an unbiased like, art science. It's like science science. And mathematics is math. And English is English, and it's not based around art. (Interview 1)

Marty's differentiation of science, mathematics, or English classes that are contextualized around the arts as being "kind of dumb" got me thinking: does she prefer to learn science, mathematics, or English as decontextualized? And what would that look like or mean for her, and why does she see "purer" versions of these content areas as more valuable? This line of thinking gave me some insight into how Marty has been trained to perceive mathematics and science as higher level when it is context-free or abstract.

Marty demonstrates in the above quote that she was motivated to obtain not only mathematical knowledge (Theme B), but also knowledge in a variety of general academic content areas. Marty also wanted the opportunity to learn mathematics (Theme C) at the community college, rather than doing a more content-specific mathematics course centered around the arts within a 4-year art university.

Marty goes on to describe her avoidance of math while problem solving in her work.

> *Marty:* I don't really use it [mathematics] anymore. As a woodworker, that's kind of a funny thing to say. Um, I just...when I do mathematics now, on the very rare occasion, it's really hard. (laughs) Um, yeah, cuz it's art math, which is a funny thing, cuz I was like, I don't wanna do art math.
>
> *Ranza:* What's art math?
>
> *Marty:* It's just complica...like, when you're trying to come up with something that...like, I was working on these weavings, and it's like, there was art mathematics that was involved in figuring out the scale, and I was like, I just can't figure this out! It's not working. (laughs) And it took me so much longer. Um, but, yeah. (Interview 2)

We see here a common occurrence demonstrated by Marty, as she categorizes her rich mathematical practices as "figuring it out without the math." This reflects not only Marty's narrow perceptions of what counts as legitimate mathematics, but also the limited ways that students are often trained with a classroom setting to identify what types of problem solving are mathematical and which are free of mathematics.

Implications of this Study

Findings of this study provide invaluable information for mathematics teachers, not only about how we can support the development of positive mathematics identities within school settings, but also how certain mathematics experiences may serve to de/humanize students by limiting their perceptions of what "counts" as legitimate mathematics, in turn creating situations that lead them to believe their experiences, interests, and problem solving do not count as mathematics. This leads students to believe that they are not learners and doers of mathematics, when in fact they very well are. It is our responsibility as mathematics educators to support an expansion of what we center as legitimate mathematics within our classrooms and schools and support students in seeing themselves and their interests as mathematical. For example, in Marty's situation, we see how engrained her invalidation is as a user of mathematics—her

experiences and messaging over a lifetime have led her to believe that the mathematics activities in which she engages are not legitimate mathematical practices. This tells us one story of how important it is to value students' mathematical knowing and doing, even when their mathematics may look different than that within the narrow gaze of the U.S. mathematics textbook.

Outcomes of the larger study help us to gain an awareness of both the patterns and unique qualities that are present within students' lived experiences around mathematics; to use this awareness to continue exploring and centering student voice as a means to creating knowledge regarding how mathematics teachers can champion their students in accomplishing the goals they set out for themselves; and to use this awareness to continue experimenting with and developing appropriate mathematics pathways and support structures so that mathematics coursework acts as a humanizing mechanism in students' lives.

The Use of Proof Comprehension as a Self-Assessment Tool in Undergraduate Proof Writing

Mitchell Alvarado
CSU, Bakersfield

Aubrey Kemp
CSU, Bakersfield

Research has shown that self-assessment techniques can improve understanding and academic performance for mathematics students. As proof construction, validation, and comprehension have proven to be facets of mathematics with which students can use more learning opportunities, Mejía-Ramos et al. (2012) present an assessment model for proof comprehension. For our project, this framework is utilized in understanding proof self-assessment, with the goal of aiding students in the process of proof construction and validation. In this preliminary report, we provide results from the first phase of our project, in which we surveyed seven university mathematics faculty about their approaches to proof construction and self-assessment. Results from this study are being used to generate a proof self-assessment tool through the lens of proof comprehension that undergraduate students may use to improve their proof writing strategies. Pedagogical suggestions are also provided based on these results.

Keywords: Self-Assessment, Proof Writing, Proof Comprehension, Evaluation, Criteria

Introduction

Recently, there have been many research studies conducted on undergraduate students' understanding of proofs, including the construction and writing of proofs (e.g., Azrou, 2015; Chamberlain & Vidakovic, 2021; Lew & Mejía-Ramos, 2019; Mejía-Ramos & Weber, 2019), validating proofs (e.g., Ko & Knuth, 2013; Powers et al., 2010), proof comprehension (e.g., Chamberlain, 2017; Dawkins & Zazkis, 2021; Selden & Selden, 2015; Weber & Tanswell, 2022; Yang & Lin, 2008) and assessment of proof comprehension (e.g., Mejía-Ramos et al., 2012; Cooley et al., 2024). Melhuish et al. (2022) and Stylianides et al. (2017) provide comprehensive reviews of research in many areas of proof in undergraduate mathematics education. Yang and Lin (2008) express it is important while constructing a proof to "have diverse ideas come to mind at the 'right time,' reorganize these ideas, and formally write the proof," (p. 73). The reorganization of these ideas is a cycle of writing, validating, reading and comprehending, and evaluating one's own proof. Selden and Selden (2015, 2017) discuss the interaction and comparisons of these various aspects of proof writing in undergraduate mathematics and point out there has been little research on how proof comprehension, construction, validation, and evaluation are related. As such, in this study, we seek to investigate how proof comprehension strategies may be used as a self-assessment tool in proof construction and evaluation.

Research shows students' academic performance can benefit from self-assessment and self-monitoring techniques (Andrade & Valtcheva, 2009; Beumann & Wegner, 2018; Kemp et al., 2020; Poehner, 2012; Stallings & Tascione, 1996) and students' proof writing can benefit from proof validation tasks (Powers et al., 2010) and self-explanation practice (Hodds et al., 2014). Further, students who use self-monitoring techniques have higher self-efficacy and self-assessment accuracy (Andrade & Valtcheva, 2009; Poehner, 2012; Stallings & Tascione, 1996). However, in some cases where students feel as though a grade is emphasized in the self-assessment, students may evaluate their work based on effort or focus on what may give them partial credit on an assignment (Kemp et al., 2020; Stalling & Tascione, 1996). Notably, in Kemp et al., (2020), the researchers describe a shift in how the participant uses her own criteria as she is evaluating her responses versus a peer's responses to proof comprehension questions.

These authors suggest future research can investigate how proof comprehension assessments for students influence their criteria in self-evaluation and understanding of proof writing. Beumann and Wegner (2018) investigates self-assessment in functional and real analysis on homework related to proofs. The authors present evidence that students can benefit from self-assessment tasks depending on several factors, and they note positive outcomes for self-assessment in small group tasks where the group can achieve full credit by hard work. They call for more research on and sophisticated implementations of self-assessment in higher mathematics education.

Beumann and Wegner (2018) advocate for self-assessment in that it should allow students to complete meta-tasks that are not marked by an instructor and help generate appropriate beliefs about mathematics, as self-assessment reinforces that checking the validity of a proof requires careful work and may depend on personal taste (i.e., the strategy used or amount of details given). Research shows students are better able to self-assess when given criteria on which to base their performance (Andrade & Valtcheva, 2009; Poehner, 2012), but Weber (2012) finds that mathematicians can greatly disagree on the validity of even simple proofs. When comparing mathematicians' and undergraduate students' beliefs about mathematical proofs, Lew and Mejía-Ramos (2019) report the following trends: (a) mathematicians believe proof language should obey conventions of academic language while students often either do not know these conventions apply to proof writing or are unaware they exist at all; (b) students face obstacles in understanding how mathematicians introduce objects in proofs; (c) students may not be aware of how important it is to focus on the context of a proof to decide how formal it should be. Since the criteria being used to evaluate a student proof can vary depending on who is evaluating the proof (e.g., an instructor, a peer) and what the purpose of the evaluation is (e.g., for effort, an assessment, peer-evaluation), it makes sense that students may not be aware of or understand the criteria under which they are being evaluated or may face obstacles in self-assessing and monitoring their progress (Stallings & Tascione, 1996; Poehner, 2012).

Based on the researchers' experiences and results from relevant research, our overall project seeks to investigate in what ways self-assessment through the lens of proof comprehension can improve proof construction and evaluation skills of undergraduate students. Specifically, we proceed with the assumption that self-assessment in proof writing necessarily requires proof comprehension skills (as one is reading their own proof), proof evaluation skills (as they are deciding if what they have written is logical and "complete"), and an awareness of what criteria, if any, is being used to evaluate their proof. This report provides preliminary results on the following research questions after a first phase of data collection investigating the perspectives of mathematics faculty on proof self-assessment: (a) What strategies and/or criteria do mathematicians use to self-assess proofs as they write them? (b) In what ways can proof comprehension assessment strategies be used in undergraduate self-assessment of proof writing?

Theoretical Framework

We focus in this preliminary report on the proof comprehension and assessment models presented in Yang and Lin (2008) and Mejía-Ramos et al. (2012). Yang and Lin (2008) provide a model of proof comprehension for proofs in high school geometry. The researchers use mathematicians' and mathematics teachers' perspectives to develop facets of reading comprehension in geometry proof. The authors emphasize that when students learn mathematical proof, there is often a gap between conjecturing and formally verifying, and their model aims to overcome this gap or eliminate limitations in proof writing. Mejía-Ramos et al. (2012) presents an assessment model for proof comprehension in undergraduate mathematics, which builds off of Yang and Lin's (2008) and Conradie and Frith's (2000) models, as well as trends found from

interviews with mathematicians and other mathematics education literature. They provide a multidimensional model with seven types of proof comprehension assessment, divided by *local* and *holistic* types of assessment. The local types are *meaning of terms and statements, logical status of statements and proof framework,* and *justification of claims.* The holistic types are *summarizing via high-level ideas, identifying the modular structure, transferring the general ideas or methods to another context,* and *illustrating with examples*. The authors emphasize there may be interesting relationships between these and call for further investigation into these relationships. For this report, we present results from adapting the Mejía-Ramos et al. (2012) model to analyze mathematics faculty responses to a survey in which they described their own approaches to self-assessment in proof writing. As this is a preliminary report, the ultimate goal of the results from this survey is to design a tool faculty can provide to students to help prompt the use of proof comprehension in self-assessment and to improve overall proof writing skills. We present and describe this adapted model in the Results section and provide examples of prompts meant to provoke these types of self-assessment via proof comprehension strategies.

Methodology

Several studies about proof comprehension and self-assessment emphasize the importance of the collaboration of mathematicians and mathematics educators, as mathematicians contribute an expertise in proof reading, an understanding of what is reasonable for students to understand, and they are more likely to embrace research results when they are actively involved (Cooley et al., 2024; Mejía-Ramos et al., 2012; Yang & Lin, 2008). Our current project takes this perspective, as we surveyed tenure-track and tenured mathematics faculty at a Hispanic Serving Institution (HSI) who regularly teach or have recently taught a mathematics course involving proof writing. We note the researchers on this project include a Hispanic male undergraduate student and a white female faculty member. The Institutional Review Board (IRB)-approved online survey was conducted anonymously, and out of the 14 faculty members recruited via email in the department at the institution, seven volunteered to participate. The 22 item survey (20 of which were open-ended) included two mathematical statements for faculty to consider: (a) For $a, b \in \mathbb{R}$, prove that $|a + b| \leq |a| + |b|$, and (b) For all integers a, b, c, if $a, b,$ and c are odd, then the equation $ax^2 + bx + c = 0$ has no solution that is a rational number. Faculty were asked questions about their own proof writing approaches for these statements, proof self-assessment strategies, other reflection questions, and then were prompted to assess a sample student proof for each of the statements. The data collected from the survey was analyzed first using open-coding (Richards & Hemphill, 2018) techniques in several passes by the researchers, and these codes were negotiated throughout. Trends emerged regarding ways that mathematicians approach self-assessment in their proof writing and the criteria faculty use for themselves and their students to evaluate the success of a proof. Many of these codes and subcodes resembled the model presented in Mejía-Ramos et al. (2012), and so we re-analyzed our data through this lens. For this report, we focus on Faculty A's responses to two open-ended questions from the survey that prompted participants to describe their self-assessment strategies and evaluation criteria in proof writing. We are using the results from this data as guidance to design a tool students may use to help with self-assessment of their proof writing. We plan to eventually interview students while using this tool to assess its effectiveness.

Results

Below, we provide the types of assessment presented in Mejía-Ramos et al. (2012), adapted for self-assessment as it was used in our analysis. We note that 1-3 below relate to *local* and 4-6

relate to *holistic* types of self-assessment (we omit the adaptation of the seventh type of assessment from Mejía-Ramos et al., (2012), *illustrating with examples*, as we found this code came up primarily in relation to constructing a proof rather than self-assessment).

1. *Use of terms and statements* - To assess clarity and use of key terms and statements, including explanations of these
2. *Logical status of statements and proof framework* - To assess validity of statements in the proof and the logical relationship between them and the given proposition
3. *Justification of claims* - To assess comprehensibility of the chaining logic in the proof and use of other assertions and assumptions
4. *Presentation via high-level ideas* - To assess presentation and communication of the main ideas of the proof and the overarching approach
5. *Logical flow with the modular structure* - To assess the logical flow and proof structure in terms of its main components/modules and the logical relationship between them
6. *Other Contexts and Criteria* - To assess "completeness" by comparing and adapting ideas from other proving tasks to evaluate the methods or procedures of current proof

In Table 1 below, we provide Faculty A's responses to two open-ended questions about both statements on the survey (listed in Methodology). Note as the survey was conducted anonymously, we do not have demographic information of Faculty A. We select this participant's responses for this preliminary report because they are thoughtful, representative of the trends found among the seven surveyed faculty, and they illustrate each of the self-assessment types in our adapted model. In this table, we utilize the numbering system above to connect each statement made by the faculty member to these self-assessment types. We describe how these results can be leveraged pedagogically in the Discussion and Conclusion section.

Table 1. Faculty A's responses to selected open-ended questions from survey.

Questions (open ended)	Responses from Faculty A with superscripts connected to adapted model
How did you assess your own proof as you were writing/sketching it? (What things do you look for in your own proof to decide if it is "going in the right direction"?)	Statement (a): [Can I justify the next line given the previous lines?][3] [Am I making unwarranted assumptions (i.e., if pressed could I explain my reasoning to a skeptic?)?][1,2] [Will I understand and agree with my own proof later?][4] Statement (b): [Are there specific details I can leverage or latch on to or are my givens still too vague.][1,3] [What can I do to get a handle on them?][3] [Can I simplify this to look like a previous or easier problem?][6]
Once you feel you are done writing a proof of this statement, how do you assess it for correctness? What things do you look for in your own proof to decide if it is valid?	Statement (a): [For a proof by cases like this one: Are my cases exhaustive?][5] [Am I making too many assumptions?][2] [Can I follow it from one line to the next using sound and valid logic?][3] [Would I be able to explain myself rigorously to another (vs. just making a persuasive argument)?][4] Statement (b): [Logical flow][3,5], [validity][1,2,4], [proof structure (in this case, exhaustive cases and good proof by contradiction structure).][5,6]

When specifically asked about the criteria that Faculty A would use to assess their own proof work, they said, "Validity, soundness, clarity, comprehensibility. Depending on use case, I might add explanatory power if it's meant to demonstrate reasons behind a mathematical principle, or

brevity if searching for 'elegant' proofs." This is consistent with Beumann and Wegner (2018) in that self-assessment should include a consideration for "personal taste," depending on the writer and the intended reader. For example of analysis, when Faculty A said, "Are there specific details I can leverage or latch on to or are my givens still too vague[?]," we interpret this as the faculty member evaluating if they have leveraged all of the given conditions appropriately in their proof, specifically to improve clarity. Thus, this question is classified as self-assessment types 1 and 3 and is focusing on the faculty's criterion of "clarity".

Discussion and Conclusion

Recall our research questions regarding mathematicians' proof self-assessment strategies and ways to incorporate proof comprehension in self-assessment. Using the Mejía-Ramos et al. (2012) model adapted for proof self-assessment, we analyzed seven faculty responses to open-ended survey questions about their self-assessment process and criteria. We used these responses and the model to guide the development of a draft of a self-assessment tool using proof comprehension strategies. Below, we provide examples of prompts that target these self-assessment types that students may use as a tool in proof validation and self-evaluation.

1. *Use of terms and statements* - Did I consider/address all conditions in the proposition? Did I use each concept from the proposition with the appropriate assumptions?
2. *Logical status of statements and proof framework* - What is the purpose of each statement? What justifies making each assumption? How does each statement contribute to the proof framework I am using?
3. *Justification of claims* - Can I justify this line given the previous lines in my proof? Am I leaving out any information that is necessary for a later implication?
4. *Presentation via high-level ideas* - Conceptually, what is the "big idea" of my proof and is it communicated clearly? Is the overarching approach of my proof sound?
5. *Logical flow with the modular structure* - What are the main modules or components of my proof? What is the purpose of each of these components? Do the components work together logically as intended for the type of proof being used?
6. *Other Contexts and Criteria* - Does my proof resemble a familiar proof of a similar statement (in structure)? Does this proof fit the relevant criteria for its intended use or evaluation? Could the intended reader understand and follow my proof?

We suggest the use of these prompts in undergraduate proof writing courses as an activity to encourage self-assessment and opportunities for self-reflection on proof writing. We believe these may improve student self-efficacy in proof writing and communication about evaluation criteria. Future research could investigate the use of this tool in classrooms, specifically in small group proving tasks, as Beumann and Wegner (2018) suggest. We are still refining this tool through deeper analysis of our faculty data, including the consideration of faculty criteria when evaluating student proofs. Our main goal is to assist students with the proof self-assessment process through the lens of proof comprehension. As part of our larger project, we plan to collect data from student interviews using the self-assessment tool to investigate its possible influence on student self-efficacy and proof writing skills. Obtaining other perspectives from additional undergraduate mathematics faculty would also help in improving this adapted model and tool.

Questions for the Audience

1. What self-assessment strategies or activities have you used in proof writing and what obstacles do you feel your students face (or would face) in this self-assessment?
2. What suggestions do you have to improve our adapted model and prompts?

Inquiring About What? Student Questions in Inquiry-Oriented Abstract Algebra

Corinne Mitchell
Virginia Tech

Michael D. Hicks
Virginia Tech

Rachel Rupnow
Northern Illinois University

Lindy Hearne
Virginia Tech

While extensive research has been conducted on curriculum development, teaching strategies, and student thinking in inquiry-oriented instruction, there is little focus on the nature of students' inquiry as it relates to question-posing; we know almost nothing about how and why students ask questions in these courses. Since inquiry-oriented mathematics teaching aims to shift mathematical authority to be shared between teacher and students, we wonder about the role of student inquiry in this shift. We present preliminary findings from an inductive analysis of students' questions and the mathematical authority relations that arise during classroom interactions where students ask questions in an inquiry-oriented undergraduate abstract algebra class.

Keywords: Questions, abstract algebra, authority, assessment

The "inquiry" in inquiry-oriented instruction (IOI) has a two-fold conceptualization in research: teachers inquire into students thinking while students inquire into advanced mathematics (Kuster et al., 2017). While extensive research has been conducted on curriculum development, teaching strategies, and student thinking in IOI, there is little focus on the nature of students' inquiry itself; we know almost nothing about how and why students ask questions in these courses. If one of the goals of inquiry-oriented mathematics teaching is to shift mathematical authority to be shared between teacher and students, what is the role of student inquiry in this shift? Further, if asking questions is a predominant mode of engagement for students across undergraduate mathematics courses, what is the mathematical nature of this activity? We present preliminary findings about students' questions and the mathematical authority relations that arise during classroom interactions involving student questions in undergraduate abstract algebra.

Questioning in the mathematics classroom has primarily been explored at the K-12 level, with just one notable study concerning undergraduate mathematics. Paoletti et al. (2018) explored the nature of 11 lecturers' questioning in advanced mathematics courses, finding that students were most often asked to recall facts or produce the next step in a proof, but questions requiring other kinds of mathematical activity were infrequently asked. These results were consistent with the findings of K-12 literature on teacher questions (Kawanaka & Stigler, 1999). K-12 research has also explored how teacher questions can be posed to impact student thinking (Martino & Maher, 1999; Van Zee & Minstrell, 1997), which questions promote students' mathematical development (Kawanaka & Stigler, 1999; Melhuish et al., 2024), and how pre-service teachers develop questioning practices (Gaspard & Gainsburg, 2020; Moyer & Milewicz, 2002; Nicol, 1998). The how and why of student questioning in math class is scant in both K-12 and undergraduate mathematics classrooms. Outside of the mathematics education literature, Van Zee et al. (2001) found that students posed questions in science class when they were invited to do so, during conversations in familiar contexts, or in discourse environments that prioritized understanding each other's thinking (p. 182-183). While Van Zee et al. (2001)

focused on the conditions that may lead to students' questions, our analysis explores the role of students' questions in class discourse.

Theoretical Framing

On the surface, the authority relation when students ask questions in math class seems obvious: students may simply be deferring to the mathematical expertise of the teacher to provide an answer. However, the framework described in this section proposes a finer grain for parsing this relation to describe the modes of authority in which students are engaged during questioning activities. Authority is often conceptualized in terms of perceived status or positionality of actors within a situation, both colloquially and in the literature (e.g., Gerson & Bateman, 2010; Otten et al., 2017). In contrast, we emphasize the actions of the actors in the situation, thus deemphasizing traditional authority roles. Like Hicks et al., (2023) we see mathematical authority as "rooted in the activities within a classroom that contribute directly to the mathematics, as well as who gets to partake in those activities" (p. 826). Bishop et al. (2022) and Hicks et al. (2024) identified the following modes through which teachers or students can take up mathematical authority. The primary contributors of the main mathematical idea under consideration are in authority for authorship. Those who are publicly communicating or extending ideas through writing or speaking are in authority for animation. Finally, participants are in authority for assessment when they are evaluating contributions made in service of an authored idea.

In this report, we frame the activity of posing questions as an authoritative action in order to investigate the authority relations that arise during such interactions. Further, we explore the conditions under which the activity of questioning transitions from being an indicator of student authority for animation, to being an indicator of student authority for authorship, or even assessment. In viewing questioning as a mathematical activity through which members of a classroom community negotiate authority, we expand both the notion of mathematical authority-in-activity (see Bishop et al., 2022) and our scientific community's understanding of questioning in the advanced mathematics classroom.
